The views of Pierre Bourdieu, who has directed attention to the symbolic processes through which potential political leaders create followings, have also been influential. Bourdieu writes of 'the alchemy of representation...through which the representative creates the group which creates him.' Hence we have Louis XIV's magical equation '*L'état, c'est moi*,' or what Bourdieu tells us amounts to the same thing: 'the world is my representation' (1991, pp. 105–6). Of great importance is determining the conditions under which

an individual is in a position to create representations that others are likely to follow, a matter dealt with by Bourdieu in terms of 'symbolic capital.' Anthropologist Simon Harrison (1995, p. 255) has picked up on this approach, viewing political conflict as a battle fought through symbolic means over symbolic capital. 'Competition for power, wealth, prestige, legitimacy or other political resources seems always to be accompanied by conflict over important symbols, by struggles to control or manipulate such symbols in some vital way.'

1.3 The Political Power of Ritual

Ritual provides one of the most powerful mechanisms through which symbolism enters the political realm. Here we adopt a broader view of ritual than the traditional equation of rites with religion. In this broader view, ritual is seen as consisting of culturally standardized, repetitive activity, which is primarily symbolic in character, yet ritual need not have any direct reference to the supernatural realm. Durkheim contributed to this perspective by linking ritual to the division of the world into two categories: the sacred and the profane. Ritual, he argued, consists of 'the rules of conduct which prescribe how a man should comport himself in the presence of these sacred objects' (1912 [1947], p. 41). The fashioning of rituals surrounding the state is in good part a matter of the creation and maintenance of sacred objects and the separation of these objects from the profane world.

Rich in symbolism, ritual derives its potency in part from its ability to arouse the emotions and the sensations through physiological stimulation. Rituals are filled with motions, gestures, colors, noises, songs, and odors. Through rituals emotions are joined to certain cognitions; that is, to certain views of the world.

Following Durkheim, scholars previously emphasized the conservative role of political ritual. Rites surrounding royalty took on a paradigmatic status. The rituals of rulers, the rites of court, and the ritualized means by which rulers interacted with their subjects—as in royal processions—were seen as means by which traditional authority was bolstered. More recently, however, a different perspective has emerged, in which ritual is viewed as a potent form of political action that serves not only power holders but also those seeking to overthrow the political status quo. In societies where the legitimacy of power is contested, we find the political battle fought, in part, through ritual. Rites (a) help develop political organization, not least through linking individuals to larger, abstract political entities (whether states or revolutionary organizations aimed at overthrowing them); (b) legitimize political power holders, would-be power holders, and political institutions; (c) create a sense of solidarity, even in the absence of consensus; and (d) foster certain views of political reality (Kertzer 1988).

The forms taken by political rituals are diverse. Individuals are linked to larger political entities through a variety of ceremonial means, from rites of membership in political parties, to rites of swearing allegiance as a new citizen (dubbed, tellingly, 'naturalization'), to participation in mass demonstrations. Leaders are legitimated through rites of inauguration, and the performance of an assortment of rituals that associate them with powerful symbols. Thus, when the president of the United States makes a public appearance, he enters to the stirring tune of 'Hail to the Chief'; all present rise, and he steps behind a podium decorated with the presidential seal, with the American flag waving from a pole at his side. Likewise, stripping a leader of his power outside regular rhythms of replacement necessitates rites of degradation, as in the case of impeachment proceedings. The death of a political leader requires special ritualization, affording a crucial opportunity for defining political reality and political values, as in the case of state funerals (Verdery 1999). These funerals have their own peculiar grammar, with the presence or absence of other political leaders sending powerful messages that can affect interstate relations.

2. Representing the State

Social scientists have long debated the nature of the state. Anthropologists have paid most attention to it as a stage in sociopolitical evolution, while political scientists debate whether there is anything necessarily Western about the modern state. For our purposes we view the state as consisting of 'the institutions of government and its individual representatives which together possess legitimate means of coercion and ability to tax and plan fiscal policy on a national level.' The state is charged with providing for its population's defense, security, and welfare (Biersteker 1987, pp. 50–70).

Having considered the nature and importance of symbolism to the political process, and the role of ritual in politics, we now turn specifically to how states are represented through symbolism, and the role played by ritual in the state.

2.1 Organizing the State

Given that people can only perceive the state through its symbolism, how do symbols do their work? The French historian, Maurice Agulhon (1985), addressing this question, distinguishes four categories of symbols through which modern states are represented. The state, first of all, must have a flag. Second, it is personified, either by a current or past head of state (e.g., a king or a dictator), or, as in the case of the French republican state, by an allegorical figure (Marianne). Third, each state has a variety of other kinds of symbolic representations of a nonanthropo-

morphic type: these include coats of arms, official seals, and the like. Finally, every regime, writes Agulhon, has its own Pantheon of historical notables, and typically places statues of such heroic figures (or, as the case in the Soviet Union, their embalmed bodies) in public squares.

Historians point to the French and American Revolutions as creative cauldrons for inventing new modes of representation of the modern state, with innovations ranging from the national flag to the national anthem. Historians have also shown that many of these forms of representation, while conveying an image of great antiquity, are in fact relatively recent. They are used by state elites both to solidify their own position internally and in international competition to bolster the state's position in the battle for influence (Hobsbawm and Ranger 1983).

The use of a variety of symbols and rites to link the masses of people to the state took on new importance with the rise of nationalism and democratic politics. When the state's legitimacy was vested in the leader by virtue of supernatural sanction (as in the case of divine right), the main requirement was for representations coming from above to reinforce the view that the rulers ruled by such higher authority. But when states came to rely on the notion that they existed at the behest of their citizenries, with no intermediate social body mediating between citizens and the state, the multifarious ways in which individuals identified with the state became much more important.

The heavy use made of such participatory representations of the state by twentieth-century European dictators, and especially by Hitler and Mussolini, led analysts to pay special attention to the importance of symbolism to the Nazi and Italian fascist regimes. George Mosse (1976, p. 39) has written of the ways in which in Nazi Germany the 'myths and symbols of nationalism, its rites, monuments, and festivals,' transformed an inchoate mass of people into a cohesive mass movement of citizens who saw themselves as in some sense acting as one. Mosse portrayed this process in religious terms, as 'the shaping of the crowd into a congregation.' Others have examined Mussolini's similar attempts to craft a system of symbols and rites to alter Italians' relationship with the state. Yet, in fact, such systems of representation and ritual are common to all modern states.

The importance of ritual in establishing the link between citizens and the state means that there are few more effective means of showing opposition to a regime than through contestation of the rites that bind the citizen to it. Postunification Italy offers a typical example. In the decades following the September 20, 1870 conquest of Rome, which brought with it the final construction of the Italian state, patriotic rites were organized each year to commemorate that sacred date. These annual celebrations, however, served only to inflame the passions of Catholic loyalists, who, following papal instructions, refused to recognize the

new state's legitimacy. The result was that every September 20 Catholics organized counter-rites to challenge the state-organized rites, and thereby challenged the legitimacy of the new state itself (Gentile 1996).

2.2 *Legitimizing the State*

If states come to be known through the ways they are symbolized, any threat to the symbols with which they are identified threatens the legitimacy of the state itself. Harrison (1995, p. 258) refers to symbolic conflict between states of this sort as 'proprietary' contests, involving competition over the state's distinguishing symbols. The bitter dispute that erupted in the early 1990s between Greece and the former Yugoslav republic of Macedonia over the use of the name 'Macedonia' is a case in point.

Harrison distinguishes a variety of means through which the political representation of the group is in a process of continuous contestation and flux. This perspective applies well to the representation of states, again seen both in terms of internal competition and the competition that is waged among them. In the 'expansionary' contest, for example, one competitor attempts to displace another's symbols of identity with its own. This is found whenever revolutionary movements take power. In the case of the Russian revolution, as in revolutions everywhere, these battles were waged in part through the symbolism of space (e.g., St. Petersburg became Leningrad).

Although leaders of new states or new regimes try to replace their predecessors' symbols with their own, they rarely attempt to displace all such symbols. The reason is that, in the eyes of the population, the new regime's legitimacy is almost always tied to its identification with pre-existing symbols of state legitimacy. Hence, the Bolshevik leaders kept the Kremlin as the symbolic center of the state. Alternatively, older symbols of political legitimacy of the state are re-introduced, as in Mussolini's attempts to link his regime to ancient Rome through the symbolic elaboration of *romanità*.

Where older symbolic forms are judged unsuitable, new regimes are as likely to transform them for their own ends as they are to abandon them, for the continuing popular influence of the rites has its uses. Hence, the Nazi regime retained most of the old state holidays—from May Day to Mother's Day—but largely altered their symbolism and ritual in order to promulgate the new state ideology (Taylor 1981). In the post-World War II period, as the Polish Communist government attempted to win popular support, leaders similarly attempted to borrow legitimacy from older symbols, while changing their meaning. Accordingly, the new state authorities chose not to replace the crowned White Eagle, which had served as a national symbol of Poland for centuries. Rather, they simply removed the eagle's crown, thought to be

too blatant a symbol of the old aristocracy. Instructively, on various occasions on which workers protested against the state, they displayed an image of the white eagle recrowned (Kubik 1994, pp. 50–1).

This emphasis on the struggle over representations also allows us to examine how political symbols and rituals are employed by combatants for power within states as a means of establishing their own legitimacy and carving out a particular political identity for themselves. A number of observers, in this connection, have cited the example of the Orange Order's annual parade on July 12, when men wear black bowler hats and orange collars, and march for hours holding aloft banners commemorating battles that three centuries earlier helped establish Protestant rule in Ireland. These rites have some parallels in Independence Day celebrations in the United States, but here the political context makes all the difference. In the United States, the legitimacy of the state is largely undisputed, and the July 4th rites are ceremonies that foster solidarity and reinforce the legitimacy of the state. In Northern Ireland, by contrast, the state's authority remains contested, and such rites as those of the Orangemen provide emotionally powerful means of organizing the combatants.

2.3 *Establishing New Regimes*

As the cases of the French and Russian revolutions show, new regimes require symbolic elaboration, and they must deal with the lingering power of the symbols of legitimacy of the old regimes that remain behind. Struggles over symbols and rites play no small part in the battle to establish such regimes and in the attempts of competitors to delegitimize them. Hence the tricolor flag appeared in France in 1789 immediately following the taking of the Bastille, then was replaced by the royal white flag on Napoleon's fall in 1814, before the July Revolution of 1830 again resulted in the banishment of the white flag and the triumph of the tricolor. Agulhon, in reviewing the history of these developments, argues that battles of this sort, fought through and over symbolism, were central to the course of political events. 'The obscure militants,' he writes, 'who, on July 28, 1830, went to raise the tricolor on the towers of the Notre-Dame and over the Hôtel-de-Ville while the outcome of the struggle was as yet uncertain, contributed to throwing the people into battle with a redoubled ardor' (1985, p. 190).

Rituals of allegiance offer particularly effective means of identifying those whose loyalty to the new regime is weak, and at the same time furnishing ammunition for the regime's claim that it enjoys widespread popular support. Because state authorities can require their performance, such rites force individuals who oppose the regime either to be publicly identifiable (and hence risk reprisal) or to undermine their own self-esteem and their sense of being opposed

to the rulers. Such was the case of the arm-stretched 'Heil Hitler' salute required in daily social encounters during the Third Reich. Similarly, in 1931, concerned about rooting out subversive university professors, and at the same time eager to offer evidence of its claim that it enjoyed overwhelming support from all segments of the population, the Italian fascist regime required that all faculty members swear allegiance to it. Only 12 (of over 1200) professors in the entire country refused to take part in the rite. Their symbolic act of resistance did not go unpunished; they were stripped of their posts (Goetz 2000).

New states formed out of former colonies continue to face dramatic problems of representation and legitimation. In sub-Saharan Africa, where many new states emerged in the 1960s, the difficulties were compounded by the fact that their boundaries were those that the colonial powers had drawn. How could such divisions of land be represented as 'natural' bases for political organization, much less objects of popular adulation? What role would continuity have in such transitions, and if the symbols of the colonial past had to be rejected, what would take their place?

Swaziland provides an intriguing example (Kuper 1978, pp. 301–4). Following decades of British colonial rule, Swaziland gained its independence in 1968, using the figure of the Swazi king as the centerpiece of the new order. The ceremonies marking independence took on great importance to the political elite, who saw them as a means both of defining the new state and building public allegiance to it.

Independence was marked by a great public ceremony, held in an open stadium, packed with thousands of enthusiastic citizens. The king made his entry in a huge new black Cadillac limousine, but as he stepped out people saw that he was wearing traditional regal garb, with high-plumed headgear. After the king took his seat, the British ambassador arrived, as the band played 'God Save the Queen.' From there the ceremonies followed Western form until, suddenly, thousands of swaying Swazi warriors began singing a traditional war song, and the king and prime minister left their seats to join them. As the song reached its crescendo, and the king along with the thousands of warriors raised his shield over his head, the crowd roared its approval. The king and prime minister returned to their seats, later getting in their stretch Cadillacs to take them to a diplomatic reception.

The Swazi case illustrates the power of symbols and rites not only to define a new political reality through the combination of symbols derived from various sources, but also their power to foster popular legitimation and a sense of identification between citizens and the new state.

2.4 The Uses of History

A common feature of representations of the state is that they contain an image of history. It is through

symbolic expressions, including rituals, that leaders link the state today to its earlier incarnations, and likewise link both themselves and their enemies to particular predecessors, viewed in certain ways.

New leaders do all they can to identify themselves with popular predecessors. American presidents need not rely solely on verbal reminders, citing Washington, Jefferson, Lincoln, and Roosevelt in their speeches. By performing certain state rites performed by these predecessors—as most notably in the Inauguration ceremonies—they effectively make this connection.

In the relationships between states, the importance of representing history in certain ways, and establishing legitimacy for the present through symbolic links of a certain kind to the past, is likewise crucial. This was evident, for example, in the difficulties the German government experienced in the decades following World War II in dealing with the historical memory of the war. These came to a head in a series of state rituals held in the mid-1980s. In 1984, leaders of the former Allied nations held a commemorative rite on the anniversary of the Normandy landing. This was similar to many such rites that served to keep the memory of the war alive, and the leaders who participated in it no doubt derived some political benefit themselves. But German leaders, representing the enemy nation, were not invited.

Angered at having the memory of the war represented in this way, German Chancellor Helmut Kohl invited US President Ronald Reagan to come to Germany to celebrate with him a commemorative ceremony in honor of the war dead, to be held at the Bitburg military cemetery. By having the American president stand with him there, the German leader hoped to refashion the history of the war. Indeed, the American President cooperated in this effort, referring to the dead German soldiers as 'victims' of the Nazis, 'just as surely as the victims in the concentration camps.' Yet, history is not infinitely malleable; the symbolism of World War II in the United States could not be so rapidly and radically altered, and as a result Reagan came under sharp attack. Attempting to make partial symbolic amends, the President added a visit to a concentration camp to his itinerary that day, yet this then opened him up to the charge that he was thereby symbolically equating the concentration camp victims with their Nazi persecutors. Despite such criticisms, however, the Bitburg rites had their effect. Opinion polls following the ceremony showed a considerable rise in the proportion of Americans who saw the German soldiers as victims of Hitler rather than as responsible for Nazi atrocities (Kertzer 1988, pp. 92–5).

2.5 The Future of Representations and Rituals of the State

As long as there continue to be states, they will continue to require cultural means of representation,

and in this, ritual in its various forms will play an important role. However, as states face competition for sovereignty and for influence both from within and from without, the role and importance of such representations are likely to change, and some of their forms may alter as well. Insofar, for example, as one role of the rituals we have discussed here is linking the individual to the state, any change in the importance of the state as a basis for personal identity will be reflected in changes in participation in and popular perception of the rituals themselves.

These competing claims for people's allegiance, in turn, will require their own forms of representation, including ritual. Regionalist, ethnic, religious, and other movements opposing the state's power presuppose both the delegitimation of the state—a battle fought in good part through efforts at altering existing representations and rituals of the state—and the creation of an alternative identity. In Italy, for example, the Northern League has devoted tremendous attention to the creation of symbols of representation and rituals that link individuals to a previously nonexistent territory—Padania—and to the League itself (Destro 1997). At the same time, ritualized display of the symbols of the Italian state—such as the Italian flag—is studiously avoided.

In addition to such threats from below (in the Balkans, south Asia, Africa, and other areas), states also face threats from above. For decades theorists have been predicting the demise of the state and the emergence of larger, supranational entities. Many of these (e.g., the Arab League) have foundered on the unwillingness of national elites to cede authority. The most notable current effort, the European Union, demonstrates the link between weak popular allegiance and an underdeveloped system of representation and ritualization (although also suggesting that causation goes both ways). French anthropologist Marc Abélès (1996, pp. 125–32) refers to '*le déficit symbolique*' of the EU, writing that the supranational organization sorely lacks both the symbols and the rituals that could furnish it with some power of popular attraction. Without such symbols and rites, it is unable to mobilize popular passions. The reasons for this deficit are many, but include the inability and indeed unwillingness of national elites to agree on a clear representation of what the EU stands for. Indicative is the fact that while the EU has its own anthem (a version of Beethoven's '*Ode to Joy*'), people cannot sing it, for it has no words. The EU's rites—such as the commemoration of the fortieth anniversary of the European Parliament in 1992—have been so devoid of emotionally resonant ritual elements that they do little but reinforce the EU's image as a creature of Euro-bureaucrats.

Future research must take aim at these potential competitors to the state from below and from above, and examine the ways in which these competitors employ representations in general and ritual in par-

ticular to delegitimize the state. In all such studies, it is crucial that people's reactions to these efforts be examined carefully. It is one thing for state elites or would-be revolutionaries to employ symbolic means to try to win the allegiance of those whose 'representatives' they would like to be. It is quite another for the 'represented' to respond to these symbolic efforts in the ways the elites would like. What is needed is a mix of methods—from participant observation to the analysis of texts—and an examination of a range of social settings, from large periodic national demonstrations to quotidian interactions in rural communities. Political scientists and sociologists need to pay more attention to the symbolic dimension, while anthropologists need to take aim more directly at state-level forces.

D. I. Kertzer

Reproductive Medicine: Ethical Aspects

In reproductive medicine a variety of diagnostic methods are used to discover causes of involuntary human infertility. Diseases in this area can be treated by a number of techniques, ranging in complexity from the simple and inexpensive to the highly sophisticated and expensive (Reiss 1998). The diagnostic methods used include both the invasive, such as laparoscopy, and the noninvasive, such as ultrasonography. They may be specific, in the sense that they give the answer to a question posed, or non-specific, providing information that has not been asked for. Some diagnostic tests are quick, while others take longer, since they have to be processed in laboratories.

The development of a variety of more or less effective approaches to involuntary human infertility, as well as the separation of human reproduction from sexuality, raises a number of ethical problems, discussed in books, journals, and the mass media (Shenfield and Sureau 1997).

1. Ethical Controversies

Cloning has recently been the subject of debate in many countries. There are different kinds of cloning, but the World Health Organization (WHO) and the Council of Europe have banned the cloning of human fertilized eggs for reproductive purposes. The objections to cloning, apart from safety issues, concern the identity and individuality of human beings. Nature produces identical twins, but many people argue that cloning of human beings will undermine the respect of the human being by making its identity and individuality subject to human ingenuity.

Current ethical issues include the disposal of frozen embryos (how and under what conditions this may take place), and posthumous treatment, much discussed in the UK in the late 1990s. Other controversies are raised by third party gamete donation and sperm cryopreservation, particularly concerning payment of donors, anonymity of donors, and selection of donors and recipients (discussed in, e.g., Council of Europe 1996). The different methods used in reproductive medicine raise different ethical problems, and hence need to be considered separately. The issues of oocyte cryopreservation, and reproductive tissue freezing (ovaries and testis), also raise issues of safety and consent—particularly for young people affected by cancer.

For example, assisted insemination using the semen of the husband or designated partner raises a somewhat different problem from that of assisted insemination using the semen of a third party. The need for careful counseling is important in both cases, but the status of the child, its right to know its biological father, needs to be considered in detail when a third party is involved. When semen is frozen, safety issues need to be considered, in addition to how long the semen may be stored as well as under what conditions and for what purposes it may be used. When semen banks are established, regulation is needed. If and when the semen is tested or manipulated, further problems arise.

At present, at the beginning of the twenty-first century, preimplantation diagnosis is limited to sorting out fertilized eggs carrying genes associated with severe diseases for which there is currently no cure, like Huntington's chorea and certain X-linked diseases. Concern has been expressed that the practice may be extended to diseases which are less serious. Obviously, there is a sliding scale between more or less serious and also room for subjective differences in this grading of diseases. There is thus a risk of a slippery slope in this area (Shenfield 1997).

A fundamental issue concerns the moral and philosophical status of the fertilized egg and to what sort of protection it is entitled (Steinbock 1992, Hermerén 1993). The status of the embryo is crucial in many debates of the ethical dilemmas of reproductive medicine. Other basic concerns include the partly culture-dependent reasons for reproduction.

2. A Framework for Analysis

The underlying values in the debates on dilemmas in reproductive ethics can be described in different ways, in terms of the rights and interests of the various stakeholders concerned, or in terms of duties towards patients and the future child. These duties may clash with each other as well as with the interests and rights of other parties. To make the underlying values and value conflicts explicit is to take a first step towards a rational discussion of these dilemmas.

An ethical problem arises in a situation where: (a) there are two or more possible courses of action; (b) one course of action satisfies or is compatible with certain interests, rights, or values, and another course of action satisfies others; and (c) all parties or all interests, rights, or values cannot be satisfied at the same time by one possible action. This is particularly the case if (c) is intensified in such a way that both options are incompatible with each other or if the values, which are included within the options, are conflicting with each other. Whatever alternative is chosen, there will be winners and losers. This is clearly illustrated by some of the well-known dilemmas in reproductive medicine, where the stakeholders (or parties involved) include the woman or the couple, present and future children, doctors and clinics, researchers, the pharmaceutical industry, taxpayers, and society at large.

3. Terminological, Empirical, and Value Issues

If a rational discussion of these ethical dilemmas is wanted, it is necessary to separate conceptual, empirical, and normative issues, as illustrated by the controversies over when life begins and the proposed distinction between embryo and pre-embryo (Jones and Schrader 1989).

Evaluation of criteria of success like 'take-home baby rate' also involves issues of all three kinds. Moreover, whether certain methods would harm children and parents or alter people's understanding of themselves or of the act of procreation are empirical issues that people may disagree about, even if they agree on the goals of reproductive medicine. To be able to substantiate these empirical claims it would be necessary to proceed with long-term follow-up studies of children produced with the help of the various reproductive technologies available.

The utilitarian principle of maximizing the utility or achieving the greatest good for the greatest number of people is open to many interpretations, some of which will clash with Kantian principles that each person should be treated as an end in itself and not as a means to an end. They may also clash with rights-based theories of the sort advocated by Dworkin (1977). This is particularly evident in the debate over research on embryos and the conditions for destruction of spare embryos. Here respect for the autonomy of the gametes providers, by requiring their joint consent, may yield different conclusions than a utilitarian starting point would do. According to the latter, the consent of the gametes providers may be disregarded if it can be shown that using the spare embryos for research or for donation will maximize the greatest good in society. Whereas Swedish legislation requires that sperm donors be willing to reveal their identity to the child when he or she is grown up, if the child wants to know, French legislation requires anonymity

(Shenfield 1997). These different requirements may have an effect on the number and kind of people willing to donate sperm. Interestingly, both requirements can be justified by considerations based on the welfare of the future child. Thus, there is a common agreement on the goal but different views about the best way to achieve it.

These differences could clearly be solved in principle by empirical research, involving long-term longitudinal follow-up studies in both countries of children who are the result of sperm donation. But these studies themselves raise further ethical problems. As the children reach a mature age, it becomes increasingly difficult to carry out the follow-up without their informed consent. How is this to be obtained in a country which makes anonymity compulsory? And can it be obtained without risk of harming or stigmatizing the children?

4. Goals

It may be helpful to distinguish between questions concerning the ethical acceptability or legitimacy of certain goals of reproductive medicine, such as the improvement of success rates in *in vitro* fertilization (IVF), and the ethical acceptability of certain methods used to achieve these goals. As indicated above, it is possible to agree on the goals and differ on the methods, and vice versa.

Do the techniques mentioned above help to achieve the goals of reproductive medicine? Do they help to achieve other goals as well?

If the goal of reproductive medicine is to cure diseases, it becomes necessary to clarify what is meant by a disease to understand this goal. If a particular condition is regarded as a disease, it falls within the goals of reproductive medicine to cure it; if not, it does not.

A fundamental issue is whether involuntary infertility is a disease, the result of a disease or a socially constructed need. This is not just a matter of semantic definition, since the different ways of regarding human infertility have social and economic consequences. If it is a disease, those suffering from it are entitled to help from the national or publicly funded health care system, whose resources should be used. Moreover, if infertility is a disease or a response to a disease rather than a social need, a case for financial support of the new reproductive technologies can also be made, as well as for research on such technologies. If, however, it is a socially constructed need, the case for financial support is much weaker.

5. Means

The methods available to achieve the goals of reproductive medicine vary, and new methods are being

tested. Owing to breakthroughs in molecular biology, development is rapid (Fauser 1999, Harris and Holm 1998). Some methods, like surrogacy, have been criticized because they lend themselves to commercial exploitation and to seeing children as commodities, as 'made' rather than 'begotten' (O'Donovan 1984).

If and when the methods of reproductive medicine involve or presuppose preimplantary or prenatal diagnostics, further issues are raised. The case for preimplantary diagnostics in connection with IVF is that it can be used to avoid X-linked diseases such as hemophilia or certain forms of dystrophy. However, concerns are raised over the possibility that, for instance, indications may be expanded, and that they may be misused for eugenic purposes. Hence regulations or guidelines are necessary, and have been proposed in many countries.

Sex selection for social and economic purposes is practiced in many countries, like India and China. If there are normally about 105 girls born to 100 boys, population statistics indicate that perhaps 100 million girls are 'missing' in the world because of sex selection. The status of women in the world is subject to many cultural differences, and the most important arguments against sex selection focus on the equality of the sexes, emphasizing that gender is not a disease (Shenfield 1994). Suppose, however, that there is no social security for parents when they reach old age. Moreover, suppose that parents have to pay an expensive dowry for their girls, and that girls are not able to make a living by working outside of the home. Then the much-criticized practice of sex selection could be viewed as a culturally chosen means to achieve a certain goal (economic and social safety for the parents). This obviously further suggests that in order to abandon this practice of sex selection, alternative means of reaching this goal have to be made available. Since this may take considerable time, compromise positions have been suggested.

Further concerns have been expressed that, because some of the technologies used in reproductive medicine are expensive they will only be available for rich people in the industrialized parts of the world. They will thus help to increase the gap between the health care and quality of life available for the rich and that for the poor or, more generally, the gap between rich and poor countries.

6. Some Important Arguments

As already mentioned, the basic ethical dilemmas of reproductive medicine involve conflicts of interests, rights, or values. The first step in the attempt at a rational discussion of these conflicts is to make the conflicting interests, rights or values explicit, and to try to separate normative and empirical issues. This is sometimes easier said than done, because, for example, in the discussion of the importance of a genetic relation

between parents and children all these issues are intertwined in a complicated way. Various arguments are used in discussing these conflicts. One rarely takes a stand on the basis of one argument or principle only—often several arguments or principles are used. Sometimes those advocating different positions use the same arguments or principles, but rank the importance of the arguments differently. The central arguments seem to be the following ones: the autonomy argument, the non-maleficence argument (an argument based on the principle that one should not harm), and justice arguments of various kinds.

6.1 Arguments of Autonomy

These are derived from a position that attaches great weight to individuality and liberty. The principle of autonomy is the basis of the requirement of informed consent. If the technologies used involve risks, the principle of autonomy requires careful counseling of the candidate couples. If great importance is attached to this principle, it may overrule also the concern over commodification of human beings, their bodies, and their bodily products. If people have a right to do what they want, they also have a right to serve as surrogate mothers, to earn money on their bodies, and to sell their organs or bodily products. The problem of the limits of autonomy then becomes an important issue. This is also an issue of power: who is to set the limits, and in accordance to what other principles?

6.2 Nonmaleficence Arguments

Arguments based on the principle that one should not harm are clearly legitimate and have a long history in medical ethics ('primum est non nocere,' a principle known already in antiquity). It has been claimed that children who grow up in nontraditional families (for example, with two parents of the same sex) or are the result of particular reproduction technologies will suffer, because they lack role models of both sexes or because their intellectual or emotional development will be impaired. At present, though, the evidence supporting this or the opposite position is missing, or at best inconclusive.

6.3 Arguments of Justice

Arguments based on the just distribution of scarce resources are also relevant. Clearly the resources for health care are not unlimited in any country, and there is always the problem of the fair use of these limited resources. Is the unequal access to treatment also unfair? If fewer than half of those who ask for it obtain assisted treatment by IVF, the reasons why some obtain treatment and others not take on an ethical

significance (Shenfield 1997). Is this a case of discrimination on the basis of economic, social, or ethnic grounds or not? Moreover, the practice in different countries as to how many cycles are subsidized is also relevant here, since incomes are unevenly distributed. For some, a fee of EUR.10000 is a small sum, but to others it is an effective barrier.

Fair access is clearly also a legitimate concern. If the available resources are to be used in an equitable way, and used to benefit those who suffer most, rather than to benefit those who are willing and able to pay, it has to be demonstrated that the methods are cost-effective. Though doctors should respect the autonomy of those who come to seek their help, doctors are not under any obligation, legal or moral, to provide patients with any treatment they might request (McCullough and Chervenak 1994). The request has to be compatible with good professional standards. The proposed treatment might be not benefit the patients or it might be incompatible with the interests of the child.

A related question that has been the subject of heated discussions is who should have access to the benefits provided by some of these reproduction technologies. Should IVF be available for single people, or for homosexual or lesbian couples? Should HIV couples or couples where one of the partners is HIV positive be entitled to treatment with artificial reproduction? Are there any age limits? Are any age limits appropriate and ethically justifiable? If the answer is yes, what sort of inquiries are appropriate before proceeding? In short, on what ground, if any, should some people be denied the access to these techniques?

7. Research Ethics

Here one set of problems focuses on the ethical acceptability of research on embryos *in vitro*, and another on the conditions of such research, if acceptable. According to the views of the Roman Catholic Church, neither such research nor IVF is morally acceptable. Embryo research is also explicitly illegal in some countries, such as Norway, and in practice illegal in others, such as Germany.

If, however, research on embryos *in vitro* is morally accepted, a number of more specific questions have to be asked and answered. They include what kind of research should be permitted, questions about the source of the embryos and for how long may embryos be used for research (14 days is a limit in many countries, like Sweden). Moreover, conditions have been laid down concerning the length of time frozen embryos may be saved and how spare embryos may be destroyed. All these issues are controversial, as is the question of whether embryos may be created solely for the purpose of research. The latter is explicitly forbidden in French legislation and in the Council of Europe Convention on Human rights and Bio-

medicine (1996). The fundamental issue here concerns the philosophical and moral status of the embryo.

The human embryo deserves 'respect,' but a much-contested question is what precisely this respect allows and what it forbids. The practice of research on embryos is subjected to strict regulations, as is experimental research on human beings. Informed consent by the male and female providers of gametes is a cornerstone in these regulations. The knowledge sought must be impossible to achieve in other ways, for instance, by research on animals. Further, this knowledge has to be of vital interest to present and future patients. Others regulations concern safety issues, in particular the safety of the applications of research.

Research on new reproduction technologies (diagnostic methods or treatment options) involves the standard issues of providing patients and healthy volunteers with information they understand and which enables them to make autonomous choices. Obtaining consent from research subjects who have deficiencies in understanding poses other difficulties. In this area of medicine, specific problems include that the fact the embryo and the future child are stakeholders, or parties concerned, but for obvious reasons, they cannot be heard. Someone, therefore, has to look after their interests. Often the parents do this, but sometimes they disagree. Who is then to look after the interests of the embryo or the child-to-be? Moreover, the women or couples seeking help may be under emotional or economic pressure, which will not aid rational decision making.

Yet another problem is over the safety of the woman or the embryo. Some of the methods used in research may involve physical, psychological, or economic risks. Protection against possible harm is a requirement for research—there always has to be a reasonable balance between the anticipated benefits of research and foreseeable harm to research subjects. If unexpected harm arises, however, measures have been taken to interrupt the study and to compensate the research subjects.

When sperm or human tissues are taken from tissue banks or sperm banks for research purposes, special problems have to be dealt with. The conditions under which such research may be performed have been regulated in many countries like the US, Sweden, and the UK.

Finally, there is the problem of fair access to research results, as well as controversies over payment or compensation to research subjects.

Reproductive Rights in Affluent Nations

Reproductive rights can be defined as the freedoms and opportunities that allow individuals to choose if, when, and how to have children. Advocates of reproductive rights have argued that this choice involves access to contraceptives, abortion, and reproductive technologies; freedom from forced sterilization; and access to health care that allows women and their partners to participate in decisions regarding prenatal care and childbirth. Many feminists argue that genuine reproductive choice requires a broad set of changes, including gender equality, employment opportunities, and available high-quality daycare.

1. Historical and Intellectual Context

The notion of reproductive rights is very much a product of nineteenth and twentieth century women's movements. Feminist perspectives on reproductive rights include both individual and social components (Petchesky 1984). The individual element, rooted in liberal thought, is the idea that women must control their bodies to be independent persons. Liberal discourse has been critical to both reproductive rights advocates, who discuss reproductive rights as essential to women's equality, and their opponents, who make claims about the competing rights of fetuses, male partners, and parents of minors (O'Connor et al. 1999, pp. 158–9). The social component, which draws on Marxist thought, is the recognition that material conditions and social relations constrain reproductive choices. As Rosalind Petchesky (1984) argues, reproductive freedom is necessarily individual, involving women's bodies, but at the same time social, involving social arrangements and class and racial divisions that affect reproduction.

In the nineteenth century, birth control movements emerged in many affluent nations. In her history of birth control in America, Linda Gordon (1976) argues that feminist efforts to gain political power through suffrage, and power within the family through birth control, were a response to rapid industrialization; by gaining power and control, women might bolster the family and help to solve social problems. Although nineteenth century advocates of 'voluntary motherhood' disapproved of contraceptives as 'unnatural,' they advocated women's right to refuse sex with their husbands. This demand for the right to refusal was part of the fight against unequal marriage laws, including legalized rape, and was considered a condition of women's independence. In the words of one voluntary motherhood activist, it was 'Woman's Natural Right to ownership and control over her own body-self—a right inseparable from Women's intelligent existence...' (Gordon 1976, pp. 103–4), a sentiment that would be echoed by twentieth-century

feminists in their continuing battles for reproductive rights.

Although nineteenth-century American feminists firmly asserted women's right to control their bodies, they never endorsed contraceptives and never rejected motherhood. Gordon explains their continued disapproval of contraception as a result of their fear that contraceptive use would lead to extramarital sex, and that this would lead to greater freedom for men, but not for women. Similarly in England, nineteenth century feminists failed to support birth control, fearing that women would be victimized by men's sexual desires (Banks and Banks 1964). Lacking economic independence, women needed men's commitment to their wives and children in marriage. The voluntary motherhood movement was an attempt to restrict sexual morality, rather than create sexual freedom, which at that time was not seen as beneficial to women. Women's movements in other Western countries were animated by similar ideologies. It was not until additional social changes made it possible for women to broaden their worlds that women's movements broadened their conceptions of reproductive rights.

By the early twentieth century, women were entering the labor force in greater numbers and sexual activity outside of marriage was on the rise. 'Birth control,' a term coined by US activist Margaret Sanger in 1915, was advocated for both economic and sexual reasons. Socialists in Europe and North America pushed for access to birth control to improve the lives of the working class. Neo-Malthusians, who were concerned about population growth, advocated contraception and were generally supportive of sexual equality (Francome 1984). Advocates of sexual liberation, influenced by European sex theorists such as Havelock Ellis, saw birth control as freeing women of their dependence on men. Early twentieth-century feminists, however, were not in complete agreement about the benefits of birth control for women. Some feared sexual promiscuity and the degradation of motherhood as a source of status for women, and some had race and class biases that influenced their views on birth control. Nevertheless, birth control movements in affluent nations expanded greatly and were linked to women's sexual freedom. When women's movements in various countries were 'reborn' in the 1960s, access to birth control was an important demand.

Movements to legalize abortion also emerged in many countries in the twentieth century. Attitudes toward sexual behavior were becoming more liberal, and various women's groups advocated liberalization of abortion laws. By the 1930s, a number of European countries passed laws that provided for some limited access to abortion. The contemporary wave of abortion reform laws in affluent countries began with the passage of the British Abortion Act in 1967, which was pushed by the Abortion Law Reform Association, an organization founded in 1936. Although the British

law gave medical practitioners rather than women control over the abortion decision, it was a significant advance in women's access to abortion (Francome 1984).

Abortion rights activism increased in the 1960s as women's movements flourished in many Western countries. Feminists demanded legal abortion as part of women's right to control their bodies and developed extended analyses of reproductive rights. In North America, collectives like the Montreal Health Press and the Boston Women's Health Book Collective distributed works such as *The Birth Control Handbook* and *Our Bodies, Ourselves*, which were early sources of information to women about contraception, abortion, childbirth, and other women's health issues. Women's health activists criticized male gynecologists, obstetricians, and other practitioners for demeaning women and failing to include them in decisions about their own bodies. They questioned the safety of some contraceptives and drugs and the necessity of some surgical procedures. They criticized high-technology childbirth practices that took control over childbirth away from women. As more black women and other ethnic minorities were drawn into the women's health movement, they raised the issue of forced sterilization of poor and nonwhite women. As alternatives to established medical control over women's health care, feminists developed 'self-help gynecology' and opened feminist health clinics (Ruzek 1978).

In countries where the women's movement was strong, feminists influenced abortion reform movements to advocate abortion as a women's rights issue. In the United States, the Supreme Court legalized abortion in 1973 on the basis of a 'right to privacy,' recognizing the rights of both women and doctors to make decisions about abortion. Other Western countries also legalized abortion in the 1970s, with varying degrees of input from feminists. In Canada, for example, feminists framed abortion as a reproductive right, but the discourse of medicalization was stronger than that of feminism, and the 1969 abortion reform law focused on the concerns of doctors rather than women (Brodie et al. 1992).

Although feminists continued to be concerned with a broad range of reproductive rights, abortion became a major preoccupation after legalization of abortion provoked strong antiabortion countermovements in many countries. In the USA, the single-issue anti-abortion movement expanded the conflict to new battlefields such as electoral politics, and the abortion rights movement was forced to engage in single-issue political tactics of its own. In the late 1970s and early 1980s, some feminist reproductive rights activists tried to influence single-issue abortion rights groups to broaden their approach, but they had little success at a time when the very legality of abortion was threatened (Staggenborg 1991). Nevertheless, abortion rights groups helped to maintain the larger women's movement in the 1980s and 1990s, attracting

many young women concerned about losing abortion rights. During periods when the antiabortion movement ebbs, reproductive rights groups have more freedom to pursue a broader range of concerns beyond abortion rights.

In sum, notions of reproductive rights have shifted with the larger socioeconomic and political environment. Nineteenth century voluntary motherhood activists, who lacked economic independence, demanded rights that would strengthen women's positions in families. As women gained more economic freedom with expanding industrialization, movement activists advocated birth control and later abortion rights. The rebirth of feminism in the 1960s inspired an elaborated notion of reproductive rights, which questioned existing medical authority. As black and other nonwhite feminists added their voices to the movement, consciousness of race and class issues, such as sterilization abuse, expanded. Countermovement threats to abortion rights since the 1970s limited the concerns of some movement organizations, but also helped to bring new activists into the reproductive rights movement.

2. Research on Reproductive Rights

Social scientific research on reproductive rights has examined reproductive rights movements and countermovements, changes in the medical profession, variations in public policies on abortion, court rulings on abortion, voting patterns of elected representatives, public opinion, demographic profiles of contraceptive and abortion users, public discourse and media coverage of reproductive rights campaigns, and a variety of other issues. Three major categories of research are described here.

2.1 Social Movement Research

Analyses of reproductive rights movements have focused on the conditions giving rise to such movements, their evolving organizational structures, strategies and tactics, conflicts with opponents, and outcomes. With regard to the origins of reproductive rights movements, research points to the importance of the political environment as well as available organizational bases and resources. The US abortion rights movement, for example, arose in the context of the protest cycle of the 1960s, in which the successes of the civil rights movement influenced the growth of other movements. Civil rights victories in the courts were certainly one impetus for abortion rights litigation. Other social movements, including both the population movement and the women's movement, provided organizational bases for the abortion rights movement (see Staggenborg 1991).

Beyond explaining the emergence of reproductive rights movements, analysts have examined their on-

going activities and outcomes. Studies of the women's health movement have examined the difficulties involved in establishing and maintaining feminist health clinics, changes in the movement over time, and the extent to which women's health concerns have become institutionalized in current medical practice. In the case of the abortion conflict, analysts have examined interactions between the abortion rights movement and the antiabortion countermovement. Organizational analyses of movement changes over time show that abortion rights movements in various countries have generally grown in strength in response to antiabortion threats.

To explain the intensity of the abortion conflict, many analysts have sought to connect the conflict to twentieth century shifts in values and lifestyles. For those opposed to these changes, abortion symbolizes a whole cluster of threatened values. In *Abortion and the Politics of Motherhood*, Luker (1984) argues that the abortion battle is a clash between two groups of women. Among activists in California, she found that advocates of abortion tended to be educated, career-oriented women who saw motherhood as only one part of their lives, whereas opponents had committed themselves to the traditional female role of wife and mother and felt threatened by its declining status.

Such case studies have been important in revealing the symbolic meanings of abortion for activists and in showing how the conflict has intensified over time. In Toronto, Cuneo (1989) found that the composition of the antiabortion movement changed over time. Early opponents of abortion were liberal Catholics who defended the civil liberties of the fetus and did not oppose changes in gender roles, but they were gradually pushed out of the movement by defenders of traditional family and religious values who regarded abortion as both a symbol and a cause of declining values. In Fargo, North Dakota, Ginsburg (1989) found that early activists on both sides of the abortion conflict actually shared some common ground, including a concern with community and collective responsibility. However, the conflict became more polarized over time, particularly as media coverage encouraged extremism in the antiabortion movement.

2.2 Analyses of Public Discourse on Reproductive Rights

Related to research on social movements are analyses of public discourse on reproductive rights, particularly abortion. Condit (1990) examines shifts in public discourse on abortion in the USA from 1960 to 1985, using sources such as newspapers and television shows. She demonstrates the persuasive force of different types of discourse, including value-laden phrases such as the 'right to choice,' narratives about women's experiences with abortion, and characterizations such as the 'back alley' of illegal abortion. Condit describes

how early 1960s narratives about women's experiences with illegal abortion, which portrayed ordinary women needing abortions, aroused public sympathy and made abortion a public concern. These narratives were limiting in that they focused on the needs of 'good' women with 'good' excuses for abortion rather than on the reproductive rights of all women. Nevertheless, they helped to change the public view of abortion as 'wrong'—and in doing so provoked 'prolife heritage tales,' which countered that abortion is always wrong. Later in the 1960s and in the 1970s, the argument broadened as abortion rights activists demanded equality for women and the 'right to choice' while antiabortionists argued for the 'right to life' of the fetus. Condit analyses in detail the social force of the different images and rhetoric used by each side and the social compromises that have been negotiated in different arenas in response to the debate.

Comparative research on abortion politics is needed to show how discursive processes vary with different political cultures and institutional structures. Myra Marx Ferree, William Gamson, Jurgen Gerhards and Dieter Rucht have been comparing the changing influences on abortion discourse in Germany and the USA. Ferree and Gamson (1999) analyse the impact of the organization and discourse of the supranational women's movement, the national women's movements in each country, and the political context of abortion policy in each country. The International Reproductive Rights Research Action Group has found both an international diffusion of feminist discourse on reproductive rights and remaining silences on the subject of female sexuality (Petchesky 1997).

2.3 Research on Public Opinion

An extensive body of literature examines public attitudes toward abortion. Analyses of public opinion surveys in the USA show that approval of abortion increased sharply between 1965 and 1973, when the US Supreme Court legalized abortion, and has remained relatively stable since then. Opposition to abortion is correlated with religiosity and other conservative positions on issues of personal morality, and is also linked, more weakly, to opposition to women's rights (see Cook et al. 1992). European data on trends in values suggests a long-term process of secularization and acceptance of individual discretion in terms of personal morality in Western industrialized countries, which may also explain trends in US attitudes on abortion (Rossi and Sitaraman 1988).

Comparative analyses of abortion attitudes in the USA and Canada reveal strikingly similar patterns in the two countries (see Jelen and Chandler 1994). In both countries, abortion attitudes are remarkably stable, with majorities of the public falling into the middle ground of continued support for abortion under certain circumstances. Nevitte and his

colleagues find that support for legal abortion is predicted by similar variables in both countries, including religiosity, 'postmaterialist' values, feminism, and education. Such analyses are important in predicting the future of the abortion conflict. With economic prosperity, increases in postmaterialism and the salience of feminist issues are likely to increase support for reproductive rights, although waning materialist concerns may also increase concerns about abortion among religious fundamentalists who oppose abortion (Nevitte et al. 1993, p. 28).

Other affluent countries exhibit similar patterns. Gallup polls taken in 1981–4 and again in 1990–4 in a number of different countries show that majorities of respondents approve of legal abortion for certain reasons such as threat to the mother's health, and that these attitudes are stable over time (Simon 1998). Although opposition to feminist positions on reproductive rights remains, public opinion in affluent countries is generally supportive of women's access to abortion.

Reproductive Rights in Developing Nations

No sharp distinction can be made between affluent and developing nations with respect to the evolution of the concept of reproductive rights. The notion developed through intense dialogues involving feminist communities in Northern and Southern nations. The concept of sexual rights developed concurrently. The two concepts occasioned theoretical controversies within the feminist community and opposition from national and global conservative political forces.

The two concepts are now enshrined in United Nations documents. In 1994, the Program of Action of the International Conference of Population and Development (ICPD Cairo, 1994) defined reproductive rights as:

[Embracing] certain human rights that are already recognized in national laws, international human rights documents and other consensus documents. These rights rest on the rec-

ognition of the basic right of all couples and individuals to decide freely and responsibly the number, spacing and timing of their children and to have the information and means to do so, and the right to attain the highest standard of sexual and reproductive health. It also includes their right to make decisions concerning reproduction free of discrimination, coercion and violence. ... (Paragraph 7.3)

A year later, the Platform of Action of the IV World Women Conference (IV WOW Beijing) reaffirmed the ICPD principle and spelled out the substantive contents of women's sexual rights:

The human rights of women include their right to have control over and decide freely and responsibly on matters related to their sexuality, including sexual and reproductive health, free of coercion, discrimination and violence. Equal relationships between women and men in matters of sexual relations and reproduction, including full respect for the integrity of the person, require mutual respect, consent and shared responsibility for sexual behavior and its consequences.

1. Historical Background

Almost a century of North–South interactions concerning birth control preceded the recent establishment of the concept of reproductive rights. From the early twentieth century, eugenic societies, neo-Malthusians, the socialist movement, and advocates of sexual hygiene had developed connections with colonial territories and Southern independent nations. Beyond these intentional efforts, ideas had been largely spread worldwide in a more incidental way, by labor migrants, colonial functionaries, and progressive political activists.

The expansion of eugenic societies and Malthusian networks has been extensively examined. The biography of Margaret Sanger, the North American birth control advocate, is a privileged subject of analysis. From the late 1920s, Ms. Sanger was involved in international advocacy in association with neo-Malthusian and eugenic networks. Research has revealed the close links between her efforts, colonial administrations, and local ideologies of class, caste, ethnic, and racial domination. These networks would play a major role in the second wave of global advocacy for fertility control in the 1960s and 1970s. By then Ms. Sanger had sponsored research leading to the invention of the contraceptive pill which, together with the first IUDs, were being disseminated in developing nations.

In contrast, the path through which Emma Goldman's socialist views on women's reproductive self-determination traveled south remains largely unexplored. The Cuban experience suggests a resonance far beyond the pioneering initiatives taken by Goldman in the early days of the Soviet Union, as abortion was legalized in 1959, immediately after the revolution. Recent research has also drawn attention

to some of the more progressive ramifications of Ms. Sanger's endeavors. One illustration is provided by Mexico where, in 1916, in Mexico, after a Feminist Congress, a booklet written by Margaret Sanger, *'Birth Regulation,'* was disseminated. In 1925, the same publication was distributed freely by the anti-clerical Calles Administration.

Having originated from contradictory theoretical sources, birth control ideas were given different meanings by diverse interpreters. In India, where the spread of neo-Malthusian ideas coincided with the intensification of the independence struggle, they sparked harsh controversies within the Gandhian movement. In Mexico, contrasting with the climate of the previous decade, a pronatalist General Population Law was approved in 1936. In the same period, mother and child care programs and family benefits were adopted in Brazil, Argentina, Chile, and Uruguay. These initiatives, which were conceived as accompaniments to early industrialization strategies, converged with the Catholic Church's resistance to all variants of birth control advocacy. This climate silenced existing progressive strands and inspired adaptations of conservative eugenic streams. In Brazil, for instance, ideologies advocating racial and ethnic miscegenation to 'whiten' the population gained legitimacy.

This background determined the immediate post-Second World War environment. In Latin America, previous such policies gained leverage from the adoption of import-substitution industrialization strategies. In other regions, the acceleration of decolonization brought the idea that large populations were a positive element in the establishment of new nation states. Rapid economic growth favored a lowering of mortality rates worldwide. However, as industrialized nations entered a second cycle of fertility decline, in developing nations, where demographic transitions were taking place, fertility rates remained high. In the 1950s, Alfred Sauvy, the French demographer, conceived the categories *First, Second, and Third World*. The central parameters for this demarcation were the demographic differentials between the three zones.

In the late 1960s, fertility control premises became a 'grand ideology,' supported by United Nations agencies, public financial institutions, bilateral donors, private foundations, and the International Planned Parenthood Federation and its national associates. Scientific evidence was collected to prove that rapid demographic growth had negative impacts on the economic development of Southern countries. Extreme positions went as far as to argue that population control would have the additional benefit of preventing revolutionary uprisings across the South.

Although pressured from outside, developing nations were not easily or immediately persuaded. Indeed, at the Population Conference of Bucharest of 1974, they counteracted by proposing a policy agenda that combined reform of the international economic

order, domestic economic growth and investments in basic needs. This position became crystallized in the lemma: 'Development is the best contraceptive.' Yet, not all developing nations remained faithful to their Bucharest commitment. By the late 1970s, draconian population control was already in place in Asia, particularly in China and India. In the other regions countries resisted longer.

Feminist initiatives were also blossoming south of the Equator. Feminist groups initially supported the Bucharest critique of population control. Gradually, however, they came to perceive that women's needs and rights were not being addressed by either pronatalist or antinatalist programs. In some settings, women's fertility was targeted. In others, women's ability to freely decide on reproductive matters was curtailed by pronatalist ideologies. In a few countries the two approaches were implemented in combination, the racial and ethnic origin of the client being the determining factor for selecting which approach was used for whom. Overall, the quality of information and care provided by both MCH and family planning programs was extremely poor.

The early feminist critique of population policies was preceded and surrounded by other relevant institutional processes. The 1968 International Human Rights Conference, held in Tehran, approved a principle ensuring couples the '*basic human right to decide freely and responsibly on the number and spacing of their children and a right to adequate education and information in this respect.*' In Bucharest, it was rephrased to extend these rights to individuals (not just couples) and to ensure access to the means of exercising them. Nevertheless, until the 1990s, individual rights in regard to reproductive matters remained subordinated to the primacy of preventing the population crisis.

Bringing gender concerns into family planning frameworks evolved along with other efforts aimed at women's equality. In 1975, the First United Nations sponsored International Women's Conference was held in Mexico City. Coercive measures of population control were debated and the final document proclaimed respect for the bodily integrity of women as '*a fundamental element of human dignity and freedom.*' This was followed by the approval of the Convention on the Elimination of All Forms of Violence against Women (CEDAW) in 1979. CEDAW affirmed women's rights to family planning, their equal right (with men) to decide on the number and spacing of their children, the right to maintain their jobs while pregnant, and to have access to maternity leave and child-care. In 1981, a UN Symposium on Population and Human Rights held in Vienna also declared that '*Both the compulsory use of abortion and its unqualified prohibition would be a serious violation of human rights.*'

Despite this emerging consensus, the climate of debates began to change. In the International Population Conference of Mexico in 1984, developing

countries expressed a broader acceptance of family planning programs and reaffirmed women's right of access to contraception. However, an alliance between the Reagan Administration and the Roman Catholic Pope made the subject of abortion a major controversy. The United States cut funding for international family planning activities, saying that the programs facilitated access to abortion. (This US policy remained in place until 1993.) Some family planning organizations openly contested this US policy and disseminated information about it among their Southern partners. Abortion was openly debated at the NGO Forum of the Women's Conference of 1985 in Nairobi. In 1988, the meeting of the International Federation of Gynecology and Obstetrics in Rio de Janeiro was preceded by the Christopher Tietze International Symposium on Women's Health in the Third World, a critical event in addressing abortion rights internationally. By the end of the decade, the World Health Organization adopted the notion of reproductive health that would be rapidly incorporated by other institutions and advocacy groups becoming an important conceptual adjunct to the idea of reproductive rights.

Other contributions to the conceptualization of reproductive rights came from women's organizations in Southern nations. Though small-scale, these grassroots organizations engaged in constant dialogue with their societies to transform sexist attitudes and practices. Sometimes they influenced legislation and policy to enhance women's health. In all contexts, feminist organizations had to confront the powerful influence of international population policies or the resistance of pronatalist ideologies.

This blossoming of feminist advocacy coincided with the first ripples of globalization. The debates evolving in industrialized countries filtered into Southern societies through various communications streams. Feminist publications such as *'Our Bodies, Ourselves'* were read in English speaking circles. Political exiles brought back home the stories of feminist struggles in relation to reproduction and sexuality and adapted innovative consciousness raising strategies, as in the case of gynecological self-examination. The mainstream media provided some information.

Local groups built connections with each other and with the Committee for Abortion Rights and Against Sterilization Abuse (CARASA) in the United States, and the International Campaign on Abortion, Sterilization and Contraception (ICASC) in Europe, which had spawned the very first formulation of reproductive rights. In 1984, a first Latin American Women's Health Meeting was held in Colombia. The International Campaign on Abortion, Sterilization, and Contraception also hosted, in Amsterdam, the first International Reproductive Rights Conference.

In Amsterdam, the International Campaign was renamed the Women's Global Network for Repro-

ductive Rights (WGNRR) and given a broad mandate to address all issues related to women's reproductive health, not only those involving abortion, sterilization, and contraception. Reproductive rights were defined as *'women's right to decide whether, when and how to have children—regardless of nationality, class, race, age, religion, disability, sexuality, or marital status—in the social, economic and political conditions that make such decisions possible.'*

The next WGNRR conference held in San Jose, Costa Rica (1987) started an international campaign on maternal mortality and inspired the creation of the Latin American Campaign for the Decriminalization of Abortion. In 1988, in a feminist meeting preceding the Tietze Symposium in Rio, the debates concentrated on ethical aspects of population control policies, abortion, and new reproductive technologies. In Manila, in 1990, during another WGNRR Women's Health Conference, the idea was raised that the international reproductive rights movement should conceptualize a feminist population policy. As globalization intensified, a clear acceleration occurred in the circulation of these ideas.

The United Nations Conferences of the 1990s were conceived as an interconnected series of global debates starting with Environment and Development (Rio 1992) and moving forward to address Human Rights (Vienna 1993), Population and Development (Cairo 1994), Social Development (Copenhagen 1995), Women (Beijing, 1995), Human Settlements (Istanbul, 1996), and Food Security (Rome, 1996). Whereas in the 1970s and 1980s, Southern feminist intellectual and political endeavors evolved largely in isolation from international policy arenas, in the 1990s, 'they involved' meant direct engagement in these negotiations. In Rio, access to reproductive health was added to conventional family planning language. Vienna's definitions with respect to women's human rights affirmed that they applied to both the public and private realms, thereby creating the basis for the further developments of Cairo and Beijing regarding reproductive and sexual rights.

2. *The Contents of Reproductive and Sexual Rights in the Southern Feminist Perspective*

The adoption of a reproductive rights framework by advocacy groups within developing nations entailed a broadening of its original focus—abortion, contraception, and sterilization—to include maternal mortality, prenatal and obstetric care, breast and cervical cancer, and adolescent and postmenopause health. The Southern perspective also underlined the need to incorporate attention to women's economically productive roles in addition to their biologically reproductive functions. This required a better understanding of the correlation between sexual and reproductive

health and endemic and chronic diseases, as well as occupational, environmental and mental health hazards, and afflictions.

In the 1980s, the scope and intensity of abortion-related initiatives varied across regions, being more visible in Latin America (particularly Brazil), the Philippines, and South Africa. Abortion was always addressed as part of a broader reproductive health and rights agenda, never as a 'single issue.' Efforts to decrease maternal mortality were prioritized by most countries and within these efforts new venues for addressing abortion have emerged. Both ICPD and IV WCW final documents recognize abortion as a major public health problem, affirming that, in circumstances where it is legal, it should be safe. The Beijing Platform of Action recommends that countries review laws containing punitive measures against women who have undergone abortion.

Contraception has always been a cross-regional concern, often involving United States and European advocacy efforts. Research has been devoted to sterilization, IUDs, injectables and implants, methods privileged by fertility control programs. Long before the feminization of the HIV-AIDS pandemic, Southern feminist organizations emphasized the disease-preventing advantages of barrier methods, such as the diaphragm.

In the 1990s, campaigns were launched against specific technologies: Norplant, the contraceptive vaccine, and Quinacrine (a method of chemical sterilization). Advocates engaged in dialogues with researchers, pressuring for better ethical standards and redefined research priorities. One critical outcome of these efforts was the investments aimed at developing microbicides to protect women against HIV-AIDS and pregnancy. Concern arose regarding the expanding use of prenatal sex-selection techniques in India and China.

In their efforts to address reproduction as a right, not merely a woman's obligation, Southern advocacy groups very early challenged gender inequalities in the sexual domain. Issues such as early marriages, rape, forced prostitution, trafficking, and female genital mutilation have been raised under the umbrella of violence against women. Sexuality, as such, however, gained enormous visibility under the impact of the HIV-AIDS pandemic. The inadequacy of contraceptive methods used in most Southern countries became clear, as they offered no protection against infections. Research in Africa showed the association between HIV and other sexually transmitted infections.

The World Health Organization coined the notion of sexual health, and initiated preventive strategies that required a better understanding of sexual behavior. Most Southern governments resisted recognizing the impact of the pandemic, partly because it was initially portrayed as affecting only certain risk groups (homosexuals, sex workers, and drug addicts). Among Southern feminists, some time elapsed before

the feminization of HIV-AIDS became a priority. An important recent political development is the multiplication of gay and lesbian rights advocacy groups in developing nations. The concept of sexual rights presently encompasses nondiscrimination on the basis of sexual orientation or HIV-AIDS status. Other ideas have diffused that promote responsibility by men in sexual matters and transforming notions of masculinity.

Thus, although the emphases do vary, the content of reproductive and sexual politics within affluent and developing nations are similar. The concepts exemplify an 'ideoscape' which, having broken through national and cultural boundaries, has gradually crystallized in a globally accepted discourse. These ideas are present in Southern national and regional advocacy groups and among Southern academic and research initiatives, particularly in Latin America and South and South East Asia.

3. Conceptual Debates

A number of inter related controversies developed as reproductive and sexual rights were conceptualized in developing nations. A first one can be retraced back to the global debates around abortion in the 1980s. In developing countries, should abortion be addressed as a single issue, as in the United States advocacy strategies, or part of a comprehensive reproductive health and rights agenda? A theoretical and political problem underlay this early controversy. In affluent societies, where women's basic needs had been largely met, restrictions in the access to abortion strikingly expresses gender inequality with respect to the individual right to decide. However, women's exercise of reproductive rights in developing regions (and among marginalized groups in affluent societies) is primarily curtailed by economic disadvantages that affect men and women.

A related controversy arose from the critique of the intrinsic individualistic and contractual nature of the Western concept of rights. Feminist thinkers recognized that any approach to sexual and reproductive politics must take into account political, economic, and cultural constraints on individuals. The full exercise of these rights is dependent upon an enabling environment including democratic conditions that allow citizenship rights, women's empowerment, and material support, such as transportation, childcare, jobs, and education. Examples of the importance of such support are easily found. In all developing nations, women die because they do not have transportation or because basic equipment is lacking in health facilities. In rural India and China, vaginal infection results from precarious sanitation. Poor women die of botched abortions, while rich women can pay for safe procedures. In India, abortion has been legal since the 1970s, but the quality of care

remains poor. Young women are infected by HIV-AIDS by having sex to get money to survive.

The emphasis on enabling conditions does not imply ignoring gender inequality and how it restricts women's ability to protect their bodily integrity and personhood. Research that explored ordinary women's perceptions of sexual and reproductive rights found that few women use these terms, but they do understand that the principles refer to being able to make decisions about procreation, to be free from harassment by men, to protect themselves against domestic violence and preventable illness, and to have access to adequate health care. When these rights are not in place, women cannot exercise civil and political rights. The framework implies both positive rights, such as reproductive health care and employment, and negative rights, such as protection against rape and discrimination, regardless of sexual orientation or marital status.

Some have criticized the emphasis on sexual and reproductive health as being too narrow when compared with the broad women's health agenda defined in the 1980s. To address this limitation requires understanding links between gender, social inequality, and health. One priority is to ensure that health reform policies improve women's access to health services. Another concern is to understand how men's violence against women affects women's health and mount policies to confront this. Exploring this topic may also lead to addressing the adverse effects on women of cultural constructs of masculinity.

4. Policy and Political Challenges

A human rights approach to sexual and reproductive politics still faces major obstacles to effective implementation. The definitions of related rights as enshrined in United Nations documents are not binding. Even if these new principles are translated into binding instruments, international human rights mechanisms have little power to enforce them, especially if violators are private parties rather than states.

Additionally, the effective implementation of women's reproductive and sexual rights must challenge a rigid and persistent 'public'-'private' distinction in international human rights law and national legal systems. This breaking up of boundaries is crucial for women, whose lives in many cultures are still locked within domesticity. To help women, human rights claims must penetrate the 'private sphere' within which marital rape, female genital mutilation, virginity codes, and repudiation of birth control occur. On the other hand, public actions of the state and its agents also very often violate women's sexual and reproductive self-determination.

Greater challenges may lurk in globalization. Poorly understood and poorly regulated, globalization is creating growing inequalities of income within and

across countries. Women are entering labor markets everywhere. Earning more income often raises a woman's value, but can also result in even tighter controls over her life. Earnings sometimes provide women with greater physical mobility, increased personal autonomy, and the possibility of breaking through gender barriers and patriarchal or other mechanisms of male control.

Concurrently—in reaction to the negative effects of globalization—political, national, religion-based, ethnic, or other identities are being strengthened which revive traditional gender systems and controls. There is a proliferation of both antiabortion and 'profamily' groups associated with religious fundamentalists—Catholic, Protestant, Islamic—and of conservative politics that systematically oppose women's reproductive and sexual freedom on behalf of 'fetal rights,' womanly duty, and the defense of hierarchical power within the family. These forces are at play in the United Nations, and other global policy arenas, whenever gender related issues arise. Moreover, racism, nationalism, and ethnic hatreds also pose threats to women's reproductive and sexual health. Chronic violence, genocide, 'ethnic cleansing,' and military occupation have often meant mass rape, abandonment, refugee status, increased vulnerability to forced prostitution, trafficking, unwanted pregnancy, and sexually transmitted diseases.

The promoters of a globalized economy often support the breaking down of traditional gender systems and greater freedom for women. Nevertheless, they remain largely unconcerned with growing economic inequality which, in most cases, lies at the root of fundamentalist trends, patriarchal revivals, and ethnic strikes. For developing countries, globalization has led to large-scale debt and trade inequities. Fiscal austerity, imposed through structural adjustment programs, has negatively affected the availability and quality of public social services.

The fulfillment of the twentieth century promise of women's sexual and reproductive freedom requires these contradictory trends to be challenged and eventually tamed. Redefining development policy priorities to create an enabling environment that will both provide a firm basis for individual self-determination while restraining the appeal of moral conservative forces remains a daunting task for the early years of the new millennium. The historical experience in both the South and the North also suggests that such fulfillment additionally demands sustained intellectual and political efforts aimed at promoting and enhancing the acceptance of all forms of diversity and tolerance within and across societies.

Republic

'Republic' comes from the Latin *res publica*, the shared or common thing. It first described the political regime instituted by the Romans after they deposed their kings in 509 BC. The founding of the Republic symbolized the rejection of rulers who treated the political community as their private property. The word *publica* probably derives from the Latin *populus*, 'people.' Cicero in the first century BC calls the *res publica* a *res populi*, a thing that belongs to the people. That the political community belongs to the people rather than those who rule reverberates throughout the long history of the term as it takes on and sheds concepts drawn from the Roman experience.

1. The Roman Legacy

Polybius, in the second century BC, described (not entirely accurately) the Roman Republic as a 'mixed regime' where monarchy, aristocracy, and democracy balanced one another, providing stability and protection from the constant cycling of regimes from one form to another. Sallust, writing during the political chaos of first century BC Rome, turned away from institutional analyses to character and emphasized the foundation of the Republic on political virtue and traditional moral values, qualities whose loss would bring about the demise of the Republic. The civil wars ended with the Principate of Augustus which returned Rome to one-man rule. Tacitus, writing in the early

years of the Principate, recalled the liberty of the Republic in contrast to the tyranny of the increasingly despotic Roman emperors. All these elements, the mixed regime, political and moral virtue, and liberty as the absence of the oppressive rule of a king have followed the word 'republic,' though neither consistently nor necessarily in unison. 'Republic' recalls Rome, but the Greek city-states, different in structure and size, also came to be called republics, and Athens and Sparta, along with Rome, became models of republican regimes for later ages.

During the Middle Ages, *respublica* simply meant the political community in contrast to the church; it was the body of which the prince was the head, the wife to whom the prince was joined in matrimony. It incorporated none of the elements of liberty, institutional balance, or political virtue that connected the idea of republic back to the experiences of Rome. At the close of the medieval period, however, republic recaptured the connotations of liberty understood as hostility to tyrannical rule. The early Italian renaissance witnessed a shift from medieval praise of the Principate as a reflection of God's rule to admiration for the political liberty of the Roman Republic. A number of the Italian city-states of the Renaissance gained political independence and instituted republican regimes of self-rule. Meanwhile, humanist writers of the early Renaissance, recalling republican Rome, appealed to the liberty and political virtues of antiquity against the faith in a God-willed monarchy that dominated the medieval period. Nevertheless, tensions arose between republican virtues which fostered renown for service to the secular community and religious virtues which glorified God. With Machiavelli in the early 1500s, concern about devotion to and participation in a secularized polity disappeared.

2. Machiavellian Republicanism

Machiavelli's begins *The Prince* by rejecting the conventional Aristotelian typology of monarchy, aristocracy, and democracy; he boldly stated that all dominions 'now and in the past' have been 'either republics or principalities.' Machiavelli's dichotomies never persevere throughout his writings, but *The Prince* largely treats principalities and his *Discourses on the First Ten Books of Livy* (1513) discusses republics with special attention to Rome. Other republics like Sparta and Venice surface as well offering variations and qualifications on the Roman model. More nuanced than works by Renaissance writers who simply identified republics with liberty, or sought to find a republican heritage for their cities in the history of the Rome, Machiavelli identifies the tensions inherent in republican regimes, their occasional need for dictatorships, their dependence on conflict between parties as a condition for freedom, and their glory in imperialist expansion. Machiavelli,

along with republican authors of the period, praised the mixed regime, but he saw it as necessary for a regime to order the conflicts that plague any free polity. Further, while praising republican virtues of devotion to and participation in the political regime, and while worrying about the effects of a corrupt self-interested citizenry, he also recognized that republican virtues entailed the conquest of others.

Despite Machiavelli's somewhat ambiguous presentation of a republican Rome that needed occasional dictators and men like Brutus who were willing to sacrifice their sons for the preservation of the regime, his *Discourses*, with its reliance on Polybius' mixed regime, became a primary source for antiroyalist, republican literature of seventeenth century England. James Harrington, for instance, begins his utopian republican tract *Oceana* praising Machiavelli as the sole retriever of ancient prudence concerning governments devoted to the public interest. In addition to praising economic equality as the foundation of a peaceful regime, Harrington continued the republican theme of the mixed government by proposing a bicameral parliament where an elected and rotating aristocratic senate would be checked by a popular assembly. As with the other republican authors of his time, Harrington relied on ancient Sparta and contemporary Venice along with Rome as models. All demonstrated the viability of the republican model with their mixed regimes, and all were frequently paraded as exemplars of popular engagement and liberty in contrast to monarchical oppression.

The participatory expectations meant that seventeenth and eighteenth century English authors often associated republicanism with the aristocratic leisure essential for an engagement in political life. The contemporaneous emergence of liberal thought based on the rational pursuit of self-interest set up a conflict between an elitist republic relying on men of public virtue with resources and leisure for public life and the egalitarian principles of a liberal society focused on rights, consent (a much weaker political act than actual engagement), and the absence of oppression. The liberal perspective did not require self-sacrifice; the liberal individual, unlike the republican, pursuing private interests could be oblivious to the public good. Liberal virtues of frugality and moderation supporting economic success were not the republican virtues that supported the moral and political life of a nation.

3. Enlightenment Republican Thought

The English republicans, drawing on the Polybian mixed regime, articulated a theory that allowed for the presence of a monarch, albeit one limited by assorted checks. Debates arose as to whether the checks were sufficient or too strong, but a monarchical regime that might allow for liberty contrasted starkly with the absolutism of eighteenth century France.

Montesquieu's *Spirit of the Laws* appeared in this latter context. Montesquieu replaced the still dominant Aristotelian typology with despotism, monarchy, and republic; the last he divides into the aristocratic republic, marked by the love of honor, and the democratic republic, characterized by 'political virtue' or the 'love of equality.' Drawing on themes of civic virtue from Sparta, the Roman Republic, and the *Discourses* of the 'great man' Machiavelli, Montesquieu writes that political virtue in a democratic republic means the denial of self for the sake of the whole. According to Montesquieu, the democratic republic would be possible only in a small, homogenous community where there was no attention to individual economic success nor worries about economic inequalities. The simplicity of the democratic republic would allow for none of the conflicts that arise with the emergence of the wealthy few. Montesquieu's democratic republic depended on political virtue, but it did not offer much happiness. In contrast to the democratic republic, Montesquieu wrote about a free and happy people who inhabited a large commercial nation, namely England, that with its 'mixed regime' could incorporate variety, economic activity, and inequality in a way that a democratic republic could not and that could offer liberty through the just execution and impartiality of its laws.

Montesquieu's praise of the English constitution suggested freedom would be possible in large, heterogeneous regimes, if laws were well executed and a proper balance between executive and legislative powers and within the legislative branch existed. Rousseau's *The Social Contract*, in contrast, affirmed that freedom was possible only in small homogenous republics where all citizens, as members of the sovereign body, participated in the life of the city through law making. A large city where citizens devote themselves to commerce, crafts, and comforts rather than to political life undermines attachment to the community. Free regimes, according to Rousseau, depend on the political engagement of all in self-rule; we are slaves if do not legislate for ourselves. Rousseau returned to Rome for his model of participatory republican life where, in addition to popular assemblies, there was a censorial tribunal ensuring the purity of opinions and morals. Rousseau's republic depended on a similar control of citizens' opinions and required a civil religion to instill 'sentiments of sociability.' A decline in morals would bring about political decay and the loss of the self-rule at the heart of free republics. Preservation of morals and attachment to the city for Rousseau rested on maintaining a small state, unperturbed by the bustle of economic activity or the cosmopolitanism of Parisian culture.

4. The Issue of Size

The question of whether republican liberty was possible in large nations or only in small ones was central

to the debates about ratification of the US Constitution. *The Federalist Papers*, arguing for adoption of the constitution, drew upon the equation between a republic and liberty. Using Publius as their common pen name, the authors of *The Federalist Papers* identified with a founder of the Roman Republic who (in a history their audience would have known) helped overthrow the Roman kings. *The Federalist Papers* famously argue for a republic, not a democracy. The republican principle affirmed: 'The people are the only legitimate fountain of power,' but when a multitude of people exercise legislative functions in person, the ambitious intrigues of the executive magistrates lead to tyranny. Freedom in a republic does not require that the people themselves exercise legislative authority directly. The power that rests in the people must be filtered. Liberty may require that all power derive from the people and that those entrusted with power remain dependent on the people, but stability requires the opposite. Admitting that the petty 'republics of Greece and Italy' evoke 'sensations of horror and disgust' at the rapid succession of revolutions, the defenders of the constitution claim that it incorporates newly discovered maxims derived from political science that apply 'republican remedies' to the 'diseases most incident to republican government': namely, representation, legislative checks and balances, and the enlargement of the sphere of government. The new republic does not rely only on the virtue of its citizens, but on institutions that protect against oppression, afford liberty for its citizens, and ensure the excellence of those elected to office.

The Anti-Federalists arguing against the new constitution feared that the large centralized government necessary for a populous and heterogeneous nation would oppress its citizens, undermine any attachment they felt for one another, and stifle self-rule. Consent, critical for a free republic, they argued, cannot be represented; it must come from the individual citizen. A 'representative republic' is a contradiction in terms. Lost would be the community of like individuals; citizens would be left to nurture vices of self-interest rather than cultivate republican public virtue. A centralized government would fall into the hands of the wealthy few transforming the new republic into an aristocracy or even a monarchy. The Anti-Federalists emphasizing a small, homogenous polity of virtuous citizens were the last great defenders of the classical republic.

5. Republic Today

Though *The Federalist Papers* distinguish democracies with their demagogues and upheavals from orderly republics, democracy and republic have over the nineteenth and twentieth centuries converged conceptually. Both identify the body of citizens as the fount

of political authority and the overlap between the two regimes has obscured distinctive political structures that might limit recollections of Roman institutions only to republics. With the absence, indeed impossibility, of direct democracy, both democracies and republics have taken on representative forms of government and most democracies have adopted variations of the Polybian mixed regime. Nevertheless, a return to republican ideals of political virtue and engagement has surfaced in an effort to address what is portrayed as the excessive individualism of citizens in liberal democracies. Among contemporary communitarians, ancient republics are symbols of a lost political world where citizens found fulfillment in political life, not in the pursuit of economic success. This evocation of ancient republics has revived discussion about the role of republican ideals during the founding of the USA with communitarians eager to find in the early years republican rather than liberal roots. The concept of the republic to which they appeal goes well beyond the people as the fount of political authority and the mixed regime to the intangibles of political virtue and a shared life of the ancient republic.

Republican Party

The Republican Party is one of the two major political parties in the United States that have dominated American politics since the mid-1850s. The Repub-

lican party (also known as the Grand Old Party—GOP) emerged amid the sectional conflicts of the pre-Civil War era. Throughout most of its lifetime the party's electoral strength was centered in northern and western states. It was not until the 1960s with the realignment of southern whites toward the Republicans that the party was able to compete effectively in all sections of the country. The Republicans are the right of center party of American politics. It has a broad, multiclass base of support, which tends to be strongest among white, middle, and upper middle-class citizens. Since the 1980s its activist base has become increasingly conservative. Republican national level organizations have become well financed and professionalized and as a result intraparty influence has shifted toward the national organization.

1. Historical Development

The Republican Party emerged amid the conflicts of the 1850s as the Democratic and Whig Parties were unable to reconcile differences within their ranks over the slavery issue and the growing economic and cultural differences between the North and South. The immediate reason for the emergence of the Republican Party was passage of the Kansas–Nebraska Act of 1854, which overturned the ban on slavery in the Northwest Territory. This action by Congress touched off antislavery protest meetings that led to the creation of the party in 1854. In its first election, the Republicans had unusual success winning approximately 40 seats in the House of Representatives (Jones 1965, Moos 1956). In 1856, the Republicans established themselves as the principal opposition party to the then dominant Democrats when the Republican presidential nominee ran a strong second in the popular vote. Abraham Lincoln, formerly a Whig, became the first Republican president after the election of 1860 as the Democratic and Whig parties splintered along a North–South axis. In the Civil War that followed Lincoln's election, the Republicans were the party of national unity and freedom for slaves.

Despite occasional losses, the Republicans were dominant in national politics from the 1860s until the 1930s. It was, however, a sectionally based party of the North and West as the legacy of the Civil War and Reconstruction made it noncompetitive in southern states. The extent of Republican electoral domination during this period is demonstrated by its control of the presidency for 56 of the 72 years between 1860 and 1932. Despite Democratic control of congressional seats in the South, the Republicans also tended to dominate the Congress—controlling the House in 23 sessions and the Senate in 31 sessions out of a total of 36 (Jones 1965).

The Great Depression of the 1930s ended Republican dominance as the party was blamed for economic hard times and the Democrats achieved electoral

hegemony. The GOP's only presidential victories between 1932 and 1964 came in 1952 and 1956 when it nominated Dwight D. Eisenhower, a World War II hero, whose appeal was above party.

2. *The Republican Party in the Post-New Deal Era*

After a disastrous defeat in 1964, Republican fortunes improved although the party continued to have fewer party identifiers among the voters than the Democrats. Benefiting from deep schisms among Democrats over the Vietnam war, civil rights, and social policy, the GOP regained the presidency with Richard Nixon's 1968 election and 1972 reelection. Evidence of the party's continuing minority status can be found in the fact that in these elections it still was unable to win control of Congress and most state governments.

The resurgence of the Republicans after 1964 was based upon fundamental electoral changes as politics became less party-centered and more candidate-centered. There were also significant electoral realignments (Aldrich 1995). Particularly significant was the movement of southern whites toward the Republicans and away from the Democrats. Beck (1999) estimates that white southerners constituted 30 percent of the GOP's base electorate in 1996. With a base of support in southern and western states, the Republicans won three presidential elections in the 1980s and in the 1994 midterm congressional elections gained control of both houses of the Congress for the first time in 40 years.

The transformation of the Republicans from a party which for most of its history drew its electoral support almost exclusively from northern and western states into one with a southern base is demonstrated by the fact that after the 1994 election, the Republicans held a majority of the seats in the House and Senate from the South. Southerners constituted the largest regional group among both House and Senate Republicans. At the same time, Republican representation from the Northeast, once a bastion of party support, declined substantially so that northeasterners were the smallest regional group among House Republicans in the 1990s.

In addition to the shift in the partisanship of white southerners, other changes in the composition of the Republican party's electoral base have occurred since 1968. Whereas women traditionally outnumbered men, by the 1990s they comprised a minority in the party and as a result the party became less sensitive to the concerns of moderate and liberal females. There was also a change in the religious composition of the party. Support among mainline and nonfundamentalist Protestants has eroded steadily since the mid-1960s when they comprised 60 percent of Republican identifiers to slightly more than one-third of party loyalists in 1996. These shifts in the demographic characteristics

of Republican identifiers have been accompanied by an ideological change as the party's loyalists have become increasingly conservative. Beck's (1999) analysis revealed that whereas a majority of Republican identifiers were self-declared conservatives in 1980, two-thirds carried that designation in 1996.

Changes in the composition of the Republican electorate and the heightened conservative ideological commitment of Republican loyalists have had significant implications for the party. Conservative ideological interests have achieved greater influence within the party organization, among elected officials, most notably in the House of Representatives, and over nominations. There is also substantial internal division within the party between committed conservative ideologues, who tend to dominate the many party organizations as well as the House Republicans, and the more pragmatic and moderate Republicans exemplified by the party's governors.

3. *Republican Party Organization*

The party organization is a layered structure of national, state, and local units rather than a hierarchy controlled from the top down. The Republicans' organizational resources, however, involve more than its formal, legally constituted units. There are the thousands of personal campaign organizations created by Republican candidates, an array of partisan campaign consultants and allied interest groups which provide assistance in voter mobilization, money, staff, technical assistance, and media advertising (Bibby 1999).

3.1 *The Republican National Committee*

The Rules of the Republican Party, which are adopted at each quadrennial national convention, call for the creation of a Republican National Committee (RNC) which is charged with responsibility for the 'general management of the party, subject to direction from the national convention.' This authorization makes the RNC the official governing body of the party between conventions. Since its creation in 1856, the RNC has evolved from an organization in which functions were sketchily differentiated and performed by party notables every 4 years into a continuous operation with a large professional staff and budget (Cotter and Bibby 1980).

The RNC resisted reform efforts in the 1970s and has maintained a confederate organizational mode in which each state, plus the District of Columbia, Puerto Rico, American Samoa, Guam, and Virgin Islands have equal representation through a national committeeman and woman and a state chairman. RNC members are selected through procedures mandated by state law and state party rules. Since the full RNC

meets only twice a year, responsibility for operations of the committee rests primarily with the national chairman and senior staff. When the party controls the presidency, the national chairman is normally designated by the President and works in close conjunction with the White House staff.

Since the 1960s, the RNC has developed the capacity to raise massive amounts of money to support party activities and candidates. Thus, in the 1999–2000 election cycle, the RNC raised \$205.3 million, plus \$156.2 million in ‘soft money’ (money raised outside the restrictions of the Federal Election Campaign Act).

With this level of financial resources, the RNC has achieved a degree of autonomy that could not have been imagined in the 1940s and 1950s when it was dependent upon contributions from state affiliates. Through an extensive program of financial and technical assistance to state and local parties, it has gained intraparty leverage because RNC aid is given with requirements attached that the state units must meet. Through this process, Republican state organizations have been professionalized and gained enhanced candidate-support capabilities, but they have also become increasingly dependent upon the RNC for the resources essential for organizational maintenance and effective performance in state level campaigns.

The RNC has also used its financial resources to gain an unprecedented level of intraparty integration in implementing national campaign strategies. For example, in the 1999–2000 election cycle the RNC transferred \$93.0 million in ‘soft money’ to state and local party organizations for spending on general party overhead, voter registration, get-out-the-vote drives, and state and local campaigns. The RNC allocated these funds among the state parties in a manner designed to implement a national strategy geared to winning critical states in the presidential race and maximizing the party’s seats in the House and Senate. Through its programs of technical assistance and fund transfers the national party organization has been able to nationalize campaigns and integrate national and state party campaign strategy to an unprecedented extent (Bibby 1999).

3.2 The Senatorial and Congressional Campaign Committees

In addition to the RNC, the national organization of the party includes two autonomous units which focus their activities upon electing members of the House and Senate. Like the RNC, the National Republican Congressional Committee (NRCC) and the National Republican Senatorial Committee (NRSC) have evolved into well funded organizations with professional staffs. These campaign committees are headed respectively by an incumbent representative and senator. They engage in programs of candidate recruitment, fund raising, technical assistance to candidates,

and media advertising. They also channel and mobilize nonparty money to candidates from political action committees, wealthy individuals, and incumbent members of the House and Senate. Support is doled out to candidates on the basis of electoral criteria—the competitiveness of the constituency—not on the basis of candidate ideology or party loyalty.

Since 1996, the congressional and senatorial committees have placed increasingly heavy emphasis on ‘issue advocacy’ advertising in support of their candidates. These are media advertisements funded with ‘soft money’ that do not expressly advocate the election or defeat of a candidate, but which effectively convey either favorable or unfavorable images of candidates. The campaign committees also engage in independent expenditures which do involve express advocacy of the election or defeat of candidates. Through the use of these techniques the campaign committees have expanded their influence over the national political agenda, helped shape the issue agendas of individual House and Senate campaigns, and attacked their candidates’ opponents (Herrnson and Dwyre 1999).

3.3 State Parties

State level party units have also gone through a process of institutional strengthening since the 1960s. Republican state organizations tend to be stronger than their Democratic counterparts in their ability to engage in party building and candidate support activities (Cotter et al. 1984). As is true at the national level, there is a division of labor among state level organizations. Republican state central committees concentrate on state-wide races, voter mobilization, and party building, while legislative campaign committees focus their resources upon electing Republican state legislators.

4. The Republican Party Network of Issue-oriented Activists

American parties are increasingly networks of issue-based participatory activists. The sources for this trend can be found in a series of complex and interacting forces: the development of a postindustrial society in which noneconomic social/cultural issues have gained heightened saliency; sociological and economic changes that have created higher levels of educational attainment, reduced blue collar employment, and increased number of white collar workers; a decline in the availability of patronage as an incentive to participate in politics. Issue oriented activists have also been aided by changes in the rules governing presidential nominations that have diminished the role of elected officials and party leaders.

In the Republican Party these changes have had the effect of significantly shifting the locus of power toward ideologically conservative activists. In the highly participatory politics of Republican presidential nominations, candidates normally find it essential to stress their conservative bona fides if they are to have any hope of winning the nomination in a process dominated by presidential primaries and participatory party caucuses. Activists taking a leading role in these events as well as national convention delegates have been shown to be substantially to the right of the party's rank and file voters (Mayer 1996). Similarly, Bruce et al. (1991) found in a study of county level campaign workers that ideological 'true believers' outnumbered 'vote maximizers' by a ratio of 4.3:1 among Republicans.

Issue-based groups have gained an increasingly entrenched position within the Republican Party. The Christian Right, for example, has become an increasingly influential and sometimes dominant force within some state party organizations. The increasing involvement of groups and individuals whose motivation is not maximizing the vote but a commitment to policy and ideological concerns has created a problem for the Republican Party. With a conservative activist base that is needed for its campaign support and often to win party nominations, candidates often find themselves catering to the GOP's most conservative elements. However, such actions tend to alienate the more moderate elements of the party and voters without strong partisan commitments—the voters that are needed to win general elections. The party's future depends in large part on how this intraparty problem is resolved.

Republicanism: Impact on Social Thought

In the modern age, republicanism influences social thought by offering a distinctly political articulation of the general belief in the historical contingency of political and social order (Pocock 1975). Modern republicanism holds that political and social order is legitimate only if it serves the constitution of political freedom as nondomination. The possibility of changing forms of rule is understood as a condition of the institution of these forms (Arendt 1963). The existence of ineradicable and productive social divisions is a fundamental presupposition of the republican idea of politics, according to which social conflicts must be given their political expression and regulation (Lefort 1992).

Originating with Machiavelli's critical reception of the tradition of classical republicanism, pursued in the English and Dutch struggles against monarchic absolutism by the likes of Harrington, Sidney, Locke, and Spinoza, and systematized in the Enlightenment by Montesquieu and Rousseau, modern republican theory is directly put into practice in the American and French Revolutions by figures such as Madison, Jefferson, and Sieyès (Pocock 1975, Bock et al. 1990, Fontana 1994). In this sense, modern republicanism has been justly termed a 'revolutionary republicanism' (Wootton 1994).

1. Political Freedom as Nondomination

Modern republicanism describes political freedom as that arrangement in which 'the rule of law, resting on the power of the people, would put an end to the rule of man over man' (Arendt 1972 p. 139). Politics should be that domain of human affairs where domination

and rule can be questioned, checked, and even possibly abolished (Pettit 1997).

The modern republican ideal of freedom as non-domination or no-rule moves beyond both the negative and positive ideas of freedom (Berlin 1965). Negative freedom is an individual and private freedom from interference that requires a noncontesting relation to the commands of the political sovereign that protect and enable it from the outside. In contrast, the ideal of nondomination is political, not private, and consists of being 'subject to no man's will' (Sidney 1798, III, 16) by having the power to contest both arbitrary and legitimate domination. Freedom as nondomination also differs from ideals of self-rule or positive freedom insofar as these view some forms of rule (e.g., of the community over its members, of reason over passion) as intrinsic to the meaning of freedom, whereas from the perspective of freedom as nondomination, political activity is primarily understood in terms of its capacity to check the dynamics of domination and processes of ruling by empowering those who would otherwise fall into relations of dependence. Political freedom 'is there only when there is no abuse of power.... To prevent this abuse, it is necessary from the very nature of things that power should be a check to power' (Montesquieu 1748, XI, 4).

Modern republicanism sees the political abolition of domination as achievable through a combination of the 'rule of law' and the 'power of the people.' Although both of these elements can be found in classical republicanism as well, their meaning and relative priority undergo important changes in modern republicanism where 'all power is vested in, and consequently derived from, the People' (*Virginia Declaration of Rights* 1776, article 2) because its members are understood as the carriers of the ideal of non-domination: 'all men are by nature equally free and independent, and have certain inherent rights of which, when they enter into a state of society, they cannot, by any compact, deprive or divest their posterity' (*Virginia Declaration of Rights* 1776, article 1). As a consequence, the republican ideal requires that the rule of law find its support in the power of the people.

2. The Power of the People

The connection between the power of the people and the ideal of nondomination can be traced back to Machiavelli in his *Discourses on Livy* where, for the first time, 'the people' is defined as that subject position occupied by whoever acts in political ways that are motivated 'only [by the] desire not to be dominated' (Machiavelli 1517, I, 5).

The 'power' that is vested in 'the people' refers to those political practices and institutions of will and

opinion formation that integrate this political subject as bearer of the desire for nondomination into political life, alongside the established practices and institutions of legitimate domination, of which traditionally the most important elements were the deliberations of the senate and the commands of the monarch (Machiavelli 1517, I, 4). Harrington does away with the monarchical element, and takes into account only the nobles, represented by the senate, and the people, in order to give ultimate say to the latter: 'as the wisdom of the commonwealth is in the aristocracy, so the interest of the commonwealth is in the whole body of the people.... Whatsoever upon debate of the senate is proposed unto the people, and resolved by them, is enacted by the authority of the fathers and the power of the people, which concurring make a law' (Harrington 1656 p. 24). As Rousseau frames the issue, 'it is only the general will which compels individuals and there can be no assurance that an individual will is in conformity with the general will until it has submitted to the free suffrage of the people' (Rousseau 1762, II, 7). It is an axiom of modern republicanism that without this kind of political power vested in the people there can be no political freedom.

Likewise, since the people is conceived as a political subject whose foremost interest is nondomination or no-rule, it follows that it should not, as a people, engage directly in the process of governing or ruling on pain of self-contradiction. For this reason Madison is perfectly consequent when he claims, in the same article of *The Federalist*, that 'the people can never willfully betray their own interests,' and that the distinguishing feature of 'American government lies in the total exclusion of the people in their collective capacity from any share in the latter' (Hamilton et al. 1787, p. 63). Modern republicanism requires the principle of representation because it understands political representation not as a condition for the pursuit of more effective ways of governing a large population, but as the primary way to limit the powers of the state as an agency of legitimate domination.

3. Politics and the Primacy of Social Division

The analysis of society in terms of the conflict between heterogeneous social subjects and its causality in the emergence of political forms is a fundamental contribution of modern republicanism to social thought. Machiavelli shows that the opposition between those who 'desire not to be commanded or oppressed' and those who 'desire to command and oppress' constitutes a basic social division that, depending on how it is politically interpreted, gives rise to 'one of three effects in cities: principality or freedom or license' (Machiavelli 1513, IX). Similarly, Harrington observes that every state finds its basis in the social division of property. For that reason, he argues that an 'agrarian law' must be set at the

'foundation' of the republic. In so doing, Harrington both acknowledges the fundamental role of social conflict and seeks to regulate it by giving it a political form (Harrington 1656 p. 33). Modern republicanism holds that social divisions provide the basis of politics, and that politics has the task of giving or taking away form (laws and orders) in response to such conflicts, thereby expressing and regulating rather than extirpating or denying them (Pocock 1975, Lefort 1992).

After the American and French Revolutions, and well into the twentieth century, this relative autonomy of politics with respect to 'the social' comes under criticism thanks to the emergence of the idea of society as a form of organization that, in and through its divisions, is self-constituting and self-regulating. This idea of society opens the prospect of the abolition of politics and of the state, under the appropriate social conditions. Much of the impetus for the late twentieth century retrieval of the republican tradition comes from the need to recover a positive conception of politics and, along with it, a sense of the productive tension between state and society.

4. Republicanism and Institutionalization

For modern republicanism, politics consists of the practice of giving an institutional expression, or interpretation, to the divisions that constitute social relations. In particular, republican politics sets out to refashion the state so as to be able to offer institutional responses to the demands for nondomination issuing from society. The state, viewed as a form of legitimate domination, can only respond to these demands by internalizing its own negation and becoming internally self-checking. This principle underlies the recurrent attacks that modern republicans wage on the very idea of a 'standing power,' against which they introduce the need for 'motion' or 'the successive revolution of authority' (Nedham 1659 *Mercurius Politicus* 4 December 1651–1 April 1652). It also accounts for the constant thematization of political change and social conflict in the very constitution of political form. The debate between Jefferson and Madison on the uses of constitutional conventions to check the power of the state is exemplary in this sense: the latter believes in designing a political form of government capable of checking itself, while the former holds that a check on government ultimately can only come from what lies outside it (Hamilton et al. 1787, pp. 49–51).

The innovation of modern republicanism with respect to thinking about institutions consists of providing both theories and examples of what may be called institutions of critique, or counterinstitutions, which take the form of inscribing a resistance to domination into the state apparatus that administers the rule of law. The most significant example of such an institution of critique is the separation of state powers

when the latter is understood as a *system of checks and balances* (Hamilton et al. 1787, p. 51) whereby 'one branch of the government may be authorized to exercise some active influence on another in order to resist and counteract its power' (Manin 1994, p. 31) in view of keeping the entire state in check with respect to the people.

Modern republicanism offers other examples of such institutions, whose sole purpose is to serve as a forum for the contestation and resistance of the normal administration of state rule. Among them stands out the Tribune of the people, interpreted by Machiavelli as a 'guard of freedom' (1517, I, 3–4), which, in the words of Rousseau, 'although it can do nothing, it can prevent anything from being done. As the defender of the laws, it is more sacred and more venerated than the prince who executes laws or the sovereign which legislates' (Rousseau 1762, IV, 5).

Another example is the Agrarian Law as discussed in Machiavelli (1517), Harrington (1656), and Hutcheson's *System of Moral Philosophy* (1755), where it serves to check the unregulated distribution of private property. Among such institutions also figures Jefferson's 'republic of wards,' designed to serve as 'a system of fundamental balances and checks for the government' (Kurland and Lerner 1987, p. 142). The same principle animating the ward system is embodied by the 'council systems' (Arendt 1963) that emerged during the republican revolutions of France in 1871, Russia in 1905 and 1917, Germany in 1918, Hungary in 1956, and Poland in 1979.

5. Republicanism and Revolution

Modern republicanism also recognizes the possibility of an external critique of the state-form or revolution. In political revolutions, it is the people that attempt to institute nondomination directly, and it can do so only by suspending or dissolving the state form as such. Although prefigured by Machiavelli with his theory that a free political life can be maintained only if there are periodic 'return to beginnings' in which the social and political orders are renewed (Machiavelli 1517, III, 1), one of the firmest formulations of the state-dissolving power of the people is found in Locke, for whom 'the community may be said in this respect to be always the supreme power, but not as considered under any form of government, because this power of the people can never take place till the government be dissolved' (Locke 1690, XIII, 149). Likewise, Rousseau insists that 'the moment the people is lawfully assembled as a sovereign body all jurisdiction of the government ceases' (Rousseau 1762, III, 14). Hamilton reaffirms in *The Federalist* 'that fundamental principle of republican government which admits the right of the people to alter or abolish the established Constitution whenever they find it in-

consistent with their happiness' (Hamilton et al. 1787, p. 78).

It is important to note that for modern republicanism, unlike other late modern revolutionary traditions, political revolutions are recurring events out of which all forms of legitimate domination emerge and into which they can all be revoked. By definition these revolutionary events cannot be subsumed into or become in turn a political form without denying themselves. Republican moments are in themselves evanescent, having as their fundamental purpose that 'men who live together in any order whatever [be able to] often recognize themselves...and look over the account for the men who are in that body' (Machiavelli 1517, III, 1). The purpose is the mutual recognition of the liberty and equality of all.

6. Political Equality and the Rule of Law

The 'rule of law' is a feature of both classical and modern republicanism. But whereas classical rule of law is substantive and intends to prescribe the common good, modern rule of law is formal and has as its essential purpose 'the restriction of each individual's freedom so that it harmonizes with the freedom of every one else' (Kant 1793, p. 73). As evidenced in the American and French Declarations of rights, the rule of law is always limited by, because it is founded upon, two elements that are absent in classical republicanism: individual natural rights and sovereign power of the people.

Following the trajectory that leads from Machiavelli through Rousseau up to the American and French Declarations, some contemporary republican theorists hold the view that unless the rule of law is grounded on the power of the people, it cannot guarantee a political life free of domination (Arendt 1963, Habermas 1992). Other republican theorists, supporting themselves on Montesquieu's definition of liberty as 'the right of doing whatever the laws permit' (Montesquieu 1748, XI, 3), believe that the relation between the rule of law and the power of the people should be reversed because it is 'the laws of a suitable state...[that] create the freedom enjoyed by citizens' (Pettit 1997 p. 36).

At stake in this discussion is the interpretation of a basic republican principle of equality before the law. On one understanding, freedom as nondomination basically requires 'an empire of laws' (Harrington 1656, p. 20) assuring that no one is above the law and thereby excluding arbitrary rule. On the other understanding, freedom as nondomination also requires equality in the making of the laws before which everyone is formally equal. So, for instance, 'No Man can be imprisoned, unless he has transgressed a Law of his own making' (Trenchard 1697, p. 2). Rousseau simply says that 'a people, since it is subject to laws, ought to be the author of them' (Rousseau 1762, pp. II, 6).

Without the equality to make law, the rule of law harbors the possibility of paternalism and legal domination (Ferry and Renaut 1985, Habermas 1992).

To be politically free is to have the power to 'make' law in the sense of having the power to constitute, and therefore check the exercise of, any constituted legislative power (Sieyès 1789). Such constituent power cannot itself fall under the rule of law but rather grants it its ultimate legitimacy ground, as is made clear not only in Sieyès, but also in Rousseau and Locke. For both, the power to make law belongs to the people originally, which is constituted by a contract that everyone makes (with everyone else or with themselves) (Locke 1690, XI, 134, Rousseau 1762, I, 6). Locke then permits the transfer of the legislative power of the people to the government (X, XI); but, as an element of the state, the rule of law is always checked by the deciding power of the people (XIII, 149; XIV, 168; XIX, 240).

The question of constituent power as it is developed in modern republicanism has an impact on social thought because it highlights the existence of political but prelegal struggles for recognition (Taylor 1994), through which individuals and groups seek the constituent power of citizenship that gives access both to political and individual rights.

7. Representation and Participation

For modern republicanism, political representation is a response to Montesquieu's call for a separation of legislation and execution 'lest the same monarch or senate should enact tyrannical laws, to execute them in a tyrannical manner' (Montesquieu 1748, XI, 6). Such a separation of powers is echoed as much by Rousseau (1762 III, 1, III, 16) as by Kant, who defines republicanism as that 'political principle whereby the executive power (the government) is separated from the legislative power' (Kant 1795, p. 101) vested in the people as 'co-legislators' (Kant 1798, p. 184).

The modern republican discourse on political participation follows, rather than contradicts, Montesquieu's doctrine of the separation of powers. Since a republic entails the division between those who have the power to make laws and those who have the power to apply it, it follows that the activity of governing or the administration of the constituted powers of the state must be given over to representatives, and in that sense all government must be representative in order to be legitimate. But the generation of constituent power has to be kept in the hands of the people, and to that extent calls forth their participation, without which no such power would come into existence in the first place. The debate between Locke and Rousseau on whether the fundamental power of the people to make law can or cannot be represented (Locke 1690, X, 132, XIII, 149,

Rousseau 1762, III, 15) is resolved in the form of the distinction between a constituent legislative power, which is what Rousseau and Kant have in mind when they advocate its inalienability from the people, and a constituted legislative power, which is what Locke, Sieyès, and Madison have in mind when they argue for its representative character. In both cases, the goal is to assure Montesquieu's requirement of contrasting government by setting power (of the people) against power (of the state).

8. Political Virtue and Corruption

The discourse of 'virtue' in modern republicanism (Pocock 1975) for the most part refers to a political conception of virtue, rather than to the classical moral conception of virtue as the pursuit of the common good (Machiavelli 1513, Montesquieu 1748). The debate about political virtue is a place-holder for the necessity of a certain kind of 'government by men' in order to maintain the ideal of nondomination in the face of the potential for 'corruption' (Skinner 1998) harbored in the modern rule of law and other systems of negative liberty, of which the most significant for modern republicans is the system of commerce and money. Since the modern rule of law and modern commerce are not viewed as being morally substantive, but rather as protecting and fostering the negative liberty needed for all nonpolitical forms of self-enactment (Wootton 1994), simple adherence to them cannot replace the political activity needed to sustain both the participatory and the representative requirements of republicanism. Left to their own devices these systems of negative liberty could degenerate into forms of bureaucracy (no-man's rule), as well as deepen social and economic inequalities, thereby threatening freedom as nondomination.

Modern republicans speak of two kinds of political virtues, depending on whether they take virtue to be synonymous with the set of characteristics that make political subjects have 'power' or 'authority,' and depending on whether they are more interested in the 'freedom' or in the 'stability' of the republican form. Harrington and Madison concentrate on the need for an 'aristocratic' virtue, to be present in the representatives, for the sake of the 'wisest' and most 'authoritative' outcome in their deliberations, which is in turn the main guarantee of the stability of the republican form. By contrast, Machiavelli, Jefferson, and other proponents of 'public happiness' offer a distinctly more 'democratic' conception of political virtue, designed to foster in the people that 'power' which comes from being, in Jefferson's felicitous phrase, 'a participator in the government of affairs' (Kurland and Lerner 1987, p. 142). As a result, the rule of law requires virtuous individuals, and there is no virtue without the power to do 'strong' and perhaps

'uncivil' actions (Machiavelli 1517, I, 18, III, 1) of the kind required by engagement in practices of active nondomination, of empowerment and resistance against practices of domination and dependency.

M. E. Vatter

Republicanism: Philosophical Aspects

Republicanism is the doctrine that laws and the state should always serve the common good (or '*res publica*') of a nation's people or citizens ('*populus*'). The basic desiderata of republican government, as articulated in the republican tradition derived from Rome, secure government for the common good through the checks and balances of a mixed constitution, comprising a sovereign people, an elected executive, a deliberative senate, and a regulated popular assembly, constrained by an independent judiciary, and subject to the rule of law (Sellers 1994). Some republicans would add representation, the separation of powers, or other new structural devices to protect public liberty ('*libertas*') and avoid Rome's eventual descent into popular tyranny and military despotism (Sellers 1998). Republican liberty signifies

subjection to the law and magistrates, acting for the common good, and never to the private will or domination ('*dominatio*') of any private master (Pettit 1997).

1. The Republican Tradition

'*Res publica*' was the Romans' term for their state, its public business, all public property, and the purposes these served. The word notoriously evades translation, most often appearing in English as 'commonwealth,' or simply (more recently) 'republic,' the use preferred here. Marcus Tullius Cicero (BC 106–43) and Titus Livius (Livy) (BC 59–AD 17) constructed the first and most influential comprehensively republican ideology, to try to explain how and why the Roman republic had failed to serve the public good. Both agreed that republican institutions collapsed when military expansion and party conflict upset traditional checks and balances between the senate, the magistrates, and the people of Rome.

Cicero and Livy inaugurated a republican tradition of 'liberty' that fortified principled resistance to demagogues, emperors, and kings for the next two thousand years. Niccolò Machiavelli (1469–1527) did the most to revive this republican tradition in Italy, in his *Discorsi sopra la prima deca di Tito Livio* (1517). The resistance of the Swiss, various Italian cantons, and the United Provinces of the Netherlands to imperial control added practical models for republican liberty, as did the constitutional and theoretical writings of various English authors, in their efforts to restrain or remove their kings during the Civil War and Commonwealth (1642–60), the Glorious Revolution (1688), and the extended British controversies over American Independence (1763–83).

2. The Republican Revival

Republican political and legal philosophy provides an enduring model for philosophers and lawyers who oppose the domination of arbitrary power. The constitutional controversies of the French and American revolutions left institutional relics, which established republican ideals in the structures of Western politics, with a pervasive commitment to 'liberty' and even (in the United States), a federal 'guarantee' that every state in the union must enjoy 'a republican form of government' (*United States Constitution*, 1787 Art. IV § 4). Similar provisions requiring senates and independent judges give republican theorists a practical foundation in the constitutions of most Western democracies. Lawyers such as Frank Michelman (1936–) and Cass Sunstein (1954–) first revived republican doctrine in law schools, to justify judicial intervention for the common good, against partisan legislation and political corruption (*Symposium* 1988).

Philip Pettit inaugurated a similar revival among philosophers, embracing three central claims of the republican tradition: that government must serve the common good; that certain institutional arrangements will do so; and that liberty will be the result (Pettit 1997). Republicanism since Cicero has offered a political epistemology for finding the common good, or approximating it as closely as possible. The republican question has not been (in the first instance): ‘What is the common good?’, but rather: ‘Which political procedures will best find and protect the common good, given the possibilities and limitations of history and human nature?’ (Sellers 1991).

3. Liberty as Nondomination

Republican liberty consists in not being interfered with by fellow citizens or the state, except as regulated by the common good of the people, established by republican politics. This conception of liberty as ‘nondomination’ contradicts a widely-held (but more recent) understanding of liberty as not being interfered with at all. Public and private actions that constrain or influence a person’s activities do not restrict republican liberty unless they violate the law or republican moral principles established to serve the common good of the people as a whole. Republican liberty cannot exist without a republican state because nonrepublics will always dominate their subjects, as masters dominate their slaves.

Domination marks the end of liberty, in republican theory, because domination subjects one person to the arbitrary will of another, without regard to the common good. The unchecked power of the *dominus* (or master) makes his subordinates slaves, whether the master chooses to exercise power or not. Slaves to good masters remain slaves, and dominated, because they have no security against their master’s will. States dominate citizens when their constitutions give legislatures or public officials arbitrary power to act, without regard to the public welfare. Private individuals dominate others when laws and public officials do not protect citizens against private oppression.

The common good is the measure of domination, and therefore of liberty, in republican political vocabulary, because only the common good distinguishes ‘arbitrary’ interference from justified state action. *Libertas* (liberty) in Rome signified the status of a free citizen in a republican state. The *res publica* (republic) represented every citizens’ common interest in the public good. Restraining citizens equally with just laws in pursuit of the common good enhances their liberty by restraining arbitrary power. Neo-republican doctrine revives liberty as a worthy object of public policy by rescuing the sense in which the word first developed as a political ideal. Liberty is not, as Thomas Hobbes (1588–1679) maliciously redefined it, the unfettered license to do what one wants, but

rather a public shield against uncontrolled license in others. Republican liberty consists in equal subjection to the rule of laws, made for the common good, through the carefully balanced mechanism of a republican form of government. For further references see *Freedom: Political*.

4. The Common Good

The fundamental republican insight that government and laws should serve the common good did not originate in Rome. Most governments have made this claim, which Cicero (Tullius Cicero *Off.* I.xv.85) attributed to Plato (circa BC 427–347). Cicero defined the purpose of the state as seeking to create harmony from the disparate interests of all members of society (*Off.* III.vi.26). This does not require that all public interests always serve every individual’s separate desires, but that laws and government exist to make every citizen’s life worthwhile. Most human goods have a social component, making liberty essentially communal in character.

The first difficulty republicans face in finding the common good lies in defining their community. Ancient republics closely restricted their citizenship, excluding women, immigrants, and slaves. Most republicans would now extend citizenship and membership in the *populus* or people to all inhabitants of a given territory. This leaves open the question of boundaries. Cicero endorsed a universal republic or society of humanity, but also recognized the value of local politics. Cultures and human relationships develop and solidify locally. Therefore, the republican interest in harmony and community implies small homogenous republics, where people will be very much the same (Montesquieu 1748). But the natural diversity of human talents and interests guarantees that small communities will find their own internal minorities to dominate and oppress. Larger republics with greater diversity better protect minorities, by making dominant factions harder to assemble (Hamilton et al. 1787–8, p. X).

The republican solution to republican boundaries has been to encourage different levels of nested republics, for different purposes, with different capacities. Immanuel Kant (1724–1804) advocated a federation of national republics, assembled in perpetual peace (Kant 1795). The formula suggested by the United States and modern European Union has been to entrust the protection of individual human rights and commerce, which local majorities might threaten, to federal suprarepublican authorities, while delegating social and cultural concerns to smaller, more homogenous republics. When regional authorities consistently abuse their powers to oppress local minorities, their oppression implicitly recognizes such minorities as separate people, entitled to separate republican homelands, within the republican federa-

tion (Sellers 1996). For further references see *Public Interest*.

5. Popular Sovereignty

Republicans realized very early in Rome, and have maintained the principle ever since, that the common good will never be found or maintained without the *imperium populi* or popular sovereignty to support it (Tullius Cicero *Cat.* IV.14; *Phil.* IV.iv.8). Macchiavelli credited Cicero with the insight that although the people may be ignorant, they are capable of grasping truth, when good men place the truth before them (Macchiavelli 1517 I.iv.10). The purpose of republican popular sovereignty is not that the people should govern every day, but rather, as Benjamin Rush (1745–1813) suggested in advocating an American ‘republic,’ that the people should select their rulers themselves. The people exercise their power on election days, then defer to magistrates that they themselves have selected (Rush 1777).

This republican reliance on popular sovereignty distinguishes republican government from liberalism, which diverged from the republican tradition at the beginning of the nineteenth century (Sellers 1998). Early liberals rejected popular sovereignty in the wake of the French revolution, while retaining republican commitments to liberty, the rule of law, and certain specific rights against of government (Constant 1819). Liberals divorced liberty from its basis in public deliberation by distinguishing ‘political liberty’ from personal independence. This left liberals dependent on judges and magistrates to verify their assertions of rights, and protect individual liberty against the state. Liberalism started as a flight from politics, but found that this implied a new definition of liberty as the ability to do what one wants, without state regulation (Pettit 1997).

Contemporary liberalism has largely abandoned the fear of democracy that separated liberalism from republicanism in the first place, and most liberals now endorse the widespread political participation of citizens in elections (Rawls 1993). Republican popular sovereignty never signified democracy in any case, but rather a carefully balanced and controlled mechanism for gathering the insights of all members of society, through a process of public deliberation, in pursuit of the common good. As modern liberals have sought a method of democratic deliberation to legitimate their sense of community, and regulate conflicting private interests, they have increasingly returned to republican principles and institutions, embedded in Western constitutional democracy. For further references see *Sovereignty: Political*.

6. Checks and Balances

The primary, process-centered challenge for republicans has been to identify those institutions that

find and secure the common good best. Popular sovereignty provides access to every citizen’s interests and insights, but democracy would become an elective despotism, without checks and balances to restrain it (Pettit 1999). Cicero blamed the Greeks’ misfortunes on the turbulence of their popular assemblies, lacking internal balance or a senate to control them (Tullius Cicero *Flacc.* 1976). Republics since Rome have maintained bicameral legislatures to prevent self-seeking in either assembly (Harrington 1656, p. 22). Democracy is one of several foundation stones of liberty, not an end in itself.

The necessary checks and balances of republican government prevent public officials from making themselves and not the *res publica* the object the state (Paine 1792, p. 168). The dispersion of power through bicameralism, federalism, and the separation of powers makes it harder for any one person or faction, including the majority, to wield arbitrary power over others (Pettit 1997, p. 177). American republicans, such as John Adams (1787–8, p. I.ii–iii) and Alexander Hamilton et al. (1787–8, IX) added representation and the life tenure of judges to bicameralism and the checks on governmental powers as basic desiderata of balanced republican institutions. If the people and judges are outside government, they can better control their government’s mistakes (Hamilton et al. 1787–8, p. LXIII).

Modern republicans such as Philip Pettit differ from democrats in viewing democracy as a derivative value, in service to the broader ideal of balanced or ‘contested’ government (Pettit 1997, p. 187). All government decisions should be subject to challenge by institutions that prevent private inclinations from ruling public interests and ideas. Republicans have proposed bills of rights, public hearings, and many other devices designed to constrain and channel public decision making, so that ordinary citizens may influence their government’s decisions, without diverting the public purposes of the state. For further references see *Constitutionalism*.

7. The Rule of Law

Republican government consists of whatever institutions ‘will compel the formation of good and equal laws, an impartial execution, and faithful interpretation of them, so that citizens may constantly enjoy the benefit of them, and be sure of their continuance’ (Adams 1787–8, p. I.128). Such institutions secure the ‘*imperia legum*’ or ‘empire of laws and not of men’ praised by all republican authors from Livy to Pettit. Laws secure liberty against domination by delimiting and protecting the line across which private or state behavior violates individual autonomy against the common good. Cicero insisted that such laws must serve the public welfare (*populi utilitas*) not the public will (*populi voluntas*) (Tullius Cicero 1906 [*Sulla* 25])

because votes cannot alter the natural laws of justice (Tullius Cicero *Leg. I.xvi. 44*). Republics need institutions that will find justice by securing the common good.

The empire-of-law condition of republican government entails that laws should be publicly promulgated, intelligible, consistent, stable, general, and apply to everyone, including the legislators themselves. This prevents arbitrary decisions by public officials, by subjecting their will to known constraints and purposes. Republics maintain a general presumption that government action, when needed, will operate by law, not by *ad hoc* or *ex post* decisions. All agencies of government must act through principled, regulated structures, maintaining the 'due process' of laws to prevent the abuse of governmental power (Pettit 1997, pp. 174–5).

Codifying the law in every detail will not be possible or desirable. Some discretion must remain, but subject to the dispersion-of-power and popular sovereignty procedures that generate republican laws in the first place. Discretion subject to constraints against arbitrariness may sometimes secure the common good, but unlimited discretion produces mistakes about justice, through the natural partiality and limited viewpoint of any individual decision-maker. The republican rule of law protects liberty by respecting the welfare of every member of society, pooling their insights to secure the common good of the people. Legislation is the public reason of the republic, protecting citizens' liberty against private power (Harrington 1656, pp. 19–20).

8. Neorepublican Ideals

Contemporary philosophical republicanism reasserts the republican conception of liberty, proposing new republican institutions to support republican liberty in the modern multicultural state. Philip Pettit has given the most detailed proposal for neorepublican politics, supplanting the Benthamite liberal opposition of 'negative' and 'positive' liberty with older republican conceptions of liberty as nondomination, and protection against arbitrary power (Pettit 1997). Pettit understands arbitrary power ('*arbitrium*') to include any action against the 'interests and ideas' of those who suffer interference. This surpasses the old republican standard, which measured arbitrary power by its violation of an objective public, common, or collective good.

Neorepublican deference to private interests and ideas reflects the residual liberal commitment to moral pluralism and cultural diversity. This enduring hesitation to overrule anyone's personal ideas makes the revised standard of nondomination very strong. Interference or influence over others' choices becomes domination unless it tracks their private values. This

introduces a subjective element into republican doctrine. Older republican ideals tolerated hierarchy and private influences when toleration served the common good of all citizens.

Neorepublican rhetoric describes the state as seeking to 'promote' freedom as nondomination, where older republicans would have understood republican pursuit of the common good simply to be freedom as nondomination. The difference lies in the pluralistic language of the newer theories. Some suggest that immigrant groups and minority cultures will maintain their separate identities in republics, because republics help to preserve hereditary differences within the larger culture (Pettit 1997, p. 144). This represents a significant departure from traditional doctrine. Republics exist precisely to create and maintain an overarching culture that embraces all citizens. This necessarily influences and discourages dissenting subcultures by promoting an image of national unity, which will tend to assimilate minority perspectives.

9. Neorepublican Institutions

The neorepublican commitment to pluralism encourages a greater emphasis on countermajoritarian aspects of republican popular sovereignty (Pettit 1997, *Symposium* 1988). Neorepublicans embrace the empire-of-law condition of republican government and the dispersion-of-power constraint, but they often seek to displace public decision-making onto independent panels of social scientists or courts (Pettit 1997, Sunstein 1993, *Symposium* 1988). This favors 'contestability' over consensus to limit the weight of unified public opinion.

Neorepublicans do not endorse interest-group pluralism in the classical amoral sense of liberal democracy, but their concept of representation favors cultural minorities. Some believe that public policy should be able to be justified according to the lights of every member of society (Pettit 1997, p. 169). This overstates the value of mistaken perceptions of the good. Republican government differs from liberal democracy precisely in that it offers a deliberative technique for overruling mistaken views, while allowing constructive dissent by those who oppose the consensus.

Traditional republics maintained geographical representation to encourage the development of local communities. Most recent proposals prefer religious, cultural, or sexual diversity. Popular elections now seem too crude to identify administrative competence, or to guarantee minimum statistical representation for every stakeholder grouping (Pettit 1997, p. 192). Neorepublicans often propose deliberation among statistically selected 'representative' officials, in place of elected representatives or public assemblies. This leads to difficulties in identifying which sub-

cultures or stakeholder 'groups' to represent. Most people have many such partial or self-defined sources of identity.

10. The People

The fundamental republican conception of the common good encourages social solidarity by seeking a community of interest among the *populus* or people of any given republic. Cicero described republics as the property of a people (*res populi*), in the most influential and frequently repeated passage in the republican canon. A *populus* is not just any collection of humans, but a partnership about justice, in pursuit of the common good (Tullius Cicero *Rep.* I.xxv.39). There will be no republic without a people and no people (in the fullest sense) without a republic, which is to say the mutual recognition of common citizenship (fraternity) and the equal importance (equality) of all citizens in the eyes of the state.

The concept of peoples represents the most contested element in contemporary republican doctrine, and the most likely source of disagreement between neorepublican philosophers. The United Nations Charter recognized the republican principle of self-determination of peoples (Article I (2)), implying a people's right 'freely [to] determine their political status' (International Convention on Civil and Political Rights 1966, Article 1). This gives the republican identity a practical importance in international politics, implying that recognized status as a 'people' entails some degree of political separation. The salient examples of liberated 'peoples' have been the inhabitants of colonial territories, who constitute peoples in international law for the purpose of pursuing their independence from imperial domination.

Some neorepublicans would separate the national and territorial principles to create politically separate republican peoples on the basis of ethnic, religious, or linguistic affinities within larger multinational empires. Different laws would apply to different subjects of the overarching state, according to their different internal 'citizenship' or status. This violates the republican principle of equal citizenship to achieve the republican ambition of social solidarity among state-maintained subgroups of the population. Traditional republican doctrine would insist that all citizens enjoy the same privileges and immunities in their public capacities, while permitting private initiatives to pursue elective affinities. This protects (but may subtly discourage) private diversity, because the people, as public citizens, will be the same under law.

11. Republican Philosophy

Republican philosophy since Cicero has sought to construct a harmony of interests and common sense of

justice among citizens through the 'empire of laws and not of men.' Republican laws draw the line between liberty and license, in pursuit of the common good. Republican theory seeks to find and establish good laws, by discovering the principles and basic structure that serve the *res publica* best. So although republican philosophy begins, as Thomas Paine (1737–1809) put it, by making the '*res publica*, the public affairs, or the public good' the object of all governments, and 'republican government is no other than government established and conducted for the interest of the public' (Paine 1792, p. 168), the idea of the republic entails a constellation of political structures to secure republican legislation, embedded in two thousand years of republican tradition, derived from Rome.

The republican commitment to political institutions that protect liberty challenges the later 'liberal' flight from politics after the French revolution. Former republicans such as Benjamin Constant (1767–1830) hoped by securing certain rights or liberties to protect their own private liberty against the state. But republican philosophy recognizes the futility of 'rights' without power. Republican doctrine offers a political epistemology to discover and protect public justice and fundamental human rights. Republicans believe that without popular sovereignty, the rule of law, deliberative senators, elected executives, independent judges, a representative popular assembly, and proper checks and balances, the people cannot know or enjoy their rights and duties to each other, or to the state. The basic desiderata of republican government may appear more (or less) important in different contexts, so that even a monarchy could seem nearly 'republican' when limited by two independent branches in the legislature, and subject to the rule of law (Adams 1787–8, pp. I. xxi–xxii). Contemporary republican philosophers adapt republican principles to new circumstances to protect public liberty against improper domination ('*dominium*') by private interests, or the arbitrary government ('*imperium*') of the state (Pettit 1997). What makes such theories republican is their fundamental commitment to the common good, and to the political structures that support the *res publica* best. Republican philosophy is a theory of freedom and government, or rather of freedom through government, to secure a shared sense of justice, in pursuit of the common good. Republicans believe that there can be no justice without community, no liberty without the law.

Reputation

A reputation exists in the form of an image shared within some public. Applied to a person, it identifies ‘not an intrinsic quality he possesses but rather the opinion other people have of him’ (Bailey 1971). It can also refer to certain collectivities, like a company, occupational category, professional group, organization, or its leadership and, by extension, to just about anything that can somehow be rated or ranked. Thus, we talk about the reputation of a dining establishment, of a vintage year of wine, of an annual event, of a

locality or city. All such reputations, whatever they be, are socially constructed. They may or may not be deserved and are always open to challenge. But, as long as they endure, they are real in their consequences.

Over 300 years ago Locke referred to the ‘law of opinion and reputation’ in order to highlight how much reputations were a part of the small politics of everyday life (1690/1894): ‘People have a strong motive to accommodate themselves to the opinions and rules of those with whom they converse ... and so they do that which keeps them in reputation with their company, with little regard for the laws of God, or of the magistrate ...’ Smith, a century later, argued in similar vein when he located the love of virtue in the desire for ‘being what ought to be approved of,’ a motive he believed to be most strongly felt among persons of middling or inferior status who, possessing none of the privileges associated with noble lineage or inherited wealth, must, in order to distinguish themselves, bring their talents into public view. Besides, they ‘can never be great enough to be above the law ... (Their) success ... almost always depends upon the favour and good opinion of their neighbours and equals; and without a tolerably regular conduct, these can very seldom be obtained’ (1804).

These ideas persist. Economists represented in a volume edited by Klein (1997) depict society as permeated by a flowing network of reputational relationships, with institutional credentials and certification substituting for reputations based on personal acquaintance.

Insofar as one can extract value from it, a reputation can be further conceptualized as a form of symbolic capital (Bourdieu 1992). It can grow or diminish yet still retain some value so long as people remember. This value is real enough for anyone who feels his or her good name to have been unjustly sullied by the careless or malicious actions of others. Redress can be sought through the courts—not always successfully, to be sure. And tax laws in some countries allow the corporate write-off of expenditures for building and protecting the reputation of a company or its brand name.

Reputations vary along three dimensions: best known is the vertical dimension that locates an agent or object on a hierarchical scale. A high reputation signifies the attribution of a level of respect, credibility, authority, or competence denied to those who do not measure up to that standard. Reputations, high as well as low, also vary along a lateral dimension, where placement is determined by the size of the public within which a name has currency. To differentiate between these two dimensions, we refer to a reputation for upright character or some talent shared by neighbors, colleagues, professional peers, and other insiders as *recognition* while reserving the term *renown* for that more universal recognition that extends beyond a particular reputational community (Lang and Lang 1990). A parallel distinction at the low

Table 1

Vertical (Status)	Lateral (Expansion)		Temporal (Duration)	
	Insiders	Public Sphere	Short	Long
High	<i>Recognition</i>	<i>Renown</i>	<i>Celebrity</i>	<i>Eminence</i>
Low	<i>Discredit</i>	<i>Notoriety</i>	<i>Ignominy</i>	<i>Infamy</i>

end of the vertical dimension is between being in *disrepute* among peers and the *notoriety* attained when disreputing information carries to the general public. The terms are diagramed in the Table 1 below.

A third *temporal* dimension has to do with duration in time. Public attention is forever being distracted by new entrants into the limelight. Reputations follow trajectories of different lengths. A celebrity is typically a person who may enjoy moments of fame but thereafter is remembered only by the few with a special interest in preserving the memory. Only the 'truly great' achieve the kind of *eminence* that accounts for their survival in the collective memory as major historical figures (Collins 1998). Alternatively, the ignominy experienced for some heinous deed may be quickly forgotten or be forever remembered in infamy. Most reputations fall somewhere between these extremes. The categories are depicted in the accompanying figure.

Sociologists, and especially historians as well as some literary scholars, have focused mainly on the lateral and temporal dimensions of high status, namely on how particular individuals attain renown and are canonized. Economists and political scientists, many of them employing game theoretical models, as well as some anthropologists have exhibited more interest in how reputations function within particular settings.

1. Effects of Reputation

Effects can be divided into two general categories: those involving the reactions of others to the reputation of an individual and those that stem from an individual's anticipation of reactions to their own conduct. Obviously, there is a good deal of overlap between these two.

The effect of a personal reputation on those with whom one directly interacts has been illustrated famously in the fable about the boy who cried 'Wolf' once too often. When a wolf actually showed up, as we all have learned, no one in the village heeded his warning, having come to expect just another false alarm. So it is that signals from a source deemed untrustworthy are apt to be ignored and dealings with a party of dubious reliability will, wherever possible, be avoided. But we do not always know enough about

the other nor are we at liberty to choose. Where such doubts exist, the willingness to co-operate or enter into an agreement becomes contingent on external enforcement.

How reputations derived from past performances of parties engaged in repetitive play affect both the strategies adopted by competitors and their preferences for partners has been modeled by game theorists. Their highly suggestive work is commendable for its logical rigor. Still, one can question how well their propositions tested in experiments, most of them with only two players interacting within controlled settings, replicate the complexities of real life. For one thing, reputational effects are based not just on personal experience but on word that gets around. Thus, collective attributions are a cardinal factor in the power an American president can wield. Neustadt locates its source, not just in the Constitution but in what others in the Washington political community think and expect of the incumbent. Justified or not, 'it is the reality on which they act, at least until their calculations turn out wrong ... (1990). What the president must demonstrate in the many different games he plays, often all at the same time, is his ability and will to make use of his bargaining advantages. Success breeds success but a pattern of repeated failure is bound to result in a loss of faith in his effectiveness that will reduce his power to persuade.

Similar self-enhancing effects show up in nonpolitical settings. Distinguished scientists get disproportionate credit for their contribution to a collaborative project (Merton 1967). The prestige of a university affects the quality of the faculty it attracts, whose members then, in turn, benefit from their position and raise the prestige of the institution; artists who are already well-known get more exhibitions; the works of writers who have already won prizes are more actively promoted. The epitomizing case is that of a celebrity, described by Boorstin (1961) as someone 'known for his being known.'

Images may be poor substitutes for more direct knowledge; yet in a world where most people are strangers to one another, there may be nothing else to govern our calculations. Images certainly affect what we buy, how we invest, and how much we are willing to pay (Fombrun 1996). The reassurances provided by an established brand name usually exacts some premium. But nowhere are the returns from a good

reputation greater than in the arts, where values are somewhat intangible, subject to fashion, highly dependent on critical and public endorsement (Moulin 1986). The name attached to a work determines not only price but also the attention it gets. The media, very much oriented toward a star system, feed this proclivity, thereby contributing to a pattern in which small differences among a number of top performers, none of them unequivocally superior to the rest, translate into large differences in acclaim (Goode 1978; Frank and Cook 1995).

Even in the corporate world the relation of reputation to measurable performance is not as close as it may seem. High publicity given the Valdez oil spill in Alaska waters was followed by a significant short-term decline in the value of Exxon stock. At least some investors, it has been found, back away from companies not so much because of any loss of faith in their future performance but doubts about their commitment to general community values (Fombrun 1996).

The fear of damage to one's reputation becomes an incentive for behavior against one's immediate self-interest. What economists, following Adam Smith, have called the discipline of repeated dealings acts as a deterrent, not always effective, against business selling shoddy goods to naive customers or against lobbyists providing clearly misleading information to legislators. But this response is not simply a matter of honesty but of strategic impression management as, for example, when a college reduces its acceptance rate as part of a marketing strategy to portray itself as highly selective. On the international scene, where to yield 'on a series of issues when matters at stake are not critical ... may (make) it difficult to communicate to the other (side) just when a vital issue has been reached,' a nation may be moved to act for no other reason than to retain its 'reputation for action' (Schelling 1966). Against such an instrumental view, Chong (1992) has argued that, when a reputation becomes part of their identity, people try to live up to it for moral reasons as well, trying to turn themselves into the kind of person they want others to think they are.

Another set of reputational incentives comes into play when the expansion of a reputation into the public sphere creates what Braudy (1986) calls the 'frenzy of renown' with numerous effects, some of which are potentially deleterious to one's moral commitments, whatever these may be. Fame and the appearance of power it gives are sometimes seductive. For example, Gitlin (1980) describes how media attention undermined the connection of some leading activists of the New Left, a movement with a weak organizational structure, to their original reputational community. Competing for a place in the limelight, these 'leaders' transformed themselves into 'un-attached celebrities,' no longer accountable to the rank-and-file but drawn toward increasingly 'extravagant, "incidental," expressive actions—actions which

made "good copy" because they generated sensational pictures rich in symbolism.' In sports, the advent of a national public for major-league baseball, largely a product of television, has been associated with a decline in the advantage of playing on one's home turf. The present-day public, according to Leifer (1995), is less loyal to home-grown athletes and teams but looks for any winner it can celebrate. It is not averse to abandoning a team that falls short of its expectations. By interpreting what were initially random performance differences between contestants, the public casts competitive equals into stable winner and loser roles. The teams react to reputations established early in the season, not only by the public at the game but also by sportscasters and writers when in fact, Leifer contends, many outcomes might easily have gone the other way.

2. *From Recognition to Renown*

Propositions about the acquisition of fame derive largely from life histories, mostly of successful individuals who by virtue of their background, talent, or associations seemed destined for success. To gain recognition within some domain for some special talent or accomplishment depends on a number of general conditions. Endowment and ability are, without a doubt, prerequisites. But the pool of talent is large and some acclaimed figures have had to overcome what would appear to have been formidable handicaps. Albert Einstein is known to have failed his school examination and Glenn Cunningham, the champion miler for several years, had legs so severely burned as a child that his doctors were not at all sure whether he would even walk again. Regardless of any such handicap, everyone in pursuit of recognition has to do what is necessary to develop the skills that count.

There is, to be sure, a world of difference between measurable improvements of athletic performance or scores in games played according to strict rules and the evolving consensus by which the less tangible abilities prized in domains other than sports come to be validated. Nothing counts unless people take notice. The achievement of a recluse working all alone is more likely to be overlooked than comparable ones by more gregarious contemporaries. Insofar as reputations carry through networks, acceptance by peers and mentors is often the first step toward gaining recognition. Thereafter it becomes a question of how far these networks extend. Persons highly esteemed in one domain may not even be recognized outside its boundaries or can be subject to all sorts of invidious distinctions. Hence, reputations do not easily transfer, even between genotypically similar activities, especially if they are as differentially valued. In most arts, where only some genres are ordained by an arts establishment, an excess of popularity can actually be the kiss of death. Kapsis (1992) traces the career of

Alfred Hitchcock, the Hollywood director of many famous films, who transformed himself deliberately from a merely successful maker of movies into a genuine *auteur* by adopting a new and more acceptable idiom.

The general rule that one is better off not straying too far from the mainstream holds even in the sciences where the highest honors usually go to the innovators. To be working on a problem whose importance has been widely acknowledged increases the likelihood of gaining attention for work that adds only incrementally to existing knowledge. Attaching oneself to important people is a second strategy, equally appropriate to the sciences and to the arts. Yet dissidents denied their place by a complacent establishment can also collectively advance their reputations by banding together, forming their own societies, and using them as a springboard to raise their status. This is how the group of artists denigrated as 'impressionists,' due to their apparent disdain for serious subject matter, drew attention to themselves.

Whether recognition within a group converts into renown is highly contingent on distribution and publicity (Becker 1982). Visual artists depend on exhibition space for display of their accomplishments; writers on publishers and booksellers; playwrights on performers and on a suitable stage, and the performers themselves on recordings and bookings in a major medium to display their accomplishments. To be singled out for special praise by influential critics and other mediators of fame is still more important (Moulin 1986). Especially if their judgments stimulate museum purchases, give a theatrical work a permanent place in the repertory, or generate substantial interest in the writings of an author, they can make a household word out of an obscure name. Most likely to bring instant fame are the feats that receive the greatest publicity, like the breaking of an established record in one of the major sports or ventures into entirely new territories in science or in space. A few individuals are singled out as stars with very little acknowledgment of the collective effort that made their achievement possible. Only a small number of scientists know the names of the many highly competent engineers who have made space flight possible.

3. Measuring Reputations

In a society set on rating and ranking everything, there are essentially two approaches to the measurement of reputation: through responses to survey questions and through aggregations of indicators about the actual reactions of some public.

Judgments expressed by survey respondents are most meaningful in settings where just about everyone knows everyone else. Accordingly, performance can be predicted from measures of certain qualities based

on average ratings by groups of their peers. No less ascertainable is what the residents of a village community think of their neighbors or which professionals are held in the highest regard by their colleagues. However, the content of any such consensus becomes more problematical the farther removed those queried are from whomever they are asked about. For years pollsters have obtained what legitimately can be called a reputational ranking by asking a representative sample of Americans to name the man and also the woman they most admire. Because respondents were free to name anyone alive, their choices have always been widely scattered with the president and the first lady almost always heading the lists. Their rankings, as well as that of others, has have as much to do with their prominent coverage in the news media as with the respect they enjoy within their particular reputational community.

The American president is of course one of a very small number of celebrities or infamous villains about whom just about everyone has some opinion. Thus, standardized questions about presidential performance approximate a vote and can be the basis for comparing a president's reputation to that of other actors prominent on the political scene. But there is as yet no general agreement on a standard for measuring other reputations in the public sphere. Should the reputations of corporations be based on the collective judgment of high-level executives, of customers, or of their employees? That of schools on responses from their alumni or of academics from those working in the same discipline? Who does the ranking is particularly important in the arts, governed as they are by the distinction between real 'quality' ascertained by art experts and what is merely popular.

When it comes to the past, there is no alternative to querying specialists. This method works best when evaluating a narrowly defined category, like American presidents or justices of the Supreme Court. In the first such survey, 55 experts on the presidency were asked to place each occupant of the office into one of five categories ranging from 'great' to 'failure' (Schlesinger 1997). Others have queried larger samples with more 'refined' methods only to find that the same three—Washington, Lincoln, and Franklin D. Roosevelt—consistently placed at the top, though not always in the same order. Choices of the best and worst presidents have also remained relatively stable with more fluctuation among those ranked in between. Most striking has been the steady rise in reputation of Eisenhower as new information about his presidency has come to light.

Citation counts are one of the most widely used indicators of the reputation of individuals and of academic departments. Such information is very accessible. Because scholars are obliged to cite prior publications on which their own work is built or with which they take issue, the number of references to the work of a scientist or scholar in any particular

discipline is assumed to indicate the level of recognition by colleagues. Yet strategic considerations also enter. Citing a particular predecessor can help a neophyte establish a link to one or more of the prestigious figures in their field, thereby drawing the attention of colleagues and enhancing the significance of one's own work (Camic 1987). The more a field is subject to intellectual fashion the more likely it is that credit for an idea that is very much in the air goes to the more famous.

The frequency with which a particular name appears in the more popular media indicates its role in a broader discourse but there are, at least in some fields and for some individuals, serious discrepancies between name counts for introductory texts and those for more esoteric publications aimed at narrower constituencies. In drawing conclusions from any such enumerations, one needs always to take into account the perspective of publications examined. But any set of similar publications can be useful in examining trends. Rosengren (1987) noted that in texts of Swedish literature the same names that turned up in an earlier period were still prominently reviewed four decades later.

A simple way of gauging the level of eminence (or infamy) attained by any individual is through the cumulation of literature in major libraries, most of whose holdings are now on line. After all, writers are the primary purveyors of fame (Cooley 1927). The number of items a search turns up is a measure of how much what the subjects did and the issues they raised have retained their salience as historical markers. The larger the universe searched the more finely do the findings discriminate. A search limited to full-length biographies would omit many minor figures somewhat renowned in their lifetime. Searches covering long time spans are open to another kind of bias. Although material evidence gets lost over time and some of the eminent of long ago may have left few traces, posterity has had many more opportunities to develop a consensus about those whose 'lives' have somehow survived. In terms of number of mentions and pages devoted to each in an authoritative encyclopedia of communication, a few 'greats' from the past outranked even the most distinguished contemporary scholars in this burgeoning field (Beniger 1990). It therefore makes sense to restrict such counts to differentiating between the luminaries of a particular time period, whose ideas remain of great interest, and their contemporaneous lesser lights as Collins (1998) does in his study of philosophers.

Another measure focuses less on citations than on decisions made over the years by the custodians of tradition as to what part of the past to preserve. The results are manifest in the number of memorials, shrines, plaques, exhibits, and commemorative events designed to keep alive the memory of a particular person or persons. To obtain a full record of these tributes is difficult, except perhaps for some of the arts

where one can ascertain the number of times a composer's work is performed by major orchestras (Simonton 1986; Mueller 1958) or a play is performed or revived (Griswold 1987). In the visual arts, the aggregate number of works in major museums and on permanent display is an appropriate indicator of collective curatorial judgment but somewhat confounded by rarity. Because there is not enough work by some of the greatest artists to meet the demand of museums, a single indicator, based on their holdings, has to be supplemented by information about the frequency with which work is circulated in special loan exhibitions, many of which are organized precisely to commemorate the artist.

The market is the ultimate but albeit imperfect arbiter of value. Many variables, like age, rarity, and condition, enter into prices paid for works and memorabilia associated with past eminence. Still, for items comparable on these variables, consistent price differentials represent the consensus of their relative worth. They are, to this extent, valid measures of reputation.

4. *The Survival of Reputation*

Over time, as memories fade, the lives of most people end up in the dust bins of history. There is a continuing sorting out of those deemed memorable. As to likely survival in the collective memory, posthumous reputations are the combined effect of two conditions: the rhetorical force of the accomplishments of the deceased on society or some domain in their lifetime and the extent to which, even if for altogether different reasons, an accomplishment still touches the imagination of posterity. 'Greatness' can also be conferred retrospectively as validation of or correction to earlier valuations.

The renown achieved in a person's lifetime enhances the chance for reputational survival. It facilitates contact with persons who become the mediators of one's reputation across generations (Zilsel 1972). Kings, popes, presidents, generals, and executives may have archivists at their command but those without an official position have to find their place in the right networks. Attention from colleagues attracts students, who will pass their valuations of a scholar on to the next generation. For an artist, critical acclaim brings wealthy collectors, whose purchases have a good chance of ending up in a museum. It is by no means uncommon for the admirers of some creative person to form a society dedicated to preserving and promoting their reputation.

Famous people also leave more traces. Anything connected with them gains value, which provides incentives for preserving mementoes of their lives, especially any pictures, diaries, and correspondence that evidence their thoughts and character. Insofar as their paths have crossed those of other famous people,

many of the letters they have written or received are likely to survive in some archive and to attract scholars prepared to ferret out still more material.

Subjects have some, though limited, control over the record on which their reputational fate will come to depend. Those who take care to keep and organize records strengthen their claim on the memory of posterity. It has become standard for a president to initiate the setting up of a library, even though his papers would be saved in any event. Some famous people are known to have taken the further step of purging from their files items inconsistent with the image they want to project. Writers have burned manuscripts they believed detrimental to their reputation. There are painters who destroyed systematically all pictures produced during a period for which they did not want to be remembered. Theodore Roosevelt dictated letters intended for posterity. Thomas Hardy actually controlled the biography his wife published under her own name following his death (Hamilton 1994). President Richard Nixon's attempt to retain control over his secretly recorded tapes failed. The same impulse shows up in instructions to estate executors to convert the residence of the deceased into a landmark or to use remaining assets to preserve his or her reputation. To be sure, these wishes are not always followed or followed only half-heartedly.

Some factors affecting the survival of reputation remain beyond the control of the individual: first, there are the accidental circumstances of birth and death. Possible candidates for reputational immortality can be born into a time or live in a place where no one acts to preserve the record of their deeds. Thus, the Chinese predecessor of Gutenberg remains unknown and Columbus rather than Leif Ericson is hailed as the discoverer of America. As to the timing or circumstances of death, a long productive life full of honors is an obvious reputational asset but to be struck down in the prime of life by an assassin, a tragic illness, or unfortunate accident has the potential to transform the victim into an icon. No one can possibly know how John F. Kennedy would have been remembered had he served for a full one or two terms. Yet the halo put around him by his untimely death overshadows the modest achievements and all too apparent failures of his administration. A still more striking example is that of Anne Frank. Would her diary, translated into many languages, have had the same impact if she had survived the Holocaust? And had she survived, would she have tolerated the publication by her father of this very private document from which he excised passages that displeased him?

The availability of survivors, like Anne Frank's father, with a personal stake in cultivating remembrance depends, in part, on such demographic factors as marriage, fertility, and longevity. Lang and Lang (1990), studying the revival of etching as an original art form in the late-nineteenth century, found that it

had attracted an unusually large number—at least for that time period—of talented women well recognized during their lifetimes, yet today much less well remembered than their male peers. Two demographic circumstances contributed to this reputational disparity: the extraordinary longevity of the women and the much smaller number ever married or, if married, with children. Hence, they outlived, often by decades, not only their spouses but also their colleagues, close friends, publishers, dealers, admiring collectors, as well as the collapse of the etching craze, so that there was often no one still around to mourn their death and write the obligatory obit. Also, because unmarried women had neither mate nor daughter to take on the tedious task of record keeping, material for an artistic biography or definite catalogue raisonné are often lacking.

All reputational communities have boundaries. The heroes celebrated in one may be largely unknown in another. Nowhere is this more obvious than in the different statesmen, military heroes, literary figures and so forth each nation celebrates. National perspectives even intrude into the allocation of credit for achievement universally recognized as breakthroughs. Obviously, the pioneers of space exploration who have received the greatest attention in America differ from those celebrated in the former Soviet Union. The inventor of the incandescent lamp, as remembered by Americans, is Thomas Edison, who was in fact preceded by Joseph Swan, who first exhibited his successful carbon-filament lamp in England, where he had greater impact. His factory near Newcastle rivaled Edison's in prosperity. But whereas Edison immediately patented everything, Swan was slow to do so. Nor did he have a wealthy sponsor like Henry Ford, who thought him the greatest man alive and started collecting Edison memorabilia as early as 1905, and ultimately erecting a shrine in Dearborn, Michigan by transporting, piece by piece, and reassembling the inventor's New Jersey laboratory. But for a reputation to cross all cultural and geographic boundaries, the achievement behind it must appear unique and be an inspiration for people all over the world.

Time creates its own boundaries. There is only so much room at the top, so that at some point what Collins (1998) calls the law of small numbers comes into play. Secondary figures recede into the background as new interests emerge. The survivors are those whose deeds and accomplishments still speak to the present. Posterity has some leeway in its view of the past. Not only does it select but it reinterprets continuously, particularly when it comes to the work of writers and artists. The qualities that contemporaries most admired in Hawthorne's oeuvre (Tompkins 1984) and in Da Vinci's *Mona Lisa* are not the same ones that touch us today (Boas 1940). Put another way, eminence derives from the persistence of beliefs about persons and their deeds and creations that have changed their domain in some fundamental way. The

larger the number of domains affected, the greater the likelihood that their reputations will live on.

The development, change, preservation, and decline of reputations as well as how they function have to be understood as part of an ongoing social process. Experiments and statistical studies provide useful information, mostly about outcomes, but require supplementation of case material on the process as it unfolds in a particular context. Qualitative evidence, when derived from more than one case and subjected to systematic analysis, is not to be discounted as merely anecdotal.

Resampling Methods of Estimation

Most scientists occasionally or frequently face problems of data analysis: what data should I collect? Having collected my data, what does it say? Having seen what it says, how far can I trust the conclusions? Statistics is the mathematical science that deals with such questions. Some statistical methods have become so familiar in the scientific literature, especially linear regression, hypothesis testing, standard errors, and confidence intervals, that they seem to date back to biblical times. In fact most of the 'classical' methods were developed between 1920 and 1950, by scientists like R. A. Fisher, Jerzy Neyman and Harold Hotelling who were senior colleagues to statisticians still active today.

The 1980s produced a rising curve of new statistical theory and methods, based on the power of electronic computation. Today's data analyst can afford to expend more computation on a single problem than the world's yearly total of statistical computation in the 1920s. How can such computational wealth be spent wisely, in a way that genuinely adds to the

classical methodology without merely elaborating it? Answering this question has become a dominant theme of modern statistical theory.

1. The Bootstrap

The following fundamental question arises in almost every statistical data analysis: on the basis of a data set $\mathbf{z}$ we calculate a statistic $s(\mathbf{z})$ for the purpose of estimating some quantity of interest. For example, $\mathbf{z}$ could be the nine cholesterol reduction scores shown in Table 1, and $s(\mathbf{z})$ their mean value $\bar{z} = 28.58$, intended as an estimate of the true mean value of the cholesterol reduction scores. (The 'true mean value' is the mean we would obtain if we observed a much larger set of scores.) How accurate is $s(\mathbf{z})$?

This question has a simple answer if $s(\mathbf{z})$ is the mean $\bar{z}$ of numbers $z_1, z_2, \dots, z_n$. Then the *standard error* of $\bar{z}$, its root mean square error, is estimated by a formula made famous in elementary statistics courses.

$$\left[\sum_{i=1}^n (z_i - \bar{z})^2 / (n \cdot (n-1)) \right]^{1/2} \quad (1)$$

For the nine numbers in Table 1, Eqn. (1) gives 10.13. The estimate of the true cholesterol reduction mean usually would be expressed as 28.58 ± 10.13 , or perhaps $28.58 \pm 10.13 \cdot s$, where s is some constant like 1.645 or 1.960 relating to areas under a bell-shaped curve. With $s = 1.645$, interval (2) has approximately 90 percent chance of containing the true mean value.

The bootstrap, (Efron 1979), was introduced primarily as a device for extending Eqn. (1) to estimators other than the mean. For example, suppose $s(\mathbf{z})$ is the '25 percent trimmed mean' $\bar{z}\{.25\}$, defined as the average of the middle 50 percent of the data: we order the observations $z_1, z_2, \dots, z_n$, discard the lower and upper 25 percent of them, and take the mean of the remaining 50 percent. Interpolation is required for cases where $0.25 \cdot n$ is not an integer. For the cholesterol data, $\bar{z}\{.25\} = 27.81$.

There is no neat algebraic formula like Eqn. (1) for the standard error of a trimmed mean, or for that matter almost any estimate other than the mean. That

Table 1

Nine men's cholesterol reduction scores after taking cholestyramine; the nine scores are an ordered random sample from the scores of 164 men (data from the Stanford arm of the LRC-CPPT experiment, courtesy of Drs D. Feldman and J. Farquhar, Stanford University (see Efron and Feldman 1991).

-21.0	3.25	10.75	13.75	32.50	39.50	41.75	56.75	80.0

Figure 1

A diagram of the bootstrap algorithm for estimating the standard error of a statistic $s(\mathbf{z})$; each of the B bootstrap samples is a random sample of size n drawn with replacement from the original data set $(z_1, z_2, \dots, z_n)$

is why the mean is so popular in statistics courses. In lieu of a formula, the bootstrap uses computational power to get a numerical estimate of the standard error. The bootstrap algorithm depends on the notion of a *bootstrap sample*, which is a sample of size n drawn *with replacement* from the original data set $\mathbf{z} = (z_1, z_2, \dots, z_n)$. The bootstrap sample is denoted $\mathbf{z}^* = (z_1^*, z_2^*, \dots, z_n^*)$. Each z_i^* is one of the original z values, randomly selected, perhaps $z_1^* = z_7$, $z_2^* = z_5$, $z_3^* = z_5$, $z_4^* = z_9$, $z_5^* = z_7$, etc. The name *bootstrap* refers to the use of the original data set to generate 'new' data sets $\mathbf{z}^*$.

The bootstrap estimate of standard error for $\bar{z}\{0.25\}$ is computed as follows: (a) a large number ' B ' of independent bootstrap samples each of size n , is generated using a random number device; (b) the 25 percent trimmed mean is calculated for each bootstrap sample; (c) the empirical standard deviation of the B bootstrap trimmed means is the bootstrap estimate of standard error for $\bar{z}\{0.25\}$. Figure 1 shows a schematic diagram of the bootstrap algorithm, applied to a general statistic $s(\mathbf{z})$.

Trying different values of B gave these bootstrap estimates of standard error for the 25 percent trimmed mean applied to the cholesterol data

B :	25	50	100	200	400
bootstrap estimate					
of standard error:	12.44	9.71	11.50	10.70	10.48

Ideally we would like B to go to infinity. However, it can be shown that randomness in the bootstrap standard error that comes from using a finite value of B is usually negligible for B greater than 100. 'Negligible' here means small relative to the randomness caused by variations in the original data set $\mathbf{z}$. Even values of B as small as 25 often give satisfactory results. This can be important if the statistic $s(\mathbf{z})$ is difficult to compute, since the bootstrap algorithm requires about B times as much computation as $s(\mathbf{z})$.

The bootstrap algorithm can be applied to almost any statistical estimation problem. (a) The individual data points z_i need not be single numbers; they can be vectors, matrices, or more general quantities like maps or graphs. (b) The statistic $s(\mathbf{z})$ can be anything at all, as long as we can compute $s(\mathbf{z}^*)$ for every bootstrap data set $\mathbf{z}^*$. (c) The data set ' $\mathbf{z}$ ' does not have to be a simple from a single distribution. Other data structures, for example, regression models, time series, or stratified samples, can be accommodated by appropriate changes in the definition of a bootstrap sample. (d) Measures of statistical accuracy other than the standard error, for instance biases, mean absolute value errors, and confidence intervals, can be calculated at the final stage of the algorithm. These points are discussed in Efron and Tibshirani (1993). The more complicated example below illustrates some of them.

There is one statistic $s(\mathbf{z})$ for which we don't need the computer to calculate the bootstrap standard error, namely the mean $\bar{z}$. In this case it can be proved that as B goes to infinity, the bootstrap standard error estimate goes to $\sqrt{(n-1)/n}$ times Eqn. (1). The factor $\sqrt{(n-1)/n}$, which equals 0.943 for $n = 9$, could be removed by redefining the last step of the bootstrap algorithm, but there is no general advantage in doing so. For the statistic $\bar{z}$, using the bootstrap algorithm is about the same as using Eqn. (1).

At a deeper level it can be shown that the logic that makes Eqn. (1) a reasonable assessment of standard error for $\bar{z}$, applies just as well to the bootstrap as an assessment of standard error for a general statistic $s(\mathbf{z})$. In both cases we are assessing the standard error of the statistic of interest by the 'true' standard error that would apply if the unknown probability distribution yielding the data exactly equalled the empirical distribution of the data. The efficacy of this simple estimation principle has been verified by a large amount of theoretical work in the statistics literature of the 1990s (see the discussion and references in Efron and Tibshirani 1993).

Why would we consider using a trimmed mean rather than $\bar{z}$ itself? The theory of *robust* statistics, developed since 1960, shows that if the data $\mathbf{z}$ comes from a long-tailed probability distribution, then the trimmed mean can be substantially more accurate than $\bar{z}$, that is, it can have substantially smaller standard error (see, e.g., Huber 1964). The trouble, of course, is that in practice we don't know *a priori*

Figure 2

Bootstrap estimates of standard error for five different trimmed means $\bar{z}\{p\}$, $p = 0, 0.10, 0.25, 0.40, 0.5$, applied to the cholesterol data of Table 1. Based on $B = 400$ bootstrap samples. Also shown is the true standard error of $\bar{z}\{p\}$, obtained by taking random samples of size nine from the population of 164 cholesterol reduction scores. In this case the bootstrap correctly indicates that $\bar{z}\{0\}$, the ordinary mean, gives the smallest standard error

whether or not the true probability distribution is long-tailed. The bootstrap can help answer this question.

Figure 2 shows the bootstrap estimates of standard error for 5 different trimmed means $\bar{z}\{p\}$, ' p ' being the proportion of the data trimmed off each end of the sample before the mean is taken. (So $\bar{z}\{0\}$ is $\bar{z}$, the usual mean, while $\bar{z}\{0.5\}$ is the median.) These were computed using the bootstrap algorithm in Fig. 1, $B = 400$, except that at step 2 five different statistics were evaluated for each bootstrap sample $\mathbf{z}^*$, namely $\bar{z}\{0\}$, $\bar{z}\{0.10\}$, $\bar{z}\{0.25\}$, $\bar{z}\{0.40\}$, and $\bar{z}\{0.50\}$.

According to the bootstrap standard errors in Fig. 2, the ordinary mean has the smallest standard error among the five trimmed means. This seems to indicate that there is no advantage to trimming for this particular data set.

In fact the nine cholesterol reduction scores in Table 1 were a random sample from a much bigger data set: 164 scores, corresponding to the 164 men in the Stanford arm of a large clinical trial designed to test the efficiency of the cholesterol-reducing drug called cholestyramine (Efron and Feldman 1991). With all of this extra data available, we can check the bootstrap standard errors. The solid line in Fig. 2 indicates the true standard errors for the five trimmed means, 'true'

meaning the standard error of random samples of size nine taken from the population of 164 scores.

We see that the true standard errors confirm the bootstrap conclusion that the ordinary mean is the estimator of choice in this case. The main point here is that the bootstrap estimates use only the data in Table 1, while the true standard errors require extra data that usually isn't available in a real data analysis problem.

2. Growth Curves

Longitudinal data are often modeled using growth curves. Our example uses educational testing data from students in North Carolina (see Williamson et al. 1991, Rogosa and Saner 1995). The data we use for the example are eight yearly observations on achievement test scores in mathematics Y for 277 females, each followed from grade 1 to grade 8. The straight-line growth curve model for each individual can be written as

$$Y_p(t) = \zeta_p(0) + \theta_p t + \varepsilon_{pt} \quad (2)$$

where the observable scores Y contain error of measurement indicated by ε_{pt} . Here t denotes time and p denotes person. The constant rate of change for each person is indicated by θ_p ; θ_p has a distribution over persons with mean μ_θ and variance σ_θ^2 .

To illustrate bootstrap estimation we pick out two of the questions that are investigated using the growth curve models:

(a) Can individual change be measured reliably? In behavioral and social science research the reliability index for the estimated rate of change, $\rho(\hat{\theta})$, is the parameter of interest.

(b) Is there a relation between initial standing (math achievement in grade 1) and the rate of improvement? The parameter to be estimated is correlation between θ and initial status (over the population of individuals), written as $\rho_{\theta\zeta(1)}$.

Maximum-likelihood estimates of $\rho(\hat{\theta})$ and $\rho_{\theta\zeta(1)}$ can be obtained from standard mixed model analyses. Standard errors and interval estimates for these quantities are not available from widely-used computer packages.

Figure 3 shows histograms for 4000 bootstrap estimates of $\rho(\hat{\theta})$ and $\rho_{\theta\zeta(1)}$. Bootstrap samples were constructed by resampling individuals (where the data for each individual is a vector of the eight observations). The 90 percent confidence intervals were obtained using the so-called 'percentile method': the endpoints are the 0.05 and 0.95 percentiles of the bootstrap histograms. (The percentile method is the simplest of a number of methods for confidence interval construction via the bootstrap: a generally better method is the 'BC_a'; see Efron and Tibshirani

Figure 3

Histograms of 4000 bootstrap estimates of $\rho(\hat{\theta})$ (left) and $\rho_{\theta\zeta(1)}$ (right).

Table 2

Results for growth curve example

Parameter	Estimate	Standard error	90% CI
Reliability $\rho(\hat{\theta})$	0.828	0.019	(0.792, 0.855)
Correlation $\rho_{\theta\zeta(1)}$	0.651	0.093	(0.510, 0.814)

1993, chap. 12–14. The results in Table 2 show good precision for estimation of the reliability, but relatively less precision for the correlation parameter.

3. Related Methods

There are a number of important related methods, with strong similarities to the bootstrap. The *jackknife* systematically deletes one or more observations from the dataset, and applies the statistic to the remaining data. By doing this for each observation or groups of observations, one can obtain estimates of standard errors and bias that roughly approximate to the bootstrap estimates.

Cross-validation is similar to the jackknife but is used to assess the prediction error of a model. It systematically excludes one or more observations from the dataset, fits the model to the remaining data, and then predicts the data that was left out. Application of the bootstrap for estimating prediction error is not straightforward and requires some special modifications. With these, the bootstrap and cross-validation have similar performance for estimating prediction error. Details and references are given in Efron and Tibshirani (1993) and Efron & Tibshirani (1997).

There is a connection of the bootstrap to Bayesian inference. Roughly speaking, the bootstrap distribution approximates a nonparametric posterior distribution, derived using a noninformative prior. Rubin (1981) gives details.

A difficult theoretical question is: when does the bootstrap work? There is much research on this question (see, e.g., Hall 1992). In 'regular' problems where asymptotic normality can be established, first and higher order correctness of the bootstrap (and modifications) have been proven. However, the bootstrap can fail, for example, when it is used to estimate the variance of the maximum or minimum of a sample. More generally, it is difficult to prove theoretically that the bootstrap works in complicated problems: but these are the very settings in which the bootstrap is needed most. Eventually, theory will start to catch up with practice. In the meantime, the bootstrap, like any statistical tool, should be applied with care and in the company of other statistical approaches.

Some popular statistics packages have bootstrap functions, including S-PLUS and Resampling Stats. In most packages that facilitate some customization by the user, it is easy to write one's own bootstrap function.

4. Conclusions

The bootstrap is a powerful tool for data analysis, with many applications in the social sciences. It is being used more and more, as fast computational tools and convenient software become widely available. Good general references on the bootstrap include Efron and Tibshirani (1993), Davison and Hinkley (1997), Hall (1992), Shao and Tu (1995), and Westfall and Young (1993).

Research and Development in Organizations

1. Increasing Division of Labor in Knowledge Production and Use

The growth of research and development activities (R & D) reflects the increasing division of labor in the production and use of scientific and technological knowledge—a process foreseen by Adam Smith at the beginning of the Industrial Revolution. Since then, professional education, the establishment of laboratories, and improvements in techniques of measurement and experimentation have progressively increased the efficiency of discovery, invention, and innovation (Price 1984, Mowery and Rosenberg 1989). Three complementary forms of specialization have developed in parallel, each contributing to the growth of R & D.

1.1 Specialization by Discipline: The Growth of Science and Engineering

First, progress and specialization in scientific disciplines accelerated in the nineteenth century with the development of more powerful research tools and techniques. Increasing opportunities for application also led to the emergence of the engineering disciplines: hence chemical engineering in addition to applied chemistry, and electrical engineering in addition to applied physics (Rosenberg and Nelson 1994). The differences in timing of the emergence of new opportunities for innovation reflected radical but uneven improvements in the knowledge base underlying technological change, and in particular the emergence of new technological paradigms (Freeman et al. 1982, Dosi 1982).

The mechanical paradigm was the basis of the Industrial Revolution. It did not grow out of contemporaneous scientific advances, but of improvements in the quality of metals and the precision with which they could be formed and machined. These enabled the *design, development, and testing* of prototypes of families of machines with greatly improved performance based on materials of homogeneous and predictable quality, and on shapes with compatible sizes. Similarly, the initial improvements in metals processing technologies depended less on scientific understanding than on *development*

activities, experimenting with different alloys and processing conditions in pilot plant. Even today, such development activities in prototypes and pilot plant typically account for about three quarters of the R & D expenditures of private business firms and for about two-thirds of total R & D.

1.2 Specialization by Corporate Function: The Growth of Business R & D

The science-based chemical paradigm (based increasingly on synthetic chemistry) and the electrical paradigm (based on electromagnetism and radio waves) laid the basis for the industrial R & D laboratory, initially in the chemical and electrical firms in Germany and the USA. Many of the initial applications—like the use of techniques of chemical analysis to control the quality and composition of materials in the increasingly large-scale processing industries—were relatively mundane, but very profitable in reducing costs. Management learned progressively that the science-based technological opportunities were applicable over a range of existing and new product markets, and therefore opened up opportunities for what is now called ‘related’ product diversification. Mowery and Rosenberg (1989) have described the spread of the establishment of R & D laboratories in the USA from the chemical industry to other sectors, and from larger to smaller firms. Similar processes have been at work in Europe, and more recently in East Asia (Caron et al. 1995, Nelson 1993).

Thus, in addition to the benefits of the cognitive division of labor into more specialized fields, the functional division of labor within business firms also augmented the rate of technical change. Corporate R & D laboratories and similar groups devoted full-time to inventive and innovative activities provided an effective method for creating, combining, and coordinating increasingly specialized knowledge. They provided improved and specialized instrumentation, which enabled firms to monitor and benefit more systematically and effectively from advances in specialized academic disciplines. They also created skills in the development and testing of laboratory concepts and prototypes, and the translation into commercialized products. Firms were able to experiment with a wider range of products and processes than had previously been possible when constrained by established products and production lines. In fields rich in technological opportunity, firms have in consequence become multiproduct as well as multitechnological.

Technological paradigms have been associated with the emergence of large dynamic firms that have been successful in exploiting the new opportunities. The largest R & D spenders today are in companies that grew with the emergence of the mechanical (and automobile), chemical, and electrical–

electronic paradigms. Aerospace is a special case, having been technologically force-fed, especially since World War Two, by government R & D subsidies and procurement linked to military requirements. The fastest growing R & D spenders today are those closely associated with ICTs and software technology.

1.3 Specialization by Institution: The Growth of Academic Research

In the nineteenth century, de Tocqueville foresaw that the dynamics of capitalist competition would greatly stimulate the development of innovative activities that showed the prospect of a commercial return. He also argued that public authorities would need to support complementary public research of a more fundamental nature, in order to avoid diminishing returns, to open up new opportunities, and to provide trained researchers. This has happened too. In all advanced countries governments have become the main source of the funding of research activities, and related postgraduate training, in universities and similar institutions. Corporate R & D laboratories have come to depend increasingly on a supply of scientists and engineers aware of the latest research results and trained in the latest research techniques (Salter and Martin 2001).

1.4 R & D and Modernization

This historical pattern of specialization and growth in knowledge production has been broadly repeated in the processes of modernization of late-coming countries, and is observable in countries at different levels of development today: R & D expenditures as a percentage of Gross Domestic Product (GDP) increase with GDP per head, both in specific countries over time, and in cross-sections of countries at any point in time. In successful modernizing countries, R & D is preceded by systematic business investments in improvement-generating activities: in particular, in production engineering, quality control, and design activities, initially making minor modifications and improvements, and later becoming the basis for indigenous innovative activities (Lall 1992, Bell 1984). At this stage, business-funded R & D increases rapidly, accompanied by the growth of university-based research in underlying disciplines, with both reflected in the growth in the numbers of international patents and scientific papers. This pattern can be observed most clearly in both South Korea and Taiwan during the 1980s and 1990s.

The centrally planned Soviet model of modernization, practiced in the former USSR and imposed or adopted elsewhere, gave high priority to R & D. By the late 1950s and early 1960s, R & D expenditures in

Central and Eastern European countries were apparently higher than those in Western Europe and the USA. Certain Western observers, therefore, concluded that the Soviet system was superior in promoting R & D and technical change. However, Soviet economic performance subsequently deteriorated, and it later became clear that a very high proportion of Soviet R & D was oriented towards weapons development, and that the government-established R & D laboratories established for each industry were decoupled from the requirements of producers and consumers (Hansen and Pavitt 1987). The major reductions in R & D activities since their collapse in 1989 can be seen as painful adjustments to make R & D activities—and the underlying activities in production engineering, quality control, and design—become an integral part of a process of economic modernization (Dyker and Radosevic 1999).

The Soviet system also had inadequate linkages with technical advance in the rest of the world economy. One important feature distinguishing today's modernizing countries from those of the nineteenth century is the availability of more productive technologies in more advanced countries. Countries successful in assimilating these more advanced technologies have had two characteristics (Hobday 1995): first, strong linkages with the more advanced countries' technology whether through inward direct investment (e.g., Singapore), inward technology licensing by locally owned firms (e.g., Japan, S. Korea), or subcontracting agreements from advanced countries to local firms (e.g., Taiwan); second, the development of local, change generating activities, culminating in R & D activities, that were essential inputs to effective imitation, as well as to innovation (Cohen and Levinthal 1989).

2. Measurement of R & D Activities

2.1 Patterns of R & D Activity

By the beginning of the 1960s, initiatives by the US National Science Foundation and the Organization of Economic Co-operation and Development (OECD) had established common definitions of R & D activities, and led to the collection by governments of systematic data on R & D activities. These have since been complemented by privately funded surveys comparing the R & D activities of individual business firms. They show the following common and largely invariant features of R & D activities.

(a) In industrially advanced countries, business and government are the main sources of funds for R & D activities. Business funding is in general larger, and spent in-house mainly on *applied research and development* activities. Government funding is divided between *basic research* performed mainly in university-

type institutes, and various types of R & D associated with health, the environment, defense, and the support of industry and agriculture. This R & D is performed mainly in the laboratories of government agencies and business firms.

(b) In the industrially advanced countries, the share of GDP typically spent on R & D varies between 1.5 and 3.0 percent of Gross Domestic Product (GDP), compared to 0.5 and 1.5 percent in the newly industrializing countries, and less than 0.5 percent in the rest. The share of national R & D funded and performed by business firms tends to increase along with GDP per head.

(c) More than 60 percent of all business-funded R & D is typically performed in the chemical, electrical, electronic, and automobile industries. The largest individual corporate spenders on R & D are the world's leading automobile, electrical, and ICT (information and communication technologies) firms.

2.2 The Economic Determinants and Impact of R & D Activities

The improved quality of R & D statistics has enabled economists and other analysts to deepen understanding of both the determinants and the economic impact of R & D activities, at the level of countries, industries, and firms. A number of analysts have been able to show that—amongst the industrially advanced countries—differences in the levels and rates of growth of national R & D activities have a significant influence on differences in national performance in exports and productivity (Fagerberg 1987).

At the industry level, considerable attention has been given to the effects of firm size and industrial structure on R & D activities. Given the dependence of specialization on scale, the proportion of firms performing R & D increases with firm size. However, there is no clear consensus on how R & D intensity varies with firm size amongst large firms: evidence can be found either way. And although R & D is found mainly in concentrated industries, there is compelling evidence that variations amongst industries in both the degree of concentration and R & D intensity are determined jointly by a third factor, namely, inter-industry variations in the extent of technological opportunities (Levin et al. 1985).

Less progress has been made so far in measuring the effects of differences in R & D expenditures on company performance. This is partly because comprehensive and comparable R & D data at the company level are only slowly becoming available. It is also because of the difficulty of defining a proper measure of corporate performance. Those used include the R & D production function, stock market evaluation, and long-term growth (Patel 2000).

2.3 Limitations

Sections 2.1 and 2.2 and show that statistics on R & D activities can be a useful proxy measure for innovative activities. But they have their limitations, the most often mentioned of which is that they measure inputs and not outputs. Equally, if not more important are the following:

(a) In large firms, R & D statistics do not measure the often considerable expenditures on complementary activities in production and marketing, that are necessary to transform the outputs of R & D into commercially successful innovations.

(b) In small firms, they do not measure part-time innovative activities, which are particularly important in the machinery and software sectors.

(c) They capture only very imperfectly the growing volume of innovative activities in software now being performed in firms in service sectors, such as finance and distribution.

Other indicators of knowledge-generating and innovative activities have therefore been developed to complement R & D indicators, the most important of which have been counts of patents, papers, citations, and numbers of innovations (van Raan 1988).

3. Some Contemporary Debates in R & D Management

Many of the characteristics and problems of managing corporate R & D have changed very little since the nineteenth century.

(a) The need to orchestrate and integrate specialized knowledge and skills across disciplines, professions, functions, and divisions.

(b) The progressive improvement in fundamental scientific understanding, accompanying the increasing systemic complexity of innovations—a process that will continue with the more widespread application of the techniques emerging from ICT.

(c) The difficulty (impossibility?) of making reliable predictions about the success or otherwise of specific innovations, especially major ones.

At the same time, new problems and challenges have emerged.

(a) With increasing specialization in both the production of knowledge, and of the components of increasingly complex systems, firms are faced with increasingly difficult choices about what products and knowledge to outsource, and what to retain in-house. An important part of the in-house R & D function is now devoted to the monitoring and co-ordination of innovative and production activities external to the firm.

(b) In addition to the well-established function of supporting foreign production, large firms are performing a growing share of their R & D outside their home country, in order to tap into the increasingly

numerous international sources of leading-edge scientific and technical advance. This poses new challenges for managers in integrating skills and knowledge over long distances (Niosi 1999), and for national policy-makers in assessing the location of the benefits of public investments in academic research.

(c) There is some evidence that academic research is becoming increasingly linked to commercial R & D activities. For some, this is the consequence of unwelcome financial pressure from governments on universities to demonstrate short term 'relevance' in their research. For others, it is the consequence of fundamental changes in the locus of knowledge production. Other evidence suggests that reductions in the costs of technical experimentation through simulation software now make it easier for academic researchers to develop and test experimental prototypes.

Research Conduct: Ethical Codes

This article will focus on the use of ethical codes in dealing with moral problems concerning research involving humans, nonhuman animals and the environment, that is, moral problems that arise mainly in the experimentally working sciences, especially biomedicine. More general issues such as truth telling, or usage of best scientific methods that if neglected may cause moral problems, will not be considered here.

1. History of Ethical Codes of Research Conduct

The (ab-)use of humans for research purposes has a long tradition reaching back far beyond the beginnings of modern experimental science in the Renaissance to ancient Egypt and Persia. Unfortunately, morally questionable experiments were also performed in the recent past. Well known are the atrocities perpetrated by physicians during the Nazi regime in Germany during the 1930s and 1940s. But even later, contemptible experiments were uncovered elsewhere (Beecher 1966): an inglorious example is the US Public Health Service Syphilis Study (better known as Tuskegee Syphilis Study) in the course of which a large number of black men diagnosed with syphilis had been left untreated in order to observe the ‘natural’ course of the disease.

Although the abuse of human experimental subjects is by no means the only moral issue in research

conduct (see Sect. 3), it gave rise to the first international moral framework regulating research conduct—the Nuremberg Code of 1947. It was followed by the World Medical Association’s (WMA) *Declaration of Helsinki* in 1964 (with several revised versions), and in 1993 by the *International Ethical Guidelines for Biomedical Research Involving Human Subjects*, which was drafted in cooperation by the Council of Medical Organizations of Medical Science (CIOMS) and the World Health Organization (WHO). Besides these widely adopted international guidelines there is a large number of further international and national guidelines. Although regulating research conduct was for a long time equivalent to regulating research on human subjects (for an overview see Veatch 1995), the debate on animal rights as well as on the protection of the environment has also stimulated the issuing of many guidelines covering these areas. (A large selection of relevant texts, including those named above, are reprinted in Spicer 1995.)

2. Ethical Codes—Philosophical Remarks

A moral, or an ethos, is understood as a set of rules of action (norms). Ethics, a scientific subdiscipline of philosophy, is the critical assessment of different morals. There are many morals (e.g., the ethos of physicians, the ethos of lawyers, etc.) but only one ethics; the latter should not, however, hide the fact that there is no agreement between ethicists as to what the correct criteria for this assessment are (see *Bioethics: Examples from the Life Sciences*).

A moral or ethos can exist in unwritten or (partly) written form. An ethical code is a written, i.e., codified, moral or ethos; an ethical code is, therefore, a moral and not, as its name might suggest, a part of ethics. Insofar as oaths (such as the Hippocratic oath), prayers, and creeds present a certain moral, they are open to an ethical assessment too.

An ethical code is an instrument of self-regulation established by a certain profession (e.g., physicians’ organizations) or those groups directly involved in the actions of that profession (e.g., patients or funding bodies). In contrast, national laws and international conventions (e.g., the Convention on Human Rights and Biomedicine adopted by the European Council in 1996) are issued by government bodies. Using the principle of subsidiarity, i.e., the principle that what can be regulated on a lower level should not be regulated on a higher level, ethical codes allow an increased flexibility in view of new moral challenges when compared to statutory regulations.

An ethical code of research conduct is a codified set of rules of action (norms) that should be adopted by every researcher to whom the code is addressed. If a researcher obeys an ethical code he or she is said to

perform her research in a morally acceptable way. 'Performing morally acceptable research' is relative to the justified ethical code applied in testing a certain piece of research. It might be the case, however, that the evaluation of a certain act of research is morally acceptable relative to one ethical code but not to another. For example, a medical experimenter by performing a certain act of research (e.g., on human embryos) might obey the ethical code to which he is subject in his country, but by the very same act might disobey the ethical code obligatory in another country. In those cases where the differing evaluations of acts of research is deemed unacceptable, the philosophical evaluation of ethical codes has its place. The main areas of interest in this context are the application of results from research, the generation of knowledge through research, and the credibility of researchers. Conflicts may arise due to the incompatibility between—as already noted—different ethical codes, certain parts of a certain ethical code, or an ethical code and what might be called public morals.

The ethics of science deals with the reconstruction (and thereby critical assessment) of rules of action, whether codified or not. This reconstruction displays presuppositions concerning the scope of the research in question, the criteria for the 'scientific' generation of knowledge, and the acceptable application of this knowledge. (Motivation of research, be it longing for social acceptance or money, does not play any role in the ethics of science; only prescriptive claims of validity related to certain acts of research are at issue here.) Ethical codes of research conduct can be subjected to such a reconstructive process. The task of ethics is to make distinguishable by way of reconstructing those moral norms that can be universalized, in other words, that are valid for everybody. This assessment should be done by using a method that is, in principle, accessible to everyone. Those moral norms that have proven to be valid can then justifiably be used to test an act of research with regard to its moral acceptability.

The application of moral rules of action in research contexts—the testing of certain acts of research concerning their norm-conforming character—is easily established in small social groups only. For example, working together in a laboratory on a daily basis, the members of the peer group develop a strong intuition of whether certain acts of research do obey the relevant rules of action or not. Acts that do not conform to the rules of action are, therefore, easily identified and the committing actor is kept from doing those acts again. This habitualization of rules of action seems to be, therefore, an appropriate measure of enforcing rules of action in small social groups (Gethmann 1989).

In complex scientific communities with a highly differentiated division of labor the habitualization of moral norms does not work satisfactorily, because the peer review between researchers cannot be sufficiently secured. In this situation it is necessary to design

procedures that achieve the control of obedience to moral norms and their enforcement (institutionalization): though not everyone can evaluate whether a certain experiment is morally acceptable (according to certain standards), because not everyone has the expert knowledge necessary for that evaluation, everyone—at least in principle—should be able to assess whether the procedure used by an institutional review board for evaluating this research (e.g., by a peer-reviewed journal, where the review is done by making use of certain rules of action) is correct. Or to give another example: not everyone can assess whether a certain clinical study obeys the relevant rules of action, but everyone should be able—at least in principle—to assess whether the procedure by which the responsible ethics committee evaluates this study is correct (see also *Ethical Practices, Institutional Oversight, and Enforcement: United States Perspectives; Ethics Committees in Science: European Perspectives*).

The codification of moral norms, that is the generation of ethical codes, runs largely in parallel with the institutionalization of these norms. Codifying norms enhances their ability to be put into operation: codified norms are less open to inter-individual interpretability of their meaning than norms that are subject to an oral tradition. This stability of meaning supports the efficiency of institutionalized procedures of control of obedience to and enforcement of those norms (cf. the legal requirement of writing for certain documents).

Connected to this is the issue of the status of obligation of ethical codes: statutory regulations must be obeyed (with the problematic exception of toleration of illegal acts or illegal acts that are exempt from punishment). In contrast to that, ethical codes can have a status of obligation varying between a mere declaration of intent and binding professional law. Depending on the act at issue, the consequences of non-obedience of an ethical code may vary from a mere moral reproof to a prohibition from practicing a profession. In addition, the status of obligation of ethical codes may vary over time. This can be illustrated by the *Declaration of Helsinki*: issued by a professional organization, the World Medical Association, it was originally seen as an ethical code binding only for the members of the WMA. Today, however, the Declaration has gained a status comparable to the United Nations' Universal Declaration of Human Rights, to the extent that even non-members of the World Medical Association cannot simply depart from the rules of action it lays down. There is a case, therefore, for transferring the ethical code into an international convention or even law issued by the United Nations.

Finally the question arises, by what procedures should ethical codes be developed and changed. Since the development of ethical codes starts from consensus statements, many codes have been blamed for being developed without a wide enough consultation of the relevant stakeholders. It is claimed, for example, that

codes with an allegedly international validity are negotiated mainly by representatives from Western countries.

Taking into account the respective opinions of the relevant stakeholders is an important step in the preparation of an ethical code. But, as said before, the task of a critical assessment of an ethical code or its draft versions is to single out those moral rules of action that can be universalized, i.e., are valid for everybody. This means, however, that the assessment and its results should be independent of the person, and their background, who is actually performing the assessment. Therefore, procedures for developing ethical codes do not make it necessary to involve all stakeholders; even involving only a very few experts can lead to an ethically justified result. But reflecting on the preconditions of a procedural development of justified norms should not lead to a neglect of the difficulties in the practical implementation of these procedures: the debate on changes to international ethical codes like the *Declaration of Helsinki* involves highly political issues such as conflicts of interest, where the involved parties persist in their claims, be they justified or not. Deciding the question of who should participate in the negotiation of ethical codes is, therefore, an important task in addition to the purely ethical assessment of the rules of action laid down in these codes (Schüklenk and Ashcroft 2000).

3. Major Issues of Ethical Codes of Research Conduct

Research bears chances and risks for, among others, patients, society, future generations, nonhuman animals, and the environment (for an introduction see Brody 1998). An important issue of ethical codes is to state criteria relative to which the weighing of these chances and risks can be achieved. An extensively discussed example is the concept of informed consent, which features prominently in many medical codes of research conduct. The lesson drawn from the history of medical research during the twentieth century led to a broad consensus that research without informed consent of the research subject—roughly, a decision made understandingly, intentionally, and without controlling influences—is highly problematic from the moral perspective. Taking this into account the Nuremberg Code demands that in research on humans ‘the voluntary consent of the human subject is absolutely essential,’ virtually making impossible research on those with diminished decision-making capacities. In contrast to that, the *Declaration of Helsinki* decreased the importance of informed consent and introduced ‘best interest’ criteria that are supposed to regulate research on incompetent research subjects (e.g., demented or comatose patients). Though vastly treated in the literature, the issue of

whether informed consent is a necessary precondition of any research—and if yes, what informed consent actually means—is not satisfactorily solved. Especially in the context of international ethical codes that are designed to supersede national codes, codes that often rest on diverging traditions, this issue remains a controversial subject of debate (see *Research Subjects, Informed and Implied Consent of*).

Another criterion used in ethical codes for the sake of weighing chances and risks is that of benefit. But benefit for whom? Basically the question is whether those affected by research may be burdened with the risks connected to research without benefiting from this research. For example, the debate on the acceptability of nontherapeutic research focuses on this problem: the research subjects in nontherapeutic research are burdened with the risks of this research (like drug side-effects) without benefiting from it (see *Medical Experiments: Ethical Aspects*).

Delivering criteria for weighing the risks and chances of research conduct is not the only topic usually covered by ethical codes. Other topics include fraud and misconduct in research, conflicts of interest, and ownership of results of research (see *Intellectual Property Rights: Ethical Aspects; Research Funding: Ethical Aspects*).

An issue of increasing importance for ethical codes is posed by moral problems connected to research involving nonhuman animals and the environment. The former brings up the question as to whether the burden of such research can legitimately be left to those animals. In particular, the so called animal rights movement has done much to raise the level of attention to these problems (see *Animal Rights in Research and Research Application*).

Although the effects of research on the environment have so far not been the main threat that pushed environmental protection forward, research nonetheless can have morally questionable effects on the environment. The release of genetically modified organisms (GMOs), for example, may endanger biodiversity, in that the number of wild-type plants and animals may be reduced by suppression. Although a large number of living species is by itself not necessarily morally preferable, a reduced biodiversity may have (probably only in the future) adverse effects on the ecosystem and thereby on mankind. This would mean, however, that the potential benefits of GMOs are allocated to the living, while the potential burdens due to a damaged environment are left to future generations. Besides postulating rules for actions that demand consideration in dealing with the environment insofar as it is the ‘subject’ of research, ethical codes may also contain the demand that research actively seeks to improve environmental protection.

F. Thiele

Research: Ethical Aspects of Long-term Responsibilities

The development of the modern sciences in the twentieth century brought about unexpected consequences for humankind both of a welcome and an unwelcome nature. The ethical issue of long-term responsibility in research takes on particular importance in view of the potential threat to future generations posed by the far-reaching and unforeseeable effects of realizing the possibilities of science. Yet our experience of the unforeseeable nature of innovation processes and the sheer impossibility of foreseeing the life circumstances of future (especially of distant) generations gives us reason for serious doubts about whether it is at all reasonable to speak of long-term responsibility in reference to research. Thus affirmation of this must be founded upon an enlightened ethical analysis of long-term responsibility. If, indeed, such responsibility is to be affirmed, it remains to be clarified who shall bear this responsibility: the researcher, the user, or those who benefit from the results of research. Finally, it may be necessary to determine how long-term responsibility should be implemented within the reality of societal decision-making processes.

1. Scientific Aspects

The discipline of the ethics of science is concerned with the systematic reconstruction of those specific orientations for action that are determined by the understanding, immanent in each field of science in respect of its individual subject area, and the understanding of the scientific procedures for its description and explanation and an appreciation of the possibilities for

action opened up by scientific knowledge. In this, ethics of science shall be understood as a part of philosophical ethics that refers to a specific, societal field of action determined by particular forms of knowledge. Above all, ethics of science, in respect of the task on hand, has to deal with two interrelated areas of phenomena. First, ethics of science draws on the specific ethos of the scientific community in order to reconstruct those orientations to which the scientist is committed, in the interest of seeking out the truth. This involves a smooth, unbroken transition from general rules of action (e.g., the prohibition of falsifying research results) to specific regulations for individual disciplines within the framework of their respective methodology. Second, ethics of science concerns itself with the relationship between general moral orientations and the problems of generating and applying scientific knowledge. Both in generating and applying, it is primarily a question of the practical consequences resulting from technical knowledge.

An example of the moral problems involved in the generation of scientific knowledge can be seen in the field of experiments on human beings in medical research and other medical science disciplines (above all in the field of psychology); more recent discussions target experiments on animals or genetic intervention into the genome of humans, animals, plants and micro-organisms, for the purpose of getting to know more about genetics. The moral problems inherent in the application of scientific knowledge and the responsibility of the scientists concerned are now under discussion in almost every field of modern science, and have been especially since the 'Manhattan Project' (the building of the atom bomb by US physicists).

The beginning of modern science, at its core, has moved away from the concept of knowledge generated by contemplation, since it is now essentially characterized by knowledge that owes its existence to technical intervention into nature under controlled conditions. Not until a fundamental appreciation of the problems of a modern concept of knowledge was undertaken by Kant and other German proponents of idealism did it become clear that this, too, is thanks to moral presuppositions. Whereas initially it was not the technical consequences of the application of such knowledge that was in the foreground but rather the self-commitment of the scientist to the truth, in the interest of generating reliable knowledge, the discussion on the ethics of science in the twentieth century, in comparison, was first and foremost determined by the experience of the technical and practical consequences of scientific knowledge. In this it was predominantly the natural scientists, in the wake of the development of weapons of mass destruction and other large-scale technical applications of knowledge, who posed the question as to the moral principles of their actions. Above all, with the development of the modern biosciences, the question of the moral responsibility involved in the generation of knowledge

has become the focus of attention. The problems arising especially in the medical disciplines and the biosciences are proving to be highly complex issues, involving the fundamental ethical orientation of societies characterized by scientific and technical civilization.

2. Fundamental Problems of Long-term Responsibility

As far as ethics is concerned, the idea that human beings not only bear responsibility for their actions towards those with whom they are faced in the 'here and now' is by no means a new idea ensuing from problems arising from modern science and technology. Nevertheless, the issue of obligation beyond the immediate circumstances of our actions is dramatically brought home to us by modern science and technology in a manner hitherto unknown, in that modern technology generates for successive generations qualitative and quantitative risks—but also chances—unknown to premodern technology, and this not only when actions are undertaken but also when they are omitted.

It is an indisputable fact that present-day actors expect the acceptance of a kind of risk that earlier generations never had to face. In the sense that this is a quantitatively and qualitatively new situation, it may be stated that humankind is now confronted with a new ethical problem. Thus the question of risk is materially the core question when considering the issue of the scientist's responsibility for the future. Taking actions involving risks, however, is not in all cases conducive to conflict and thus is not always of ethical relevance. It is only of interest in those cases where others are expected to accept the taking of actions that involve risks. As far as and as long as the consequences of the actions concerned involve risks that are of a purely private nature, e.g., because (a) the consequences only effect the actors themselves; or (b) the consequences are not recognizable due to insufficient knowledge concerning the relevant causal or conditional nexus; or (c) though the consequences are foreseeable, the persons concerned, as moral subjects, are not deemed equals to the actors, so that as far and as long as this position is held, taking actions involving risks is not an ethical problem; it may be reduced to the problem of acting with predetermined consequences.

The ethical problems of taking actions involving risks are now exacerbated even more by a further dimension, i.e., when it is a matter of the consequences of technical activities for coming generations in the distant future. These are the guiding problems in the issue regarding long-term obligation. Thus, in principle, it should not be necessary to demand a new code of ethics but rather to attempt to come to terms with the 'at any time' concept of our obligation as seen in

existing ethics. The question is to be asked more precisely as to what it means for human beings to be under obligation to other human beings in the distant future in view of the unforeseeable long-term consequences of their actions in applying the means of modern scientifically founded technology.

In issues of applied philosophy, like the question of responsibility for climate consequences, for the problems of the final disposal of nuclear waste, for the consequences of intervention in the human genome or for population growth, the problem of obligation and responsibility mainly concerns generations in the distant future. This entails asking a series of nontrivial questions that have to be answered if one seeks to justify the reason for and nature of such long-term responsibility. In this connection it is of primary importance to answer the following three fundamental questions:

(a) Are actors only under obligation toward those with whom they are concurrently interacting?

Only if the answer to this question is negative can there be any talk at all of obligation that extends beyond the actor's present into the future. This question is to be answered in the affirmative by proponents of such ethical concepts from which obligations arise exclusively from claims uttered by currently existing conscious beings (this primarily implying preference-oriented utilitarian approaches). Within the framework of such concepts the paradox arises that for members of a generation G_0 in relation to members of future generations G_n no obligations will ever be able to exist if the future generations are in reality not in a position actually to raise claims against the members of G_0 , which after sufficient passage of time (approx. $n > 3$) is always the case. In respect of concepts that reduce obligations to the actual voicing of claims of this nature it must be pointed out that there is a distinction between having the right to make claims on the one hand and the ability in reality to assert such claims on the other.

However, if future generations have justified claims against earlier generations (even when they are not yet able to assert them), then, in appropriate cases, corresponding obligations are incumbent upon the earlier toward the later generations.

(b) Does obligation end with generation $k > i$ (e.g. where $i = 3$)?

Everyday intuition would seem to suggest what many economists profess, namely that due to the lack of knowledge concerning the needs of future generations, which increases with the growing distance in time, obligations extending into the future must end with a generation of a certain, relatively large magnitude of k . However, if one attempts to pin down this intuition precisely, it does, in fact, begin to seem implausible: on principle to allow obligations to end at certain generation markers would mean in effect that for the members of G_0 in relation to G_{i+1} , in contrast to the members of generation G_i there would be no

obligations whatsoever, and this for the only reason that the former belong to a grade $k > i$ generation. A restriction of this kind on the scope of obligation would be incompatible with an ethical universalism, in principle presupposed both by obligation ethic as well as more recent approaches to an utilitarian ethics. If one grants recognition of moral justification to moral subjects at all, then it seems simply arbitrary to allow this to end at a particular time (or spatial) limit. To allow obligations to end with however near or distant a generation would be particularism of the present, an 'ego-preference' of those consciously concerned at the time. And in any case, such a form of particularism would be in contradiction to cognitive universalism, which is also inherent, so to speak, as a sort of regulative idea, in the search for scientific truth.

(c) Are actors under the same degree of obligation to members of the k th generation as they are to the first generation succeeding them?

The conclusion is often drawn from an affirmative answer to question (b) that the answer to question (c) must also be affirmative: Either there exists an obligation on the members of generation G_k or there exists no such obligation—but if it does exist, then it does so for the members of generation G_k just as for the members of generation G_{k-1} , G_{k-2} , ... G_1 . This consequence, however, is not inevitable. On the contrary—irrespective of the question of temporal distance between those under obligation and those entitled to make a claim—a distinction must always be made between the existence of an obligation, on the one hand, and the degree of real liability on the other. Correspondingly the gradation of obligations must be sharply distinguished from the concept of discounting liabilities. Whereas, in fact, the idea of discounting (at any rate in most of the variants put forward) presupposes an ego-preference that is not compatible with universalism and which is therefore rightly rejected by most moral philosophers, the idea of a gradation of obligations, on the other hand, is unaffected by the presupposition of ego-preferences of those consciously involved at the time.

3. Social Implementation of Long-term Responsibility in Research

Obligations come into existence through discursively justified claims. In the case of long-term responsibility, however, the very element that is missing is the moral proponent. It can merely be introduced as an entity not yet asserting claims, albeit entitled to make claims. In such cases the process of justifying claims and obligations is therefore not based on real but on fictitious discourse. It must be said, of course, that fictitious discourses are not confined to long-term responsibility. Even in the case of short-term responsibility, moments of fictitious discourse are a

matter of course, e.g., concerning forms of delegated, anticipated and representative obligations to act. The fictitious discourse has to be conducted as though the proponent were actually raising claims (with all the difficulties involved in the growing distance between the generations).

It is just as difficult to reconstruct the discursive arguments of the proponent as it is to reconstruct those of the opponent, i.e., the addressee of the claims introduced. Whereas the real proponents bring themselves to the notice of the real opponents, it can easily happen in the case of long-term responsibility that no one feels addressed by the issue. Thus the question must be posed as to who exactly shall be obliged to bear the long-term responsibility. Also for this question, the starting point is short-term responsibility because here, already, there is the problem of determining the addressee.

One of the first conclusions that can be drawn is that an answer like 'Everyone shall take care of their own claims' cannot constitute a satisfactory solution, since actions likely to result in conflict (distribution of resources, exercising usufruct etc.) are the very ones that do indeed concern other people. In respect of long-term responsibility, however, a special case arises in that 'the others' are not known to the actors and as yet may not even exist. Indeed, however, the 'everyone for themselves' solution already comes up against insurmountable barriers in connection with short-term responsibility.

Individuals who have come to the conclusion that they cannot take responsibility for the application of chlorinated carbohydrates as a propellant gas, that individually this conclusion is being justified, nevertheless fail to achieve the aims of acting because they are not in a position to evade the use of CFCs. Such examples can also be cited from the field of large-scale technical plant.

Examples taken from the field of short-term responsibility show that in addition to individual obligation there is also a responsibility of the kind that devolves upon the actors since 'all' the addressees constitute a plea and thus the claim which arises from it. In short it shall be referred to as 'collective responsibility.' Of course, this only indicates the direction of the solution. Collective responsibility could be regarded as a concept of escapism from obligation. It must therefore be clarified in what manner the validity of collective obligations may be asserted in real discourses.

For the further clarification of this question, it is necessary to make a terminological remark. A distinction must be made between obligation arising from an action and the responsibility for an action. Actors are subject to direct and undivided obligation for their actions, and responsibility is borne by them according to delegation of collective obligation. Responsibility arises from obligation through 'moral division of work.' Thus there exists not only the productive

division of labour (in the economy) and the cognitive division of work (in the field of science). A moral division of work is especially applicable to those moral problems that exist in connection with the weighing of risks and chances in respect of the possibilities to act and the compulsions and constraints pertaining to actions in the context of modern science and technology. Due to the complexity of these problems the obligations of all concerned towards future generations must be delegated to the responsibility of individuals.

The first solution that springs to mind in this respect is the creation of bodies of scientific experts. In this, however, the problem of (non)acceptance arises which manifests itself in mistrust towards a perceived 'expertocracy.' According to the degree in which obligations are delegated to those bearing responsibility there is naturally a growth of uncertainty as to whether those responsible are (in generalizable terms) properly assuming their responsibility.

Thus it constitutes a basic problem of modern scientifically and technically based civilization to organize the social assumption of responsibility in such a way that, on the one hand, the effect of preventing an overburdening is maintained through the process of delegating obligation, while, on the other hand, the moral competence of the decision maker remains transparent. Although not every action is relevant in respect of distant consequences, the question must be asked in those areas that are sensitive to such distant consequences as to which social agencies are in a special way capable of, and therefore should be entrusted with, bearing long-term responsibility.

In this there are many complicated issues that have to be resolved. Above all the question of who should bear the responsibility is particularly explosive at present. Is it primarily a matter for the state and its three main organs of power or is it a matter for society and its subsystems to take over responsibility for the future? The state, through the medium of its legal system, is not a good advocate of long-term responsibility for several reasons. First it is subject to the specific democratic rules governing the lifetime of a parliament and secondly, the functionality of its laws is restrictive. The democratic rules controlling the period in which a parliament stays in power have the effect that the parliamentary system is geared to ultrashort periods of obligation, i.e., the members of parliament, as mandate holders, assume responsibility for four or five years, after which they have to answer to the electorate; the voters, in their turn, have to optimize their decision as to how they should vote with regard to a wide variety of political dimensions. Since the support given by the mandate holders to the idea of long-term responsibility is only one dimension among many, it is likely that for many voters this will be the dominant dimension—as long as voters each have only one unweighted vote.

For a restructuring of the political system, which could be imagined, it would not be sufficient to introduce marginal changes like merely extending the period of parliament or establishing a system of overlapping parliamentary recruitment. In accordance with the principle of diminishing obligation, as adumbrated above, it would be ethically not permissible—and certainly not enforceable either—to abandon the foundation of parliamentary democracy in the (putative) interests of distant generations. For another reason the state is not a good agency to take over long-term responsibility, because its most important medium, the law, is not suitable to regulate subtle moral issues. An essential difference between ethics and law consists in the fact that there is no judge for morally reprehensible actions. Ethics apply rigorously—in contrast to the law; which is why in ethics the saying, 'Where there is no plaintiff, there is no judge' makes no ethical sense at all. Otherwise, there would be no such thing as long-term responsibility since persons who do not yet exist cannot stand up as plaintiffs. Thus there would be no defendants either. A further problem with regard to law in connection with future generations is the difficulty arising from the fact that the relevant occurrence that would be subject to legal punishment has not yet taken place, or may only take place with a certain (possibly very small) degree of likelihood. It can be seen clearly that principles of law are inapplicable here. Furthermore, in respect of the relationship between law and morals the principle of subsidiarity applies, i.e., if something can be accomplished by moral discourse, no attempt should be made to regulate it by law.

Without the necessity of excluding the possibility that in many issues the law may be utilized as an instrument in establishing the long-term responsibility of the members of society, these reflections show that when it comes to answering the question of who should bear responsibility, the focus of attention naturally turns to society with its moral forming and preserving groups and their respective subsystems. In this process a number of subsystems play a prominent part, such as religion, culture (in the narrow sense of the arts), education, and the economy. The findings of the sciences and their respective applications, however, are only of particular importance from the point of view of long-term responsibility.

Their future perspectives are characterized by being particularly concrete and particularly long-term and are marked by having an especially profound effect on human life as we know it. Therefore, it is a paramount task of the scientific community to promote the capability of institutions of assuming long-term responsibility.

Research Ethics, Cross-cultural Dimensions of

For the researcher working in a culturally distant setting, for whom cultural and behavioral differences impinge directly on methodological design, data collection, and everyday life in the field, maintaining ethical equilibrium can be a difficult, never-very-satisfying discipline. Anthropologists are most prone to this situation and have reflected the most about it, but to the extent that other practitioners (political scientists, demographers, geographers, etc.) utilize ethnographic approaches, they, too, expose themselves to significant ethical dilemmas. Faraway places are perhaps somewhat extreme in this regard, but studying ethnic minority groups in one's own society can present particular ethical challenges, especially when the observed practices are illegal or are more legitimately at odds with the tastes and standards of the wider community, to which the researcher typically belongs. The difficulty stems from the researcher's need to balance the demands of multiple moral codes, not only those based on personal and professional values—a requirement common to much scientific investigation, whatever the content and venue—but, in addition, those of the host culture and the laws of its land, and those derived from the interests and cultural traditions of persons to whom the researcher has become emotionally attached and obliged during the course of research. Ethical clarity is not helped when, as frequently happens, some of its elements are invisible or incomprehensible to the researcher—from whom, at least early in the project, but to some extent throughout, blunders are to be expected. Charity from the hosts usually redeems the investigator, but not always, and those are the instances of ethical infirmity which rarely survive as classroom and dinner-party anecdotes in the after years.

1. Changing Ethical Circumstances

In the early days of fieldwork among 'native peoples,' prior to about 1920, ethical issues were not so pressing. For British, French, German, and Dutch researchers of that era, the terms of engagement were largely governed by colonial authorities; in North America and South America, comparable oversight was exercised by internal government agencies, such as the

Bureau of Indian Affairs of the US Department of the Interior. Whatever retrospective moral judgment one might pass on those institutions, they were taken for granted at the time, and were the reality within which ethnographic inquiry was conducted. Considerable research was actually carried out by scientists employed or sponsored by colonial or governmental administrations, though with little effect, apparently, on the policies and procedures of rule. Access to field sites was readily achieved by bona fide researchers, who, so long as they disturbed neither village peace nor administrative purpose, were left alone. Host communities had little power to resist being studied, should they have wished to do so. In any case, such communities could not have understood very fully why the equipment-toting sojourner was there, nor could they have foreseen the consequences of the study for themselves and their posterity.

In those days, too, ethnographic research often consisted of participation in regional survey work conducted by teams of scientific specialists and government officers. Theirs was a 'collecting' mentality, with no need to stay long in one place. The expedition would record cultural inventories (word lists, kinship terms, technology surveys, basic institutional forms, various traits that were part of the standard ethnological catalogue, etc.), take anthropometric measurements and photographs, and, particularly if a museum was its sponsor, collect artifacts (see Sect. 2). Gifts and payments would be distributed—items such as steel tools, for example, which were relatively inexpensive for the expedition but highly prized by the recipients—and the party and its carriers would move on to the next group.

Beginning in the 1920s a revolutionary new field-work methodology expanded the ethical implications. Based on a technique loosely known as 'participant observation,' the approach involved prolonged (1–2 years or more) residence in a host community with the aim of acquiring intimate familiarity with the people and their culture. Close familiarity in turn invited the innovation of the 'case method' approach, in which specific events (often disputatious in nature) were contextually examined as indicative of underlying cultural understandings or social organization. Beyond their analytic usefulness, well-executed case studies added vividness and probity to the ethnographic account. Case studies embedded in monographs usually identified individuals by name, along with relevant genealogical histories and information of a potentially embarrassing or inflammatory nature. Risks to informants thereby entered into the research equation, but, initially, only to a slight degree. Missionaries and colonial administrators might have searched out published information and used it to the detriment of individuals or cultural traditions, and yet it appears that this was a rare occurrence. As for the people themselves, information revealing the hidden deeds and motives of neighbors and enemies might

have been very useful, and damaging to the persons named but, under those remote, preliterate conditions, the idea that some explosive item from a book or journal would find its way back to the village and there make mischief would have been very farfetched.

Nowadays, such possibilities are quite thinkable. With the spread of literacy, some monographs are finding their way back to the village, or into the courts, where facts and events previously noted are being used, for example, in litigation concerning land claims. Starting in the late colonial period and continuing until the present day, educated elites in many of the countries traditionally included in cross-cultural studies comprise a new community of critics: some are the children of cultures ranking as 'classics' in the ethnographic literature, some are social and behavioral scientists, some are even anthropologists. The new intelligentsia, many of them educated in the (self-) critical Western tradition, many of them eager to forget the past and move on, are harshly critical of their colonial past and willing to condemn out of hand studies carrying the odor of those times. Ready allies are to be found from within the various critical movements that swept Western academic institutions during the last two decades of the twentieth century. Anti-orientalism, postmodernism, neomarxism, 'science studies,' the idea of ethnography as a constructed text, the distrust of studies conducted under pre-feminist, 'patriarchal' assumptions—these are part of the ethical-cum-intellectual apparatus currently used to discredit the tradition of cross-cultural study.

Although a good deal of this criticism is ill-informed and irrelevant, the best of it is very good indeed, offering novel insights and perspectives, the value of which even the most diehard traditionalist cannot reasonably deny; devising new concepts and new research goals and relationships, such as befit the new parameters of cross-cultural studies in a world very different from what it was as recently as a generation ago. Gone are the reassuring isolations which formerly shielded cultures, and those who studied them, from outside scrutiny—the never-perfect isolations which lent credence to the always dubious doctrines of cultural essentialism and cultural relativism (Gellner 1985, Cook 1999). Globalization engenders recurrent issues, such as local environmental degradation, the AIDS epidemic, poverty, war, and political revolution, which pique not only the researcher's interest and intellect, but his or her deep questionings into the ways of goodness, justice, beauty, and the future of the human species. These are supremely moral and ethical questions, which, while not displacing the urgent quest for objective findings, are adding immense complexity to the task of the researcher.

2. Cultural Property

Reference was made to the routine practice of earlier researchers of collecting information and emblematic

artifacts from peoples they visited. Now, generations later, descendants of some of these peoples, or those speaking for them, have come to demand the return of these objects. Never mind that perishable objects, both tangible and intangible, would never have survived in their home place, their removal is retrospectively construed as a form of cultural banditry. Today, legal claims concerning cultural patrimony and indigenous peoples' exclusive rights to traditional property—material or intellectual, commercial or sentimental—circumscribe an international, cross-cultural arena of high-stakes ethical debate. The cases, to name a few, include the longstanding litigation between Greece and the United Kingdom over rights to the 'Elgin Marbles'—sculptures from the Parthenon and other buildings of the Athenian acropolis which were removed by Lord Elgin in the early nineteenth century and were later sold to the British Museum; the legal contest between scientists and local Native American groups over custody of the remains of a prehistoric individual of obscure genetic provenance known as 'Kennewick Man'; more generally, the repatriation of skeletal material to indigenous descendant groups—a process now mandated by US federal law; efforts by Australian Aboriginal groups to recover legal title to ancestral lands containing sacred sites; the question of potentially huge royalties payable to various Amazonian groups who have guided drug companies to forest products having pharmaceutical properties; and the commercial exploitation of design elements taken from among Native American traditions of the US Southwest.

Social scientists are being ever more frequently drawn into these issues as witnesses, commentators, teachers, analysts, and advocates. Increasingly, sometimes unavoidably, the role of the researcher is shifting from that of detached observer to that of social activist. What to a previous generation of investigators would have seemed an unconscionable abandonment of scientific objectivity is nowadays becoming a common, practical necessity—a commitment demanded by newly sophisticated, politically aware groups as a condition of their acceptance of a research visitor. Other researchers, decrying 'scientific objectivity and detachment' as simply one ideology among others, gladly construe their mission to be that of assisting in the struggle of powerless ('subaltern') groups to improve their lot vis-à-vis dominant state or corporate interests (D'Andrade 1995). Wherever one stands on the detached vs. committed gradient, social movements and the emergent social and political aspirations of postcolonial groups are, themselves, of compelling intellectual interest to the social scientist, further blurring the ethically consequential line between actor and observer. Gone is the age of innocence during which many ethnographic habits were formed, when ethical choices were a good deal simpler.

In less controversial terms, professional ethics now calls for the dissemination and preservation of re-

search findings. Some host countries require, as a condition of granting research permits, that copies of field notes be deposited in their national libraries or archives, or that debriefing talks be given to academic groups. Fearing the continued neglect and eventual loss of much unpublished material, some research communities are establishing specialized archives for the preservation of field notes and other cultural records, and for their systematic repatriation to the host countries, with the aid of microfilm, microfiche, or other inexpensive, readily accessible technologies (Tuzin 1992). Not only do such practices secure priceless cultural information and benefit future generations of researchers, they also contribute immediately to goodwill and a collaborative spirit between scholars belonging to reciprocal sides of the cross-cultural divide. These trends are further assisted by the requirement of many host countries that foreign researchers be sponsored by a local academic institution or engage an assistant or co-investigator from among the local scholarly community. The importance of behaving responsibly toward host peoples and nations and toward the long-term scientific good is an explicit principle of professional ethics. Some funding agencies, such as the Wenner-Gren Foundation for Anthropological Research, are actively encouraging, and committing resources to, an approach that emphasizes custodianship rather than ownership as properly describing the researcher's relationship to cultural treasures he or she is privileged to collect.

The distinction between custodianship and ownership further points to an unresolved issue of looming ethical importance: on moral and legal grounds, what should be the tenurial relationship between a body of cultural ideas and the persons who, by accident of birth, happen to be carrying them? Or, as put by one commentator (Brown 1998), can culture be copyrighted? The alternative would be to say that, just as culture is an attribute of humanity, so all cultures, none of which are formed in perfect isolation, are manifestations of that attribute, and therefore are ultimately the property of all humanity—granting that particular groups have contingent, custodial rights over particular cultural assemblages. The former view accords with notions of cultural distinctiveness and cultural relativism, the latter with ideas of universal ethical standards and a body of interests common to the human species. The former view would seem to revere human rights—the right to their cultural traditions being the only right left to many otherwise dispossessed groups—while the latter would appear to remove the last protection against wholesale cultural trespass.

This issue is a minefield of ethical problems that will be prominent in the landscape of intercultural relations and research in the twenty-first century. The seismic convulsions of that landscape will be traumatic moments in the globalization of social and economic relations; increased human migration, possibly in

response to local population pressures and global-warming effects, bringing different cultural groups increasingly into competition with one another; the collapse of autochthony as an argument for indigenous groups in fending off migrant groups beating on the gate—groups once autochthonous themselves, driven by necessity rather than choice, with human rights of their own. In such a world, the conflation of cultures and peoples, collective memories and current circumstances, could produce dangerous vulnerabilities, generating the kind of xenophobic, stereotyping mentality that justified campaigns of ethnocide and 'ethnic cleansing' in the darker moments of the twentieth century. The better alternative, perhaps, is for universalist ethics to have a rightful place alongside the value of respecting and preserving cultural identities, and the rights that may be attached to them. Whatever shape that future takes, however, it is certain to affect the ethical circumstances of cross-cultural researchers.

3. Regulations and Codes

In recent decades, research ethics, once the privileged business of conscience, personal character, professional integrity, and scientific organizations, has come to the attention of lawmakers. During the 1970s federal government regulators in the USA developed rules for the protection of human subjects (Sieber 1992). With ethical reasoning rooted in the Nuremberg Code developed after World War II, the regulatory impulse was triggered by certain scandals involving biomedical research. Early in the lawmaking process, however, authorities recognized that potential risks to human subjects also existed in the social and behavioral sciences. Social and psychological hazards were recognized, as were the need for confidentiality and the importance of informed consent by subjects—not only at the outset, but through the entire course of the research. Procedures were instituted to disclose risks to peer reviewers and granting agencies, assess whether or not they are outweighed by potential benefits of the research, including to the human subject; and, in the field or laboratory, inform subjects of these risks as part of the consent process. A plan for compliance with these procedures, formally approved by university-based, faculty-run internal review boards, became a prerequisite for receiving government grants. Research centers quickly adopted these federal guidelines as their own, mandating the safeguards regardless of funding source.

These measures address ethical anomalies that are egregious in the sense of being built into the research design. No regulatory guideline can govern the many unforeseeable, quotidian dilemmas that may arise over an extended period of research in another culture—a reality acknowledged in the Code of Ethics promulgated by the American Anthropological Association (1998). Still, these measures have the salutary effect of

heightening researchers' consciousness and accountability concerning the welfare of human subjects, while helping to shield institutions and innocent investigators from liability if things go wrong and unethical conduct is alleged. On the other hand, regulatory experience and input from practicing social and behavioral scientists have shown that applying the 'biomedical model' to research in their fields raises problems, some of which are peculiar to cross-cultural studies. Even if language differences *per se* are not an obstacle, other communication barriers can impede the way of genuine 'informed consent.' If the research subjects are lacking in literacy, this would preclude written consent—a circumstance for which official guidelines permit equivalent oral procedures—but there are more subtle, cultural, difficulties. Even where written consent is feasible, subjects usually would not be accustomed to direct questioning by strangers (except, ominously, by police authorities) nor would they be likely to understand the foreign culture of litigation and the bureaucratic concept of 'risk' which jointly inspired the formal consent procedure in the first place. Depending on the political environment in which such an encounter occurs, a procedure innocuously designed to identify and mitigate risk triggers, instead, reactions of suspicion, alarm, and flight. For the would-be subject, for whom the compensatory benefits of the research may seem ethereal and remote, refusal might well be the easiest course, ending the research before it begins. Where traditional communities are receptive to the researcher, an overzealous concealment of individual identities would deprive the people of the only documentary history they might ever have. And so on. Government overseers and internal review boards, acknowledging such technical difficulties, have revised the regulatory guidelines so as to accommodate the special needs of ethically responsible research in other cultural settings.

The protections just discussed focus on the welfare of individual human subjects. What ethical imperatives pertain when not only individuals but entire cultural traditions are potentially at risk? Anthropology, by virtue of its disciplinary investment in cross-cultural research, celebration of cultural diversity, and preoccupation with the culture concept, has a special affinity for ethical issues that arise when science crosses cultural boundaries. Even if the threat stems not from the research *per se* but from other external factors (missionaries, commercial interests, etc.), is the anthropologist not duty bound to intervene vigorously in defense of the host culture? After all, in its submission to United Nations Commission on Human Rights, in 1947, the executive board of the American Anthropological Association recommended that the UN Declaration should be a statement 'of the rights of men to live in terms of their own traditions' (quoted in Cook 1999, p. 169). Should not anthropologists be willing to intervene, by word or deed, in defense of those traditions?

Critics might condemn such intervention as a veiled form of paternalism verging on racism—a denial of the ability or right of individuals to make their own decisions, to dispose of their cultural legacy in a manner they, and not well-meaning outsiders, choose. From this standpoint anthropologists are sometimes accused (sometimes by designing outsiders, with self-serving plans of their own for the group) of being culturally conservative, of wishing to see traditions preserved, of standing in the way of perceived material development and ‘modernization.’ Whatever their motives, the critics have a point. If the idea of indigenous rights is to mean anything, it must hold sacred the element of choice—even if the choice in question proves to be an unfortunate one in the view of contemporary observers or of future generations who must inherit the consequences. The role of the concerned outsider (anthropologist or other) is to help, if invited, to insure that the choices made are informed choices, based on the advisor’s experience, expertise, and external perspective. Such advice would be offered with knowledge of authority relations occurring in that cultural setting, specifically, the mechanisms through which decisions affecting individuals or the group are made.

4. Conclusion

Social and behavioral science research has ethical implications in any setting. Though we may control the interaction to a maximum extent, we are still humans studying other humans. Lives can be affected. To a greater or lesser degree, expectations, projections, aspirations, and the reflexivities accompanying all of these, are part of the immediate research situation. They influence what we observe and how we observe it; they shape the larger lessons we draw in the long afterthought. The publication of results can further affect the original subjects or, years later, their descendants. All of these ethical implications are greatly compounded when the research engagement is intimate and prolonged, and extends across a cultural boundary separating the investigator from the persons he or she is attempting to understand (Geertz 1968). Obligations accrue. Reminiscent of the methodologically engineered interplay of transference and counter-transference in psychoanalytic practice, as the ethnographic relationship deepens, complex personal motives intervene, and the desire to belong and to assist can become so strong as to compete with the desire to know. The whole point of maintaining ethical equilibrium is to transform this competition into a synergy. This is not an easy task; it requires thoughtful, honest reflection upon the ethical dimensions of what one is doing, together with the courage not to be paralyzed by them. In cross-cultural research the effort is worth the candle, for it is this synergy which stands

the best chance of producing a result that is at once truly humane and truly informed.

Research Ethics: Research

Research topics, approaches and contexts bring with them ethical issues—some well understood and easily resolved, some unexplored and potentially risky, and some in which one’s moral outlook is inadequate to the problem. Sometimes the social or political context is such that morally wrong actions are rewarded and morally right acts are punished. Thus, ethical issues in research include conflicts between ethical principles, questions of what action will produce the most good, questions that call for a new outlook or approach, pursuit of personal gain at the expense of others (e.g., research fraud, endangerment of research participants) and research in contexts where the scientist is not free to choose his or her own scientific goals or methods.

Until issues are understood, scientists can only guess about the risks involved and how to ameliorate them. Although ethical questions are normative (What is the morally right action to take?), answers must often be grounded in scientific inquiry. For example, when investigators first undertook major field research on illegal behavior (e.g., prostitution, drug dealing, child pornography) and promised confidentiality in order to obtain honest responses from informants, perceptive researchers wondered, e.g., Can I protect

my data from subpoena, and can I gather valid data otherwise? How serious is the threat of subpoena? Would I go to jail if I were to ignore a subpoena of my data? What will happen to research careers and research in criminal behavior if protection from subpoena cannot be assured? Research by criminologists, sociologists, and political scientists has answered these questions, and led to the development of legal protection of data from subpoena. Research administrators, researchers, and students have learned to use these tools.

Empirical and methodological research coupled with social science theory is used to explicate how ethical issues arise, their possible consequences, and how they might be resolved. This article outlines a range of topics and approaches employed in research on research ethics. Other articles herein on ethics provide detailed examples.

1. History

Prior to the 1960s, most scientists considered their work value free or inherently good. Some scientific societies developed codes of ethics that were quite general and largely ignored. Some survey researchers worried about possible breaches of confidentiality; and some applied researchers recognized that knowledge is power that may be used for good or evil. However, most researchers were oblivious to the ethical dimension of their work. The field of research on research ethics was beyond the imagination of almost everyone.

With the rise of concern about ethics of human research, scientists found that social and behavioral research methods and theories could be used to explore and resolve problems in research ethics. Government funding for such research began to be offered. Increasingly, scientific societies encouraged such research, scientific journals published the findings, and new journals devoted to ethics and science came into existence.

2. Approaches

Most research on research ethics uses theory, has methodological components and involves empiricism. However, for simplicity, the discussion in this section focuses on main approaches:

2.1 Empirical Research

The entire range of empirical social/behavioral research methods may be used in pursuit of empirical answers to ethical questions. For example, survey research methods have been used to assess whether psychology departments comply with federal regu-

lations in the operation of their subject pools. Experimental methods have been used to examine the effects of various approaches to informed consent on comprehension and decision making, and entire research funding programs have invited proposals on this topic. Psychometric methods have been used to study the scientific and ethical values of scientists in various disciplines and their relationship to kinds of problems studied and methods employed (e.g., Kimble 1984, Tarnow 1999). Participant observation methods have been used to study the nature of communication concerning informed consent. Econometric measures have examined the costs and benefits of increased institutional monitoring of human research.

2.2 Methodological Research

Methods of designing and organizing research, evoking and measuring responses, and collecting, storing, and sharing data have ethical implications. For example, does a given procedure or method evoke trust, respect privacy, assure confidentiality, or yield valid results? The design and evaluation of methods to ensure that they meet ethical criteria require methodological research. Two major areas of methodological research in the service of ethics are privacy/confidentiality, and the design of field experiments. The development of methods for protecting subject privacy and data confidentiality has focused on such diverse contexts as interviews, sampling, collecting data from internet chat rooms, and inter-file linkage of shared data. Technological developments increasingly permit unobtrusive observation and measurement of behavior which could destroy trust in major institutions in society; discovering and evaluating uses of such technology have become topics of intense interest (e.g., Agre and Rotenberg 1999). The second major area of intensive methodological research has focused on field settings where rigorous experimental methods with well designed controls are needed, but ethical considerations prohibit jeopardizing the well-being of subjects by placing them in conditions not of their choosing. This has led to development of quasi-experimental methods that are responsive to both ethical and scientific requirements.

2.3 Theoretical Research

This approach conceptualizes and synthesizes what is known about a given ethical problem in the service of ethics and good science. For example, Laufer and Wolfe (1977) developed a theory of privacy that accounts for how age, culture, and status determine persons' regulation of the access of others to themselves. Thompson (1992) synthesized what is known about youngsters' age and sensitivity to risks of research. Gunsalus (1998a, 1998b) has summarized

the destructive conflicts and institutional mishandling that often surround whistleblowing, and has synthesized best practices for institutional and individual handling of whistleblowing situations.

2.4 Legal Research

The regulatory environment that is growing around scientific endeavors inevitably brings with it ambiguities and conflicts when applied in areas that the lawmakers did not anticipate. Exact standards of research conduct may leave no room for intelligent interpretation or for resolution of conflicting ethical principles. The effort required to follow a given law may be disproportional to the expected results. As examples, Western standards of informed consent and signed consent forms are inappropriate and even disrespectful in many contexts such as fieldwork in cultural anthropology and research in third world cultures. Oral histories often involve sensitive details about living persons but cannot meaningfully be rendered anonymous. Examining and challenging laws governing research and proposing more effective laws requires ability to research and interpret laws in relation to their effect on research within specific disciplines, methods, and research topics.

3. Topics of Research on Research Ethics

Topics are organized into 17 categories, nested under five major headings:

3.1 Theory, Method and Design Issues. These Background Issues Set the Ethical Context of Research

3.1.1 Values and epistemology. Scientists' beliefs about knowledge and reality determine what are considered valid scientific problems and how data should be collected, organized and disseminated. Whether knowledge is regarded as an unlimited good or as power affects perception of research risks and benefits. Whether reality is regarded as something 'out there' or as a construction composed of interaction between investigator and subject influences which methods (e.g., deception) are acceptable.

3.1.2 Validity. To be ethical, research must be valid; otherwise it disrespects subjects and society by producing false information. Conversely, in pursuit of validity, investigators may use unethical methods (e.g., putting subjects at risk). Much research on research ethics focuses on finding ways to optimize both beneficence to participants and validity of findings.

3.1.3 Equitable treatment of participants. Procedural and distributive justice issues may arise in planning, conducting, and applying research. Who sponsors the research? Who benefits? Will the results be used in a way that may harm the subjects or their culture? How are subjects selected? How is the power of the researcher balanced against that of the subjects? What kinds of control groups are acceptable? Who sponsors and pays for the research? When is it unethical to withhold information about sponsorship from subjects?

3.2 Risk and Benefit

The perspective of scientists is influenced by their research objectives, culture, and experience with the circumstances of those studied. A narrow perspective may negate the promise of scientific research to be beneficial. Research on risk and benefit seeks to broaden this perspective and enhance the value of research to subjects, their community, researchers, their institution, funders, science, and society. Risks and benefits are generic to all ethical considerations and research topics. However, specific risks vary markedly in relation to the research context (e.g., laboratory, community, school, workplace, hospital, prison).

3.2.1 Risk, wrong, and harm. How does one weigh moral wrongs (e.g., deceiving subjects), versus risks of harm? What determines perception of risk and safety? How can this determination be reached accurately and usefully? How can risk, wrong or harm be assessed?

3.2.2 Benefit and promise. Benefit is the moral justification of research, but it is often simply taken on faith that research is, by definition, beneficial. How are benefits identified, estimated, and maximized? Who benefits? Often research has little likelihood of benefiting society; does the researcher therefore have a duty to benefit the subjects or their community directly via some services, products, training, or job opportunities connected with the research?

3.2.3 Risk/benefit assessment. The price of scientific knowledge is risk and financial cost. How is risk justified in relation to benefit? What is the risk or cost to society of research opportunities that are lost due to financial, regulatory, or political pressures? (e.g., see Rosenthal and Rosnow 1984.)

3.3 Agreements and Communication

Research participants have some understanding of what is occurring; how correct and complete is that

understanding? How informed and autonomous is the decision to participate?

3.3.1 Informed consent. There are many possible modes of communication between researcher and subject about the purpose, procedure, and intended outcome of research. What modes are most effective? What information should be included? How can comprehension and decision making ability be enhanced, especially when subject competency (e.g., of children, institutionalized persons, the mentally ill) is at issue? When must guardians and gatekeepers be included in the consent process?

3.3.2 Deception. This may include concealment, mental reservation, lying, self-deception, and distraction of subjects from the main purpose of the study in order to study spontaneous behavior. Deception raises many difficult questions, e.g., how does deception affect persons across their life span? What are methodological alternatives to deception? When is deception acceptable?

3.3.3 Relationships as a source of data. Qualitative research may involve getting to know persons then reporting on some aspect of their lives, often from a critical perspective that differs from the way the persons describe themselves. How is the research problem defined and is this disclosed to the persons? The nature of the relationship, as perceived by the participant and the researcher, may affect how the research problem is defined, how the data are collected and organized, how the research report is framed, how the results are disseminated and used, and whether the participant is wronged or harmed by this incursion into his or her private life. With the advent of the Internet, researchers are now free to observe or participate in chat room discussions of quite personal and intimate topics. What are their responsibilities to those they study? Should they reveal their presence as researchers? Will subjects' knowledge of the researchers' presence have a chilling effect on their chat room participation? What steps should be taken to disguise the identity of the chat room and its participants?

3.4 Acquisition, Presentation and Use of Data

The many facets of privacy, confidentiality, and data use have been topics of much theory, and subsequent empirical and methodological research.

3.4.1 Privacy. The need to establish boundaries between oneself and others is universal, but differs depending on learning, cultural, social, and developmental factors. People may want to disclose to researchers more than the researcher wants to know, or lie to protect privacy. Researchers' views on privacy may be inadequate for judging what privacies others want, expect, or create. How can researchers learn what people consider as private and respect that privacy? What new threats to privacy are emerging? New technology brings with it new threats to privacy, but also more powerful safeguards, and a new generation of privacy activists to establish better policies for deterring invasions of privacy.

3.4.2 Confidentiality. Part of the informed consent process typically includes an agreement about how the researcher will limit access of others to individually identifiable data. Many risks to confidentiality are not immediately obvious, e.g., subpoena of data, theft from computer files, or deductive identification. How can researchers understand sources of risk to confidentiality and prevent their occurrence? A wide range of statistical, procedural, and legal solutions continue to be developed.

3.4.3 Uses of data: data sharing and dissemination. How should scientific data be disseminated and used? Some data such as videotaped data cannot be rendered anonymous as individuals might be recognized; what safeguards are appropriate to protect the privacy of the research participants? Who may be benefited or harmed? Should harmful data be suppressed? How is misunderstanding of findings avoided? What should be included or omitted? What are effects of various modes of dissemination? What is the obligation of scientists to contribute to the scientific literacy of society? How should raw data be documented, archived and shared? Who owns data and knowledge (intellectual property)?

3.5 External Influences on Research

3.5.1 Government regulations. Studies of the regulatory process contribute to the development and improvement of research regulation.

3.5.2 Institutional review boards. Studies of IRBs focus on their processes, and on their effects on science.

3.5.3 Questionable, taboo or controversial topics of research. Some espouse prohibiting research that could cause irreparable social harm, produce misleading findings, or be used in politically harmful ways. Which is more harmful, suppression or publication of such research? Studies of the impact of research that blames the victim or otherwise seems to misdirect society's response to problems seek to answer this difficult question.

3.5.4 Scientific integrity and responsibility. Pressures to obtain grants and to publish may interfere with self-correcting scientific procedures, and motivate scientists to resort to unethical practices or outright fraud e.g., fabrication of data, plagiarism. Research has investigated conditions that inhibit or facilitate scientific responsibility.

3.5.5 Ethics and politics. Scientists who investigate controversial topics may be accused of scientific irresponsibility. Charges of scientific irresponsibility or immorality often mask profound political disagreements. Who sponsors or employs the researcher and how the data are used raise complex ethical and political questions. Because these issues usually arise in highly partisan settings, the ensuing conflict often fails to enlighten either side. Analysis of specific case studies can clarify the issues somewhat and suggest guidelines and safeguards.

3.5.6 Animal rights activism. An extraordinarily high degree of political activism has surrounded animal research. In what ways has this stimulated the advancement of theory and methodology? In what ways has it damaged scientific endeavors? Controversy surrounding specific cases of activism is usually aimed at proving the other side wrong, rather than resolving conflicts. Scholarly examination of activism and of the changes that have occurred as a consequence of conflict holds promise of guiding scientists to methods and principles that are both more acceptable morally and more beneficial scientifically.

3.5.7 Education in research ethics. In recent decades, there has been increasing concern to educate scientists and research administrators about issues of ethics. The goals have been, variously, to impart greater sensitivity to ethical issues, to teach approaches to conducting research ethically, and to examine and interpret current laws and regulations governing research. A variety of educational formats have been employed within Western societies. The rise of worldwide research programs on sensitive

issues such as the epidemiology of AIDS and the intense ethical concerns this has raised, has now resulted in the development of ethics education programs in collaboration with scientists and applied ethicists in Third World countries. Despite significant expenditures on research ethics education, there is little understanding of the effects of these various education programs, of the relative effectiveness of the diverse approaches to teaching, or even of the best ways to measure their effectiveness.

4. Summary

While ethical theory and codes of ethics offer important general guidance, intelligent application requires understanding of how ethical problems may arise and of effective solutions to those problems. By its nature, social/behavioral research continues into new territory, raises new ethical issues, and requires research to explicate those issues and, where possible, to develop better methodology. Such research may be conducted as part of a project that raises an ethical issue, or as a 'stand alone' research activity. It may be the main focus or a sideline of one's research career. Whatever its origins, it deepens and broadens the ability of social and behavioral research to respect and be responsive to human (or animal) nature, to produce more valid results, and to better serve society.

Research Funding: Ethical Aspects

The issue of ethics in research funding, a feature of research policy generally, is closely connected with the issue of freedom of research, an ideal of high standing in the science community. Special focus is on relations between providers and recipients of funding (see Orlans 1967). A vitally important principle says that research must be free in the sense of being shielded against any influences that may interfere with the obligation to seek truth. Yet, research must cope with regulation and restrictions, and discussions of these issues are concerned with questions of what freedom in which areas and with what consequences (Alver and Øyen 1997). The quest for freedom of research requires that conflicting and contradictory concerns and objectives be weighed against each other. In the process, the consideration of the policies, principles, procedures, and objectives of research funding often demands ethical reflection. Some principles of ethics seem self-evident. For example, no source of funding may be used to 'buy' a researcher to produce 'right' answers. Other issues require careful consideration—and there may be no clear-cut solution.

1. Sources of Ethical Concern

A sound process of research funding depends on organization and guiding principles. Research must meet standards of quality under conditions that favor innovation and contribute to knowledge accumulation. Research ought not to be done on problems that

have already been solved and where sufficient knowledge exists. But who ought to organize and govern? The science community may favor the view that the researchers themselves are in the best position to face new challenges and play key roles in deciding what research objectives to pursue. Nevertheless, responsibility for research must be shared between several partners: political authorities, research councils, universities and other research agencies, and executors of concrete research tasks. Research is cost demanding and requires highly qualified personnel resources and efficient infrastructure services. Also, research involves risks to people and environment. Priorities have to be set independently of the aspirations of researchers, and particularistic ambitions require tempering in view of universalistic standards. Coordination is needed to secure teamwork or to assure that researchers in different locations contribute their share of a totality. Funding agencies must deal with such issues, often involving rivalry among research institutions, among representatives of disciplines or fields of specialization, and among individual researchers. All of these matters may evoke ethical concern. The main point is to assure sufficient freedom and autonomy, protect the research process against unnecessary control, and guard against interference having undue effect on conclusions.

Thus, a decision to fund research is a result of a process involving several actors and partners whose goals hardly ever are identical. Provider and recipient of funding are main partners, but they cannot relate to each other without considering the interests of the context from which they act. The funding agency cannot defy interests of its hinterland or constituency, whether voters, taxpayers, or stockholders. The recipient of funding must relate to norms of scientific conduct, principles of data access and use, interests of institution of affiliation, and personal career interests and breadwinning needs. Ethical concerns become accentuated when different values and normative systems confront each other, and thus through the process of defining unified direction, seeking alignment of goals, and establishing common ground.

Traditionally, the institution of science asserts moral obligation to seek 'knowledge for its own sake,' without specific concern for applications. The ideal of basic or 'pure' research, driven by intellectual curiosity and awareness of missing links in the body of knowledge, plays a fundamental role in building and updating an integrated knowledge base. The universities have special responsibility for basic research and its integration in higher education. However, the mechanism whereby basic research is funded is going through significant changes as the role of research assumes new dimensions. Scientific discoveries accelerate change in society, but at the same time, scientific research becomes an instrument for solving problems brought about by change. Events during the

twentieth century contributed to widespread distrust in knowledge as intrinsically good, and perceptions of evil consequences of scientific findings brought public opinion to hold that some discoveries ought not to have been made—and thus not funded. These and other circumstances create a demand for more control and more pronounced goal orientation. Some funding agencies routinely demand that even basic research be justified in terms of applicability. Then, as an increasing proportion of research funding goes to applied research, the goals, and subsequent utilization of findings, become matters for ethical evaluation.

Standards of applied research bear heavily upon criteria of assessing the merits of basic research. The science system demands investment priorities, coordination for optimal utilization of funding, efficiency, and a favorable cost–benefit ratio. In academia, the freedom to pursue theories challenging scientists’ imagination is under pressure from funding sources needing quick answers to urgent problems. But at the same time, large sectors of the science community are morally devoted to research on issues of environment, poverty, health, inequality, and political instability, to mention but a few critical themes.

2. Sources of Research Funding

Funding for research comes from a multitude of sources. Governments channel public funds through foundations or research councils to individual researchers and to research establishments. Industrial corporations engage researchers as their employees or commission researchers on contract for particular research jobs. International organizations have special budgets for research. Private endowments and voluntary organizations provide funding for specialized research areas. The pluralism of research funding provides opportunities for research across an extensive array of issues and problems. Yet, there will always be concern that funds are skewed in favor of certain research goals at the expense of others. Not surprisingly, a host of ethically loaded questions concern funding priorities and processes of assuring optimal conditions for research.

2.1 Funding from Public Sources

Political authorities establish guidelines and policy principles for research, usually without entering into details of strategic decision making or interfering in the design of programs or projects. However, when investments in research are perceived as vitally important in view of political or national interests, funds may become earmarked for specific purposes. In rare instances, politicians address questions of whether

certain disciplines are worthy recipients of funding from public sources, as in the recurrent debates in the US Senate about the place of social sciences in the National Science Foundation (Larsen 1992).

Generally, the science community has a strong hand in strategic decision making in research funding, as much authority is delegated by politicians to science foundations, research councils, and academies of sciences, where researchers influence policies, grant funds, and resolve ethical issues. However, their performance may be subject to evaluation by political authorities in terms of criteria of political expediency and objectives. The representatives of the science community may have to accommodate to demands from above, under threats of reduced flows of public funds. Within this contest area, the flow of public funds to basic research is particularly vulnerable, as evaluation tends to follow criteria of applied research.

Increasing internationalization of research requires attention to issues of compatibility across national boundaries of legal and ethical principles bearing on the use of public funds, as for example, privacy protection and confidentiality provisions. Standards of ethical conduct have been adopted by most professional organizations, while modern versions of globalization, internationalization, and interdisciplinarity of research bring up new issues needing continued attention. For example, when research funds transgress national boundaries, sensitive issues of sponsorship and of true or hidden agendas may stir up moral and political controversy, as in the case of ‘Project Camelot’ (see Horowitz and Katz 1975, Homan 1991).

2.2 Funding from Corporate Sources

In corporate funding, a corporation enters into a contract with a researcher or a research agency engaged to produce knowledge applicable for a defined purpose. Normally, a contract is preceded by negotiations to secure mutual rights and duties. It may not be possible to foresee all problems involving ethical aspects that may come up in the course of an investigation, but it is always helpful when potential sources of problems may be dealt with at the time of negotiating a contract. In applied research, the linkage of funding and spending often involves a certain urgency and a limited time horizon. While the funding source has an interest in attaining a useful research result quickly and efficiently, the investigator is eager not to sacrifice researcher rights. The investigator must relate to ethical principles adopted by the professional association and also wishes to clarify questions of ownership to research data and results, respect for rules of confidentiality, freedom to publish—and perhaps, freedom to have second thoughts about the results of an investigation. A funding source may want provisions for secrecy or first use, while the

researcher is on guard against any clause that restricts truthful reporting. Other issues requiring clarification involve the funding agency's participation in planning and execution of research, terms of monitoring a project while in progress, publicizing or utilizing partial information before the conclusion of a project, and terms of application of findings. Both parties in a contract negotiation must be acquainted with relevant legal provisions concerning intellectual property rights. Attention to 'small print' may require qualified advice, and researchers may be well served when the institution with which they are affiliated provides backing and takes part in contract negotiations.

3. Researcher Influence on Funding

Research policy formation as well as decision making in matters of concrete research tasks requires input from the science community. Science policy advice may be solicited or volunteered; in either case, the decision-making process invites attention from lobbyists and special-interest groups seeking influence on policies, budgets, and the allotment of funds. Although the process is regarded as necessary and legitimate, it may generate many ethical issues that concern political authorities, funding agencies, the science community, and the general public. It is assumed that those scientists who possess the highest professional competence within highly specialized fields are best qualified to serve as judges and gatekeepers for research programs and initiatives. However, as research plays an important role in the pursuit of social, economic, and political goals, the role of scientists in research funding, as policy advisors and as participants in the decision-making process, may to some appear too closely interconnected with the political process.

Furthermore, fair disbursement of research funds requires safeguarding against unfair delimitation of turf, undue promotion of special interests, and questionable manipulation of the research opportunities of friends and foes. Yet, measures to secure competence and impartiality ought not to lead to the paradoxical situation that researchers having specialized knowledge of an area have to recuse themselves from participating in evaluation and decision making within that area. In fact, the system needs mechanisms for the protection of the integrity of the science advisor.

4. Freedom, Market, and Control

Research has become closely linked to the solution of pressing problems encountered through rapid social change. At the same time, the possibilities of controlling research—and the desire to control—have become stronger. With increasing control, in a situ-

ation where research functions much like a market commodity, the center of gravity is shifting from basic to applied research. Increasingly, the firm linkage of research to practical utilization determines the criteria by which decisions to fund research are made. For the research community, there may be a price to pay in terms of freedom of research and standards of research. Surely, there will be more attention paid to the ethical issues surrounding decision making and policy formation in the area of research funding.

Research Publication: Ethical Aspects

Ethical aspects in research publications are all the moral issues and problems raised by any behavioral misuse or abuse of the system for communicating and disseminating scientific results and information within the international scientific community. It is intended as a social body genuinely co-operating for the cultural and material improvement of mankind regardless of any personal, political, economic, or racial interests. Misuses or abuses include plagiarism, fraudulent and repetitive publication, guest- and ghost-authorship in multi-authored papers, conflict of interests in peer reviewing, censoring, and rejecting publications.

Scientific knowledge is community property unceasingly increased by individuals or groups in mutual co-operation and fair and honest competition. Even in the professional and competitive world of today researchers are intended as primarily engaged in the disinterested pursuit of truth and in the quest of new

insights and discoveries. Honesty towards oneself and towards others is considered as a fundamental condition for co-operation and fair competition since researchers depend on each other and cannot be successful unless they are able to trust each other and their predecessors. Publications are the primary medium through which scientists give an account of their work, co-operate, contribute to the advancement of knowledge, and claim the rights to be recognized for their discoveries. Therefore, dishonesty in publication not merely throws research open to doubt but destroys the very fundamentals of science.

The publication of a fraudulent article (the very outcome of a scientific fraud consisting in the fabrication, falsification or in 'cooking' and manipulation of statistical data) remains the most serious transgression of ethics of scientific publication. It is commonly considered to be an essential part of the scientific misconduct as well as plagiarism, the deliberate presentation of another's ideas or texts as one's own. Compared to these repetitive publications (publishing the same article in different journals), sequential publication (reporting follow-up of the same study with additional subjects but without new results), 'salami slicing' (dividing up different parts of the same study for publication in different journals), and guest and ghost authorship (giving or not giving authorship credit to persons who did or didn't take part in the research or in drafting or revising the article) are all considered as minor transgressions. These result in a huge amount of unwieldy and polluted literature that distorts the direction of science. It has been roughly calculated that flawed papers published on the 5,600 scientific journals indexed by The Science Citation Index amount to about 10,000 each year. This raises the problem of the reliability of the peer-review system designed to assess the quality of scientific literature, and that of the fate of the invalid ideas and data generated by fraudulent publication (Friedman 1990).

Good scientific journals today publish original articles only after they have been examined by competent reviewers for their validity and originality. Antecedents of peer review practices go back to the seventeenth century and the first organizations of scientific societies in Italy, France, and Germany but the modern system was only fully developed after World War II and it was adopted firstly and mainly in the Anglo-Saxon cultural area. The system is credited to have greatly contributed to the efficiency and professional organization of the scientific enterprise but since the eighties it has been severely criticized not only for its enormous costs in time and money but also for the progressive loss of accuracy (Lock 1986). Reviewers have indeed some moral obligation to make every necessary effort to recognize manipulations and falsifications. However, to expect irregularities to be reliably detected would be misleading: the original data are not available to reviewers, and if they were

they would not have time to replicate experiments and observations. This is why, according to many, peer review is so vulnerable to dishonest conduct. Other flaws have been detected in negligence (it resulted from inquiries that the higher the academic status and age of the reviewer, the lower the quality of the review), in vested interests of the referees and in many forms of bias (against particular individuals, subjects, or institution), the worst of which is that against the innovators. Some critics maintain that the peer review system favors mediocre basic science and fails to recognize and promote creativity, originality, and innovation (Horrobin 1990, Campanario 1996). Even the anonymity of the referees has been questioned for its finality as contrary to the moral norms of universalism, communality, disinterestedness, and organized skepticism that are thought to characterize the ethic of science. In fact the peer review system holds some risks for the authors because ideas, research findings, and texts which are unprotected by patents or intellectual property rights are submitted to persons whose identity is unknown to the authors and who may happen to be their direct competitors.

As for the fate of invalid data generated by transgressions to the ethics of scientific communication, the scientific community has yet to agree on the level of inaccuracy required to mandate a retraction vs. an erratum or who may retract an article. Although early in 1987 the International Committee of Medical Journal Editors published guidelines for the format and terminology of retraction notices, articles known to be fraudulent may be not retracted at all, or are retracted with ambiguous retraction. In other cases, only part of the data or conclusions are retracted. Editors of journals have little leeway for action since publishing corrections is fraught with juridical risks unless all authors jointly sign them. However, omitted or ambiguous retractions are not the only reasons of invalid work not being effectively purged from the scientific literature. It resulted from inquiries on US authors (Pfeifer and Snodgrass 1990) that after retraction the invalid information they produced continues to be used since the majority of retractions are not indexed by their own journals and no reliable source exists to locate fraudulent or erroneous work.

Some ethical relevance also has the soft censoring activity by which administrations and companies tend to control and restrict the dissemination of sensitive scientific and technological knowledge on the grounds of national security and economic reasons (Relyea 1994).

Such ethical problems depend on the very structure of the scientific enterprise as shaped in the seventeenth century but they have only grown in relevance and extension in recent times. Cases of plagiarism or fraudulent publication have been noticed in the past history of science, some of which involving such outstanding figures as Ptolemy, Luca Pacioli, Ernst Haeckel and even Galilei and Newton. However, it is

generally admitted that if not the number, the relevance and the social impact of the transgressions to the ethics of scientific publication began to rise in the 1940s. This was when modern science policy was established in view of the expected contributions of the scientific community to national defense and industrial progress. The new reward and funding system enhanced the traditional competition between scientists and it was then, in 1942, that the sociologist L. Wilson apparently coined the expression 'publish or perish.' It could hardly be said however that in the first 30 years competition did in some way sensibly promote fraudulent behaviors or the pollution of scientific literature. The turning point has in fact been stated in the late 1970s when the social structure of the scientific community underwent some crucial changes due mainly to the exponential increase of the number of people involved in research and the proportional (though not absolute) decreasing rate in assigning funds to research activity. The ensuing economic constraint (upon which the resources poured in by private companies had no or little effect) led to a situation of even stronger competition among scientists for academic rewards, position, or research funds. One crucial decision was that of the adoption of publication as the main performance indicator and of measuring productivity as the number of publications per length of time. The additional tool of citation analysis which was introduced in those very years (Garfield 1972, 1979) and based on the key concept of 'impact factor', (as the ratio of the number of citations a journal receives to the number of papers published over a particular time period) and then extended to calculate the impact of the work of individuals, groups, or departments generated a race to produce, in the shortest possible time, the least publishable unit in a journal with the highest impact factor. At the same time the growth of the scientific population implied a statistical decline in ethical standards and in the quality of production. Lotka's law of productivity in fact states that in a certain field, half of the scientific literature is produced by a population of the square root ($\sqrt{N}$) of all N scientists. De Solla Price pointed out that the exponential growth of the scientific population implies a proportional increase in the number of scientists able to author professional papers, but not important and innovative articles. From a statistic compiled by the Institute for Scientific Information (ISI) 55% of the scientific papers published between 1981 and 1985 in journals indexed by the Institute received no citation at all (Hamilton 1990). This led some students to draw the conclusion that more than half, or perhaps more than three-quarters, of the scientific literature are worthless. Others reacted against the notion that most uncited papers are without value. As for the use of citations as a measure of impact and of the quality of a publication, it has been questioned whether this may not lead to abuses such as citation cartels. It was estimated by the

same ISI, that self-citation accounts for between 5 percent and 20 percent of all citation.

It is from, or in any case within, those changes that according to the current views (see, for example, Petersdorf 1986) the pathological phenomenon of scientific misconduct arose to which the major ethical issues in scientific publishing are tightly related. As a consequence the analysis of these issues, the evaluation of the frequency and gravity of the transgressions, and the discussions on how to manage the problems they pose have been conducted as part of a general study on scientific misconduct.

Unfortunately, despite increasing publicity during the past 25 years, attempts to assess the quantitative dimensions of the problem of scientific misconduct did not lead to conclusive results: its magnitude is unknown and its detection largely serendipitous. Guidelines and actions adopted to manage scientific and (as a consequence) publication frauds and other abuses vary according to which of the two main different approaches they are based on. Sociologists and the vast majority of scientists share the opinion that the frequency and incidence of misconduct did not sensibly change during the twentieth century. The impression that fraud has vastly increased may be the result of the heightened self-consciousness in society coupled with strong moral expectation that scientists in the pursuit of reliable knowledge will live up to a higher standard of probity. This view seems to be substantiated both by the reports of the two most important US authorities responsible for dealing with misconduct cases, the Office of Inspector General (OIG) of National Science Foundation (NSF), and the Office of Scientific Integrity (ORI) of the Public Health Service and by that of analogous authorities in Denmark, Norway, Finland, and Australia. The ensuing suggested strategy is firstly, and mainly intended to save the autonomy right and self-regulation privilege of the scientific community from legal or government unnecessary intervention. It also recommends that inquiries primarily be made by local academic bodies, at the same time stressing the crucial role of education to improve the ethical standards of researchers.

Opposite is the view according to which, though there are no official data on the scale of the problem, the reports suggest that only a comparatively small proportion of cases of misconduct is actually detected and that what emerges is just the tip of an iceberg (Lock 1993). According to this view, self-regulation has proven to be ineffective and unsuitable. Scientists are not trained in conflict and conflict of interests resolution. Their intuitive response is usually wrong and they tend to set up shaky ad hoc procedures that do not guarantee the accused notice of all the charges; the opportunity to respond to all the charges and to the evidence; and a decision based on rigorous standards. In this view the setting up of national agencies, rather than local committees, is recom-

mended. The attention is focused on the economic and social background. It is assumed that those transgressions simply reflect the problems of a science which is today too big, too entrepreneurial, and too competitive to guarantee its very scope—the cultural and material improvement of mankind, in due and reasonable proportion to the intellectual and economic resources and at the same rate of the past three centuries. As far as scientific publication is concerned this second approach led the Committee on Publication Ethics (COPE), created in the UK by 20 editors of scientific journals, to ask for an independent agency to detect, handle, and prevent research publication abuses.

However, there is no general agreement on this view that led some of its proponents to recommend for some radical adjustment in the scientific policy first of all in connection to the ratio between scientific population and funds. While universities, scientific societies, funding agencies, and governments have opposed those proposals tacitly or patently, even their advocates acknowledge the importance of improving the ethical standards via the teaching of research ethics. This is currently considered by competent institutions and single students, besides and before, any disciplinary, economic, or legal action. Likewise, all agree on the necessity of suitable ethical and professional guidelines and measures which have in fact been proposed or adopted, though independently and according to different experiences and aims, by learning societies, agencies, journals, or individual students.

The primary importance of ethical (coupled with methodological) education emerge particularly in connection to some of the problems of scientific publishing, which seem less directly linked to the social and economic structure of the scientific system than to the peculiarity of research areas which involve cultural diversity or human and animal rights. In fact though science is largely transcultural, the human community has not yet developed a completely corresponding body of transcultural ethics. In some areas this may affect both methodology and ethics. Uncritical and unwitting reliance on the researcher's own culturally received principles and values regarding personal and physical identity, health, loving, suffering, death, etc. may generate potentially distorted initial observations which can lead to systematic divergence from truth in anthropological, psychological, sociological, or medical inquiries (where also systematic infringements of human or animal rights or the exploitation of subjugated populations may occur). Scientific publications based on such inquiries are, in principle, to be considered as poorly or improperly designed and performed studies. Current ethical and methodological standards do not include clear and effective rules for authors, editors, and peer-reviewers though the problems they raise have been debated in connection to some controversial cases.

A first general attempt to mitigate the pressure to publish that lies behind most deviant practices is, according to many, to place a ceiling on the number of publications that can be considered in evaluating a candidate for promotion or funding. However, some experts have also suggested that the number of scientific journals be drastically reduced (Bracey 1987). On the same line; although the use of quantitative indicators of scientific performance seems unavoidable, it has been recommended that impact factors shall not by themselves serve as the basis for funding decisions and that the quality of publication must be the primary consideration (Bucholz 1995). While no effective measures (other than severe sanctions) seem foreseeable against major authorship transgressions, as plagiarism or the publication of fabricated data, it has been recommended to journals to cooperate in cross-checking control activities and to research institutes and universities to store the primary data on which publications are based. All sources and methods used to obtain and analyze those data should be, when required, fully disclosed and the disappearance of primary data from a laboratory considered as an infraction of the basic principles of careful scientific practice. On the other hand, since there is no universally agreed definition of authorship, specific criteria and requirements have been invoked as an acknowledgment or footnote in every co-authored paper to state the exact contribution by each author. Or, the signing of a form where each author affirms having seen the final version and agrees to its publication. According to those proposed criteria the award of authorship should balance intellectual contributions to the conception of studies or experiments, to the generation, analysis, and interpretation of the data, and to prepare the manuscript against the collection of data and other routine work. If there is no task that can reasonably be attributed to a particular individual, then that individual should not be credited with authorship. In principle all authors must take public responsibility for the content of their paper and honorary or guest authorship is in no way acceptable. Against repetitive publication since 1969 the so-called 'Ingelfinger rule' has been proposed (Angell and Kassirer 1991) according to which papers are submitted to journals with the understanding that they (or their essential part) have been neither published nor submitted elsewhere. Reviewers are supposed to vigilate upon transgressions and it is stated in some journals' guidelines that if they suspect misconduct, they should write in confidence to the editor. As for the same reviewers it is reminded that they are bound to the duty of confidentiality in the assessment of a manuscript and asked to disclose conflict of interests and to provide speedy, accurate, courteous, unbiased, and justifiable reports. The submitted manuscript should not be retained or copied and both editors and reviewers should not make any use of the data, arguments, or interpretations, unless they have the

authors' permission. Editors should regard their function as ensuring that authors are treated fairly and their decisions to accept or reject a paper for publication should be based only on the paper's importance, originality, and clarity. To avoid the suppression of originality and creativity it has also been recommended that studies that challenge previous work should be given an especially sympathetic hearing and that independent ombudsmen for journals be appointed. Some few suggestions have also been advanced on the subject of external pressures as, for example, that editorial decisions must not be influenced by advertising revenue or reprint potential, but it seems that little can be done for the secrecy imposed by industries or governments on sensitive research fields.

Envisaged actions and sanctions rank from a letter of reprimand and warning as to future conduct, or publication of a notice of redundant publication or plagiarism, to formal withdrawal or retraction of the paper from the scientific literature, informing other editors and the indexing authorities or reporting the case to the authorities or organizations which can investigate and act with due process.

There is however no suitable insight on the impact those guidelines and measures had, or may have, in the long term.

Research Subjects, Informed and Implied Consent of

'Informed consent' denotes a person's autonomous agreement to a proposed course of action, usually in a treatment or research context. Consent is not considered to be informed unless the person: has received disclosure of the information that a reasonable person would consider material to the decision at hand; has the capacity to use that information in a rational process of decision making; and reaches a decision in the absence of coercive offers or threats (Appelbaum et al. 1987a). Broad agreement exists that informed consent is an indispensable requirement for the ethical conduct of research with human subjects, at least

when the research renders them liable to more than minimal risks of harm. But considerable controversy remains regarding the precise contours of the doctrine and of the circumstances that might constitute exceptions to the general rule. And since the rules have been devised largely with biomedical research in mind, issues more characteristic of social and behavioral science research have been relatively neglected.

1. History of Informed Consent to Research

The history of informed consent to research is usually traced back to the decision of the court in the Nazi doctors' trial at Nuremberg after World War II, which declared, 'The voluntary consent of the human subject is absolutely essential.' It is clear, however, that the Nuremberg tribunal neither originated nor established the concept of consent to research. References to requirements for consent from research subjects can be found in the writings of physician experimenters and in governmental pronouncements dating back to the late nineteenth century, when experimental medicine grew out of its infancy. Indeed, George Bernard Shaw's *Pygmalion* contains an explicit statement of the principle. Two of the leading instances, ironically, derive from Germany, where the advanced state of empirical medical science made consent an object of at least periodic concern (Grodin 1992). Nonetheless, however much the Nuremberg court desired to root the principle in contemporary practice, it appears that researchers in many countries, even after the Nazi atrocities came to light, frequently neglected to obtain consent from their subjects.

Nor did the Nuremberg decision immediately change these practices. Investigators using human subjects apparently saw the Nuremberg Code, as the ten principles embodied in the court's decision came to be known, as applying only to the anomalous situation of concentration camp inmates. Thus, the history of the postwar decades is marked by repeated revelations of questionable ethical practices, including studies in which persons were subject to clear harms without their knowledge or consent (for one of the most influential reports of problematic studies, see Beecher 1966). Pressure built for clearer rules and mechanisms of enforcement.

The World Medical Association responded to these concerns with its *Declaration of Helsinki* in 1964 (World Medical Association 1964), the first attempt to forge an international professional consensus on the ethics of research. The *Declaration* endorsed a requirement for informed consent, albeit in less sweeping terms than the Nuremberg Code. National professional organizations developed similar documents, but their nonbinding character left research subjects with few certain protections. A move to legally enforceable rules came in the USA in 1974, with the adoption of regulations governing federally funded

research. Most of the industrialized countries in the world have since followed suit, by way of legislative or regulatory enactments, or binding guidelines (for a summary of the status of research regulation internationally, see Brody (1998). The general principle that research should not be conducted without the informed consent of participants has been accepted around the world.

2. Current Contours of Informed Consent to Research

The requirements for informed consent are rooted in the ethical principle of autonomy, which demands respect for the free, informed choice of a competent person (Faden and Beauchamp 1986). Valid informed consent requires three elements to be present: disclosure, decisionmaking capacity, and voluntariness.

2.1 Disclosure

The Nuremberg Code (1948) declared that the research subject 'should have sufficient knowledge and comprehension of the elements of the subject matter involved as to enable him to make an understanding and enlightened decision.' Brody (1998) summarizes the international consensus regarding those items that need to be disclosed to achieve this end as follows:

- '(a) the purpose and the research nature of the project;
- (b) the duration of the subject's participation, the treatment and procedures that the subject will undergo (with a clear specification of which are experimental), and the subject's responsibilities;
- (c) the risks of harms and discomforts that might result from participating in the research;
- (d) the possible benefits to the subject or to society from the research;
- (e) the alternatives to participating in the research;
- (f) the right not to participate and to stop participating at any time without penalty or loss of benefits to which the subject is otherwise entitled;
- (g) the measures to protect confidentiality;
- (h) the anticipated payments, if any, to the subjects and the anticipated expenses, if any, that will be borne by the subject;
- (i) the compensation and treatment available for injuries sustained in the research;
- (j) the identity of a contact person to discuss questions about the research;
- (k) the circumstances under which the subject's participation will be terminated;
- (l) the assurance that new information relevant to participation that becomes available during the research will be provided to the subject;
- (m) the names of the sponsors of the research and the ownership of any commercial results.'

This information is generally provided in written form, though often supplemented by verbal disclosures. Frequently, the result is a lengthy form (12–14 page, single-spaced forms are not uncommon in clinical research) that is difficult for potential subjects to read and assimilate. Provision of a mass of detailed information means, moreover, that important data, such as those dealing with significant risks, are frequently neglected by subjects. A common resulting problem is the so-called ‘therapeutic misconception’—a belief on the part of subjects that procedures are being undertaken for their benefit (including randomization and use of placebos), when they are actually designed solely to advance the research effort (Appelbaum et al. 1987b). Though investigators are often urged to provide additional disclosures in more understandable formats (e.g., illustrated brochures that subjects can read at their leisure), this still represents the exception rather than the rule.

2.2 Decision-making Capacity

The subject’s capacity (in legal terms referred to as competence) to give a meaningful consent was considered a *sine qua non* in the Nuremberg Code. Although formulations of the requirements differ somewhat across jurisdictions, decisionmaking capacity generally involves the abilities to understand the information relevant to a decision, to appreciate its implications for one’s own situation, to reason in a rational fashion, and to evidence a choice (Appelbaum and Roth 1982).

Capacity is generally presumed to be present, unless there is reason to believe otherwise. When studies involve populations at elevated risk of incapacity, however, including persons with severe mental disorders, mild dementia, head injury, and the like, particularly when the research may present significant risks to participants, investigators are increasingly assessing capacity prospectively. This can be done by means of clinical evaluations or formal screening instruments. Identification of a potential subject as having impaired capacities does not necessarily mean that the person must be excluded from research participation. Many such persons can be brought up to acceptable levels of functioning with extra educational efforts.

Were capacity to be an absolute requirement, as the Nuremberg Code suggested, no research could be conducted with children—who lack capacity as a matter of law—or with many patient groups, including potential subjects who are comatose, suffering from moderate to severe dementia or mental retardation, or severely psychotic and disorganized. The desirability of allowing research to be conducted with these groups, so that progress might be made on the disorders from which they suffer, led the drafters of the Declaration of Helsinki, and most subsequent com-

pilers of codes, regulations, and statutes, to make some provision for the entry of incapable subjects into research projects. Rules governing their recruitment differ, but common limits include that the research be directly applicable to their conditions, not able to be performed with capable subjects, hold out the prospect of some therapeutic gain, or present no more than minimal risks of harm. Innovative proposals that would allow persons to make advance decisions while competent about whether to enter research projects should they later become incompetent have been much discussed, but rarely implemented.

2.3 Voluntariness

Overt coercion—the application of threats or unfair offers to a prospective research subject—is universally recognized as vitiating that person’s decision and thus rendering consent invalid. The effects of more subtle influences on the legitimacy of subjects’ consent to research is a matter of greater controversy. Some environments may be considered so intrinsically coercive—prisons, for example—that research with the persons detained therein has been severely restricted in many countries. Whether hospitals, institutions for the mentally ill or retarded, schools and colleges, places of employment, and other entities fall into that category is more difficult to say. Paradoxically, efforts to protect inmates, patients, workers, and others by prohibiting their participation in research deprive them of their residual decisionmaking power, and may increase their feelings of helplessness and their perceptions of being coerced.

Research subjects are often compensated for their participation with money or its equivalent. Fair compensation for the time expended in a study is generally considered acceptable. To the extent that payment is so substantial as to lead subjects to give insufficient attention to the risks they may run by participating, however, it may be considered an undue influence on their decisions, which renders their choices substantially involuntary.

3. Special Considerations in Behavioral and Social Science Research

Rules governing informed consent to research, from the Nuremberg Code to most contemporary governmental regulations, typically have been formulated with biomedical research in mind. Issues more characteristic of social and behavioral research have been relatively neglected. Indeed, the federal regulations in the USA categorically exempt many types of behavioral and social research from their purview, including: educational research; studies designed to evaluate governmentally provided benefits or services; and testing, surveys, interviews, or observations of

public behavior, unless information is recorded in a manner that would render subjects identifiable, and subjects would be likely to suffer harm if the information were released (Code of Federal Regulations 1991).

Yet, many behavioral and social science studies involving human subjects raise important issues related to informed consent. One of the major questions is when, if ever, it is appropriate to deceive subjects about the purpose of a research study, a frequent technique in psychological research (see *Deceptive Methods: Ethical Aspects*). Other issues concern consent for access to records, consent in observational and field work studies, and the appropriateness of seeking consent—or some equivalent—from entire communities that may be affected by an intervention that is part of a research project.

3.1 Consent in Studies Based on Review of Records

Analysis of existing records, often aggregated into large databases, is a frequent technique used by behavioral and social scientists. These records may have been collected originally with subjects' consent but for nonresearch purposes (e.g., medical records) or without subjects' consent (e.g., national birth registries, educational testing results, or census information). When individual subjects are not reasonably identifiable in the database, it is generally agreed that consent need not be obtained prior to granting researchers access. Even with identifiable data, researchers have usually been allowed to utilize such records as long as they agree to protect the confidentiality of those persons whose information they are reviewing (e.g., by publishing data only in aggregate form).

This practice has been criticized as insufficiently protective of subjects' interests in both autonomy and privacy. The autonomy argument is predicated on the belief that persons should have the right to control access to information about them, preventing its use, for example, for research purposes of which they may disapprove. Privacy concerns have been given greater weight of late with the growing ability of researchers to correlate information obtained from different databases about the same individuals, thus accumulating large amounts of information that, were it to be used or accessed for unauthorized purposes, could prove embarrassing or harmful to the people involved. Strong arguments have been made for obtaining consent from the subjects of these records prior to their release for research purposes.

Researchers object to these proposals on the grounds that they would materially increase the costs of research and, insofar as subjects' refusal of consent would bias the resulting data, decrease the validity of their findings. In many cases, it will simply be infeasible to track down and obtain consents from the persons

whose data is in question. No reasonable argument can be made for precluding researchers' access in these circumstances, so long as the study is of some significant value and appropriate safeguards are in place. When smaller and more recent repositories of data are involved, and obtaining consent would not involve unreasonable expenditures of resources, it is clearly more respectful of subjects' interests to seek their agreement. When records are being compiled prospectively with the intent of using them in the future for research purposes, there is no ethical justification for failing to obtain subjects' consent at the time.

3.2 Consent in Observational Studies and Field Work

Many of the behavioral sciences have a long tradition of sending researchers into the field to study the behaviors of persons in their natural environments. This often involves requesting access from those to be observed to otherwise private interactions and territory (e.g., discussions between spouses in the subjects' home). Considerable controversy exists over whether and how truly informed consent should be obtained in such cases. Insofar as researchers may observe and/or report embarrassing or frankly criminal behavior, subjects may be placed at risk of psychological or tangible harm. Thus, the case for obtaining consent in such studies would seem strong, bolstered by the discomfort some investigators report in withholding this information from their subjects.

On the other hand, researchers have an understandable concern that informing subjects clearly of the goals of their studies may lead subjects to alter their behaviors, thus obscuring the very phenomena that are under study. Though many subjects appear remarkably prone to ignore such information, especially once they become accustomed to the observer's presence, this concern needs to be taken seriously. It should usually be possible to accommodate both parties' interests by disclosing the intent of the study in general terms, along with the likely risks to which subjects' may be exposed. If some modification of subjects' behavior occurs, this is an unavoidable price to pay for acquiring a meaningful consent.

3.3 Consent in Community Intervention Projects

Social science research increasingly involves large-scale interventions directed at particular communities or segments of a community. These may include interventions designed to avoid undesirable outcomes (e.g., juvenile delinquency, teenage pregnancy, illegal drug use) or to promote what are generally seen as salutary ends (e.g., moving persons off welfare and

into paying jobs). When such interventions occur at the level of the community as a whole—such as broad-based educational programs concerning drug abuse—it is impossible to obtain informed consent as it is usually conceptualized. Moreover, when studies are based on changes to entitlement programs that have been enacted through the political process, the consent of individual persons may be seen as irrelevant.

There may, nonetheless, be a role in such instances for a modified form of consent interactions with the relevant community. Although each person's consent cannot be obtained, disclosure of the nature and purpose of the study and its risks and benefits can still take place. Consultation with the community at large and its designated representatives may result in suggestions for modifications in the study culminating in a general consensus concerning its desirability (Trickett 1998).

4. Research on Informed Consent

The last decades of the twentieth century have seen a flowering of empirical studies on informed consent to research that promises to shape for the better a debate that has frequently been waged on theoretical grounds alone. Among the areas of investigation have been: the adequacy of investigators' disclosures and how they can be improved; the prevalence of incapacity among various groups of research subjects; subjects' understanding of the information they have received and their appreciation of its implications for their situation; and subjects' retention of information over time (Sieber 1996).

Naturalistic research on the consent process involves overcoming the reluctance of investigators to grant access to the research setting, and of subjects to consent to yet another research project. Subject recruitment can be both difficult and time-consuming. The willingness of funding agencies to sponsor such research is often related to the degree of public scrutiny of and concern about the agencies' research portfolio. But such research is likely to increase over time and to play a greater role in helping to shape investigators' practices and official policies governing informed consent.

P. S. Appelbaum

Residential Concentration/Segregation, Demographic Effects of

Segregation is the differential distribution of social groups. Most commonly, the use of the term refers to residential segregation, the differential distribution of social groups across geography. Residential segregation has served as a key indicator of social differentiation for decades. (See *Residential Segregation: Sociological Aspects* for a general review.) Segregation is usually measured by one or more summary indices, designed to reflect the differential distribution of persons or other social units across neighborhoods, occupations, or other categories (White 1986). Segregation is often seen as a multidimensional phenomenon tapped by a variety of indices (Massey et al. 1996). While the bulk of work has centered on residential segregation

among ethnic groups, virtually any trait could be considered, and research has examined segregation by income, education, occupation, nativity, age, and other demographic traits. Racial segregation across schools and occupations remains an important indicator of social distance, and residential segregation can feed school segregation and limit access to jobs, city services, and other public goods (Farley 1984, 1996).

Beyond the measurement of segregation itself, there has always been interest in the consequences of residential clustering. Theory can be invoked to suggest positive as well as negative consequences (Cutler and Glaeser 1997). This ranges from the ways in which residential concentration might generate employment networks or social support institutions, to the consequences of residential isolation for educational attainment or health outcomes. From the point of view of policy, the determinants and consequences of segregation are of particular interest. There has been heightened attention to the aftermath of living in, or being raised in, a segregated or disadvantaged neighborhood. More recent discussions of social capital are pertinent, as the concept of social capital is extended to include the influence of neighbors and nearby peers and role models on such outcomes.

Empirical work at the beginning of the twenty-first century has begun to evaluate the effects of residential segregation. The underlying concept is that residential clustering carries behavioral consequences beyond those of ethnicity, socioeconomic status, or lifestyle. Such notions have been present in demography for some time, but data and multilevel statistical techniques are now available to directly evaluate hypotheses. Social behaviors clearly vary across urban space, or equivalently other categorizations. Yet it is important to distinguish the influence of composition from that of causation. For instance the receipt of public assistance varies appreciably across urban neighborhoods. The degree to which this behavior can be linked causally to the concentration of social groups in neighborhoods (and the sociological patterns that arise through clustering) needs to be weighed against an explanation based just on composition. The key question turns on whether geographic clustering itself influences human behavior, beyond that attributable to other background traits, such as age and education.

Many demographic traits are segregated in urban neighborhoods, and there is a consistency to the ranking. Although empirical results on these matters derive preponderantly from North America, similar results have been obtained for other high-income societies. Race and ethnic groups remain very highly segregated in most urban areas. Several decades of study, from straightforward segregation measures through factorial ecology and the like, have verified the sorting of urban space along the lines of socio-

economic status. Life cycle stage is also differentiated. Segregation indices for sex and age are modest, although segregation for household size and type is more discernable. Of course, certain special concentrations of population, such as group quarters for military populations, students, and those under correctional supervision, are highly segregated and are often excluded from consideration by analysts.

While one can identify and rank the levels of segregation illustrated by various traits, the consequences of this segregation are more difficult to discern. A common causal model advanced in these cases was that persons, especially children, adapted to their disadvantaged environment, learning criminal behavior, reducing achievement motivation for school, and developing dependence on the dole. Observers cited the higher incidence of single parenthood, labor force participation, high school dropout, and the like in such disadvantaged, inner-city neighborhoods.

A demonstration of the presence or absence of the links remained for subsequent waves of investigations. Statistical estimates of neighborhood effects rely on hierarchical and multilevel models. While strategies differ, the general approach is to develop a multivariate model, in which the behavioral and demographic outcome (employment, childbearing) is taken to be first a function of unchanging (ascriptive) personal traits and a set of family and household background factors. Neighborhood and community characteristics are introduced to the model simultaneously or hierarchically. Thus, neighborhood effects are generally measured net of other characteristics. With the availability of multilevel statistical techniques and associated software, it is possible to derive more sophisticated (and econometrically appropriate) estimates of these neighborhood or community effects. Some of the same conceptual and methodological apparatus can be applied to patterns or demographic unevenness found in other social institutions, such as the workplace or schools.

1. Mechanisms Through Which Segregation May Influence Demographic Outcomes

Beyond the simple mechanism of demographic composition itself, segregation, and differential concentration might influence outcomes in several ways. These include (a) contagion effects; (b) resource allocation; and (c) institutional structures. Contagion models, also closely linked to epidemic effects and diffusion models, have a long history in social science thinking. Simply stated, individuals alter their behavior on the basis of their interpretation of those around them (Jencks and Mayer 1990, Crane 1991). The influence of peers on child behavior is one such mechanism. Such processes have been particularly prominent in thinking about school context (Alwin

1977). Role models provide a related mechanism. Much of the recent discussion of adverse inner city outcomes draws on this line of thinking. The general reasoning (see, e.g., Wilson 1987) is that low income or disadvantaged neighborhoods offer fewer mainstream role models (dual parent families, stable adult workers, school completion), and so those growing up in such areas do not acquire mainstream norms. Massey and Denton argue that the intersection of poverty and segregation creates an environment where such conditions abound (Massey and Denton 1993). Social capital is a contemporary phrase that taps some of the same mechanisms. Resources available to the individual beyond the family or household may influence a wide range of behavioral outcomes. Certainly this is of interest in schooling and neighborhoods, and recently it has become of increasing concern in the field of health.

A second line of thinking, far less readily articulated, involves resource allocation. Residents of affluent neighborhoods (or workers in advantaged workplaces) can provide superior public goods, either through direct community provision or through the political process. More than that, these public goods are likely to confer advantages that go beyond the immediate advantages of household and family. Thus, superior schools produce a benefit for all residents in the district (neighborhood) over and above the advantage of family background. Other externalities of clustering include relative advantage or deprivation in local sanitation (exposure to pathogens and toxins), public safety, and the like. Housing experiments, such as those relocating low-income individuals to middle-income communities, are premised on such mechanisms.

The third line of thinking involves the growth and maintenance of local institutions, whether formal or informal (Duncan 1994). The literature identifies both positive and negative consequences of segregation. In the realm of economic outcomes, the notion of the ethnic enclave suggests that concentration, building on ethnic networks, may provide benefits. Occupational and residential segregation with co-ethnics may generate employment opportunities unavailable in a more integrated economy. A long-standing argument is that racial residential segregation enables integration by social class. In an urban neighborhood, local institutions, such as a church or neighborhood association, might foster social ties across class boundaries, although even historical accounts of ghetto life do not always portray a comfortable coexistence of disparate groups. What is relevant in the present circumstance is that these evolving structures can serve as social actors and then influence behavioral outcomes for other members of the community. Empirical social science evidence on these points is scant, especially evidence that can tease out the influences of institutions, net of individual, family, and other community traits.

2. Methodological Issues

Concerns about the effects of segregation raise several methodological issues. A fundamental issue is one of definition. A 'neighborhood' might have several competing geographic boundaries. Tracts, wards, block groups, and other urban statistical subdivisions become *de facto* neighborhoods (White 1987). This has two consequences. First, such units serve as the basic geography for calculations of segregation measures. Second, these small statistical areas are the units that serve as the proxy for social conditions in multilevel models. Another methodological evolution is the shift from ecological inference to multilevel modeling. For decades of social science research, analysts were constrained to a choice of individual level analysis or 'ecological' models, which relate aggregate values of demographic characteristics to one another. While ecological analysis was the only route available for certain questions, and while some might argue for the focus on the neighborhood only, multilevel analysis has grown over the last several years as the favored approach (Diez-Roux et al. 1997, Garner and Raudenbush 1991). In multilevel models, individual behaviors are taken to be the result of both individual characteristics and traits of an aggregate. The level of segregation in the city, or the demographic composition of the neighborhood, could be one of these aggregates.

It remains a challenge to properly specify models, so that individual and contextual effects are fully distinguished statistically. The very process of residential assimilation—the achievement of neighborhood status through residential mobility—also generates correlations between community and individual. Thus, separating endogenous and exogenous elements of a process is no easy task. Even then, one must still be concerned that events are properly allocated to local administrative units.

3. Empirical Evidence

Interest in community effects in urban settings was rekindled with the discussion and debate over the urban 'underclass' in the 1980s social science literature. Again much of this debate was focused on US settings, but parallel issues of urban neighborhood deterioration and behavioral consequences can be raised for other high-income nations. Despite the level of concern for the effects of residing in ghettos and inner-city disadvantaged zones, one major contemporary review argued that national social and economic conditions more powerfully determined the incidence of and concentration of poverty (Lynn and McGeary 1990). After expressing reservations about the quality and consistency of data, a related recent review of empirical studies of the effects of neighborhood SES, racial mix, for both neighborhoods and schools,

concluded that there is no general pattern of effects across a wide range of outcomes (Jencks and Mayer 1990). There is some modest evidence that growing up with affluent neighbors (for those of modest means) and in less segregated environment (for blacks) predicts higher levels of educational attainment (Jencks and Mayer 1990). One recent review of about 24 studies of neighborhood effects did tend to find that community-level (often census tract) measures of neighborhood advantage were associated with superior individual-level behavioral outcomes in several phases of childhood (Gephhardt 1997). Not surprisingly, this review was critical of the state of knowledge, for the weakness of the link to the appropriate community-level empirical measures and the absence of other characteristics (school, family traits) that would be likely to exert an influence on individual outcomes. One comprehensive compendium of neighborhood level studies on poverty, a study that coordinated data and research approach, again detected neighborhood effects in several investigations (Brooks-Gunn et al. 1997). Typically family-level measures swamped neighborhood-level measures in predicting child behavioral outcomes. Perhaps more interesting is the finding that neighborhood measures could be discerned for pre-school children, despite the conventional thinking that such youngsters' social world was limited to the home.

Substantial effects of neighborhood factors, particularly neighborhood affluence and poverty, have been linked to later life achievement (IQ, teenage childbearing, and school-leaving) in US nationally representative longitudinal data (Brooks-Gunn et al. 1993). Longitudinal data only sometimes detect effects of neighborhood socioeconomic status and racial composition on later earnings, after controlling for selected background traits (Jencks and Mayer 1990). Conceptual models of the influence of neighborhood effects concentrate on the pathways through which these aggregate effects carry to the individual. At the same time qualitative approaches can suggest coping mechanisms for those in disadvantaged neighborhoods (Jarrett 1997). There is some empirical evidence that local organizational structure may mediate community disadvantage (Elliott et al. 1996). The effect of schools may outweigh neighborhoods on risky health behavior (Ennett et al. 1997).

One reasonably long-standing line of work looks at the influence of segregation itself, often introducing the value of a segregation statistic to a regression model of a behavioral outcome. The behavioral mechanism underlying the inclusion of such a covariate is not always clear, but higher level residential segregation may tap into underlying housing market constraints, a more hostile climate of local race relations, or differential access to public sector resources. Predictive power of such segregation indices is not always strong, but on balance they tend to show that individuals (usually minority group members)

living in more segregated urban areas experience detrimental outcomes, such as higher levels of unemployment, or violence, or less mobility out of poverty (Iceland 1997, Peterson and Krivo 1993, South and Crowder 1997, Wilson et al. 1995). Even after including several individual and neighborhood controls in a multilevel model, residential segregation does appear to be associated with lower residential mobility on the part of both blacks and whites, supporting the housing market constriction idea (South and Dean 1993). Neighborhood concentration and metropolitan racial segregation, especially among African Americans does appear to be linked to adverse health outcomes for both adults and infants (Williams and Collins 1999, Hart et al. 1998, LaVeist 1989, LeClere et al. 1997, Polednak 1996). There is no consensus on the scale of neighborhood effects, and the magnitude of such effects would be expected to differ by behavioral outcome. The current state of knowledge is that neighborhood effects on demographic outcomes can be detected—especially when investigators use more robust data and more contemporary methodology—yet these neighborhood effects are modest by comparison to personal fixed traits and household characteristics.

Residential Environmental Psychology

Homes and residences are not merely physical and economic structures. They are centers of psychological and cultural life. Home is the most important place in many lives, which affords it great potential for facilitating or threatening human development. People think about their homes, are satisfied or not with them, plan, dream, move, use them in various ways, and often must cope with difficult social and physical conditions in their homes, if they have one.

1. Definitions

A house is not necessarily a home. A *residence* (house, apartment, condominium, loft, flat, tipi, or, in general, any dwelling) is a physical structure that varies tremendously in form around the world. *Home* is the rich set of evolving meanings that people often (but not always) attach to their residences (Lawrence 1987). Residences may be bought, sold, or rented; homes cannot.

1.1 Background

Vernacular residences in traditional societies gradually evolved to suit local building materials, climates, and social practices. In recent times, awareness of other cultures, technological advances, and prosperity in industrialized countries have permitted more choice in residential form and structure. The psychological aspects of residences became relevant, and with the growth of environmental psychology and sociology in the late 1960s, researchers began to examine the impact of residences on residents.

1.2 Dimensions of Residences and Homes

Residences vary in any number of physical aspects such as form, age, style, size, or cost. However, residences may be characterized in more psychological and cultural ways (Altman and Werner 1985). First, residences may be permanent or temporary. In industrialized countries, residents usually have permanent dwellings, although apparently this situation is not entirely satisfactory because many householders also maintain temporary residences such as cabins, cot-

tages, and recreational vehicles. In less-industrialized countries, residents move frequently or seasonally and often construct temporary dwellings in new places.

Second, residences range from differentiated to homogeneous, which refers to the separation, or lack of it, in the functions of rooms. A highly differentiated residence has many rooms, each of which houses a specific activity; in a homogeneous residence nearly any activity may occur in nearly any room.

Third, residences may be communal or noncommunal, in terms of the degree to which nuclear families live together or in different homes. In contrast to the typical single-family dwelling of the Western world, in many Eastern cultures several generations of a family live in one household. In some African and Native American cultures, numerous unrelated families live in one dwelling.

Fourth, identity versus communality refers to the extent to which residences are contextually unusual. Communality (the same word as above, but with a different meaning here) is the extent to which a residence is physically typical of dwellings in that culture. A tipi on a suburban lot in North America would be low on communality, but high on identity; the same tipi at a pow-wow on the open plains of central North America would be high on communality.

Fifth, residences vary in their openness to outsiders. This varies both within and between cultures. In some places, houses typically are surrounded by walls or hedges; in others they are not. Dwellings signal willingness or unwillingness to interact with outsiders.

Home, in contrast to residence, is a set of personal meanings. The word's earliest meaning probably was the village or community of one's origin; not until the sixteenth or seventeenth centuries did it refer to one's dwelling. To be a home, a residence should provide haven, order, identity, connectedness, interpersonal warmth, and physical suitability (Smith 1994). As a haven, a home must surround a person with privacy, security, and protection from the slings and arrows of life outside it.

A home provides order by helping individuals to know their place in the world. As a center from which people venture and return, home orders one's existence in the world, both spatially and temporally. Home is central to a sense of identity and connectedness because it offers a sense of kinship, belonging, and status. Through self-expression and personalization, the home comes to resemble or represent the self. When people have the means and the time to personalize their residence, home becomes a symbol of self (Cooper 1976). To the extent a residence does not provide these felt amenities, it is not a home.

1.3 Houselessness

The homeless, those who live in the streets, properly should be called houseless. Many houseless people

have a home, a residence with personal meaning that—for one reason or another—they are unable to live in. Home is the most important refuge from the stresses of work, school, and public life. Unfortunately, many people live in residences that do not provide protection and rejuvenation, and therefore they are homeless. Probably one billion people have inadequate housing, and about 100 million are houseless. Institutionalized individuals often are in this situation. Houselessness is more than lack of a residence; many other social negative social consequences follow. Individuals who are both houseless and homeless do exist, and are extremely unfortunate.

2. Residential Preferences and Satisfaction

Residential preference and satisfaction are related but distinct concepts. Their measurement is not straightforward. Some residences would dissatisfy anyone, and there are some individuals who will not be satisfied by any residence. Between these extremes, however, lie most homes and most residents. Different homes satisfy different residents. Preference involves comparison, whereas satisfaction may be mainly based on residents' evaluations of their own dwellings.

2.1 Measurement Issues

Residential satisfaction is multidimensional. David Canter (1983) has described two cognitive processes related to residential satisfaction, *purposiveness* and *comparison*. Purposive evaluations have three facets: level, referent, and focus. Level, or specificity, refers to evaluating a single part of the residence (such as the kitchen), or a larger portion of it (such as the bedrooms as a whole, or the entire residence). Referents refer to different qualities of the residence (its beauty, or spaciousness); each suggests a certain purpose which is served well or poorly. The lighting referent, for example, is important when the resident considers tasks such as reading or sewing that require good lighting. Focus depends on the referent, and refers to how broadly the resident is asked to evaluate a referent. For example with lighting, focus might refer to the ability of a particular lamp to light a study desk, or about the ability of all the residence's lamps to light the home as a whole.

Purposiveness arises out of the resident's relationship to the residence, such as long-term vs. short-term residence, ownership, renting, or landlordship; these different purposes will make important differences in the resident's evaluation. In general, a resident's purpose in doing an evaluation is itself a crucial factor in satisfaction.

The second factor is comparison. Whether observers are explicitly asked to compare a specific residence against a series of others, or merely asked for a rating

of a particular residence without explicit comparison with others, they cannot help at least implicitly comparing the residence in question with others in their experience. Thus, different observers will be comparing the residence in question against different houses in their experience.

Residents who are unaware that their friends live in mansions might be more satisfied with their huts. Residents compare residences, and this can be an important source of satisfaction or dissatisfaction. A study of Army personnel who lived in mobile homes and apartments found that comparison with other housing accounted for much of the variance in their housing satisfaction.

Perceived physical qualities of a residence (such as its appearance) are important predictors of satisfaction, and so are preferred physical qualities. However, the difference between perceived and preferred qualities is a separate but important predictor of housing satisfaction.

2.2 Personal, Social, and Physical Influences

Residential satisfaction is influenced by many personal characteristics, including age, stage in the life cycle, socioeconomic status, personality, values, and hopes for the future. Social factors such as age and community norms, others' opinions, and neighbors also influence satisfaction. Gender and sex roles are important. In a study of Canadian households that had recently moved, for example, husbands and wives were asked to list the things that made them happy about their new homes and apartments (Michelson 1977). Among couples who moved to a downtown apartment, more than 40 percent of the wives mentioned that they were satisfied with the quality of the home, but only 5 percent of the husbands mentioned this. On the other hand, among couples that moved to suburban apartments, more than 50 percent of the husbands mentioned quality of the home as a source of their satisfaction but only 5 percent of the wives did.

As men enter the kitchen more, similarities and differences in men's and women's preferences for kitchen designs become more important. Both men and women prefer kitchens that open to dining and family room areas over kitchens that are separated from those areas. However, women who work outside the home prefer open kitchens more than women who do not work outside the home and, despite their agreement on the open-closed aspect of the kitchen, men and women differ in many other kitchen spatial preferences.

Residential satisfaction is also related to socioeconomic status. In general, of course, wealthier individuals are better able to supply themselves with homes that meet their standards, and thus are more satisfied. However, wealthier and poorer residents may be attuned to different features of their homes:

One study found that wealthier individuals were more sensitive to the aesthetic qualities of their home, whereas poorer individuals were more sensitive to safety, health, and family needs.

Naturally, physical and architectural factors such as house form, architectural style, floor plan, and colors affect residential satisfaction, but these should not be considered the sole, or even the main, source of housing satisfaction. Most individuals prefer higher (than the usual eight-foot) ceilings, flat or sloping ceilings (4-in-12 slope but neither more than that nor smaller slopes), and walls that meet at 90 degrees or more (not walls that meet at smaller angles). In general, highly detailed designs are favored over plain and simple designs. In places where fear for personal security is high, enclosed and guarded enclaves are highly valued, as shown in a recent Brazilian study (Carvalho et al. 1997).

Color has been the subject of much research, but most of it has been based on preferences for small patches of color that resemble paint chips, in no particular context (that is, subjects are not usually asked if they would paint their kitchen or bedroom that color). These findings may not apply to choices in real-life situations. A study in Japan tried to overcome these limitations by showing slides of living rooms that were painted different colors (Kunishima and Yanase 1985). Preference is not merely a matter of hue (red vs. blue vs. green); it also depends on the hue's saturation (or 'denseness') and brightness (from light to dark). The study concluded that each of these three dimensions of color was related to a different aspect of preference. Hue was not strongly related to preference; instead it was primarily related to perceived warmth (reds are warmer, blues and greens cooler). Saturation (regardless of hue) was most closely related to what we usually call preference: More saturated hues were evaluated as more elegant, more comfortable, and better. Brightness or lightness (regardless of hue) was related to how 'active' the room seemed: Brighter colors were rated as fresher, lighter, and more cheerful than darker hues.

There remains a general preference for the single-family dwelling that has persisted in North America for many years. As for style, some trends are evident: In one study, farmhouse and Tudor style houses were preferred to saltbox and Mediterranean styles (Nasar 1989). However, preferences for style clearly change in part with changes in fashions.

2.3 Cultural Variations

Residences clearly vary in form around the world. These variations are not merely decorative, they are psychologically meaningful. For example, an examination of house form across 73 cultures revealed that the extent of partitioning indoor space (differentiation) is related to the degree of sociopolitical complexity in

the culture, that is, how much segmentation, specialization, and hierarchical ordering is typical of the culture. Thus, a worldwide trend is for our dwellings to mirror the complexity of the society in which it is embedded.

3. Behavior in Residences

The environmental psychology of dwelling interiors is not very developed because the study of behavior in and round homes understandably meets with a resistance on privacy grounds.

3.1 Vernacular Residential Design

Residents arrange and decorate their interiors according to certain patterns that reflect such dimensions as simple–complex, conventional–unusual, and rich–plain decor, and messy–tidy upkeep. These patterns are related to culture, social class, and marital or living arrangement differences. For example, French and Italian living room arrangements were examined (Bonnes et al. 1987). French living rooms could be described using three dimensions—decoration, functional organization, and structuring of space. For example, at one end of the decoration dimension were living rooms that were low on ambiguity and complexity; these living rooms tended to have velvet antique couches with armrests, copies of period wallpaper, and books for show (not use) in a wall-unit that also included cupboards and a bar. Italian living rooms could be described using the same three dimensions, but they tended to be combined differently.

3.2 Use of Interior Spaces

Men, women, and children use the interior dwelling spaces unequally; sex role changes have not changed the traditional use of rooms much; women still spend more time in the kitchen (Ahrentzen et al. 1989) and more time with children, and men spend more time in leisure activities. Children (until the teen years) have restricted territories: Parents generally can enter their space, but children generally cannot enter their parents' space.

In a rare study that actually monitored behavior inside homes (as opposed to asking residents to report their activities), cameras were placed (with the residents' permission) in New York homes (Ashcraft and Scheffen 1976). The study found that although definite territories exist within the home, the degree to which the boundaries of these territories were respected varied considerably. For example, parents may feel they have the right to enter a teen's bedroom, but do not think the teen should enter their bedroom. But

both territories are sometimes intruded upon, which creates conflict.

When space is limited, residents use time scheduling, territoriality, and social agreements to manage household space. Half our leisure time is spent in the home, but it could be better spent. When teens spend more time sharing leisure with their parents, they report greater well-being. More TV time is associated with less time spent on intellectual and cultural pursuits.

4. Coping with Residential Shortcomings

Much housing is substandard, and there are consequences. Well-executed recent research conducted in the USA suggests that poor-quality housing adversely affects the mental health of both adults (Evans et al. 2000) and children (Evans et al. in press).

4.1 High Density

High density in the residence has been shown to have many adverse effects. High-density homes as a whole have more psychological distress and psychiatric illness and have been associated with increased substance abuse, juvenile delinquency, fertility and mortality rates, and may lead residents to believe they have less social support. Crowding at home has more serious consequences than crowding in public environments. Some of these are mitigated by social support, if the resident has any. Density appears to have negative effects apart from poverty. Very low densities (living alone) also cause problems for many people.

4.2 Housing Forms

Not every housing form is good for every resident. High rises probably are not good for families or children, and one study suggests that young children are better off if they attend a good child care center than if they stay at home. Apartment living has been associated with numerous childhood afflictions, including retarded movement skills, respiratory diseases, aggression, insomnia, nervous disorders, reduced social skills, and disrupted play. If all this is true, we may wonder how any child can survive in an apartment. However, many of these studies lack experimental rigor; their results must be questioned.

5. Residential Mobility

All of us must unwillingly adapt to new dwellings sometimes; at other times, we choose to relocate. In any given five-year period, about half of all North Americans and Australians move, as do over one-third of Britons and Japanese (Stokols et al. 1983).

People move for many reasons, including both negative factors such as stress from and dissatisfaction with the current residence, but also for positive reasons such as improved finances. Life cycle changes that add or subtract family members living at home can also spur mobility. Mobility is not necessarily pathogenic, then, but it can be, depending on one's residential history, present circumstances, and hopes for the future. For example, among those who move less often, those with less choice about moving report more illness-related symptoms than those who have greater choice about moving.

Mobility-related stress is moderated by personal characteristics; people who are highly mobile and those who were generally less inclined to explore the environment report more illness than those who are more exploratory by nature. Conversely, more illness occurs among residents who move less often but are unhappy with their present residence and feel they have little choice of residence. Thus, a lack of mobility also can be damaging—when one's options for moving are restricted.

6. Conclusions

Home usually is the most important physical setting. The physical building must be distinguished from the meaning structure (home). Residential satisfaction is complex and multiply determined, but life cycle stage, socioeconomic status, personality, values, and hopes for the future are important factors, as are physical features such as house form, architectural style, floorplan and colors, outdoor areas, and cultural background. People arrange residential interiors in nonrandom patterns that reflect culture and lifestyle. High indoor density is difficult for virtually anyone, but can be made less intolerable with social support. Moving is stressful or not depending on whether a person has some choice in doing so, likes to explore new settings, and likes the present residence.

Residential Segregation: Geographic Aspects

Residential segregation refers to the practices and ideologies by which socio-economic characteristics are expressed in, and shaped through, the organization of residential space.

1. The Division of Residential Space

Residential space is a geographically uneven resource, and the land and housing which constitute it vary in quality, character, condition, and value. Land values vary according to demand and have traditionally been highest in city centres. Housing characteristics vary according to the circumstances of housing production and use, including the macroeconomic climate, the legislative and regulatory framework, the fortunes of the construction industry, the availability of loans and subsidies, changing architectural fashions, and so on.

A primary determinant of access to housing (and neighborhood) is cost, but the markets and institutions that make up the housing system also allow a range of social characteristics to mediate the process of inclusion within, or exclusion from, different parts of the residential environment. It is this interaction of the spatial structure of the housing stock with social structures, property values and with the operation of

commercial and public institutions that gives rise to the geography of residential segregation. These processes are, furthermore, embedded in, and legitimized through, the wider set of entitlements, obligations, and ideologies built into the constitutions of states and societies.

Housing and the residential space it comprises is both a commodity and a welfare resource. Housing is bought and sold in the market place, but housing policy can also be a means by which states intervene to meet social needs and alleviate social inequality. Both market forces and governmental priorities therefore play a part in structuring residential space; and such space is fractured in many ways. This fracturing occurs because of differences in 'need' and in 'ability to pay,' and it occurs too because the processes governing access to housing tend to discriminate on the basis of social characteristics. Direct and indirect discrimination has been documented in all sectors of the housing system. In the housing market, access to housing opportunities generally, and to housing finance in particular, may be dictated as much by who people are (or are presumed to be), by what they do, and by where they currently live, as by their actual ability to pay. In the public or social sector, the principle of allocating homes according to 'need' is always hard to operationalize and in practice may be compromised by, for example, subjective discretionary judgments about what types of people 'deserve' what kind of housing, and where.

As a consequence of all this, while class, income, wealth, and other economic indicators provide one set of fault lines in the residential landscape, ideas about 'race,' ethnicity, religion, and language provide another. Health inequalities are also expressed and reproduced in the residential environment; and although most research on segregation refers to the experience of 'households' (implicitly lumping men, women, and children together, and often referring mainly to the experience of men), the division of residential space is also fundamentally gendered and sexualized.

2. Measurement: The 'Index Wars'

A strong empirical tradition underpins the literature on residential segregation, and this has become the province of geographers (see *Social Geography*) and of those whom Peach (1975) terms 'spatial sociologists.' The idea implicit in all this work is that there is some kind of link between society and space; that social processes literally 'take place'; and that where people live is both an expression of who they are and a factor affecting who they can become.

Empirical studies of residential segregation are dogged by the problems of measurement and interpretation. The problem of measurement is apparent

from the large literature comprising the so-called index wars. One debate concerns the appropriate index with which to measure segregation. This has revolved around a group of indices of segregation and dissimilarity, which were favored for their simplicity and apparent (though questionable) scale independence. The index of dissimilarity (ID), for example, measures the difference in the distribution of any two population groups over a given number of areal units (e.g., census districts). ID is calculated very simply as half the sum of the difference in the proportion of each group in each areal unit. The index varies from 0 (complete similarity) to 100 (complete segregation) and the value of the index refers to the proportion of either group that would have to move from one areal unit to another in order for the two distributions to be the same.

ID is a special form of the more general index of segregation (IS) which measures the residential dissimilarity of one group from the rest of the population. Several other indices can be derived from this to capture the spatial segregation and isolation of one or more population groups from one another. Perhaps the best known of these is the asymmetric index of segregation, P^* , which describes the spatial isolation of a social group and provides a measure of potential interaction between that group and another (Lieberman and Carter 1982).

A second point of dispute in the measurement of residential segregation concerns whether the degree of segregation should be gauged against a norm of evenness or randomness. If populations were randomly distributed across space, some clustering would be expected as part of this random pattern. The index of dissimilarity refers to the proportion of a population that would need to move to achieve evenness, and it may therefore exaggerate the amount of segregation that is enforced (or chosen). There is still no consensus on the best way forward here. Nevertheless, all these debates are dwarfed by the problems of how to conceptualize the groups in the study, of whether to standardize (e.g., for income when measuring 'racial' segregation), and, crucially, of how to interpret the results of applying the measures.

3. Interpretation: The 'Choice-constraint' Debate

A major debate over the interpretation of measures of residential segregation concerns the question of causality. It hinges around the extent to which people choose to live separately from one another, and the extent to which segregation is forced upon them. This has become known as the 'choice-constraint' debate. In the UK, for example, all the major cities display enduring patterns of residential segregation between the white, African-Caribbean and (South) Asian populations. However, within the Asian populations,

Sikhs, Hindus, and Muslims tend to live in different neighborhoods to one another, while West Indians in London are segregated according to the island of origin of those who are migrants. Given these findings, it might plausibly be argued that the residential separation of Hindus and Muslims, or of Jamaicans and Trinidadians, is a matter of choice. Indeed in the USA, Clark (1992) draws on Schelling's (1971) ideas about the aggregate effects of small variations in residential preferences to argue that, in the wake of declining institutional discrimination, the accumulation of own-group residential choices is a key factor sustaining current patterns of segregation in US cities (see *Spatial Choice Models*).

While most people do have some choice over the precise space they occupy in the residential environment, the fact that, for the poorest people, these choices are highly limited, leads many authors to focus more on sources of 'constraint' than on elements of 'choice.' Smith (1987, 1989), for example, has argued that while it might well be the case that intragroup segregation is the result of household preferences, it is hard to sustain the argument that a very substantial proportion of such a diverse group as, say, South Asians in Britain, would choose to live in neighborhoods that are on average cheaper, poorer, less well serviced, and more deprived than any others. The demonstrable links between segregation and inequality, the marked extent to which poverty overlaps with (or is constructed through) these spatial processes of marginalization and exclusion, suggests that households segregated into the least desirable residential locations have very little room for maneuver.

Despite a number of conceptual and methodological problems, the empirical tradition has established beyond question that residential segregation is a key feature of the residential landscape, and that, preferences notwithstanding, patterns of residential segregation tend more often than not to be linked systematically with patterns of social inequality (see *Spatial Equity*). Some have suggested that this means that residential segregation has the capacity to act as a catalyst in the process of class formation or as a springboard for collective action more generally. However, in one of the most influential theoretical accounts of the relationships between class structures and residential differentiation, David Harvey (1985) argues that residential segregation is part of the reproduction of social relations within capitalist societies. From this perspective the fracturing of populations into residential communities mainly serves to fragment the class consciousness which might otherwise be used to improve the quality of local life.

Some of these fragmenting, isolating effects of segregation are uncovered by Pratt and Hanson (1994) in a study of women workers in Worcester, Massachusetts. They show how residential neighborhoods are differentiated by the distinctive mix of 'race,' class, gender, and work traditions within them.

This mix influences the locational decisions of employers, who work with stereotypes about the differences between men and women's work, and about the suitability of different ethnic groups for particular types of task. Employers' locational strategies thus reinforce a spatial division of labor which already emphasizes the gender divide. But because this division of labor also operates along class and ethnic lines, the potential for solidarity among women is undermined, despite their common interests (see *Gender and Feminist Studies in Geography*). Residential segregation is thus experienced as isolating and exclusionary rather than as a potential resource.

4. *Segregation and Inequality*

The literature on residential segregation explores the many social dimensions embedded in the division of residential space. While there is some interest in the location of elites, and in the continuing residential segregation of predominantly 'white' ethnic groups (for example Poles, Jews, and Italians in US cities) despite their economic integration, perhaps the bulk of writing focuses on disadvantaged and marginalized minorities. There are therefore studies of residential segregation among people with mental health problems, the old and impoverished, disabled people, single mothers, and so on. However, the main research effort has been concerned with the impact of segregation on the lives of marginalized racialized groups in Western societies (see *Ethnic Conflict, Geography of*). This perhaps reflects the magnitude of the challenge of 'otherness' that most developed countries face in a postcolonial world, where 'people of color in the historically white counties of the West are treated as second-class citizens' (Bonilla-Silva 2000, p. 194). Failure to acknowledge this—that is, failure to recognize the intensely racialized nature of much residential segregation in the Western world—has been criticized by Wacquant (1997) who (writing with specific reference to the USA) is concerned that by reducing the problem of racial segregation to one of poverty and disadvantage, analysts underestimate the power of history and ideology.

A growing literature on the racial dimension of residential segregation shows that segregation is not just an economic process and a material fact of life, but that it also has powerful ideological underpinnings. Historians George Fredrickson (1981) and John Cell (1982), for example, show that segregation is part of the changing character of racism. The idea of 'race' may have arisen from the notion that particular places (climates and environments) produced different kinds of people ('races'), but the tenacity of this idea is now secured by an unequal distribution of power which allows particular kinds of people to be restricted to particular types of place. Thus racisms become institutionally normalized in and through the spatial

configuration of the residential environment (cf. Goldberg 1993)

So, whereas many writers once assumed that racial residential segregation is a declining legacy of a racist, colonial past, Cell and Fredrickson show how segregationism emerged during the early twentieth century as a new and powerful way to manage power relations. In the US South and South Africa, this was initially legally enforced through the Jim Crow laws and apartheid, respectively. But what Cell's analysis vividly shows is that one of the key characteristics of segregationism is its tenacity, flexibility, and ability to survive as a practice even with the declining respectability of racism and even with the end of *de jure* racial separatism. Indeed, Cell goes so far as to define segregation as one of the most successful political ideologies of the twentieth century. 'In a segregated society,' he argues, 'we expect job restrictions and unequal wages; inferior housing, education, transportation, health and social services; prejudiced courts and police forces.' And to the extent that all these forms of exclusion are enacted through the practice of residential differentiation, segregation represents what he calls 'the highest stage of white supremacy.'

4.1 Residential Segregation and Racial Inequality

In the USA, the tenacity of these discriminatory and exclusionary forms of segregation has been closely documented by Massey and Denton (1993). Their analysis of the 1990 US census identified 20 metropolitan areas in which racial segregation was so complete and so expressive of the social and financial exclusion of black Americans that they merit the label 'hypersegregated.' Massey and Denton argue for the case of the USA that 'residential segregation lies beyond the ability of any individual to change: it constrains black life chances irrespective of personal traits, individual motivations or private achievements' (1993, pp. 2–3). A startling demonstration of this is given by Polednak (1997) in his study of the relationship between segregation and health which shows, among other things, that mortality rates and infant mortality rates in segregated communities in the USA can exceed those in parts of the less developed world.

In a series of related studies, Massey and colleagues suggest that not only is segregation problematic because it creates spaces of deprivation, exclusion, and neglect, but it is problematic too because the fact of residential segregation acts to concentrate poverty during times of macroeconomic change. So, while all poor people have been affected by those structural changes in the economy which increase income inequality, the most highly segregated communities—in the USA, African Americans—fare worst because of the way that residential segregation interacts with economic restructuring to concentrate urban poverty (Massey and Eggers 1990, Massey et al. 1991).

This work has been contested on both theoretical and methodological grounds by authors who place more emphasis on 'class' than 'race' in explaining recent increases in the spatial concentration of poverty among black Americans. However, Massey and Fisher (2000) have responded with a persuasive empirically-based argument that the same socio-economic changes in a given society have radically different consequences for the concentration of poverty as segregation rises. Residential segregation, they argue, 'is the key factor differentiating the experience of racial and ethnic groups in the United States, dividing them into two basic categories: those whose poor experience a high degree of class isolation in neighborhoods characterized by unusually high concentrations of poverty, and those whose poor do not' (p. 689). Because black Americans are by far the most highly segregated of the studied populations, 'the population of poor experiencing high concentrations of poverty is overwhelmingly black' (p. 689).

This kind of finding is by no means only a feature of societies with a historical legacy of *de jure* segregationism. In Britain, with no history of domestic slavery or legally enforced racial separatism, the residential segregation of racialized minorities has been a persistent theme for more than half a century (Smith 1989). There has, it is true, been a fierce empirical debate over whether British inner cities are as segregated as many US ghettos. This has centered on whether, for example, an ID of 60 calculated using British enumeration districts is somehow 'better' or less problematic than an ID of 80 for US census districts. However, Smith (1987) argues that while segregation persists at any of these levels, it is the form not the intensity of the phenomenon that is at issue. Whether or not ghettos are the same thing in all places, that higher levels of segregation are associated with higher rates of poverty, unemployment, poor health, and so on, is indisputable. Indeed, Smith (1989) goes on to argue that segregationism is as effective in Britain as in the USA as an interlocking system of economic institutions, social practices, and political strategies designed by one group to keep another in its place. Residential segregation, then, is a material fact of the lives of marginalized, racialized groups in Britain, and it goes with poor housing, limited employment prospects, limited service provision, poorer health prospects, and a range of other inbuilt disadvantages.

A key finding in several studies of racial segregation is that, once established, residential segregation is not just an expression of the marginality of racially 'othered' groups, but that it is also a determinant of their future life chances and opportunities. So the iniquitous form that segregation takes not only expresses marginality, but also reinforces it.

This reinforcement takes place in a number of ways. In the USA, for example, it has been suggested that there is a spatial mismatch between those who are

unemployed and the jobs they need to survive (see *Spatial Mismatch*). The argument here is that the spatial restructuring of the economy has taken jobs and incomes away from the areas in which black Americans live (see *Economic Restructuring: Geographic Aspects*). Residential segregation can, in short, act as a constraint on labor market participation. In the UK, a similar process has been observed—there too, entrapment in spaces of deprivation can prevent already disadvantaged groups from seizing opportunities opened up by the restructuring of the economy. In the British example, moreover, this process is overlaid by what might be thought of as a ‘welfare mismatch’ as those most dependent on welfare find themselves excluded spatially and economically from the range of commodities, insurances, and financial services that have expanded with the ‘rolling back’ of the welfare state (Smith 1989) (see *Welfare State, Geography of*).

So residential segregation both expresses social inequalities, and materially affects the participation of spatially excluded groups in social, political, and economic life. But because of its ideological dimension (noted above) segregation is not just a material fact, it is also a political idea—and one which often bears little resemblance to the lived experience of those it refers to. Smith (1988, 1993), for example, shows how, in Britain, ‘racial segregation’ as a political construction has helped sustain common-sense assumptions about the natural origins of racial differentiation without tackling the problems of racism and discrimination which underpin the inequalities embedded in the structure of residential space. The importance of ideas and images (ideologies) about residential space as a factor structuring people’s life chances and opportunities is further illustrated by Anderson (1991) in her work on Canadian constructions of Chinatown. She shows how that segregated space known as ‘Chinatown’ grew out of, and came to structure, a politically divisive system of racial discourse that justified domination over people of Chinese origin in late nineteenth-century Vancouver. In a similar vein, Wilson (1996) illuminates the power of metaphor to drive the process of uneven development between segregated segments of urban Indianapolis in the USA. His aim is to illustrate what potent political instruments metaphorical symbols can be. In the example of Indianapolis, USA, ‘they injected a constellation of representations into everyday thought that rendered a form of growth as value-free and neutral that was, in fact, directly adverse to the interests of the black inner city poor’ (p. 96).

Because of its ideological underpinnings and material effects, residential segregation is something that those who are marginalized and excluded by it can have little control over. However, iniquitous forms and practices of segregation can be, and are being, resisted in a number of ways. There is a policy dimension to this, of course, the relevance of which is

firmly established by Bashi and Hughes (1997). In a thoughtful account of the likely implications of globalization for the character and intensity of residential segregation by race they argue that the main problems and their likely solutions are located locally (nationally) rather than globally. ‘On the topic of segregation,’ they note, ‘the real problem is less one of sustained explanation than one of sustained action’ (p. 120). This adds new significance to the work of those who argue that the best weapon with which to tackle segregation is the law (Goering 1986, McGrew 1997).

Other ways of illuminating and challenging the inequalities embedded in residential segregation range from urban unrest to artistic expression. The first of these is extensively documented. The second is less fully recognized, though a glance at the work of artists like photographer Ingrid Pollard, painter Jean-Michel Basquiat, or filmmaker Spike Lee soon illustrates its potency. Ingrid Pollard’s exhibition ‘Pastoral Interludes,’ for example, locates a series of ‘black’ figures in the ‘white’ English countryside. This contrasts with the ‘usual’ positioning of black Britons within the segregated inner city, and challenges the taken-for-granted assumption that it is somehow normal for black people to be absent from rural areas. The other side of the coin—a stark vision of (and dissatisfaction with) the experiences of confinement within residentially segregated urban spaces—finds expression in the stick-like black figures which characterize so many of Basquiat’s paintings and in the rise of rap and hip-hop which was used so effectively in Spike Lee’s *Do the Right Thing* to speak about life in the segregated space of New York’s Brooklyn.

5. Overview

To summarize, residential segregation is both an expression and a mediation of the ideologies and practices which structure social life. It is a product of the uneven development of residential space and of the selective operation of the markets and institutions that govern access to housing. Residential space is a gateway to services, educational, and employment opportunities, health, and social services. Where people live is therefore a reflection of who they are, but it is also an influence on who they can become. It has therefore been argued that tackling the inequalities embedded in residential segregation is a key priority for public policy and an urgent focus for social concern.

S. J. Smith

Residential Segregation: Sociological Aspects

Segregation refers to the differential location of social groups across categories of a social structure. It may arise from voluntary forces, whereby members of one group choose positions that are different from those of other groups; it may reflect involuntary processes, whereby systematic barriers prevent certain kinds of people from occupying particular positions within the structure, or it may reflect a combination of voluntary and involuntary forces.

By far the most studied kind of segregation involves the differential location of social groups across neighborhoods of a city, a topic generally known as *residential segregation*. This field has attracted strong interest over the years because social scientists have recognized the close connection between where people live and the socioeconomic outcomes they experience. This insight originated with the Chicago School of Sociology in the early twentieth century (Park and Burgess 1925). According to Robert Park (1926, p. 8), 'it is because social relations are so frequently and so inevitably correlated with spatial relations; because physical distances so frequently are ... indexes of social distances, that statistics have any significance whatever for sociology.' In other words, because social and economic resources are distributed unevenly in space, where one lives plays a significant role in determining one's prospects for attaining education, health, employment, income, and prestige (Massey and Denton 1985).

Ernest Burgess (1928) was the first to measure patterns and levels of residential segregation, but he was unable to establish standard methodology for doing so. As a result, social scientists became bogged down in a prolonged debate about the best segregation index. The issue was settled in 1955 by Duncan and Duncan (1955), who recommended using the index of dissimilarity. This straightforward measure varies between 0 (no segregation) and 100 (complete segregation) and represents the relative percentage of minority members who would have to exchange

neighborhoods with majority members to achieve an even, or integrated, residential distribution.

For the next 20 years, social scientists working in the tradition of the Chicago School employed this index to measure levels of segregation in a variety of urban settings. Duncan and Duncan (1957) undertook their classic study of the levels, causes, and consequences of black segregation in Chicago. Lieberman (1963) followed with an analysis of segregation among European-origin groups living in US industrial cities. In their ambitious study, Taeuber and Taeuber (1965) documented patterns of segregation and neighborhood change for African Americans in cities throughout the USA. As the racial and ethnic composition of other nations has been transformed by postwar immigration (Massey et al. 1998), social scientists have applied the index to study the segregation of minority groups in Britain, Germany, France, The Netherlands, Israel, Canada, and Australia (Massey 1985).

In 1976, Cortese et al. ignited a new debate about the measurement of segregation by questioning the applicability of the index of dissimilarity under certain circumstances. In response to their critique, numerous alternative indices were proposed to yield considerable confusion in the literature. Massey and Denton (1988) once again brought order to the field by demonstrating that residential segregation was a multidimensional construct characterized by five distinct axes of spatial variation—evenness, exposure, clustering, concentration, and centralization. They showed that the index of dissimilarity measured the evenness dimension fairly well, thus confirming Duncan and Duncan's earlier work. After clarifying the conceptual and empirical properties of the remaining dimensions, they went on to recommend a specific index for each one.

Massey and Denton (1989) used this multidimensional conceptualization of segregation to define the concept of *hypersegregation*, which occurs whenever a group experiences high segregation on at least four of the five dimensions at once. They showed that whereas blacks in 20 metropolitan areas displayed high levels of segregation on four or more dimensions simultaneously, Asian and European ethnic groups in US metropolitan areas never achieved a high level of segregation on more than one dimension at a time. As of 1990, more than one third of all African Americans lived under conditions of hypersegregation (Denton 1994).

Despite the widespread recognition of residential segregation as a multidimensional construct, the most commonly used measure continues to be the index of dissimilarity. The next most common index is the P^* isolation index, which Massey and Denton identify as a measure of exposure. It represents the percentage of minority members living in the neighborhood of the average minority person. An index of 80 for African Americans, for example, means that the average black person lives in a neighborhood that is 80 percent

black. Unlike the index of dissimilarity, this index is strongly influenced by the relative number of minority members within an urban area, so that intergroup and intercity comparisons are best made using the index of dissimilarity.

A convenient rule of thumb for interpreting the latter index is that values under 30 are 'low,' those from 30 to 60 are 'moderate,' and those above 60 are 'high' (Kantrowitz 1973). In general, voluntary processes of segregation yield index values in the low-to-moderate range. Whenever dissimilarity indices persist at levels above 60 for any length of time, it usually signals the operation of involuntary forces of one sort or another. Studies done in the USA reveal that African Americans continue to experience high levels of discrimination in real estate, banking, and insurance markets, and that they remain objects of considerable prejudice by whites (Massey and Denton 1993). As a result, black-white residential dissimilarities in US urban areas generally range upward from 60, and unlike those of other ethnic minorities, they do not fall as socioeconomic status rises (Denton and Massey 1988).

In the USA, black residential segregation has also displayed little tendency to decline over time, except in places where the number of blacks is so small that complete desegregation would yield little interracial mixing within neighborhoods (Kriwo and Kaufman 1998). Other than African Americans in the USA, the only documented case where a racial or ethnic group has experienced a prolonged, high level of segregation is that of black Africans in the Union of South Africa under apartheid (Christopher 1993). Blacks in neither Canada (Fong 1996) nor Brazil (Telles 1992) encounter the extreme levels of segregation experienced by their US counterparts.

New interest in the consequences of residential segregation was stimulated by William Julius Wilson (1987), who argued that the social isolation of blacks within neighborhoods of concentrated poverty systematically lowered their chance of success in employment, marriage, and education. Although he attributed this growing isolation to structural shifts in the economy and the changing geography of employment, Massey and Denton (1993) showed that these changes necessarily produce high concentrations of poverty when they occur under conditions of high racial segregation. Given rising income inequality and the high degree of residential segregation experienced by African Americans in the USA, the concentration of black poverty is mathematically inevitable.

Studies drawing on longitudinal data files reveal that growing up in a poor neighborhood has negative socioeconomic consequences that are independent of personal characteristics or family circumstances. Coming of age under concentrated poverty undermines cognitive development in early childhood, reduces academic achievement in later adolescence, and elevates the risk of antisocial behavior throughout

the life course (Brooks-Gunn et al. 1997). Males experience a higher likelihood of withdrawing from the labor force and increased risk of criminal involvement, whereas women are less likely to marry and more likely to become single parents (Massey and Shibuya 1995).

The link between racial segregation and stratification prevails no matter what one assumes about the extent of segregation by social class, but when high levels of class segregation occur in addition to racial or ethnic segregation, the concentration of poverty is exacerbated. Although the necessary data are not available for most countries, studies done in US cities reveal a marked rise in the degree of income segregation from 1970 to 1990 (Massey 1996), a trend that occurred across all regions and racial/ethnic groups (Jargowsky 1996).

Although rising income inequality and growing class segregation may undermine the socioeconomic welfare of all racial and ethnic groups, the consequences have been particularly severe for African Americans because they are also so highly segregated by race. Under these circumstances, poor blacks experience far higher concentrations of neighborhood poverty than the poor of other groups. Although few studies have explored segregation by class, race, and ethnicity simultaneously, to the extent that rising income inequality, growing class segregation, and persisting racial/ethnic segregation coincide in other nations, a similar ecology of inequality is expected to prevail.

In the new century, social scientists are working to disentangle the effects of metropolitan structure, neighborhood composition, and family circumstances on individual socioeconomic outcomes. In this effort, researchers have turned increasingly to multilevel models and longitudinal data sets. Although the questions may be similar to those posed by the Chicago School theorists in the 1920s, the measures, methods, and data are now far more complex and sophisticated. Specifying the theoretical nature and empirical strength of connections between ecological structure, neighborhood conditions and individual outcomes will remain a central preoccupation of social science in the twenty-first century.

Resource Geography

Resource geography is part of a broad tradition of geographical inquiry examining the reciprocal relationships between socioeconomic systems and physical environmental processes. Within this ‘nature society’ tradition, resource geography is defined by its focus on how economic, political, and social institutions and practices determine patterns of resource use over space and time (see *Nature–Society in Geography*). This article begins with an explanation of the term ‘resource,’ outlines the scope of resource geography, and identifies four principal approaches within the field.

1. Resources Defined

Resources refer to those properties of the physical environment that can be exploited to meet the needs and desires of society. Resources can be understood, therefore, as culturally mediated appraisals of the physical environment. A resource does not exist *a priori*, but it is produced from ‘neutral stuff’ through its interaction with a set of prevailing cultural norms which collectively define its social utility and economic viability: thus ‘resources are not, they become’ (Zimmerman 1951, p. 15). The cultural milieu consists of economic variables (markets, prices, and technology); political institutions (property rights, legislation, and regulatory codes); social attributes (perception, behavior, and practices of decision-making); and cultural belief-systems (cosmologies of nature, society, and development). For example, just as sperm whales were regarded in the early nineteenth century as a valuable resource from which to obtain high quality lighting oil, so the recent appraisal of tropical forests as resources to be ‘mined’ for pharmaceutical benefits derives from the confluence of a specific set of economic, legal, technological, and cultural processes.

Resources are most commonly categorized based on their renewability. Renewable (or flow) resources are those depleted by use in the short term but which can replenish themselves over the longer term (e.g., forests, soils, and fisheries). Non-renewable (or stock) resources have a finite supply: consumption today comes at the expense of future use (e.g., minerals and

fossil fuels). In practice, however, this distinction is more accurately represented as a continuum since the renewability of many resources depends on when, where, and how they are consumed. For example, the experience of many communities with fisheries, forests, and groundwater demonstrates that if the rate of use exceeds the rate of renewal, even a potentially renewable resource can be depleted. In this context it is possible to speak of the ‘mining’ of renewable resources like soil or groundwater.

The ‘resource question’ has deep and enduring roots within Western intellectual history and is characterized by two distinct questions (Rees 1990). The first is the role of resource availability/resource scarcity in limiting opportunities for economic growth and development. Early explorations of this theme can be found in Malthus’s (1798) thesis on the differential rates of growth of population and food supply, and Marx’s (1967) account of the productive capacity of the labor process to liberate humankind from natural limits. More recently it appears in debates over the long-term availability of water, soil, and energy resources for a growing world population (Barnett and Morse 1963). The second is the sociopolitical implications of resource use and the impact of resource management on environmental quality, equity, and human welfare across a range of temporal and spatial scales. Examples of this can be found in conservationist writings of the late nineteenth century, in studies of social inequalities in exposure to environmental risk, and in current engagements with global environmental change and sustainable development.

Resource geography has tended to shun theoretical development in preference for a pragmatic engagement with concrete problems and a prescriptive approach to policy formation (see Wescoat 1987). Four principal lines of inquiry can be identified: resource inventory and evaluation; resource management institutions and decision-making; the political economy of resource use and the environment; and critiques of resource management and the question of ‘nature.’

2. Lines of Inquiry within Resource Geography

2.1 Resource Inventory and Evaluation

The stock-in-trade of resource geography has traditionally been the identification and analysis of resource distribution at spatial scales from local to global (e.g., Murphy 1954). For example, descriptions of natural resource distribution conventionally form a central component of regional geography, where they provide a logical segue between the description of a region’s geological, hydrological, pedological, and biological characteristics and discussion of the region’s

socioeconomic geography. Using this spatial mapping approach, resource geographers have quantified natural resource endowments, evaluated the capacity of particular natural resource bases to support economic development, and determined the extent to which current strategies of resource acquisition, conservation, and environmental protection are adequate.

By providing assessments of the spatial extent, utility, and economic viability of mineral, biological, and hydrological resources, resource geography has often played the role of handmaiden to regional planning and economic development. Early examples from within US geography can be found in the watershed and irrigation survey work of geomorphologists such as Grove Karl Gilbert (1877) and John Wesley Powell (1879). Their evaluations of water resources in the arid western states in the second half of the nineteenth century helped promote the federal government's involvement in dam construction, irrigation, and inter-regional water transfer systems. In the UK, the development of the national Land Utilization Survey by Dudley Stamp (1934) is indicative of how resource geography has historically contributed to land-use planning and, more generally, to the implementation of a conservationist utilitarianism towards natural resources. Professional affiliation between resource geographers and public resource agencies continues to generate empirical resource inventories and practical approaches for implementing integrated resource and environmental management (see Mitchell 1997).

The strategic and military value of mineral and energy resources has often provided an overtly political focus to the work of resource geographers, confirming MacKinder's (1887) maxim that geography serve as an aid to statecraft. For example, resource geographers served as part of a multidisciplinary team of social scientists compiling a series of Area Handbooks commissioned by the US Department of the Army (see www.hqda.army.mil). These 'compilations of basic facts' describe economically and militarily significant aspects of selected countries including identification and inventory of natural resource endowments. Whether part of regional or applied geography, the primary objective of local, regional, and global resource appraisals is informational. As a consequence, this line of inquiry has produced maps of resource location, atlases, and descriptions of resource availability, but has contributed little in the way of theoretical or methodological development.

2.2 Resource Management Institutions and Decision-making

A second major focus of resource geography is practically orientated research on the management of natural resources and the environment. The historical

and intellectual foundations of this approach lie within welfare economics with its objective of utility maximization. Adopting this welfare framework as its core paradigm, resource geography has sought to maximize the social utility of resources such as coal, oil, water, and open space by assisting in their rational and efficient management. A central objective has been to understand the influence of institutional frameworks (e.g., the distribution of property rights, the nature of environmental legislation, and the structure of commodity markets), decision-making processes, and differences in resource perception on the allocation, exploitation, and conservation of natural resources over time.

Under this paradigm, resource shortages and environmental degradation are understood to result from market failure and pervasive externalities. As a consequence, research adopts a prescriptive stance, advocating public policy approaches to intervene in existing markets to address the causes of failure (e.g., via government regulation for environmental quality or resource taxation), create markets where none had previously existed (e.g., pollution permit trading), or re-design the institutions of property ownership to internalize external costs (e.g., resource privatization, see Anderson and Leal 1992).

Prescriptions for resource management drawn from neo-classical economic models came under criticism from behavioral studies during the 1960s. Work by Gilbert White (1964) on river basin development and floodplain management, for example, argued that existing public policies for resource and hazard management over-simplified the process by which management alternatives were selected. Arguing that flood control engineering was just one of several possible responses to flood risk (others include flood insurance, disaster warning systems, and comprehensive floodplain management), White's work—and that of the Natural Hazards Research Group at the University of Chicago—focused attention on the range of choice in resource management decisions (*Environmental Adaptation and Adjustments; Environmental Risk and Hazards*).

In contrast to the neo-classical model which interpreted resource scarcity or deteriorating environmental quality in terms of market failure, the Chicago School argued that poor resource management decisions resulted from misperception or limited awareness of better alternatives. It rejected the assumptions of utility maximizing individuals operating in a field of perfect knowledge and instead adopted a behavioral approach in which resource managers operated under conditions of bounded rationality. Initially focused on water resources in USA, natural hazards research expanded to include other geophysical extremes in North America and in different cultural contexts. As an alternative to the unitary and utility maximizing assumptions of conventional resource management, the behavioral approach captures the

role of perception and sociocultural rules in determining the relative success of strategies such as energy and water conservation or the construction of international regimes for environmental governance (e.g., marine pollution, migratory species, ozone depletion—see Young 1999).

In an effort to contextualize the process of decision-making and explore the opportunities for co-operation as well as competition in the management of natural resources, resource geography has looked to traditional societies for alternative to market-based resource regimes. Research has focused, for example, on management regimes for common property resources—those for which control of access is difficult and joint use affects the welfare of each resource user (e.g., fisheries, river systems, wildlife, pastures, and public parks.) (see *Environmental and Resource Management*). Interest in management regimes for the commons centers on Hardin's (1968) provocative assessment that common property resources were inevitably prone to environmental degradation as a result of the cumulative decisions of economically rational individuals. Using the analogy of herders stocking a commonly held pasture, Hardin argued that the pursuit of individual self-interest will lead each herder to add to his or her stock; while the benefits of an additional animal (increased income) will be captured by the individual, the costs (declining grassland productivity) will be shared among all users. Describing this as the 'tragedy of the commons,' he concluded that either government ownership or privatization of the commons was necessary to forestall this degradation since 'freedom of the commons brings ruin to all.'

However, subsequent work by resource geographers and anthropologists has revealed historical and contemporary examples of successful common property resource management (e.g., Feeny et al. 1990). This has generated a two-pronged critique of Hardin's conclusions: first, Hardin failed to acknowledge that his herders could communicate with each other and, therefore, that they could undertake collective rather than individual action to maintain the environmental integrity of the commons; and second, Hardin conflated the nature of a common property resource with the type of property regime under which it was managed. He assumed, therefore, that his pasture—a classic common pool resource—would be managed as an open access resource regime. Historical experience illustrates that common property resources can exist under open access, communal, state, and private property regimes and that these need not be mutually exclusive but can coexist.

2.3 *The Political Economy of Resource Use and the Environment*

A third line of inquiry within resource geography explicitly rejects the applied management orientation

of earlier approaches for failing to capture the social stratification of economic and political power. In contrast, it engages the political and social dimensions of resource use, emphasizing the ecological and socio-economic context in which resource managers and their decisions are embedded. By embracing a broadly defined political economy, resource geography has sought to understand the nested scales of activity—from the actions of local institutions, through national public policies, to the global strategies of corporations—which constrain and influence the choices of individual resource managers.

Three distinctive subfields have emerged from this critique of conventional resource management: political ecology (e.g., Blakie and Brookfield 1987, *Feminist Political Ecology*); radical hazards research (e.g., Hewitt 1983); and environmental justice (e.g., Pulido 1996, *Environmental Justice*). Common to all three subfields is a perspective that locates the origins of resource depletion and environmental degradation in the economic, political, and social institutions of production. As a result, recognition is given to the socioeconomic—as opposed to purely physical—environmental—dynamics of vulnerability. For example, Watts' (1983) analysis of vulnerability to drought among the Hausa peasantry of northern Nigeria locates the cause of this vulnerability in the articulation between pre-capitalist modes of production and a global capitalist system.

2.4 *Critiques of Resource Management and the Question of 'Nature'*

Resource geography remains an evolving field influenced by both topical issues in society and theoretical trends within the academy. For example, recent public policy debates in North America and Europe have provided a topical context for research on: the effectiveness of conventional environmental policy approaches; the integration of different spatial scales in managing natural habitat; managing socio-economic transition within natural resource communities (e.g., those based on coal mining, fishing, or timber harvesting); the environmental implications of industrialization and modernization in the developing world; and the challenges of operationalizing sustainable development.

Resource geography has traditionally shown theoretical restraint in favor of practical application (Wescoat 1987); however, the 1990s has seen an increased interest in praxis—the integration of theoretical perspectives with the day-to-day issues of producing, consuming, and managing natural resources. Indicative of this are recent engagements between resource geography and:

(a) theories of economic restructuring and rural sociology in seeking to understand the implications for communities of agricultural restructuring, resource

privatization, and the links between local and global regimes of food production;

(b) the question of 'nature' and environmental ethics, and their implications for the welfare of non-human species;

(c) discussions within critical legal theory and discourse theory on the ideologies and institutions that sustain particular actions towards nature (Proctor 1998, Wolch and Emel 1998).

Collectively these new directions offer a broad critique of the instrumentalism inherent in the categorization of parts of nature as 'resources.' A central objective is to destabilize conventional views of nature as a collection of severable, tradable resource components valued solely for their commodity value. By recognizing such common-place notions as 'resources,' 'wilderness' and 'nature' as historically and geographically specific social constructions, new directions within resource geography contribute to an understanding of the roles gender, race, and class have played in domesticating the natural world.

Resource Institutions

Human beings use, manage, or conserve resources through institutional arrangements. The absence of institutions leads to open access to resources, a condition in which overuse and depletion may be unavoidable. Institutions exercise an influence over resource management outcomes that is independent of the forces and dynamics that created them. Institutional innovation is therefore critically important in all efforts to influence resource use and conservation. Whether one attempts to rejuvenate depleted fisheries or prevent trade in endangered wildlife, to protect forests, or prevent the erosion of biodiversity, institutional change remains a crucial part of such efforts. Given the crucial role of institutions, it is clear that an understanding of the nature of institutions and their relationship to resources is necessary if the goal is sustainable management or conservation.

Despite variations in approaches to institutional analysis, resource institutions can be defined as sets of rules that can be crafted collectively or individually, and that have the power to shape actions related to the conservation and use of resources. Resource systems and institutional arrangements are distinct entities, and it is important to pay attention to the factors that lead to a better fit between a given resource and the rules that govern the management of that resource.

However, it is only in the second half of the twentieth century that the role of institutions in resource management has found substantial recognition in the scholarly and policy world. Part of the reason institutions are recognized as important is that many resources critical to human existence and subsistence are becoming increasingly scarce, and are difficult to manage under some universalizable institutional form. Very different institutional regimes may be necessary for different types of resources. Consider,

as examples, wildlife species that need hundreds of square miles as their habitat, scattered forest patches upon which thousands of households depend for their livelihood, or irrigation systems that are too small to require government intervention, but too large to be managed by a single user. International agreements among governments may be appropriate institutional mechanisms to restrict the production of ozone depleting chemicals because they are mostly generated by a few major industrial producers. But for reduction in the levels of greenhouse gases, a far more widespread program of restraint may be necessary because of the nonpoint nature of the production of these gases. Another reason for the importance of getting institutions right are transactions costs that are associated with the allocation, processing, and exchange of resources, and that vary with institutional arrangements. Institutions that rely on external enforcement may require higher levels of expenditure to ensure that users conform to rules in comparison to those situations where it is in the interests of users to monitor each other and enforce institutional provisions directly.

The range of rules that comprise institutions is potentially infinite. But three institutional forms are possibly the most familiar: markets, states, and communities. Within each of these categories it is possible to find many variations; other forms span these categories. The precise combination of rules and how rules influence human behavior and outcomes are the basis on which it is possible to judge the performance of institutional arrangements. Typically, the objective of creating or forming institutions over resources is to enhance the efficiency, equity, or sustainability of resource use. However, a truly enormous and highly complex set of factors are at play. At the same time, the application of institutional analysis to resources is a relatively new field. It also requires collaboration across disciplinary boundaries. These are two reasons why the precise nature of the relationship between social and physical/biological systems, signified by the phrase 'resource institutions,' still requires considerable scientific research.

1. A Brief History of Institutions and Their Place in Resource Management

Contributions to institutional theories have flowed from economists, sociologists, and political scientists (Goodin 1996). Such contributions resonate with larger themes in social theory about the relationship between social structure, agency, and outcomes. In explicit counterpoint to the neoclassical paradigm in economics that finds little role for institutions or organizations in social life, advocates of institutions such as North (1990) and Williamson (1985) emphasize the unavoidable influence of institutional constraints on all social action. New institutionalists,

property rights theorists, and scholars of the commons have been the most influential in providing insights about the nature of resource institutions. Efforts aimed at understanding institutions have drawn from rigorous mathematical approaches as well as more descriptive and interpretive orientations.

Although resource institutions may serve as constraints upon certain groups and individuals, or certain kinds of actions, they also facilitate and advantage others. In addition to facilitating or constraining actions, and advantaging some people over others in terms of power and benefits (Knight 1992), resource institutions may also help shape desires, motivations, and preferences of groups and individuals. They are rooted in past human actions, and are the result of choices made by individuals and groups. It is easy to see, therefore, that institutions are seldom stationary; they change over time because of human choices.

For a long time, scholars viewed markets and states as the appropriate institutional mechanisms to address externalities that result from the collective goods nature of a vast class of resources. Advocates of market solutions argued for privatization of collectively owned and managed resources such as fisheries and forests, and argued that without privatization collective goods are likely to be overexploited. Voluntary exchanges among private owners on the basis of pricing signals, they held, would lead to the most efficient use of resources. Advocates of state control and ownership, pointing to asymmetric allocations that often result from the operation of market mechanisms, suggested that centralized control of resources was far more likely to promote conservation and sustainable use. Without centralized enforcement, according to them, attempts to manage resources could turn out to be futile. Through much of the 1950s and 1960s, writings on resource use and management viewed community institutions as backward, inefficient, and likely to promote overexploitation.

From the late 1970s, and especially since the mid-1980s, there has been a significant shift in views about the role of community as a resource management institution. This is partly because resource management strategies that rely exclusively on exchange (market) or enforcement (coercive, state-based) have obvious deficiencies. One tends to benefit a small group or a few individuals, and the other tends to create highly asymmetric relations of domination and dependency. Both have shown a tendency to disadvantage and exclude rural residents relying on local resources, who then do not cooperate in management of these resources. Both at the level of policy initiatives, and in terms of theoretical developments, the option of collective management of resources through new types of resource institutions based in communities has found wide appeal (National Research Council 1986, Ostrom 1990).

Despite heated assertions about the superiority of one type of resource management institution over

another, in real life most resource institutions do not easily fit the mold of market, state, or community. For the operation of each of these forms of institutions, implicit or explicit understandings that shade into other forms are necessary. For example, often markets and private property arrangements work better only when the force of the state is available to enforce the security of property.

2. Resource Institutions, Rules, and Power

Since resource institutions are sets of rules and norms that shape action, it is necessary to understand the broad types of rules that are most important in making institutions effective. Effectiveness implies three categories of rules: the ability to create new rules and modify old ones pertaining to resources; the ability to implement and ensure compliance to existing and new rules; and the ability to adjudicate disputes that arise in the effort to create rules and ensure compliance. Rules pertaining to resources define who gets to access a resource, who gets to use them, who is excluded from a resource, and how and when a resource can be transferred from one individual or group to another. Institutional arrangements are likely to be ineffective when human beings can make these above rules but not enforce them, or enforce existing rules but not change them in case of deficiencies. Mechanisms that allow adjudication of disputes among resource users and managers are necessary if resource institutions are to retain their force over time. These three categories of rules correspond to a more familiar division in government: executive (making, implementing, and enforcing of decisions), legislative (creation of rules), and judicial (adjudication of disputes).

The constituent parts of all resource institutions are born as a result of human choices. Three important determinants of human institutional choices are scarcity, risk, and redistribution. Greater scarcity of resources in a group creates incentives to define institutional arrangements ever more precisely so that benefits from resources are not dissipated. Indeed, some scholars have seen this dynamic of induced institutional change to be prominent enough to argue that it is universal (Netting 1981). Institutions may also change in response to higher levels of risk in the environment. Collective action necessary for institutional emergence can be conceptualized as a response that addresses the need to smoothen intertemporal fluctuations in production (Wade 1994). These views of institutional change are insufficiently attentive to variations in the incentives of group members, and to the politics that such variations generate. A more political view holds that institutional change need not occur only in response to greater scarcity in a group, nor lead to greater efficiency

(Knight 1992, North 1990). Instead, individuals and groups often act to create new resource institutions that would benefit them, rather than address problems of scarcity or risk. Particular institutions reflect existing distribution of power and wealth in a society or a group.

3. Sustainability of Resource Institutions

Perhaps the most critical question about resource institutions is how and under what conditions do they lead to sustainable management and conservation of resource systems. Group size, heterogeneity within groups, migration levels and population change, technological innovation, changing levels of demand for resources, uncertainty and sudden shocks, and cross-scale effects play an important role in determining the sustainability of institutions and resource systems (Keohane and Ostrom 1995). For certain kinds of resources, especially global commons, new institutional mechanisms have emerged to address issues of complexity and heterogenous subpopulations (Haas 1997).

Writings on resilience and adaptive management have generated important insights about the extent to which resource institutions can be sustainable in the long run (Holling 1973). Human institutions perform best when environments are predictable, yet many resource systems are characterized by potentially highly uncertain and variable processes. To date, research on institutions has not incorporated all the lessons learnt in risk-hazard studies on how sudden variations and uncertainty affect resource management needs. In part this is so because a formal theory of resource institutions requires a theory of human behavior that is mathematically rigorous and tractable, withstands empirical testing, and fits into a model of resource systems that can address fluctuations and surprise.

Resources and Environment: Contingent Valuation

A major impediment to performing a benefit–cost analysis involving the provision of a new public good or a change in an existing public good is that public goods are not routinely bought and sold in markets. Hence ‘prices,’ the economic data routinely used by economists as indicators of the economic value of goods, are not available for public goods such as environmental amenities. To overcome this obstacle, economists have developed (Freeman 1993) an indirect valuation approach that infers economic value from observations on consumer behavior with respect to marketed goods having a relationship to the public good, and a direct approach that gives consumers the opportunity to make choices with respect to the public good. The indirect approach relies upon one of two factors: that the public good can be ‘bundled’ in as one of the attributes of a private good (e.g., close proximity to a public park) and that it is sometimes necessary to make expenditures of money or time to use the public good (e.g., driving to a hiking trail in a national forest). The direct approach can be implemented by subjecting consumers to a constructed choice situation involving the public good, such as a vote in a referendum to provide the public good. The now common survey variant of the direct approach has come to be known as contingent valuation (CV) because the estimates of economic value obtained are ‘contingent’ on the features of the scenario posed in the survey.

CV surveys differ from other surveys on public policy issues in several important ways. First, the entire survey is devoted to describing the public good (or a small number of public goods) of interest.

Second, they differ in that their major purpose is to obtain an estimate of the relevant Hicksian consumer surplus measure; maximum willingness-to-pay (WTP) to obtain a desired good not currently possessed, or minimum willingness-to-accept (WTA) compensation to voluntarily give up a good currently possessed. CV surveys are typically organized in the following manner which reflects current practice: (a) an introductory section identifying the sponsor and general topic, (b) a section asking questions about prior knowledge about the good and attitudes toward it, (c) the presentation of the CV scenario including what the project was designed to accomplish, how it would be implemented and paid for, and what will happen under the current status quo situation if the project were not implemented, (d) question(s) asking for information about the respondent’s WTP/WTA for the good, (e) debriefing questions to help ascertain how well respondents understood the scenario, and (f) demographic questions. Mitchell and Carson (1989) provide a comprehensive overview of the issues involved in the design and analysis of CV surveys.

1. Development

Ciriacy-Wantrup (1947) put forth the first well-developed proposal on the need for CV surveys in a piece on the difficulties of measuring all the benefits of soil conservation programs. Empirical implementation of CV initiated by Davis (1963), in his Harvard dissertation, sparked considerable interest in the technique. He later compared a CV estimate with a corresponding estimate based on the travel cost method (an indirect approach then also being newly developed) and found that the two approaches produced similar estimates.

CV surveys were initially seen as having three distinct advantages. First, CV can obtain useful information where data on past consumer behavior had not been collected. Second, CV permits the creation and presentation of scenarios that provide new goods or changes in existing goods that were substantially outside the range of current consumer experience. Third, CV allows measurement of the desired Hicksian consumer surplus measure rather than its Marshallian approximation. For many economists, the major drawback to CV-based estimates was that they were based upon stated preferences rather than observed behavior.

A paper by Randall et al. (1974) greatly increased interest in CV. It valued changes in air quality necessary to maintain scenic vistas in the Southwest. The indirect valuation approach was not capable of being applied in this instance because all people in the area share the good equally (and hence, not bundled differentially into housing prices) and no expenditure of time or money is needed to enjoy it.

Randall et al. estimated what had been termed 'existence value' in an influential paper written by Krutilla (1967). The novel element in Krutilla's framework was that existence values were not generally revealed by market purchases. He argued that some people care about environmental resources, such as wilderness areas, irrespective of their desire to visit them. Krutilla did not measure existence values but rather recommended determining how large they would have to be to tilt the decision in the other direction. Failure to include existence values in policy-making, he contended, would likely entail too great a loss of existing environmental amenities and the provision of too few new environmental amenities. Other related concepts were soon enumerated (e.g., non-use value, stewardship value, bequest value, option value) and eventually encompassed into a single term, 'passive-use value,' first used in the 1989 court decision *Ohio v. Department of Interior* (880 F.2d 432, D.C. Cir.), which held that government trustees should include passive-use values in damage claims.

What Krutilla had called existence values had often been termed intangibles. They were not well integrated into welfare economic theory and thought to be unmeasurable. The key to measuring them lies in the recognition that due to scarcity effects, any form of economic value is a relative and not an absolute concept. Monetary measures of economic value are implicitly defined by choices made subject to an income constraint. CV permits the construction of the appropriate choice scenario. Also, economic value can be expressed in terms of any constraints/tradeoffs appearing in a choice scenario including time, other public goods, or private goods.

The quantity of CV research steadily increased throughout the 1970s and early 1980s. The importance of CV in the USA was raised considerably by presidential executive orders that required an assessment of the benefits and costs of all major new government regulations and reauthorization of existing ones. Outside the USA, CV was incorporated into OECD reports on measuring the economic value of pollution impacts and into World Bank reports on providing basic infrastructure. The rapid growth in the use of CV since the mid-1980s, in the USA and elsewhere, was a response to the growing demand for more comprehensive benefit-cost assessments for policies with substantial environmental or health impacts.

By far the greatest stimulus to the current CV debate, however, was the enactment of US laws that allowed for the recovery of monetary damages for injuries to natural resources. The focal point was the Exxon Valdez oil spill where the government's case was largely based upon a monetary claim for loss of passive use (Carson et al. 1992). Potential liability for lost passive use values should increase a firm's precautionary activities and environmental restoration efforts. Not surprisingly, industry facing such liability questioned whether passive use values should be

counted and whether CV estimates are reliable. A set of papers highly critical of CV from an Exxon-sponsored conference appear in Hausman (1993). In response to the industry critique, the US National Oceanic and Atmospheric Administration (NOAA) convened a Blue Ribbon Panel co-chaired by two Nobel Prize winners (Arrow et al. 1993) which concluded that passive use values should be included in damage assessments and that 'CV studies can produce estimates reliable enough to be the starting point for a judicial or administrative determination of natural resource damages—including lost passive-use value.' That report has also been influential for the guidelines that it suggested for conducting reliable CV studies for natural resource damage cases and the issues that it identified as requiring further research.

CV has been applied in more than 50 countries and there are now several thousand CV papers. Most US federal agencies with environmental, health, or natural resource responsibilities have relied upon CV studies in making policy decisions, as have many state agencies. The use of CV has dramatically increased over time in other OECD countries and international agencies regularly commission CV studies. The range of CV applications is broad. It has been used to estimate the benefits of: improving national and regional air/water quality; reducing risk from drinking and groundwater contaminants; improving outdoor recreational opportunities; protecting wetlands, wilderness, rainforests, and endangered species; providing public education; improving food and transportation safety; reducing queues for public health care services; increasing the reliability of electric and water utilities; providing cultural amenities; and improving sanitation services in developing countries.

2. Initial Research Focus

Two concerns first voiced during the early phase of CV development have been particularly influential: the possibility that respondents would not take seriously a 'hypothetical' survey question with no money directly changing hands and Paul Samuelson's warning that people would not truthfully reveal their preferences for public goods. Random response to a CV survey which was feared due to its 'hypothetical' nature could be ruled out by noting whether WTP responses systematically varied with particular covariates in the expected way. The tests economists paid the most attention to, however, were those comparing CV estimates with those from indirect techniques (e.g., hedonic pricing and travel cost analysis) for quasi-public goods, where both approaches are applicable. Early work suggested reasonably close comparison between the two, thus ruling out the extreme random behavior or strategic behaviour initially feared. Carson et al.'s (1996) meta-analysis of these comparative studies (616 comparisons from 83 separate

studies) found that CV estimates on average were slightly lower than their corresponding indirect technique estimates and the CV and indirect estimates were highly correlated.

For pure public goods, the indirect approach is not possible so one can only compare estimates based upon different types of constructed markets. With coercive payment (e.g., taxes), incentive theory suggests that CV responses should be similar to those obtained from observing voting in an equivalent referendum, the observed empirical result. With voluntary payment, theory suggests that survey estimates will be larger than true (and unobservable) WTP that in turn should be larger than actual contributions due to free riding. The observed empirical result is that survey WTP is substantially larger than actual contributions.

Other issues that concerned early CV researchers were whether the payment vehicle used should influence WTP estimates, how much information should be provided to respondents about the good, what fraction of WTP/WTa was due to passive use considerations, what the 'best' elicitation format was, why the difference between CV, WTP, and WTa estimates was larger than expected, and the relative merits of different modes of survey administration. Some of these issues have been resolved whereas others continue to be debated. The latter are discussed in the next section.

WTP estimates for the same good were shown to differ, often considerably, with different payment vehicles. Respondents were not indifferent to how public goods were financed. This was distressing to many who believed, or at least hoped, that the value of a good should be independent of the exact manner in which it was supplied and paid for. The CV estimates suggested that this was not the case.

As one would expect, WTP estimates were sensitive to the nature and amount of information provided. However, this sensitivity entailed the thorny issue of what information should be provided. CV researchers began undertaking extensive survey development work including focus groups to determine what information people wanted in making their decision. Many early CV surveys asked respondents to apportion their WTP estimate into different parts corresponding to various types of use and passive use values. Such decompositions were shown not to be unique and the various components had no distinct policy implications, so this practice has largely been abandoned.

3. Research Issues

The issue of the best elicitation format continues to be debated but is increasingly being cast in terms of a bias-variance tradeoff. The binary discrete choice format with random assignment of respondents to

different amounts (Bishop and Heberlein, 1979) has gained prominence owing to its desirable incentive properties for truthful preference revelation, in many (but not all) situations. This format has two major drawbacks. First, it collects relatively little information about a respondent's value for the good (i.e., only whether this value is above or below the amount asked), thus requiring large samples for precise estimates. Second, its estimates are sensitive to the particular parametric functional form chosen. Response formats directly asking for WTP provide the maximum amount of information (the amount making the respondent indifferent between the status quo and the alternative). This format, however, invites non-truthful strategic behavior and typically results in a sizeable fraction of the sample providing either a zero WTP amount or no response. CV researchers have proposed a number of different response formats falling between these two extremes.

Early CV WTa estimates were considerably larger than corresponding WTP estimates. This was originally thought to be a defect of CV surveys but similar divergences now appear to be typical of experimental and actual markets. A number of reasons for large divergences have been suggested (Bateman and Willis, 1999), some consistent with neoclassical economic theory and some more psychological in nature. As a consequence, interest has been renewed in measuring WTa, since the substitution of a WTP measure in its place can substantially underestimate the value of a good.

The merit of different modes of survey administration also continues to be debated. Many CV studies need visual representations of the good (e.g., pictures or maps) precluding the use of telephone surveys. The in-person vs. mail survey debate has several elements, including the much greater cost of personnel interviews, the importance of controlling the order in which material is presented, the importance of being able to read material to respondents, potential sample selection bias due to interest in the topic, and the potential influence of the interviewers.

CV researchers also came to realize that they faced the standard array of survey design issues. Adequate presentation of the material in the typical CV survey is now seen as a much more difficult task than the standard public opinion survey and is one for which most economists have had little training or experience. Further, several cognitive psychologists (e.g., Kahneman and Knetsch 1992) argued that the estimates of economic value obtained in CV surveys were likely to be subject to several undesirable effects. Chief among these was that the estimates obtained in a CV survey would be insensitive to the scope of the good being valued. They argued that stated intentions and actual behavior will diverge because respondents get a 'warm glow' from 'giving' in a survey context. While there are a few study results consistent with this prediction, a fairly large number of split-sample tests

using more fully developed CV scenarios have tested this hypothesis and reject it. Nonetheless, the Kahneman and Knetsch paper stimulated considerable interest in testing the properties of CV estimates against predictions from economic theory.

4. State of the Debate

Although there is widespread general agreement among CV practitioners on many issues, they often disagree regarding the extent and applicability of various best-practice standards, such as those proposed by the NOAA Panel, when cost and complexity factors are introduced. The recent Bateman and Willis (1999) volume considers these issues.

Participants in the early years of the CV debate were mostly environmental economists. One now finds that corporate executives, ecologists, lawyers, microeconomic theorists, philosophers, psychologists, public administrators, statisticians, and survey researchers have joined in. The increasingly interdisciplinary nature of this debate attests to the complexity of the issues and importance of CV for policy decisions (Portney 1994). Opponents of CV often conclude that CV is fundamentally flawed (Diamond and Hausman 1994). Their typical recommendation is to let the 'experts' decide. Proponents of contingent valuation acknowledge that poorly designed and implemented studies have produced problematic results that should not be used. However, they believe that these problems are not inherent to the method and are not found in the better studies (Hanemann 1994). They argue that without CV it is not possible to conduct a comprehensive economic analysis of many environmental issues and that the public's preferences concerning the provision and payment for public goods cannot be adequately represented to policymakers.

Respiratory Disorders: Psychosocial Aspects

Man can do without food for weeks, without water for a few days. A few minutes without air, however, means death. Experiencing shortness of breath is associated with strong feelings of anxiety and panic. In this article, the three most prevalent respiratory disorders will be discussed, from a behavioral and social science perspective.

1. Asthma, Chronic Bronchitis, Pulmonary Emphysema

In order to understand the relevance of the contribution of behavioral and social sciences to the study of patients with respiratory disorders, in this paragraph definitions of asthma, chronic bronchitis, and emphysema, and risk factors, epidemiology, and medical management will be discussed briefly first.

Asthma is derived from Greek, meaning 'panting or distressed breathing.' A universally accepted definition of asthma is not available, reflecting changing views over time in the area of pulmonology and gaps in the

knowledge about the precise nature of asthma. Learned societies in the US, the UK, and in other countries proposed various definitions in an attempt to standardize epidemiological studies and diagnostic and therapeutic medical strategies. One of the most comprehensive definitions of asthma is given by the American Thoracic Society: Asthma is a clinical syndrome characterized by increased responsiveness of the tracheobronchial tree to a variety of stimuli. The major symptoms of asthma are paroxysms of dyspnea, wheezing, and cough, which may vary from mild to almost undetectable, to severe and unremitting (status asthmaticus)' (ATS 1987, <http://www.ginasthma.com>). Three characteristics stand out: Asthma is defined as reversible, intermittent, and variable. The episodes of airways obstruction causing dyspnea (shortness of breath) either disappear (are reversible) spontaneously or as a consequence of adequate medical, pharmacological treatment. Attacks of asthma vary in their occurrence over a certain period of time—some patients experience asthma attacks almost daily, some only once a year—and the severity of the episodes of shortness of breath varies within and between patients.

Chronic bronchitis is defined in behavioral terms: 'The presence of chronic productive cough for three months in each of two successive years in a patient in whom other causes of chronic cough have been excluded' (ATS 1995). Patients who fulfill criteria for the diagnosis of chronic bronchitis cough frequently and produce sputum over extended periods of time, and may be short of breath. In contrast to asthma, chronic bronchitis is an irreversible medical condition. Eliminating the most important risk factor—smoking tobacco—reduces the symptoms and severity of the disorder somewhat without leading to a complete reversal of the condition of the lungs and their airways.

Pulmonary emphysema is defined in terms of anatomic pathology as 'abnormal permanent enlargement of the airspaces distal to the terminal bronchioles, accompanied by destruction of their walls and without obvious fibrosis' (ATS 1995). In patients with emphysema continuous shortness of breath is the most important symptom, almost always associated with significant impairments in the ability to perform activities of daily life. Here, as is the case in patients with chronic bronchitis, smoking tobacco is the major cause of the disorder.

Over the past decades, pulmonologists, epidemiologists, researchers in related medical domains, and behavioral and social scientists viewed asthma, chronic bronchitis, and emphysema as three related disorders. Despite the differences between the three disorders, the rather similar consequences (shortness of breath, coughing, producing sputum) formed the basis for this 'lumping view.' More recently, the advocates of a 'splitting view' dominate the scientific arena. Differences in the views on causation and pathophysiological bases of the disorders are respon-

sible for this change (Vermeire and Pride 1991). This is why asthma will be discussed separately from chronic bronchitis and emphysema. These last two disorders usually are subsumed under the heading Chronic Obstructive Pulmonary Disease (COPD), defined as 'a disease state characterized by the presence of airflow obstruction due to chronic bronchitis or emphysema' (ATS 1995, <http://www.goldcopd.com>).

2. Epidemiology and Some Medical Characteristics

2.1 Asthma

The prevalence of asthma varies between different studies in different parts of the world because of differences in the definition of asthma. Large differences in data on prevalence of asthma are also attributable to differences in genetic susceptibility and environmental conditions. Asthma has a clear genetic basis: Chances for a child, conceived by a man and a woman who both are asthmatics themselves, of being asthmatic are about 75 percent. Environmental stimuli appear to play a role in worsening asthma symptoms. However, air pollution as such does not appear to be a factor that causes asthma. Interestingly, a recent study in Germany demonstrated that the prevalence of asthma in the more polluted Eastern part of Germany was lower than in the Western, more highly developed, and less polluted, part of the country (Nicolai and Von Mutius 1997). This has led researchers to hypothesize about the 'hygiene effect': Having young children growing up in a relatively unpolluted environment, with a high level of sanitation (i.e., low chance of exposure to germs causing flu and colds) predisposes a child to a higher chance of being sensitive to relatively low levels of allergens and respiratory infections, increasing their chances to develop asthma.

The prevalence of asthma is about 7 percent in the US, about 15 percent in the UK, about 1 percent among Inuits, and about 30 percent among inhabitants of Tristan da Cunha, an island in the southern part of the Atlantic ocean between South America and Africa (Gergen and Mitchell 2001). The prevalence of asthma is increasing, especially in industrialized countries. The reasons for this are largely unknown. The increased attention by physicians for a possible diagnosis of asthma in a patient with respiratory problems probably is a contributing factor in the increase of asthma prevalence: Asthma used to be underdiagnosed and undertreated (Kaptein et al. 1987). In young children, boys outnumber girls in prevalence of asthma in a ratio of about 2:1. In adult patients, hardly any sex ratio differences are observable in the prevalence of asthma. Contrary to popular beliefs, one hardly ever outgrows one's asthma, 'one only outgrows one's pediatrician.'

2.2 Chronic Obstructive Pulmonary Disease (COPD)

The prevalence of COPD is about 5 percent (ATS 1995). Recent studies predict considerable increases in the prevalence of COPD (Murray and Lopez 1997), with COPD becoming the third leading cause of death in the future. Despite reductions in the number of smokers of tobacco in industrialized countries, the post-World War II generation with their smoking habits of decades, will fall victim to becoming patients with COPD. Also, as the number of women who smoke cigarettes increased substantially after World War II, COPD will no longer be an illness for men only.

Chronic bronchitis has 50 years of age as the average age of onset, emphysema sets in at around 60 years of age. COPD has a SES-gradient, with a lower socioeconomic class dominance. COPD can be labeled as a blue-collar worker disorder due to the fact that poor housing and working conditions contribute to developing COPD.

The great majority, about 80 percent, of patients with respiratory disorders are seen by the general practitioner (or primary care physician, family physician). Based on critical views and evidence on the quality of care provided by these physicians to patients with asthma in particular, considerable effort has been devoted to improving this quality. In many countries, societies of general practitioners developed guidelines on the optimal management of patients with asthma. In these guidelines early diagnosis, aggressive medical treatment, and a great emphasis on teaching patients self-management skills are the cornerstones of modern management of asthma. Similar guidelines have been developed for the management of patients with COPD in a primary care setting, with an emphasis on stopping smoking techniques.

The remaining 20 percent of patients with respiratory disorders are seen by medical specialists: pulmonary physicians, allergologists, pediatricians. Only a very small percentage of patients is being managed on an in-patient basis—for status asthmaticus in patients with asthma, for severe respiratory problems in patients with COPD. In various countries in the world, specialized long-stay respiratory clinics provide care for those patients with asthma and/or COPD in whom the intractability combines with severe psychological and social problems.

3. Asthma and Psychology

Looking back over some 100 years of behavioral and social science research on patients with asthma, one cannot help but be impressed by the gains that have been made, gauged in terms of behavioral outcomes for these patients. Three periods in this line of research and clinical care can be discerned.

3.1 Psychosomatic Views on Asthma

Between World War I and World War II, psychosomatic views on various psychosomatic disorders and illnesses represented an influential line of research of clinical care. Given the unknown etiology of a number of major diseases (e.g., hypertension, diabetes mellitus, and asthma), theories were developed in which it was postulated that psychological factors played a substantial role in causing a number of specific illnesses. With regard to asthma, a combination of three factors was supposed to be a necessary and sufficient condition: (a) a 'weak spot' in the body of the patient, (b) a characteristic psychological profile of the patient, and (c) a situation eliciting the illness.

Patients with asthma were supposed to have a respiratory system which was sensitive to disruptions. In addition, due to faulty mother-child interaction in the early years of life, a specific personality profile was assumed to be established in the patient: A combination of excessive love of the mother for the child ('smothering with kisses') and an unconscious wish of the mother to reject her child, was supposed to render the child sensitive to asthma. In the event of a stressful life event (e.g., being separated from the mother, experiencing social conflicts), an asthma attack would happen.

Empirical evidence for these psychosomatic views is lacking. No study identified the supposed mother-child psychopathology put forward by the theory. Psychosomatic therapy (i.e., psychodynamic interventions) failed to demonstrate any positive effect. It is safe to state that the highly selected sample of patients with asthma seen by the theorists (psychiatrists and specialists in internal medicine) represented patients who exhibited psychosocial problems as a consequence of having to cope with the adaptive tasks of having severe, brittle asthma.

3.2 Psychological Consequences of Asthma

The second theoretical and empirical approach to asthma from a behavioral and social science perspective focused on the consequences of asthma on the daily lives of afflicted patients: their quality of life. Using disease-specific questionnaires with adequate psychometric properties, limitations in functional, psychological, and social domains were identified. Asthma patients experience excessive absenteeism from school and work, heightened levels of anxiety and depression, and feelings of social isolation (Maille et al. 1996).

The first studies on the effects of psychological interventions in order to reduce the limitations caused by asthma adopted a learning theory perspective: relaxation training, biofeedback, and systematic desensitization. In these studies, pulmonary function was the major outcome measure. The effects of

behavioral interventions turned out to be limited, however (Lehrer 1998).

The research performed by a group of psychologists in Denver, Colorado, USA, in the 1970s and 1980s set the scene for the third phase in psychological research on patients with asthma. Kinsman et al. (1982) demonstrated how the affective and cognitive responses of asthma patients to their illness and symptoms predicted important outcome measures such as length of hospitalization and rehospitalization, irrespective of the medical severity of the respiratory condition.

3.3 Self-management Training

A logical next step, given the evidence for the impact of the psychological response (coping behavior) of patients to their asthma, pertains to teaching asthma patients to optimize their handling, or self-management, of the disorder. Creer (1979) represents the first psychologist who studied the effects of this type of intervention in children and adults. In self-management training, patients with asthma are taught skills to perceive the first signs of periods of shortness of breath, take appropriate action to prevent or control episodes of shortness of breath, and manage bouts of asthma if they occur. Reviews of the effects of self-management training report reductions in symptom frequency and severity, use of medical resources, and fewer disruptions of daily life (e.g., absenteeism from school or work, levels of anxiety) (Clark and Gong 2000).

Current research on asthma by psychologists focuses on refining self-management training, symptom perception, and the effects of emotional expression on pulmonary function (Smyth et al. 1999).

4. COPD and Psychology

In contrast to the considerable amount of research performed by psychologists and social scientists on patients with asthma, patients with COPD have been the subject of research from this perspective only relatively recently. There are at least two reasons for this. The impact of smoking tobacco, the major cause of COPD, has become clear only after World War II; psychologists and social scientists joined medical professionals in their therapeutic pessimism for decades. The first empirical study on the psychological consequences of COPD was published only in 1961.

No psychosomatic theories were developed on patients with COPD. Studies on the neuropsychological consequences demonstrated that severe grades of COPD negatively affect cognitive functioning of patients. Depression, fatigue, and feelings of social isolation are the dominant psychological and social consequences of COPD. Restrictions in daily activi-

ties, absenteeism from work, early retirement, and invalidity are major functional consequences of COPD. The quality of life, therefore, of patients with COPD is significantly lower than in healthy persons (Kaptein and Dekker 2000).

Psychologists contribute to the care for patients with COPD in two areas: pulmonary rehabilitation programs and self-management training. Pulmonary rehabilitation pertains to 'an art of medical practice wherein an individually tailored multidisciplinary program is formulated which through accurate diagnosis, therapy, emotional support, and education stabilizes or reverses both the physio- and psychopathology of pulmonary diseases and attempts to return the patient to the highest possible functional capacity allowed by his pulmonary handicap and overall life situation' (Ries 1997). Physical therapy, breathing exercises and training, smoking cessation techniques, graded exercise aimed at improving ambulation, and coping skills training usually are parts of pulmonary rehabilitation programs. Reviews and meta-analyses of the effects of these programs indicate that use of health services, limitations in daily activities, and psychological problems tend to be reduced to some degree (Kaplan and Ries 2001). High dropout percentages, however, are the rule. Identifying the separate contributions of the various components in pulmonary rehabilitation programs to various outcome measures is not feasible, however.

The current emphasis in health psychology research in COPD focuses on teaching patients self-management skills. Cognitive behavior modification techniques are used to alter nonadaptive cognitions and behavior. In a study of patients' pessimistic self-statements ('I can't walk very far without getting short of breath, so what's the use?') were addressed and altered into more active ones ('This walking is uncomfortable, but I can handle it. Soon I will be able to walk farther.'). Results showed that levels of exercise tolerance and quality of life increased in comparison to various control conditions (Atkins et al. 1984).

Increasingly, guidelines on the medical management of patients with COPD include results of psychological research on self-management (ATS 1995). This development is positive: it reflects how pulmonary physicians acknowledge the relevance of topics such as compliance or adherence, and incorporating self-management into clinical care. Patient empowerment is instrumental for the wellbeing of patients with this chronic respiratory disorder.

Future research efforts will strengthen the position of patients with COPD. Health psychologists who work in the area of COPD face many challenges. Smoking cessation is a primary subject for health psychologists and other social scientists, given the psychological and societal determinants of smoking tobacco in particular. Simplifying self-management skills and incorporating the teaching and uptake of these skills into medical care are additional challenges.

COPD is an under-funded medical disorder (Gross et al. 1999). Future research both from a medical and a psychological perspective will help in preventing COPD to develop, and in improving quality of life in patients with COPD.

Responsibility: Philosophical Aspects

1. The Concept of Responsibility

The focus of this entry is moral responsibility. Although it begins with an examination of the concepts of causal responsibility and of responsibility as duty, the discussion in these sections is intended to orient the reader to the distinctive character of the concept of moral responsibility and to attendant philosophical theories about what is meant when moral responsibility is ascribed to a human agent for some act or state of affairs. Attributing responsibility to an agent as to a cause is logically and conceptually distinct from claiming that the person is morally responsible for causing an event. Equally, discerning those tasks for which a person has a responsibility or a duty to perform is different from claiming that they bear moral responsibility for the performance of those tasks. In short, the *concept* of responsibility has a number of distinct applications, the analyses of which point to the variety of *conceptions* of responsibility.

1.1 Causal Responsibility

One interested in action theory may investigate *causal* responsibility. Thus, in claiming 'Alice is responsible for spilling the coffee on the floor,' we may be saying that Alice spilled the coffee as a result of some action on her part. In such a causal context, responsibility ascriptions credit a person or an entity with a role in bringing about an event or state of affairs, and nothing more. Assigning causal responsibility consists in identifying a salient factor that must actually operate in order for an event to transpire—its cause—and not in evaluating the moral quality of an event with which an actor is instrumentally associated.

Moral responsibility, and responsible agency, cannot be identified with causal responsibility. This is true for at least three reasons. First, that someone or something is causally responsible for some event or state of affairs is not sufficient for the thing being morally responsible for the event. The kind of responsibility attributed to one who is identified as

causally responsible for something is not a sufficient basis for moral evaluation. That the agent is causally responsible is not, in and of itself, a reason to judge the agent a good or bad, praiseworthy or blameworthy, person as a result. But judgments of moral responsibility are typically of this sort.

Second, a person need not be causally responsible for all those acts they are held morally responsible for—causal responsibility is not necessary for moral responsibility. For example, parents are vicariously responsible, legally and, although this is controversial, perhaps morally, for at least some of the acts of their nonadult children.

Third, that someone or something is causally responsible for some event or state of affairs is not sufficient for the cause to be an agent who can be held morally responsible. Because causal responsibility can be ascribed to events, things, nonhuman animals, and to irrational or underdeveloped humans as well as to fully mature, rational persons, it does not single out a class of things that might properly be described as moral *agents*, or *members of a moral community*. When we hold a person such as Alice morally responsible for something, it is in light of certain expectations we have of Alice, given a maturity we assume of her, given what we have reason to believe she knew herself to be doing, and given the circumstances that led her to act. But the conditions for responsible agency met by Alice, and considered more fully below, are not met by very young children, or animals, or trees. Thus, while we might claim that faulty construction is to blame for the collapse of a building, what we mean is that a salient cause of the collapse was poor construction. We might allege that the baby was causally responsible for the broken lamp. But neither the baby nor the faulty construction are morally responsible for the states they cause because neither are moral agents.

In sum, an account of agency must make sense of moral approval or disapproval. Even if the act for which we deem a person responsible is morally neutral—is neither praiseworthy nor blameworthy—we appraise the moral quality of the person who acts, and not simply the state of affairs the person initiates.

Baier's notion of 'task responsibility,' or the 'forward-looking aspect' of agent responsibility. In its forward-looking sense, agent responsibility consists in being socially entrusted, on either customary, legal, or moral grounds, with a specified event, state of affairs, or duty.

Thus, parents are responsible for overseeing the well-being of their children, adult wage earners are responsible for paying taxes, attorneys are responsible for respecting the confidentiality of their clients, and so forth. In this forward-looking sense, the claim that Alice is responsible for giving Bernie the medicine would mean, at a minimum, that Alice has a duty to give Bernie medicine. The sentence is then ambiguous between (a) the sense in which it attributes a prospective duty to Alice; (b) the sense in which it attributes mere causal responsibility to Alice for Bernie's having been given the medicine, and (c) the sense in which it attributes moral responsibility and implies, perhaps, praise or blame.

In the latter sense, to be morally responsible is not a matter of having or owing an obligation to another. A person may be morally responsible for those things they have a moral obligation to do, such as caring for their children. But the things for which a person can be held morally responsible in the sense of being praiseworthy or blameworthy is not restricted to things they had an obligation or a responsibility to do. I might be held responsible for my slovenly habits, or for my acts of bravery, where neither of these attends the discharging of an obligation. Equally, the fact that an act is one I am obliged to perform does not decide whether I am morally accountable for performing it or for failing to do so.

Once we have set aside causal responsibility and responsibilities in the sense of duties, we are left with the idea of responsible agency and the idea of responsibility for action. What we are interested in is the idea of *being* responsible—both being a responsible person and being responsible for an act.

2. *Being a Responsible Agent and Being Held Responsible*

1.2 *Duty and Obligation*

By contrast, in describing a person as 'responsible' for some act or state of affairs, we may be expressing the belief that the person has a duty. Here, the judgment 'X is responsible for Y' is intended as a statement to the effect that X has certain responsibilities to others: tasks, duties, or obligations pertaining to Y, usually in light of X's position in society or role. Claiming that a person is responsible for Y in this sense is to credit responsibility *prospectively*; it is to look forward to what the person is duty bound or obligated to do. This idea of having responsibilities is analogous to Kurt

2.1 *The Conditions for Responsible Agency*

In order to be morally responsible for an act, or trait of character, a person must be a responsible agent. Responsible agency typically requires that an individual satisfy certain *epistemic* conditions and certain social and psychological conditions of *control*.

The epistemic conditions guarantee that the responsible agent is self-aware, that they are rational, that they are not ignorant of the circumstances in which they act, that they are cognizant of and able to act within established moral guidelines, and that they

are responsive to reasons to adjust or amend their behavior in light of these guidelines. In order to be held responsible, the moral agent must know that doing a particular act (or an act of a given type) or cultivating a particular trait of character (say, jealousy, rage, bigotry) is right or is wrong. The moral agent may be held responsible if, suffering from none of the conditions that exempt a person from responsible agency, they should have known the nature of the act or trait, and could have been motivated by the relevant moral guidelines. A person's ignorance in this case might be called culpable. By contrast, a person should not be held responsible, if they did not know, and should not be expected to know, that the act is of an undesirable moral quality.

The control conditions ensure that the agent acts freely. The morally responsible agent is not hostage to debilitating and uncontrollable neuroses of a sort that incapacitate their resolve; that is, they can control the manifestations of neuroses by medical means or by strength of will. A person who is prone to neurosis of a certain type or scope, or who finds themselves the victim of coercion or manipulation, may be a responsible agent but one whom we excuse from responsibility for specific acts when it is plain that on a particular occasion coercive or manipulative elements played a decisive and ineliminable role in action.

Satisfaction of the control conditions for responsible agency ensure that the agent, rather than a mechanism foreign to them, actually guides or actually executes the agent's actions and those traits of character for which the agent is morally responsible. A mechanism of action is foreign to a person when it is one to which the person does not assent as a force by which they wish to be moved. Although the responsible person may lack the power to alter the mechanism that leads them to act—to do otherwise than they in fact do—they are moved by their own lights. At a minimum, the morally responsible agent is capable of deliberate, intentional behavior.

Absent some of the epistemic and control conditions, a person will be a less likely candidate for responsible agency. The satisfaction of some set of these will mean that the entity is a responsible agent. There is obviously a threshold that decides when a person is a responsible agent, but it is not within the scope of this discussion to explore the specifics of the threshold. Let it suffice to say that the responsible agent is someone who acts knowingly and freely, and the actions and characteristics for which they are responsible are 'their own.'

2.2 Holding Responsible and Being Responsible

Generally speaking, when we describe someone as a morally responsible agent, we mean that the person is someone whom we recognize as bearing characteristics of the sort that make them a member of the moral

community. They are someone with whom morally relevant relationships are possible, and they are a fitting subject of moral appraisal. But there are different theories about the analysis of judgments that a person is morally responsible for their character, their choices, their actions or omissions. Three accounts, in particular, bear mention.

One possibility is that we might simply be signaling that an actor, having met certain conditions for responsible agency, is a suitable candidate for certain kinds of corresponding regard and treatment forthcoming on the part of others and, perhaps, on the part of himself. This approach has been coined the reactive attitudes analysis of responsibility ascriptions. The idea is that when we say a person is responsible we mean that the person is liable, through their behavior, to a response on the part of others marked by attitudes such as gratitude and resentment, and that the person is an appropriate object of such attitudes in light of certain conditions for agency that they have met. On this analysis, the claim 'X is responsible for Y' (or, for Y-ing) will amount to the conjunction of the claims 'X did (or is) Y,' 'X possesses the qualities of a responsible agent,' and 'X is rightly subject to the favorable or unfavorable responses of others as a result.' The reactive attitudes analysis offers an account of the emotional dynamics at play where decisions about responsibility occur. That a person is appropriately subject to certain attitudes and practices gives us reason to consider them a free, responsible agent, and as good or bad, praiseworthy or blameworthy, and so on.

A second possibility is that, in judging a person responsible, we may be saying the person is accountable for their behavior, in the sense that we think it appropriate that the person offer an explanation of their intentions or beliefs about their behavior. That is, we may be focusing on the phenomenon of holding an agent answerable for their actions. Construing judgments about moral responsibility as judgments about accountability is appropriate for a number of reasons. One reason is that holding persons responsible is part of a social practice of ascribing responsibility, first by making clear any moral expectations we have of persons vis-à-vis behavior and character, and then by having in place certain social instruments that ensure adequate redress where necessary. Making moral expectations clear presumes the existence of a shared set of beliefs, and a system of norms against which actions and traits of character are assessed.

A third possibility is that judging a person responsible for some act, omission, state of affairs, or trait of character is essentially a statement of attribution. The philosopher Gary Watson advocates this perspective, which he labels the *aretaic* face of responsibility, for its focus on ethical appraisal of conduct that can be attributed or imputed to an individual as its agent and thus as the author or adopter of ends. Because these ends are self-adopted,

acting upon them discloses the quality and character of the agent's life. The attributability approach does not merely assign causal responsibility, for the focus is on the behavior of a human agent, his/her character, and his/her ends—the object leading to action. Acts of attributing responsibility on this account differ from both the reactive attitudes and accountability analyses. Attribution need not involve the registration of emotions such as resentment or gratitude, nor need it be true that an explanation of the act in question is expected of the actor.

Two varieties of cases illustrate the differences among these three analyses. First consider examples of extreme and, some would contend, irremediable evil. If we consider the behavior of someone such as Hitler, it may well appear that he is morally 'beyond the pale' so that none of the standard reactive attitudes is an appropriate response to, for instance, his 'Final Solution.' Hitler, and like-minded persons, are seemingly incapacitated for ordinary adult interpersonal relationships. Such persons simply will not be responsive to the demands of membership in our moral community. At the same time, the heinous acts they have committed are properly attributed to them as perpetrators. The attributability account allows for Hitler, and similarly sociopathic or psychopathic persons, to be deemed responsible for their immoral behavior, yet permits the hesitation some might have in regarding such actors as moral interlocutors, as the accountability approach demands, or as appropriate objects of any of the ordinary moral attitudes.

A second, ostensive, merit of the attributability approach is that it enables us to credit persons with responsibility for matters that are essentially private, matters that are the affair of none but the actor himself. It seems unreasonable to reply to my slovenly garb, or foolish financial practice, with resentment or indignation, just as it seems unreasonable to expect that I account for these practices if they affect no one but myself. Where these practices reveal something about ends I have chosen for myself, they speak to my character—they express, as Watson claims, my own evaluative commitments and my identity as an agent. Thus, on the attributability account, they can be attributed to me as practices for which I bear responsibility.

3. Responsibility and Free Will

3.1 Causal Determinism and Moral Responsibility

An adequate discussion of the central problems faced by any account of moral responsibility will include the problem causal determinism poses to the idea that we have freedom of will. In brief, the problem is that if our present choices and conduct are causally determined by past events and states, then it appears that we do

not have any freedom with respect to the performance or occurrence of our present choices and conduct. The past is something over which we have no control. And it is equally true that we have no control over the laws of nature operative in the world. Together, these claims suggest that we have no control over the present.

It is a matter of lively debate among philosophers whether or not the truth, or the likelihood, of causal determinism would affect our status as responsible agents. Some philosophers argue for the incompatibility of determinism and responsibility; if either obtains, the other does not. We cannot be both determined and responsible for our conduct. Others argue that the conditions for responsible agency are independent of determinism. On this view, the truth or plausibility of determinism aside, we can control our conduct in a manner sufficient for responsible agency. At the very least, to deny responsibility of persons whom we regard as participants in our moral framework would be to strain the limits of our natural practices. It is undeniable that persons treat one another as agents, as individuals answerable for their conduct, and that the alternative—that persons cultivate an attitude of detachment from the conduct of their human associates merely because of the truth of determinism—would signal an impoverished state of human interaction that few, if any, could bear.

Retail Trade

The term ‘retail geography’ describes the spatial structure of retailing, especially its transformation. The dominant methodology of the retail geography literature combines analyses of spatial demand patterns, producer behavior, and travel patterns, within the broader spatial patterns of economic activities. The geography of retailing is related to ‘marketing geography’ and the two terms are used somewhat interchangeably, although marketing geography encompasses the geographic patterns of consumption more broadly.

Explanations of the geography of retailing have traditionally been based on the conceptual frameworks of location theory (see *Location Theory*), especially the classical models of central place theory (Christaller 1933, Lösch 1941). Two themes, differentiated by the type of locational system investigated, developed early. The first studies the spatial pattern of periodic markets. The second focuses on regional systems of permanent retail outlets. A corollary of the difference between the two themes is their different regional foci. Studies of periodic markets are mostly centered in Asia, Africa, and Latin America, while the second theme has more of an Anglo-American focus. The third theme in the retail geography literature presents analytical methods of studying travel patterns to retail stores and of determining optimal locations.

1. The Geography of Periodic Markets

Periodic markets, which continue to be an important element of rural retail trade in many parts of the world, meet periodically at specific locations with set schedules, separated by market-less days or by days with limited trading activities. Such periodic markets are the basic component of the spatial structure of rural retailing in Asia, Africa, and Latin America. Skinner (1964) posited that periodic markets cor-

respond to the lowest levels of the hierarchy of central places that serve the need for goods and services in an economy. The markets associated with each level possess distinctive size, functionality, and periodicity characteristics (Berry and Parr 1988). Central place theory is a leitmotif in most studies of the geography of periodic markets.

1.1 Models of Periodic Market Systems

Stine (1962) was the first to develop a theoretical model to explain why markets are periodic. In low-density areas the level of demand is often too low to cover the fixed cost of a permanent store. Traders can overcome this constraint by visiting several marketplaces in a regular, periodic sequence to aggregate demand from a wider geographical area. Hay (1977) and Ghosh (1982), among others, extended Stine’s analyses. They outline the conditions under which a trader will adopt one of the following strategies—mobile or itinerant trading, part-time trading from a fixed location, or full-time trading from a fixed location. Traders may choose an itinerant strategy even when the expected profit at a fixed location exceeds the cost of operating a permanent store, if the incremental net earnings from a new location are greater than the sum of relocation and overhead costs. Similarly, mobility may allow traders to reduce prices and forestall competition. In general, the lower the relocation and overhead costs in relation to demand, the greater the likelihood of mobile systems. This is one reason why in many rural areas one tends to find large numbers of itinerant traders in markets that do not have a single permanent outlet.

1.2 Spatio-temporal Organization of Markets

An important geographic characteristic of periodic marketing systems is their integration of both the spatial and temporal dimensions of demand. Consumers perceive the adjacent marketplaces held on consecutive days—the market ring—as belonging to a particular spatio-temporal set of markets that serve their needs. According to a number of observers, the location and timing of markets have evolved to maximize access to consumers within a specified interpurchase interval. This leads to an inverse relationship between the location of two markets and the time interval between their market meetings. Markets that meet simultaneously or are separated by only a short time interval should be more geographically dispersed (Fagerlund and Smith 1970). A counter-hypothesis is that itinerant traders develop a sequence that minimizes their travel costs (Hill and Smith 1972). Empirical studies provide only partial support for the hypotheses.

2. *The Morphology of Urban Retail Outlets*

The organization of retail centers within cities follows a hierarchical pattern characterized by greater functional complexity of centers as one moves to higher levels of the hierarchy. The geographic reach of the center expands as one moves up the hierarchy due to its centrality, and retail businesses locate in different levels of the hierarchy depending upon the sizes of the market area required to generate adequate economic returns. The result is a hierarchical structure of retail locations similar to the tenets of central place theory. Much of the early literature on retail geography comprises empirical studies of urban retail hierarchies in North America and Europe conducted to test central place theory. Later the emphasis shifted to investigating the dispersion of retailing from urban areas by combining the analyses of spatial demand patterns with that of the changes in the social and economic conditions as well as changes in the organizational structure of the retail sector.

2.1 *The Transformation of Urban Retail Geography*

The dominant feature of the transformation of the post-World War II retail geography in North America and Europe is the shift of retail activities from city centers to suburbs. Before World War II, the central business district (CBD) ranked as the pre-eminent metropolitan shopping district, offering a vast array of goods and services and attracting shoppers from throughout the metropolitan region. That premier position started to fall in the 1950s and 1960s in large urban areas, and later in smaller cities too. While retail activity declined in the metropolitan core, however, it grew rapidly on the suburban periphery both in North America and Europe, reflecting the spatial redistribution of population and income in metropolitan areas (Davies and Rogers 1984). The suburb's share of retail sales increased significantly, and major shopping centers started to rival the CBD in retail sales volume.

The decentralization of sales was linked closely to the emergence of new retail formats. Shopping centers, housing diverse retail stores under one roof, represented a dramatic departure from earlier retail formats. Unlike the traditional downtown shopping district, they were planned, integrated complexes developed and marketed as a unit (Dawson and Lord 1985). Initially suburban shopping was concentrated along highways in strip malls and in neighborhood convenience centers. This was followed by the development of large, regional shopping centers, which became the focal point of the metropolitan retail structure, drawing shoppers from a wide geographical area. Thus, the new geography of retailing is much more dispersed than in the past, comprising a well-developed retail network focused on various levels of

regional and neighborhood shopping centers and shopping districts.

2.2 *The Context of Change*

The suburbanization of population and the evolving transportation infrastructure provided the motive force for the spatial dispersion of retailing. But institutional, financial, and governmental policies also shaped this new geography. The establishment of shopping centers was greatly encouraged by suburban municipal governments, who viewed shopping centers as an important source of tax revenues. Small municipalities on the outskirts of larger towns encouraged the establishment of shopping centers within their jurisdictions to attract shoppers from the larger towns, and, thereby, increase tax revenues. The growth of shopping centers was also facilitated by easy access to financing and financial arrangements that greatly reduced the developer's risk. The consolidation of the retail industry and the growth-oriented philosophies of department and specialty store chains further fueled the expansion.

While local governments in suburban communities actively encouraged the growth of shopping centers, their counterparts in urban areas viewed them as grave threats. Retailers in older, urban shopping districts faced two competitive disadvantages. First was the lack of population, income, and employment growth. Second was the general deterioration of the shopping environment, which reduced the CBD's ability to attract middle- and upper-income shoppers. Concerned by the erosion of urban retail business and its impact on city finances, a number of governmental programs and policies were initiated to encourage retailing in CBDs. Some of these new downtown retail projects included pedestrian shopping malls, retail facilities built within large downtown office complexes, and anchorless centers housing entertainment, recreation, food, and specialty retailing. They all represented departures from the traditional hierarchical structure of retail organization.

3. *Analytical Models of Store Location*

3.1 *Retail Forecasting Models*

The rapid expansion of suburban outlets created the need for a systematic approach to determining store locations, resulting in an array of techniques for site selection and retail sales forecasting. The key to forecasting retail sales is to delineate accurately the store's trade area—the geographic area from which the store draws most of its customers. The foundation of contemporary approaches to delineating trade areas was laid by Applebaum (1968) in his 'customer spotting' method. Huff's spatial interaction model (see

Spatial Interaction Models) extended the approach by looking at the complex interactions within the total system of retail trade areas in a region (Huff 1963). Underlying spatial interaction models is the premise that the share of customers a retail outlet attracts from an area is inversely proportional to distance and directly proportional to the attraction of the store. These models develop an empirical basis to determine the relative impact of distance and attraction on store choice, and conceive trade areas as probabilistic rather than deterministic, with each store in an area having some probability of being patronized. Huff's probabilistic revealed preference approach to modeling store choice was extended with more sophisticated analytical techniques and the definition of a broader set of variables to measure store attractiveness (Ghosh and McLafferty 1987).

3.2 Location-allocation Models

Determining the optimal locations for a network of retail outlets is a complex task, requiring decisions on the number of stores to locate, their locations, and their characteristics. All the decisions must be integrated within a single decision-making framework, taking into consideration the geographical pattern of demand, transportation, and corporate objectives. Location-allocation models systematically evaluate a large number of locations to find sites that optimize objectives such as market share or accessibility, taking into consideration system-wide store-location interactions (Ghosh and McLafferty 1987). Because the models can look at the impact of each store on the entire network of stores, they are ideally suited to analyzing the location decision of retail chains operating multiple outlets in the same market area (Achabal et al. 1982). Location-allocation is a flexible analytical system in that a variety of objective functions and constraints can be incorporated (Ghosh and Harche 1993). The combination of machine-readable economic and geodemographic data, geographical information systems software, and location-allocation models create effective location decision support systems (Birkin et al. 1996).

4. Conclusion

The structure of retail trade, like most economic activities, is shaped to a large extent by geography. Indeed, it is often said that the three secrets to retailing are location, location, and location. Although this oft-repeated adage is somewhat of an exaggeration, even in the era of e-commerce and electronic retailing, the geographical pattern of retail trade is shaped by the relationship between the patterns of consumer demand and store locations, mediated by consumer travel patterns. The literature on retail trade provides

frameworks for understanding how these forces, mediated by public and corporate policies, shape the observed pattern of retail trade and presents empirical studies from diverse regions of the world. It also presents analytical methods for locating retail outlets.

Retirement and Health

1. Retirement in Historical Perspective

Retirement as a structural aspect of the life course is a relatively recent phenomenon, institutionalized in industrialized societies only in the twentieth century. 'Retirement' is typically defined as later life withdrawal from the workforce, often in conjunction with public and/or employer-provided pension benefits. But growing numbers of workers retire from their career jobs and then take on employment in another job and/or unpaid community service. Retirement—in terms of eligibility for a pension—can no longer be equated with a one-way, one-time exit from the workforce or with the cessation of all productive activity. Neither is retirement occurring at one set age (such as 62 or 65). The proliferation of public and private retirement income programs have encouraged a worldwide trend toward progressively earlier retirement from career jobs (Delsen and Reday-Molvey 1996, Guillemard and Rein 1993), and greater heterogeneity in the age and nature of retirement.

2. Linking Health and Retirement

Scholars are only beginning to unravel the health correlates of both the exit from one's 'career' job and the final exit from any paid employment, as well as life after retirement. Three processes link health and retirement: social selection, role loss, and reduction of role strain.

2.1 Social Selection: Health as an Impetus to Retire

Declines in workers' health have been shown to shape their decision-making regarding retirement (Anderson and Burkhauser 1985, Mutchler et al. 1999). The best-laid plans for long-term employment or retirement timing can be destroyed by acute or chronic illness of oneself or one's spouse (or other relatives requiring care), with the onset of poor health promoting unexpected exits from the labor force. Thus, it is crucial that research on the health impacts of retirement appropriately control for preretirement health status.

2.2 Retirement as Role Loss

The second process is that of role loss. Leaving the workforce can have deleterious effects on health, given the corresponding loss of routine, relationships, identity, and purposive activity. Research has documented the importance of role occupancy for both physical and psychological well-being (Moen et al. 2000). Retirement can increase the vulnerability of those in later adulthood, removing them from the mainstream of society.

2.3 Reduction of Role Strain

Role exits such as retirement can also be viewed positively, as when workers leave a demanding or stressful job. In line with this reduction of role strain perspective, those who see their jobs as stressful or unrewarding are likely to leave the labor force early. Jobs that are demanding and provide little sense of control have been shown to be negatively related to health and well-being (e.g., Karasek and Theorell 1990). Moreover, poor health is more likely to encourage those with demanding jobs to retire (Hayward et al. 1989).

3. A Life Course, Role Context Perspective

A life course, role context approach to retirement (Moen et al. 2000, Musick et al. 1999) emphasizes the complexity of this transition. The three processes described above may well be operating at different points in the retirement transition for different subgroups or in particular circumstances. For example, health correlates may be related to the timing of retirement as well as retirees' location in the social structure (gender, race and ethnicity, socioeconomic status), their previous health, and the quality of their prior employment experience. Moreover, experiences and activities after retirement may be key to understanding health and well-being in the retirement years.

3.1 Timing of Retirement

Both policies (governmental and corporate) and cultural norms shape individual expectations and beliefs about the 'right' time to retire (Kohli et al. 1991, Settersten and Mayer 1997). The implications of 'early' or 'late' retirement or of postretirement employment for health and well-being are not clear. For example, research in the United States shows that men retiring early are not necessarily doing so for health reasons (Burkhauser et al. 1996). Some studies suggest that early retirement may have deleterious health consequences in men's lives, with early retirement pro-

ducing more negative effects than later retirement (Palmore et al. 1985), while others have found no change in health based on early retirement (Streib and Schneider 1971). However, in a survey of relatively young retired men in the United Kingdom (McGoldrick 1989) more than half reported improved health as a benefit of retirement, with a quarter seeing it as a major benefit. Health and retirement timing are obviously intertwined; if individuals retire because of health problems, they often feel better off without the physical and psychological demands of their jobs.

3.2 Gender and Linked Lives

Most studies of retirement have focused on men, but women are increasingly retiring from paid work with different experiences and consequences. For example, married women are more likely to retire at an earlier age than single or divorced women and often retire as a consequence of their husbands' retirement exit. A spouse's poor health may cause employed wives to remain in the labor force, possibly for financial reasons (O'Rand et al. 1992). And having to care for ailing relatives may become an impetus for retirement, especially for women (Moen et al. 1994, Pavalko and Smith 1999). The coordination of both spouses' retirements and its implications for each spouse's health remain topics for future research.

3.3 Conditions of Work

The psychological impact of retirement appears to depend both on gender and on previous job stress, with men who leave high-stress jobs experiencing a reduction in distress symptoms, and men who leave low-stress jobs reporting an increase in distress symptoms. There are fewer effects, in either direction, for women undergoing retirement (Wheaton 1990). As Herzog et al. (1991) found among older US workers, being able to work one's preferred number of hours (rather than more or less) is positively related to physical health and life satisfaction, and negatively related to depression, regardless of gender or occupational status. Those who stopped work and felt they had little or no choice reported lower levels of health and well-being than both the voluntarily retired and those working the amount they would like. Another study (Gallo et al. 2000) found that late-life involuntary job loss through downsizing was related to declines in both physical functioning and mental health. While particular conditions of jobs at one point in time have been associated with health and well-being on the one hand, or stress and illness on the other (Karasek and Theorell 1990), a life course, role context approach suggests the importance of considering an individual's work patterns throughout adulthood.

3.4 Employment Patterns, Health, and Mortality

The nature of jobs and career trajectories can have long-term health implications. Studies have shown that men retiring from high-status occupations and 'orderly' career paths experience better health and greater longevity than those in manual occupations or those who have held a series of unrelated jobs (Moore and Hayward 1990, Pavalko et al. 1993).

Most of the studies linking health with career patterns have focused on men. The whole process of retirement may well be a different experience for women than men, in part because of the historical difference in their attachment to the labor force. When men leave their jobs they are exiting from a role that has typically dominated their adult years. Women, on the other hand, commonly experience greater discontinuity, moving in and out of the labor force and in and out of part-time jobs in conjunction with shifting family responsibilities. Consequently, they are less likely to have the same duration of employment or accumulation of work experience as men (Han and Moen 1999), and may be more likely to already have fulfilling roles outside of employment. Whether the findings about the longevity and health benefits of orderly career paths and high-status jobs apply to women as well is an important topic for future investigation. One recent study suggests that employment for women in their 50s and 60s may slow the onset of physical limitations (Pavalko and Smith 1999).

Ethnic and racial minorities, as well as those low in socioeconomic status, are more disadvantaged in terms of their career paths, health, and retirement pensions, creating a cumulation of disadvantage in addition to their increased risk of retiring because of a disability (Shea et al. 1996).

3.5 Life After Retirement

Postretirement employment is a key, yet understudied, aspect of employment history. 'Bridge jobs' following retirement are often very different from the career jobs from which workers retired (Henretta 1992), but they may ease the potentially disruptive transition out of the labor force. It is important to examine both pre- and postretirement employment histories to fully understand the linkages between work, retirement, and health, and to consider various forms of productive engagement following retirement.

Both paid and unpaid work after retirement have been linked to longevity, health, and psychological well-being (Moen et al. 2000). This confirms the protective effects of role participation, but studies have shown that the *context* of that participation matters as well. For example, Musick et al. (1999) found that volunteering had a protective effect on

mortality for those with low levels of informal social interaction.

Another key context shaping life after retirement is marriage. Pienta et al. (2000) have shown the health benefits of marriage for those moving into the retirement years.

4. Retirement Exigencies and Possibilities

Most research shows that being retired has no deleterious effects on either physical or psychological health; most retirees say they are satisfied with their retirement and some even report better health (Atchley 1976, Quick and Moen 1998). The issue is not whether retirement influences health, or vice versa, but the pathways to health and well-being in the post-retirement years. Research evidence makes it clear that good health is an important prerequisite for the enjoyment of the retirement years, as is economic security (Szinovacz and Washo 1992).

Both increasing longevity and the aging of the baby-boom cohort suggest that the retirement passage is in considerable flux, as growing numbers of workers can expect to spend a considerable proportion of their life course retired from their primary career jobs. Moreover, retirees in the twenty-first century tend to be healthier, better educated, and more active compared to those in the middle of the twentieth century.

The retirement transition can offer an occasion for the development of a new identity and can foster the adoption of new roles and new health behaviors. Workers retire, not only because of poor health, but sometimes because of good health, wanting to do something else. And retirees with excellent health are more likely to return to the workforce (Mutchler et al. 1999). But there are few institutionalized opportunities for meaningful engagement after retirement (Riley et al. 1994). Existing structural arrangements, policies, norms, and practices fail to provide the opportunities and challenges that can fully exploit the possibilities of life—and health—after retirement.

P. Moen

Retirement, Economics of

When most people retire, they leave a full-time job and stop working entirely. However, for a substantial minority, retirement is not a simple transition from working full-time to not working at all. It is a complex process. Those who have been working for an extended period for a particular employer may leave that job. They may continue to work for someone else on a job that is less demanding. In some less common circumstances, the long term employer will allow the individual to phase into full retirement, by reducing the demands on the job, or hours of work. Some people may even leave the labor market and then return. This article describes the complex patterns that comprise retirement, and discusses the leading explanations for retirement outcomes.

Given this diverse set of outcomes, various researchers and government agencies define retirement differently. Because of the complexity of the retirement process, each definition of retirement oversimplifies the story. According to one definition, retirement occurs when a person stops work completely. Among the problems with this definition, many who continue to work are already in the process of retiring. Thus, this definition classifies many as not retired, even though they have left a long term job, are working in an easier job than they held for most of their work life, are employed on a part-time basis despite having normally worked full-time, are receiving a lower rate of pay than they were paid before they changed their job or work conditions, even though they may be receiving pension or social security benefits. Another definition pertains to leaving long term employment. This definition classifies a person as retired when the

older individual leaves a job held for 10 or 20 years. A problem with this definition is that it classifies those who have left a long-term job but are still at work as retired people. Not only does this definition classify those who are continuing to work, but are phasing into retirement gradually as retired, but according to this definition, people who are working full time but lost or left a job in their 40s or 50s are retired, even though they are not yet in the process of leaving the labor market. From the perspective of government agencies such as the Social Security Administration, or a firm's pension plan, a person may be considered retired when benefits are accepted. But many people work after having applied for or have received benefits. None of these definitions of retirement is correct or incorrect. Each definition attempts to reduce a complex process to one or another two-dimensional outcome. Consequently, a definition of retirement that is quite useful for one purpose may be not very helpful for another.

1. Data Describing Retirement Outcomes

To understand how retirement varies with age, it is useful to consider data from the Health and Retirement Study. This study is the leading source of data on retirement in the USA. It is also a model for retirement surveys that are now being adopted in other countries. Funded by the National Institute on Aging, every other year since 1992 this survey interviews 12,650 respondents who were born between 1931 and 1941, extensively tracking their retirement and other behavior. In a recent article some of the basic findings on retirement outcomes from the Health and Retirement Study are presented (Gustman and Steinmeier 2000b), and these findings are summarized here. One way to measure retirement is with self-reported status, a measure that incorporates the influence of a number of factors in determining whether an individual is retired, and considers three states: not retired, partially retired, and fully retired. At age 53, about 85 percent of men and 76 percent of women consider themselves to be not retired. Starting at age 54, the fraction not retired begins to decline, falling three or four percent for each year of age until age 61. At age 62 the share not retired falls precipitously, with a fifth of men and a seventh of women leaving non-retirement in that one year. At age 65, there is another large decline, with the fraction of men who are not retired falling 11 percent, and the fraction of women falling by 5 percent, leaving a little under a fifth of men and women reporting they are not retired at age 65. Thus from the perspective of many of the definitions of retirement noted, most people are retired after age 65. At the same time, from age 53 to age 65, the share of men reporting they are partially retired increases from 6 percent to over 22 percent, with the increase for women from 4 percent to 15 percent.

About 8 percent of full-time men and 6 percent of full-time women are still working after having left a long-time job, that is a job they held at age 45 that lasted more than 10 years. Although less than a fifth of the men and women are working full-time after reaching age 65, roughly another fifth classify themselves as partially retired. The percentages at each age of men and women who report they are completely retired are similar, but women are around 15 percent more likely to report that the retirement question is not relevant, presumably because they have not worked outside the home in a number of years.

Retirement status is not static. The number who are not retired in any year is determined in part by how many of those who reported they were not retired in the previous year remain not retired. It is also determined by how many who were not retired in the previous year leave that state for partial or full retirement. Finally, some people may classify themselves as not retired in a particular year, having previously been retired or partially retired. The same is true for the number who are partially retired or fully retired in any given year: those numbers depend on how many continue in the particular state from the previous year, how many leave the state from the previous year, and how many enter that state. Thus to understand the number reporting a given retirement status by age, we need to understand the flows into and out of, various retirement states over time. The Health and Retirement Study (HRS) is a panel data set that resurveys each respondent every other year. It records changes in retirement status over time as respondents age. In the HRS panel, 77 percent of the time respondents continue in the same Retirement State between waves of the survey—retired, partially retired, and not retired. In 17 percent of the cases there is a transition from greater to lesser work, and more difficult to model, 6 percent of transitions are from lesser to greater work. These transitions cumulate over the course of the survey. Altogether, 17 percent of the sample experienced a reversal in the course of the survey, moving from a state of less work to a state of more work.

Also of interest to students of retirement are trends in retirement outcomes. The aging of the baby boomers and decline in mortality have increased the financial pressure on social security and other retirement programs. One solution would be to postpone retirement. If people worked longer, the retirement period would be shorter and less costly. Instead, despite improving health, throughout the post World War II years, and until the end of the twentieth century, there was a continuing trend toward earlier retirement. Indeed, the trend to lower labor force participation by older males is one of the strongest labor market trends witnessed in recent years. (The trends in labor force participation and retirement for older women are not nearly as sharp. They are difficult to discern as the increased par-

ticipation of women in the labor market offsets a tendency to leave earlier.) According to data from the US Current Population Survey cited in Anderson et al. (1999), continuing an earlier trend, from 1947 to 1985, the fraction of married men over 65 in the labor force fell from 55 percent to less than 20 percent. For those aged 55 to 64, the trend to lower labor force participation started later. From 1957 to 1985, the share of married men in the labor force fell from 90 percent to less than 66 percent. Similar trends are found in other countries. Indeed, the decline in the labor force participation rate of males in the US from 1960 is actually relatively modest compared to other countries, with Japan and Sweden experiencing milder trends, while the UK, Germany, Belgium, Spain, the Netherlands, France, and Italy have experienced even greater withdrawal (Gruber and Wise 1999).

There is evidence, though, of a leveling off in the middle 1980s in the trend toward reduced labor force participation of older men. For example, in 1985 in the USA, men who were 55 years old in the Current Population Survey had a labor force participation rate of 79 percent; in 1991 the participation rate of 55-year-olds had increased to 81 percent. Similarly, between 1985 and 1991, the participation rate for 60-year-olds increased by one percentage point, from 66 percent to 67 percent, and for those 65 years old, participation remained the same at 26 percent. Participation rates did not resume their downward trend in the 1990s.

The trend to earlier retirement for men is apparent when retirement outcomes from the Health and Retirement Study, collected from 1992 to 1998 in the USA, are compared with retirement outcomes from the Retirement History Study, collected from 1969 to 1979. Using figures from Gustman and Steinmeier (2000b), between these two surveys, the fraction of 60-year-olds who considered themselves to be not retired fell from 80 percent to 66 percent. The fraction of 62-year-olds not retired fell from almost 66 percent in the 1970s to a little more than 33 percent in the 1990s. Only at age 65 are the fractions not retired similar in the 1970s and 1990s. A very large number of people retired in the 1970s RHS at age 65, with almost 20 percent of the sample leaving nonretirement. In the 1990s HRS, the comparable number leaving at 65 is a little more than half as large—many more have already left. These trends can be seen in the numbers who retire at any given age. In the 1990s HRS sample, 20 percent of the men left nonretirement at age 62. Although there is evidence that the trend to earlier retirement has abated in the past few years, there is a continuing debate about whether the trend will reassert itself.

Researchers have also focused on other aspects of retirement. The family is the center of decision making. Thus there is a question about whether couples coordinate their retirement decisions. It seems they do. Researchers have documented the coincidence of retirement dates for husbands and wives, despite age

differences and differences in incentives to retire (Gustman and Steinmeier 2000a, Hurd 1990).

2. Explaining Retirement Outcomes

Students of retirement behavior would like to explain what determines these patterns of retirement by age. Of special interest is the onset of substantial flows into retirement beginning at age 53 or so, the sharp increases in retirement that are observed at ages 62 and 65, and the transition for most out of non-retirement by age 65. Also of interest is the question of why a majority of people proceeds directly from full-time work to complete retirement. A substantial minority partially retires, but what determines how long a person stays partially retired? Why do most people reduce their work effort as they age while others sometimes increase work effort after having reduced it? Also, why do different people choose different ages to enter and leave full time-work, partial retirement, and full retirement? Similarly, researchers would like to know what has caused the trends to earlier retirement over time. Why has the number of people retiring at age 62 increased while the large spike in the number retiring at age 65 has been halved, and more generally what caused the changes in retirement outcomes at each age? They also would like to understand other key patterns in the data, such as the coincidence of retirement by husbands and wives, and how the new patterns of increased participation by women are affecting retirement outcomes.

To understand what determines the wide variety of retirement patterns, economists rely on a model in which forward looking decision-makers weigh the benefits and costs of alternative retirement dates. Older people decide when to retire by taking into account not only current work and leisure opportunities, but also future opportunities. These opportunities include the pay that would be offered for work on the current job, now and into the future, and the pay on alternative jobs. Involuntary layoffs affect these opportunities, reducing the offer for continuing full-time work. Incentives created by pension plans and social security play important roles, especially in shaping the future consequences of a decision to retire. These programs have features that may change sharply the incentive to work at different ages, first encouraging workers to stay in the labor market, then at a later age, reducing the reward to continue work. Against the monetary rewards to continue work, older individuals weigh the difficulty of the work. Whether these demands are physical or mental, they are likely to increase with age at different rates, depending on the job held. The opportunity cost of working is the value of leisure time. Health problems may increase the difficulty of work, and lower the reward to continued work if the individual becomes less efficient at certain tasks. Retirement decisions of spouses, and

demands from dependent children and elderly parents also help to shape the retirement decision.

It is differences in the rewards to continued work, the effects of social security and their differing pension plans on these rewards, differences in health status, job conditions, as well as different evaluations of the same set of benefits and rewards, that create wide differences in decisions of when to retire. There is also an interaction with the decision to save, and accumulated assets, leaving some more able to afford retirement at a given age than others with the same earnings history. Similarly, changes over time in wages, pensions, social security, and other factors determining the reward structure to continued work, as well as changes in the valuation of leisure, may affect the trends observed in retirement outcomes.

2.1 Key Explanatory Factors Affecting Retirement Outcomes

Consider now in more detail some of the leading factors shaping retirement outcomes and how they influence retirement behavior.

2.1.1 Wage offers for full-time work. Theory does not tell us what relationship to expect between the wage a person makes and retirement age. On the one hand, a higher wage implies greater forgone earnings when one leaves work. On the other, a higher wage implies a higher lifetime income, which should lead the high waged worker to prefer more leisure, just as those with higher incomes prefer more of other luxury goods. To date, the evidence suggests these effects are roughly offsetting, so that higher wages on long term jobs do not have a strong relation to retirement outcomes. There are other possible explanations that might allow the wage to account for an increase in retirement with age; for example, if wage offers declined with age, that might reduce the reward to continued work for older individuals. But they do not. Sometimes researchers record the wage rate received by workers at different ages and find that the observed wage declines with age. This effect is illusory. As workers age, some of the older workers have left their main jobs and are holding lower paying full- or part-time jobs as they transit to retirement. To be sure, some older workers experience layoffs, and, once laid off, older individuals certainly have greater difficulty locating new jobs, but that is not a dominating factor in shaping retirement.

2.1.2 Minimum hours constraints and lower wages when partially retired. There is evidence that many jobs do not permit older workers to phase gradually

into retirement. Rather, at the job they have held for many years minimum hours constraints allow the worker to choose only whether to work full-time, or not at all. Work is available on a part-time basis, but only at much reduced wage. These minimum hours' constraints, together with a lower wage offer when one works part-time, account for the decision by many to move directly from full-time work to full retirement.

Pensions and their provisions may account for some of the diversity in retirement ages. There are two basic types of pensions. One plan, called a defined benefit plan, provides a periodic payment after retirement that is based on a formula. The amount of the benefit is typically determined by years of service, age, and pay. So is the age of eligibility for receiving a full, unreduced, benefit (normal retirement age) and the age of eligibility for a reduced benefit (early retirement age). Defined contribution plans, which at the beginning of the twenty-first century are most often in the form of 401(k) plans, are essentially tax-favored retirement saving plans. Both the covered worker and the employer may contribute to an account, often with the employer matching the worker's contribution according to a set schedule, up to a predetermined amount.

'Defined contribution plans' do not create sharp incentives that affect the reward to remaining on the job, but defined benefit plans do. Those who leave a 'defined benefit plan' before qualifying for early retirement benefits may be penalized heavily. Conversely, an individual who stays until qualifying for early retirement benefits may be heavily rewarded. Studies of workers employed at firms offering defined benefit plans indicate that workers respond to these incentives. Among studies that pioneered in investigating the relation of pension plan incentives to retirement outcomes, see Burkhauser (1979), Fields and Mitchell (1984), and Stock and Wise (1987). According to pension data for respondents to the Health and Retirement Study (Gustman and Steinmeier, 2000c), defined benefit pensions on average had an early retirement age of 54, and an average normal retirement age of 61. Only 6 percent have an early retirement age above 60. Forty percent face a normal retirement age of 65; with 14 percent having normal retirement at age 62; over 20 percent with normal retirement at age 60; and over a fifth having a normal retirement age below 60. A man who has a defined benefit (DB) pension plan and works the year before qualifying for early retirement, on average, will find benefits increased by an amount equal to about 120 percent of one year's of pay. For a woman, the increase amounts to about a third of a year's pay.

In addition to contributing to the explanation for the diversity of retirement dates, changes in pensions account for some of the trend to earlier retirement. For the 1970s and 1980s, it has been estimated that

about 10 percent of the trend to earlier retirement is due to the decline in ages of early retirement in defined benefit pensions and to other changes in pensions (Anderson et al. 1999).

2.1.3 Social security. Analyses of retirement behavior suggest that social security has had a modest effect in influencing retirement, and that effect will decline for those now approaching retirement. Social security benefits are determined from past covered earnings history, where past earnings are indexed to age 60 and are averaged to a summary statistic called the Average Indexed Monthly Earnings (AIME). For those reaching age 62 after 1991, AIME is calculated using the highest 35 years of indexed earnings. If an individual has covered earnings for fewer than 35 years, then zeros are entered into the AIME calculation for the remaining years. From the AIME, the basic benefit, called the primary insurance amount (PIA), is computed. A progressive benefit formula is applied so that those who have low computed lifetime earnings have higher benefits, relative to earnings, than do those with high earnings. The earnings measure is typically expressed as a monthly amount, but when annualized, the formula for the year 2000 specifies benefits that are 90 percent of the first \$6,372 of annual earnings, 32 percent of the next \$32,052, and 15 percent of remaining earnings. Benefits to spouses and survivors affect the relationship between benefits and earnings, both at the level of the individual and at the level of the family. Spouses are entitled to roughly half of their partner's benefits, and survivors are entitled to an amount roughly equal to the benefits that would have been payable to the deceased spouse. The social security benefit is subject to an earnings test for those between the ages of 62 and 65. But any benefits that are lost to the earnings test are restored at age 65. Indeed, for married couples, the additional benefits from waiting until age 65 to claim benefits are worth slightly more than the benefits that were lost.

However, this was not always the case. In the past, the earnings test applied to earnings of respondents up to the age of 72. However, the age at which the earnings test no longer applies has been reduced slowly, until in the twenty-first century it only applies to those between the early and normal retirement age. Moreover, in the past, the adjustment for lost benefits was not nearly as generous as it is today. Initially, the social security benefit structure discouraged work after the age of 65. With recent changes, the program is roughly neutral in its effects on the incentive to retire. Thus social security in the past may have created incentives that accounted for some of the retirements, perhaps both before and after age 65. For example, it is estimated that changes in the benefit formula in the 1970s and 1980s may have increased early retirement by about an eighth. But social security should not have

any effect on retirements after the age of 65 in future years.

International evidence reinforces the view that pensions and social security have important effects on retirement behavior. With the aging of the baby boom, the worry in many countries is that pensions and social security discourage still productive individuals who would otherwise work to leave the labor force.

Different countries have very different pension and social security systems than the USA. Differences in design among countries create incentives to retire at different ages. The different retirement incentives created by the diverse retirement systems among countries provide another test of the influences of social security and pensions in shaping retirement behavior. Gruber and Wise (1999) have brought together researchers from a number of countries, both to describe retirement outcomes, and to see how their pension plans and social security systems affect retirement behavior. They find a close correspondence between the early retirement dates and other features of the programs, and the ages at which older workers tend to leave the labor force. Moreover, they find that when these dates of early retirement and normal retirement specified in the social security systems of these countries change, retirement behavior changes correspondingly. Compared to many other countries, the USA has a low relative tax rate on work after the early retirement age specified in the social security system, which is one reason for the higher labor force participation of older men in the USA. Countries with very high tax rates, which include Belgium, Italy, France, and The Netherlands, have lower participation rates by older workers than the USA.

Many researchers believe that social security has substituted for other forms of retirement saving. Many people enter retirement with no assets, and social security benefits as their sole support. Low-income families may have half or more of their earnings replaced by social security. Those who rely entirely on social security cannot retire before the age of 62. They do not have savings to draw on to support their consumption until they became eligible for social security benefits at 62. As a result, if the social security early retirement age were raised from 62 to 65, there would be a large increase in the number delaying their retirement.

2.1.4 Health status. Health changes are perhaps the most important of all the uncertain events affecting older workers' labor force participation. Data on the course of HRS respondents' health events from 1992–8 suggest a wide variety of health problems among workers, including limitations in activity, difficulties in carrying out mental and physical tasks, and medical problems such as high blood pressure. Both the level of health status and changes in health

status are associated with different patterns of labor force participation in the HRS (Bound et al. 1998).

2.1.5 Retirement decisions in the family. Findings at the end of the twentieth suggested that many spouses retire together, even though wives typically are younger than their husbands. Available estimates suggest that each spouse, and husbands in particular, values retirement more once their spouse has retired (Gustman and Steinmeier 2000a). It does not appear that husbands and wives time their retirements to coincide simply because of their pensions or social security. Other family related considerations might help to shape retirement. Some families married or remarried late, have young children, had a spouse who never returned to the labor market once having had children, or faced great demands on time to care for older parents, or a spouse. These and other differences among families may help to account for differences in retirement.

2.1.6 Other factors affecting the retirement decision. There is also evidence supporting the influence on retirement of many other factors that differ among individuals and their jobs. Labor market demands for older workers have been investigated. It is clear from this work that many firms are reluctant to hire older workers, because they will not work over a long enough period for their hiring and training investments to be repaid, together with other reasons (Hutchens 1986). The business cycle also influences the demand for older workers. On the one hand, in times of tight labor markets, firms will have difficulty replacing older workers and will encourage them to postpone retirement. On the other hand, in times of slack demand, firms adopt policies such as one-time windows that are designed to encourage earlier retirement. Those who invested more in training for the labor market by staying in school longer may work longer to justify their investments. Unions may shape retirement conditions both to accommodate the preferences of their older workers, and to share work with younger union members. Government policies might have had profound effects, but they have been pushing against the trend. Thus the government since 1980 has outlawed mandatory retirement, forced firms to make pensions more actuarially fair so as not to penalize work after the normal retirement age, and eliminated the penalty to work after age 65 under social security. Perhaps these policies have had some small effect in mitigating the trend to earlier retirement in the 1990s. However, there is no firm evidence to support that view.

2.1.7 Imperfect information and nonmaximizing behavior. Of course, the choices we see are deter-

mined by more than the maximizing choices made by people who fully understand all their opportunities. Many people do not understand fully the incentives from their retirement programs. Some plan well, some don't plan at all. In addition, some that are well aware of the importance of preparing for retirement do not have the discipline to follow through. Most people are well prepared for retirement. But if they have not prepared, they will either have to consume less when retired, or to work longer. Economic models are now being expanded to understand better the behavior of those who may not understand fully all the incentives, or for other reasons may not be choosing their retirement date according to a model of strict maximization. Certainly this work will modify our perception of how each of the factors discussed influence retirement choices. Nevertheless, the modifications are expected to be modest, and the major influences on retirement are the forces discussed.

3. Conclusions

Most of the information we have on how pensions, social security, health status, and other factors affect retirement outcomes comes from analyses that were based on 1970s data (e.g., see Gustman and Steinmeier 1986, Rust and Phalen 1997). The data from the new Health and Retirement Study are being used to estimate comprehensive models of retirement. With these newly available data, researchers are in a position to quantify how the factors noted in Sect. 2 influence retirement outcomes for those who are just a little older than the baby boomers. The wave of research now in process should also leave us in a good position to understand what will determine the retirement behavior of the baby boomers, and how changes in government social security and pension policies will affect their retirement outcomes.

Reviews, Critics, and Cultural Gatekeepers

It is argued here that the expertise of cultural gatekeepers does not pertain to the identification of those intrinsic properties that make cultural products into works of art. The expertise of cultural gatekeepers rather consists in following procedures that enable them to classify cultural products according to genre and to rank them according to quality. The use of these group-bound procedures enhances the chance that proposed classifications and evaluations will meet agreement from other gatekeepers. Empirical research has clarified the nature and effects of procedures used by gatekeepers, in particular by literary critics. These procedures seem to be endogenous to the institution of criticism, thereby suggesting its autonomy from other realms of society. However, when other cultural gatekeepers are taken into account, e.g., publishers, and when questions are posed about the content and value they attribute to cultural products, the procedures involved in this process manifest a complex interplay between a specific cultural sector and other fields of society. The autonomy of the cultural sector from other social sectors is relative in nature. All labels attached to cultural products, referring to their content, genre or value, are multi-dimensional in nature. What is to be understood by the value various parties attach to cultural products calls for cooperation between sociologists and economists: the former can profit from their insights into the nature of the procedures followed by cultural gatekeepers; the latter have their sophisticated analyses of value ('utility') to offer.

1. The Traditional View of Cultural Gatekeepers' Expertise

Cultural gatekeepers—reviewers, publishers, gallery owners, film producers—occupy institutional positions between cultural producers and consumers. They determine which products cross the boundary between the private and the public domains, and when this boundary is crossed, they propose classifications and evaluations of the products that are included in cultural repertoires. Gatekeepers are credited with

having professional expertise on what makes cultural products into works of art.

Giving or denying access to the public sphere is an eminently social task, yet the social sciences have been slow in developing a general perspective on what gatekeepers do, the conditions under which they operate, their practices, and their impact on the reputations of cultural products and their makers. One of the reasons why cultural gatekeepers have remained so long outside the scope of the social sciences is that, for centuries, cultural expertise has been believed to pertain to the *intrinsic* properties on the basis of which an individual cultural product may count as a work of art. This is an instance of 'charismatic ideology', to use a term coined by Bourdieu and Darbel (1969, p. 161). According to this ideology, works of art have the power to convince any rational being of their particular nature (i.e., that of being a work of art), and of their quality. If works of art can induce by themselves the recognition of their nature and quality, they must have specific characteristics which are lacking in other cultural products. The expertise of gatekeepers is believed to consist essentially in the ability to identify those intrinsic characteristics that induce the judgment that we are dealing with works of art.

However, as far as cultural gatekeepers are concerned, it is extremely hard to identify sets of general and firmly established procedures for interpreting or judging a poem, a movie, or a painting; similarly, there seem to be no clear-cut procedures by which works of art are classified as having a 'style' in common, or as differing from one another in this respect. In light of the charismatic ideology, the question of what procedures cultural gatekeepers use seems to lose its urgency: If one believes that works of art have persuasive powers, and if one believes that each work of art is unique, then it seems useless to suppose that the successful distinction between cultural products that belong to the respective domains of 'art' and 'non-art' requires explicit, let alone general, procedures.

In the nineteenth and twentieth centuries, the study of the arts developed into specialized academic disciplines. As a result, the question of which procedures should be observed in order to arrive at sound conclusions became preeminent. Literature offers a key example, for among the human sciences, the study of literature has produced the largest number of approaches to what counts as its central object of research, the literary text. Russian Formalism, Czech

Structuralism, New Criticism, Jakobson's linguistic poetics, reception aesthetics, and narratology are cases in point, not to mention Marxist, psychoanalytic, feminist, and deconstructivist studies of literature—all of which encompass a considerable number of widely diverging approaches. The privileged position of literature in secondary education has facilitated the proliferation of valutive procedures. Young students are initiated into how to 'appreciate' a nation's great literary works, and to a much lesser extent into appreciation for a nation's great movies, paintings, or musical compositions. The assessment of the value of the canonical works is constantly adapted to the needs of new generations.

In the recent past, two parallel, but mutually independent, developments have undercut the idea that cultural gatekeepers' expertise essentially pertains to those intrinsic properties that endow cultural products with the specific nature and quality of works of art. First, researchers have come to the view that value judgments are not statements which can be shown to be true or false. Moreover, they cannot be derived logically from descriptive or analytical statements to which the true/false distinction applies. Instead, any logical derivation of an evaluative statement from a descriptive one involves an appeal to 'institutional facts', i.e., to constitutive rules embodying norms and obligations to which one is committed (cf. Searle 1970, p. 175ff.). This has contributed to adopting a relativistic attitude towards values, in that they were seen as beliefs or views that are endorsed (or not) by specific social groups. A sociological approach to norms and values, and, in particular, to the value-laden distinction between 'art' and 'non-art' became urgent. It soon became a viable option because Bourdieu's work offered a framework within which the adjudication of 'symbolic value' to products, i.e., value deemed to be specifically cultural in nature, could be assessed empirically.

The second development, which made Bourdieu's views a viable alternative for research done in the humanities, was the extensive discussion of the methodological status of interpretations of literary texts and other forms of cultural expression. Again taking literature as the exemplary case, the outcome of this discussion showed literary criticism, as practiced in newspapers, in literary magazines, and at universities, to be linked tightly to normative conceptions of literature, i.e., to mostly implicit ideas about the characteristics a text should have in order to count as a form of literature (Verdaasdonk 1979, Van Rees 1986). In consequence of this, critics' statements about literary texts cannot be regarded as assessments of intrinsic properties these texts possess. Their statements show an inextricable mixture of classificatory and valutive aims (cf. Verdaasdonk 1994, 2001). It should be emphasized that not only literary criticism, but all studies of art and culture current in the humanities suffer from a similar lack of clear and

reliable procedures for identifying properties that are supposed to make cultural products into works of art.

2. *Empirical Research on Gatekeepers' Adjudication of Value to Cultural Products*

Bourdieu (1980) offers a comprehensive view of what critics, reviewers and cultural gatekeepers do in dealing with cultural products. The questions Bourdieu (1980) addresses are: What constitutes the authority of cultural gatekeepers? What factors affect the consensus they attain on the nature and value of cultural products? How do gatekeepers interact with one another in this process? Under what conditions do gatekeepers have an impact on audiences of art and culture?

In deciding that a product counts as a work of art, gatekeepers assign 'symbolic value' to it, thereby setting it apart from the set of products to which they refuse to give artistic status. Evidently, gatekeepers act as representatives of cultural institutions, such as criticism, publishing houses, movie studios, theaters, concert halls, etc. This largely accounts for the legitimacy of their decisions: as representatives of specific institutions, gatekeepers are seen—and see themselves—as being endowed with expertise that is socially acknowledged. However, Bourdieu stresses that this form of legitimacy is not sufficient in itself: gatekeepers may criticize decisions made by their counterparts; and critics and reviewers often have sharply contrasting opinions about the nature and value of particular cultural products. Gatekeepers' authority adds strongly to the legitimacy their decisions have in the eyes of other gatekeepers. Bourdieu holds that gatekeepers' authority essentially is the credit they have earned by making previous successful decisions—decisions that were adopted by their fellow gatekeepers. Authority is a reputation for success: it is *believed* that authoritative gatekeepers will be as successful in the future as they were in the past in discovering and promoting artists and their work. In this view, authority is not thought to be based on a successful determination of those intrinsic properties that account for the artistic status of cultural products; authority is rather conceptualized as the impact of a gatekeeper's stances on those of others.

Consensus formation among reviewers and critics about the value of cultural products, and the interaction these gatekeepers engage in, have been taken up by researchers. So far, the nature of gatekeepers' expertise and their relations with audiences have received much less attention.

Many researchers have taken a closer look at the forms of institutionally determined behavior that gatekeepers manifest in attuning their selections to those of their counterparts. It has been found that they strongly agree on which products have to be regarded as being of superior quality; and, conversely, they

attain much less agreement about how to classify and to characterize individual products. New literary releases that in the majority of newspapers were hailed as 'important' stand a much better chance of becoming, after a certain period of time, objects of scholarly attention (Verdaasdonk 1983). This suggests that, in the course of time, the selections made by a first group of gatekeepers are taken over by other groups of gatekeepers—with a certain amount of downsizing of the choices that were made previously. Van Rees (1983) has argued that reviewers in newspapers, critics in literary magazines, and academic scholars act as three successive filters through which, gradually, a repertoire of 'important' literary works is established. Ultimately, this repertoire enters the literature curriculum of secondary schools. The universities seem to follow the selections made by the scientifically less prestigious institutions of newspapers and literary magazines. Such research suggests that consensus formation among reviewers and critics is a process that is strongly reproductive in nature: Previous selections shape subsequent choices.

Do gatekeepers, in composing repertoires of noteworthy products, characterize them in the same way? This seems doubtful. Critics classify books, movies, paintings, etc. as having a certain 'style' or 'content' in common. De Nooy (1993) found that such classifications do not cross the borders of one single institution. The classifications which, in the 1970s, reviewers and critics proposed of the recent Dutch literary production appeared to be unknown to other gatekeepers, such as booksellers, librarians, and teachers of literature. De Nooy performed network analyses on these classifications and came to the conclusion that the groupings of authors were based on the specific magazines and publishing houses that featured these authors—although the critics held firmly that stylistic and thematic analogies, and differences between the texts concerned, provided the basis for their clustering.

The 'production of culture' perspective, advocated by Peterson (1976, 1985), holds that 'the nature and content of symbolic products [...] are significantly shaped by the social, legal and economic milieu in which they are created, marketed, purchased and evaluated' (Peterson 1985, p. 46). This view is fully congenial to Bourdieu's approach. However, posing questions about gatekeepers' behavior other than those addressed by Bourdieu, leads to different assessments of the interaction between factors which are thought to be 'endogenic' or 'exogenous' to specific cultural institutions, and to a fresh view on the nature of such factors. In their study of the American publishing industry, Coser et al. (1982, p. 146) found that, in judging book proposals or manuscripts, there were systematic differences between editors according to the type of publishing house where they were employed: Fewer than half of the university press editors or commercial scholarly editors rated profit-

ability or commercial prospects as the most important factor; in contrast, more than 60 percent of both textbook and trade editors listed commercial prospects as the single most important consideration. Trade and college editors are more concerned with first-year profitability, while scholarly editors pay more attention to long-term commercial success. Here, organizational differences affect the weight and the nature of judgments of quality and profitability, and of their interrelations. For these gatekeepers, 'denials of the economy', to use Bourdieu's term, are less possible than for gatekeepers deciding on a product's artistic status.

When questions about content are posed—the content of cultural products or of what gatekeepers say about them—the nature of the factors that seem 'endogenous' to the cultural sector and of those that seem 'exogenous' to it will shift. Griswold (1981) notes that after the USA recognized international copyright agreements in 1891, the themes of trade novels showed a strong convergence. American publishers did not concentrate any more on English novels about love and domestic life that could be obtained free of rights; American authors did not compete any more with these novels, by treating other themes that could also appeal to a large audience. Economic viability appears to be a major factor shaping the fare trade publishers brought out at the beginning of the twentieth century.

The cultural sector offers a huge and rapidly changing supply of products. Audiences also change—in size and composition. In many Western countries, an increase of participation in higher education has led to a growth and a refined segmentation of the audiences of art and culture. Of course, this has an impact on the behavior of gatekeepers. Cameron (1995) observes that classical music is marketed now by record companies as a mass consumption good. A number of marketing ploys has been used to reduce the entry barriers for consumers. One of these ploys is to provide excerpts of classical works. A free CD featuring these excerpts is distributed together with a magazine which reviews the CD in nontechnical language. This represents a change in the function of criticism and in its major task: The adjudication of symbolic value to cultural products. Cameron (1995, p. 328) says: 'The aesthetic dimension remains in the product but consumption is increased despite it.' In this example, the awareness of the market place takes a form that is very different from that envisioned by Bourdieu.

3. *Perspectives on Future Research*

As the above discussion shows, considerable progress has been made in pinpointing factors affecting the behavior of cultural gatekeepers. However, most models are 'static' in that they do not account for the impact of time on interactions between dependent and

independent variables. Gatekeepers' activities encompass a considerable period of time; their decisions are conditional on previous ones. Audiences change, as do the factors—and their interactions—that have impact on the production of cultural objects, and on their classification and evaluation. Many commentators, e.g., Peterson and Simkus (1982) and Griswold (1998) have pointed out that the traditional boundaries between 'high' and 'popular' culture undergo rapid and fundamental changes. This entails a focus on the variations in cultural products, their appraisal, and their consumption manifest over time. Griswold (1998, p. 34) speaks of a 'cultural swirl of mutual influence with multiple flows, no impermeable boundaries and few fundamentalists.' If cultural consumers are to be seen as 'occupying different positions in a differentiated distribution of knowledge and cultural resources' (Griswold 1998) this calls for a 'dynamic' approach to analyzing the behavior of gatekeepers, distributors, reviewers, and producers serving these audiences. As yet, longitudinal, time series, and event history data are rarely used in sociological research on culture. However, such data may be essential to capture the time-varying impact some independent variables may have on dependent variables.

Although many studies address the *modus operandi* of cultural gatekeepers, there has been scant attention paid to what constitutes their expertise. It has been argued here that gatekeepers are unable to identify those intrinsic properties that are deemed to account for the artistic nature and value of a cultural product. When it is acknowledged that meaning is not holistic or fixed, but is whatever works for a specific group (cf. Griswold 1998, p. 35), then the focus should be on the procedures gatekeepers actually follow in reaching agreement on the nature and value of cultural products. In the final chapter of *Distinction*, Bourdieu distinguishes between the practical mastery of classifications and the reflexive mastery that is required in order to construct a taxonomy that is coherent and adequate to social reality (1984, p. 472). This idea may also be useful to analyze the ways in which gatekeepers come up with taxonomies and value judgments. If one admits that cultural expertise does not pertain predominantly to knowledge of the intrinsic characteristics of cultural products, gatekeepers may be seen mainly as experts in executing specific tasks with regard to cultural products. Such tasks may be: Presenting a product to connoisseurs or laymen, elaborating on its meaning or value by making comparisons with other products, assessing a product's eligibility for a subsidy or an award, etc. The use gatekeepers make of their experience with individual products may vary with such tasks; the procedures they follow in order to arrive at results that are condoned by other gatekeepers may also vary, and may lead to different groupings and evaluations of the same products.

Future research on cultural gatekeeping is likely to address the still considerable gap between economic and sociological analyses. Frey and Pommerehne (1989, p. 12f), two founding fathers of economic research on culture, remark that sociologists tend to focus on the demand side of culture, whereas economists take the interplay between supply and demand into account. Most contributions to the economics of culture follow the neoclassical approach in asking questions about the determinants of prices of works of art, the rationality of multiple art markets (Singer and Lynch 1997), or the profit-maximizing behavior of consumers of culture. In these studies, a strong similarity is assumed to exist between the symbolic and economic value of cultural products (an assumption that sociologists, as discussed above, have been at pains to attack). The finding, for instance, that successful blockbuster movies feature megastars who account for the large audience these movies attract comes very close to making the assertion that movies with a huge production budget—megastars get gigantic fees—are more likely to enter the top 20 than movies made with smaller sums of money (cf. Albert 1998).

Economics and econometrics are well equipped to analyze many types of value assignments—manifested by preferences and by choices. Gatekeepers engage in choice behavior and develop preferences, but these processes have not received much attention from sociologists. Not only the process of value attribution, but also the question of how value develops over time—under what conditions does it accumulate or diminish?—is important. Combining economic and sociological techniques, it should be possible to determine how gatekeepers and 'ordinary' consumers perceive differences between individual cultural products, and how they go about assigning increasing, decreasing, or stable values to them.

Revolution

The term 'revolution' has evolved from a general notion of political 'turning-over' to refer more specifically to a rapid, fundamental transformation of the state and social structure, accompanied by mass uprising from below. Theories of revolution that emphasize structural conditions tend to focus on the revolutionary seizure of state power, while theories emphasizing actor motivations view revolution as an open-ended process of social transformation. This article examines the definitions and alternative explanatory frameworks, and considers the future of revolution in a changing global context.

1. Conceptualizing 'Revolution'

The earliest studies of comparative politics noted recurring conflict between elites and populace, sometimes leading to power 'revolving' from one group of rulers to another within a society. After the French Revolution of 1789, the term 'revolution' took on new meaning as a radical overthrow of the social and political order itself (Goldstone 1998). The nineteenth century European challenges to monarchic authority by the rising bourgeoisie and the class conflicts of industrial capitalism, punctuated by Marx and Engels' [1848] (1998) publication of *The Communist Manifesto*, focused attention on historical processes in analyzing revolution. After Lenin and Mao adapted Marxist theory to the Russian and Chinese revolutions (see *Marxism/Leninism; Maoism*), the decades following World War II saw a wave of national liberation movements against colonialism and neo-colonialism (see *Third World; Colonialism: Political Aspects*; and *Imperialism: Political Aspects*). Contrary to Marx's expectation that revolution would occur in the most industrialized capitalist countries, led by the proletariat, revolutions in the twentieth century occurred in the global periphery through mobilization of peasants and artisan workers.

1.1 Common Usage

The eclectic 'socialism' of many Third World revolts and nationalist movements, and their use of unorthodox tactics of guerrilla warfare—analyzed by practitioners such as Mao Zedong, Che Guevara, and Vo Nguyen Giap—led those characteristics to be generically associated with 'revolution,' as in Régis Debray's (1967) *Revolution in the Revolution?*. This usage was reinforced by Cold War counterinsurgency strategies aimed at forestalling radical change in national political systems, which were seen as extensions of the global East–West contest. The term 'revolution' moved away from this historically specific usage after the conservative religious turn in the 1979 Iranian revolution, the Eastern European uprisings against Communist Party states after 1989, and the end of the Cold War and other global power shifts.

Sometimes the term 'revolution' is used loosely to refer to any kind of paradigmatic shift, as in 'the Industrial Revolution,' 'the Reagan revolution,' 'the behaviorist revolution' in social sciences, or Thomas Kuhn's *The Structure of Scientific Revolutions* (1997). In another variant usage, 'revolution' is contrasted with reformism (see *Reform: Political*) to connote a radical political program, short time horizon, and willingness to use extreme (violent) means; as in Malcolm X's call for African-American liberation 'by any means necessary,' or J F Kennedy's warning that 'those who make peaceful revolution impossible

will make violent revolution inevitable' in Latin America.

1.2 Political Revolution and Social Revolution

The term 'political revolution' is employed to specify the application of the concept to a national political system. This usage does not include issue-specific social movements, nor all sudden changes of political power through *coup d'état* or civil war (see *Internal Warfare: Civil War, Insurgency, and Regional Conflict; Political Protest and Civil Disobedience*). However, 'political revolution' can refer to a wide range of revolts, rebellions, and mobilizational seizures of power—including those led from above such as the Japanese Meiji Restoration of 1868, Nasser's 1952 coup in Egypt, or the 1944–54 period in Guatemala—if they propose major lasting changes in the political order (Goldstone 1998).

Skocpol's influential work (1979, p. 4) proposed a more restrictive focus on 'social revolution':

Social revolutions are rapid, basic transformations of a society's state and class structures, and they are accompanied and in part carried through by class-based revolts from below. Social revolutions are set apart from other sorts of conflicts and transformative processes above all by the combination of two coincidences: the coincidence of societal structural change with class upheaval, and the coincidence of political with social transformation.

Even accepting Wickham-Crowley's (1997) substitution of 'mass' for 'class-based' to include ethnic and populist upheavals, this defines a relatively rare phenomenon. This definition is widely used by scholars of revolution.

2. Alternative Ways of Understanding Revolution

Goldstone (1980) usefully grouped explanations of revolution into three generations of theory, with a fourth generation emerging since the late twentieth century. In the 1920s and 1930s, a first generation of 'natural histories' of revolutions used techniques of 'thick description' and inductive logic based on empirical observation of major Western revolutions. These efforts to identify key actors, factions, sequences, and patterns helped establish the phenomenon of revolution as a distinctive subject of comparative study; for example, Brinton's (1938) classic, *The Anatomy of Revolution*.

2.1 From Description to Explanation

In the 1950s and 1960s, the upheaval associated with decolonization led to a second generation of 'general theories of political violence.' Some focused on the

individual psychological motivations of people experiencing frustrated expectations, as in the 'relative deprivation' approach later refined in T R Gurr's *Why Men Rebel* (1970). Frantz Fanon's *The Wretched of the Earth* (1965) interpreted political violence as redemption, healing the psychological wounds of colonization. Another branch of general theories sought explanations of political violence at the societal rather than individual level. Huntington's (1968) influential work drew on modernization theory, attributing revolutionary upheaval to economic modernization in developing countries, which raised expectations faster than they could be accommodated by the lagging development of political institutions (see *Modernization, Political: Development of the Concept*).

Critics of modernization theory in the late 1960s and 1970s pushed general theories of political violence in new directions. Tilly (1978) challenged the assumption that social systems were in natural equilibrium, arguing that conflict was normal, so explanations of political violence should focus on the relative resource mobilization capacity of power contenders. Moore (1966), in a sweeping macrohistorical comparative work, showed that there is no single, unilinear process of modernization. Extending Marx's class analysis to a more detailed classification of landlord–peasant relations, he combined this variable with distinct political forms of class struggle in agrarian societies undergoing commercial modernization, to map out different possible revolutionary outcomes.

Moore's (1966) work was the point of departure for Skocpol's (1979) ground-breaking study most associated with a third generation of 'structural theories' of revolution (see also her critique of Moore in Skocpol 1994). Shifting from the actor-centered focus that characterized general theories of violence, these theories highlighted the structural relations between units that created revolutionary opportunities. They built multicausal explanations based not only on class dynamics, but also on other aspects of the structures of society, the state, and the international system. Structural theories identified revolutionary conditions in the combination of administrative breakdown of the state, dissident elite political movements, a permissive world context, and widespread rural rebellion. Some like Skocpol and Goodwin 1994 focused on the types of state structures most vulnerable to revolutionary overthrow, including politically exclusionary authoritarian regimes (see *Authoritarianism*), neopatrimonial dictatorships, and directly ruled colonies. Goldstone (1991) examined the interaction of factors such as population growth with political institutions and social structure, developing quantitative indicators of revolutionary conditions. Structuralists defined revolution in terms of successful outcomes, distinguishing revolutionary seizure of state power from cases in which one or more necessary conditions were absent (Wickham-Crowley 1992).

2.2 Structure vs. Agency: Emerging Fourth-Generation Theory

An alternative to defining revolution as a set of structural conditions is to conceptualize it in terms of distinct systems of ideas and beliefs that subjectively mobilize actors. An emerging fourth generation of 'actor-centered' theories of revolution emphasize the defining role of ideology, culture, and identity of the subjects who make revolution. To borrow Mao's metaphorical observation that a single spark can ignite a prairie fire, these theorists shifted attention from the wind, temperature, and dryness of the grasslands to the spark itself. This contrasts with Skocpol's (1979) quotation of Wendell Phillips's statement that 'revolutions are not made; they come.'

Fourth-generation theories inspired new debates about whether revolutions can be accurately predicted on the basis of structural conditions (Keddie 1995), particularly in light of the surprising developments in the Iranian and Eastern European revolutions of the late twentieth century. Structuralists began re-examining the role of ideology in revolutions and the interaction of states with other domestic and international structures (Skocpol 1994). New insights from cultural studies and feminist theory challenged the more state-centered concepts of revolution (Foran 1997). These new perspectives defined revolution not as an outcome achieved by overthrow of the state, but as an ongoing process of transformation of society, involving both the institutionalization of a new order and the consolidation of a new ideology, guided with different degrees of success by different styles of leadership (Selbin 1999). As the Central American revolutions moved from armed conflict to a new dynamic of mobilization and negotiation, the idea of a revolutionary outcome or endpoint seemed less useful than the concept of revolution as process.

2.3 Rethinking Revolution in the Context of Globalization

The emergence of late twentieth century movements that both resembled and differed from earlier waves of 'revolution' suggested a need to rethink the concept. Some interpreted uprisings such as the Philippine 'people's power' movement and the Czech 'velvet revolution' as part of a new, democratic revolutionary wave. Others drew on world-systems theory to suggest that revolutions should be defined not as discrete phenomena of nation-states, but rather as transformations in the world system (Boswell and Chase-Dunn 2000). Thus the 'world revolution' of 1989 might be seen as an outgrowth of the shift in the capitalist world system, from the Fordist regime of capital accumulation based on industrial mass production to a regime of flexible accumulation, now regulated by global institutions governed by neoliberal ideology.

When Nicaragua's revolutionaries made history by turning over the state power they had won through insurrection in 1979 after losing elections in 1990, Sandinista leader Daniel Ortega vowed they would 'govern from below.' This vision, albeit unrealized, suggested a new way of thinking about where the essence of a revolution is found. The demise of state socialism fueled the search for radical democratic alternatives, rooted in autonomous action within civil society. As globalization undermined territorial definitions of social and political organization, shifting decision-making authority to transnational structures (see *Globalization: Political Aspects*), revolution seemed less about seizing state power. From the Internet-savvy Zapatista rebels of Chiapas, Mexico to the transnational antisweatshop movement and the 1999 Seattle protest against the World Trade Organization, there were intriguing signs of an emerging global civil society. These new forms of resistance against globalization stretched the boundaries of existing concepts of 'revolution.'

Revolutions, History of

This brief article on the general problems of studying revolutions is divided into five sections. The first will discuss the term 'revolution' as an historical phenomenon which has changed its meaning over time with important consequences. The second will discuss the issue of taxonomy or classification, attempting to exclude upheavals which are not really revolutionary, and to distinguish different types of genuine revolution. The third will discuss etiology or origins, examining the attempts of historians, political scientists, and sociologists to find common causes of revolution. The fourth will discuss morphology or the possibility of finding a paradigm. This section will discuss the problems of drawing a graph which has validity for the all of the great revolutions of modern times. This subsection will question the appropriateness of trying to place the course of major revolutions on a grid showing extreme right, right, center, left, and extreme left. The fifth subsection will make some concluding remarks.

1. The Evolution of the Term Revolution

Only a handful of historians and social scientists have paid much attention to the history of the term 'revolution,' despite the fact that this history casts light on important developments since the Renaissance. The term emerged from an obscure Latin word

meaning the periodic return of a moving object to its point of origin. Throughout the Middle Ages it was used in its Latin, French, and English forms to describe the supposed cyclical movement of celestial bodies around the Earth. Then it was popularized by heliocentrics following Copernicus's *On the Revolution of the Heavenly Orbs* in 1543. Galileo and his followers used the term repeatedly. Contemporary dictionaries reflected the domination of the term by scientists. In his famous French-English dictionary published in 1611, Randle Cotgrave defined the word as 'a full compassing; rounding, turning back to its first place, or point, th'accomplishing of a circular course.' Significantly, he gave no non-scientific meanings.

Gradually the meaning of the term began to expand. Poets and playwrights had already begun to appropriate the word. In *The Complaynt of Mars*, (1.03), written c. 1378 Chaucer speaks of 'hevenish revolucioun.' Then at the beginning of the seventeenth century Shakespeare pre-empted the word to describe his view of death. In *Hamlet*, when the grave-digging clown unearths a skull, the prince of Denmark reflects that it might have belonged to a politician, a courtier, or a lord: 'here's a fine revolution, an we had the trick to see't (v.1).' Shakespeare thus used the word to mean the return to one's original condition, earth to earth, ashes to ashes, dust to dust.

While literary men were using the term 'revolution' to mean a cycle, political commentators were already using it to mean a political upheaval. Several Italian authors used the word during the Renaissance to describe political turns of fortune, the replacement of one prince by another, in the city-states of Italy. Then in 1674 Alessandro Giraffi published a book entitled *Le Rivoluzioni di Napoli* to describe the rebellion of the Neapolitans against the Spanish viceroy. Another Italian and a Frenchman used the term to describe the same event. Moreover, Giraffi's book was translated into English within a few years.

In the UK most writers referred to the struggle in the middle of the seventeenth century between parliament and the king as the Great Rebellion, but some authors on both sides referred to it as a revolution, for instance the radical parliamentarian Anthony Ascham and the royalist Matthew Wren. In a letter to the Earl of Dorset in January 1646, the royal historiographer James Howell used the word to mean both a political upheaval and the cycle of the years: 'for within these 12 years there have been the strangest revolutions and the horridist things happen'd not only in Europe, but all the World Over, that have befallen mankind, I dare say since Adam fell, in so short a revolution in time' (James Hollowell, 1890. *Epistolae Ho-elianae*, Bk. III, 512). His contemporary John Milton also used the word in these two senses (*Paradise Lost*, II, Lines 597-603; VIII, lines 15-31).

Although the radical parliamentarians in mid-seventeenth-century England claimed that they were restoring ancient rights, they already had some

inkling of a new beginning. After the overthrow of the monarchy they spoke of Year I of Liberty, Year II, Year III, and so on for a few years. Some radicals even had a vision of society completely transformed. 'But why may we not have our Heaven here,' Gerrard Winstanley asked, 'and Heaven thereafter to?' (Sabine, 1941, p. 409). Nevertheless the idea of reversion persisted: even Winstanley was thinking of a return to a primitive simplicity. The royalists also used the word to mean a return to a previous state. For William Temple the return of the Stuart dynasty in 1660 and the Orange dynasty in The Netherlands in 1672 were revolutionary events in the cyclical sense of the word. Although in the second of his *Two Treatises on Government*, published in 1690, Locke defended the right to revolution, he used the word only twice, each time to mean a return via the state of nature to a previously existing constitutional position (1964, Cambridge edn. Paragraphs 223 and 225, 432–3).

Oddly enough it was not the Great Rebellion of mid-seventeenth-century England which made the word an important term in political vocabulary. Only after the Glorious Revolution in 1688 did lexicographers assign the word a political meaning. The use of the word to describe the overthrow of James II and the signing of the Bill of Rights by William and Mary gave the word a wider meaning. It was not quite a restoration of a previously existing order, rather it consolidated and advanced rights for which parliament had fought for the preceding century. Nevertheless, it was a very conservative event, entrenching the power in parliament of aristocrats, landed gentry, and rich merchants. Also, the Revolution was not seen as something with a universal application; it was viewed as English, unique, unrepeatable. The Bill of Rights of 1688 was not for all humanity.

Then in the last quarter of the eighteenth century the term came to mean a profound rupture with the past and the beginning of a new era. On the Great Seal of the US we see 1776 associated with the Latin motto *Novus Ordo Seclorum*, 'a new order in the ages.' Then the French Revolution consolidated and intensified the idea of a new beginning in history. Like the Commonwealth-men earlier, they renumbered the years starting in 1789. When the Republic was established in 1792 they began to number the years Year 1 of the Republic and so on. Finally, in October 1793 the Convention introduced a new calendar numbering the years, not from the birth of Christ, but from the inauguration of the Republic on September 22 of the previous year. Even more significant was that the French revolutionaries believed that their ideals would have a universal appeal. The three Declarations of Rights—1789, 1793, and 1795—were to apply to all men, not just Frenchmen.

Because of the cluster of revolutions in the late eighteenth and early nineteenth centuries revolution became recognized as a recurrent phenomenon. This in turn led to the appearance of a new character on the

world stage: the professional revolutionary. There was an apostolic succession of such characters—Filippo Buonarroti (1761–1837), Auguste Blanqui (1805–1881), Mikhail Bakunin (1814–1867), Piotr Kropotkin (1842–1921), Victor Serge (1891–1947), Sun Yat-sen (1866–1925), Mao Zedong (1893–1976), and many others. These life-long revolutionaries anticipated revolution, created organizations to bring it about, and formulated plans about what to do when it arrived. Thus was born the revolutionary political parties which changed the course of modern revolutions. Once such parties capture power, they are able to suppress opposition for very long periods. Until these parties are finally dislodged from power changes in policy can only take place by decisions within the party leadership.

2. Taxonomy

Many upheavals are labeled revolutions, but few actually qualify for the term. Most *coups d'état* do not qualify since participation in them is limited and their result is often confined to a change in government personnel. So-called 'palace revolutions' usually involve struggles with factions or families within the government. Rebellions should probably be excluded, not only because they do not succeed, but also because they usually lack a clear program and are often led by nobles who do not really want to destroy the existing political and social order. Even wars of independence are dubious candidates for the term, contrary to conventional usage. Even the American Revolution scarcely deserves this title. Although the War for Independence saw individual rights entrenched, considerable exchange of property, and a large emigration, the internal institutions of the new states were not radically different from those of the former colonies. Some African struggles in the twentieth century against European imperialist powers had arguably deeper internal repercussions.

Even among upheavals which deserve the title there are many degrees of revolution. There are political revolutions such as the Revolution of 1830 in France, which produce a change in the groups enjoying power, but do not shake society up very much. The great vertical upheavals or social revolutions such as the French Revolutions of 1789, the Russian Revolution of 1917, or the Chinese Communist Revolution of 1949, have led to deep social changes. The latter two, however, are not only political and social revolutions, but socialist ones as well. The Babouvist Conspiracy of Equals in France in 1796 was probably the first case of a group, in which some members supported a primitive communist ideal, which actually tried to seize power. Genuine socialist revolutions, attempting to control and redirect the means of production, could obviously not occur until socialism developed in the nineteenth and twentieth centuries.

Revolution in the deepest sense involves not only a change in the groups exercising power, profound changes in the social structure, and in modern times an attempt to change the control over the means of production, but also an attempt to change the way citizens think, feel, and act. There are glimmerings of such an attempt in the Hussite and Puritan Revolutions, but the French Revolution of 1789–1799 was the first to try to implement it in a large way. At the peak of the Revolution in Year II the *gouvernement révolutionnaire* tried to ‘regenerate’ citizens through an attempted mobilization of all the existing media: art, architecture, festivals, music, newspapers, theatre, and children’s books and games. Such use of the media has since become a feature of major revolutions on both the left and right, such as Nazi Germany, Bolshevik Russia, and Communist China. Comparative studies of revolutions seldom discuss this added dimension to revolution.

3. Etiology

There has been great attention to the question of the origins of revolution. If it were possible to establish common causes for revolutions, it would greatly simplify the study of the great revolutions since the seventeenth century, each of which has produced thousands of studies. Once common causes were identified, this knowledge would also be useful both to those anxious to promote revolutions and those intent on preventing them. The hope of applying social science for such purposes has produced such books as Michael Velli’s *Manual for Revolutionary Leaders* published in 1972, and on the other side the collection edited by Harry Eckstein (1963), intent on curbing such internal violence.

Since Aristotle there has been wide discussion of the etiology of upheavals, rebellions, and revolutions. Most historians, however, do not find the literature comparing revolutions of much use in understanding the revolutions in which they specialize. Many of them point to the problem of assessing the weight to be given to various factors at work, before and during revolutions. Unlike scientists who can run experiments in which all factors except one are held constant, historians cannot rerun events to test the role of certain factors. An historian, for example, cannot demonstrate precisely how the closing decades of the eighteenth century in France would have been different if reformers had been able to solve the financial problems, if those problems had not been exacerbated by intervention in the American War for Independence, if there had been a different King from Louis XVI, if he had not called royal troops into Paris in July 1789, if he had not tried to flee the country in June 1791, if the Girondins had not led the country into war in 1792, or if Robespierre had never been born. Similar questions can be posed about all subsequent revolu-

tions. Specialists try to weigh various factors by getting as deeply as possible into the complexities of each upheaval.

Aristotle argued that rival concepts of justice led to upheaval. Modern theoreticians such as Karl Marx, Max Weber, Pitirim Sorokin, Lyford Edwards, Jaroslav Krejci, Mark Hagopian, Peter Calvert, Chalmers Johnson, and host of others have focused on increasing tensions in societies leading to revolutions, provided there are precipitants and triggers. These tensions are described in various way including class conflict, other contradictions of various kinds, frustration of the expectations of certain groups, dissynchronization between social development and existing values, and other sources of disequilibrium. The fact that there have to be severe tensions in society in order to have an internal war seems a truism. The difficulty with such generalizations is in applying them to very different circumstances. Take, for example, the varying role of war. The American Revolution was made possible in part because the threat of invasion from French territories to the north had been removed by British victory in the Seven Years War. France was not at war when revolution broke out in 1789. In contrast, the government in Russia had been severely undermined by war by 1917. Also in China the long struggle with Japan contributed to the collapse of the Guomindang and the Communist victory in 1949.

Another important variation among revolutions is their very different objectives. As was mentioned earlier, there were no socialist revolutions before the twentieth century. Twentieth-century revolutions in Russia, China, Cuba, and elsewhere have attempted to seize and redirect the means of production. Related to this has been the attempt of countries such as Russia, China, and North Korea to force development in order to catch up with Western Europe and North America. Such a drive was not present in the Hussite, English, or French Revolutions, in fact the hope for a sudden increase in productivity could scarcely have arisen before industrialization, steam power, electrification, and the internal combustion engine. Comparing revolutions over five or six centuries seems to minimize new ideologies, in fact novelty in human history.

One way of looking at the objectives of various revolutions is to study how they were symbolized. In the French Revolution the dominant symbols were the figure of Liberty, which gradually evolved into the figure of the Republic, the Liberty Bonnet, and the Liberty Tree, none of which reappeared in the Bolshevik Revolution. Russian revolutionary symbolism featured giant figures of workers holding Hammers and Sickles, workers depicted as part of industrial machinery, electric lights in modernized villages, and of course red stars and flags. In Maoist China there were no symbols of liberty, but thousands of images of Mao like a red sun in the sky, numberless little red books of Mao’s writings, and endless images of peasants using muscular power to create terraced

hillsides, build dams, canalize rivers, and irrigate the lands. In fact their terraced hillsides became a symbol of using intensive labor to 'conquer nature.' Machinery was relatively inconspicuous until after Mao's death in 1976. The figure of Liberty was absent until students made her prominent briefly in the abortive democracy movement of 1989. Comparative studies of revolution have so far largely ignored different allegorical figures and symbols.

4. Morphology

There are similar problems with the attempt to find common patterns in the course of revolutions. One of these is that most historians, sociologists, and political scientists give much more attention to the origins of revolutions than to the inner dynamics which drive them forward, producing the curves so dear to social scientists. A further problem is how long a period one considers a curve. Jaroslav Krejci extends the Hussite Revolution over 50 years, the English Revolution over 60 years, and the French Revolution over 100 years. Can one speak of a single French Revolution over a century which saw two empires, three forms of monarchy, five revolutions (if one considers 1792 a revolution within the revolution of 1789–99), and numerous coups? Also, if you compare his graphs of the six revolutions that he covers—the Hussite, the English, the French, the Russian Bolshevik, the Turkish, and the Chinese Communist Revolutions they vary considerably from each other (1983, pp. 35, 67, 82, 117, 149). Moreover, his curves vary considerably from those published by Mark Hagopian (1974, p. 245). Also it is strange that Hagopian shows the Chinese Revolution dipping in 1958, the precise date of the Great Leap Forward. Obviously reducing great revolutions to scientific-looking graphs is a risky endeavor.

A further problem arises from placing revolutions on a grid marked extreme right, right, left, and extreme left. These terms arose from the accidental seating of conservative deputies to the right of the speaker in the Constituent Assembly in the French Revolution of 1789. In the liberal democratic revolutions in Europe and North America the left has usually meant those who supported genuine parliamentary government, political opposition, and defense of human rights. Can one, however, put the English, the American, and the French Revolutions on the same right-left grid as the Russian, Chinese, and Cuban Revolutions? Placing modern communist revolutions on the left distorts the original meaning of the term. These twentieth-century revolutions have introduced single-party regimes, have created assemblies which approve decisions already made by the leaders, and have violated human rights. In fact the way they have operated is very similar to governments on the extreme right, '*les extrêmes qui se touchent*,' as the French put it. This is another example

of the perils of applying the same grid to revolutions with very different objectives and consequences.

5. Conclusion

While it seems very difficult to establish a common taxonomy, etiology, and morphology covering all the major revolutions in the last five centuries, this does not mean that the comparative study of revolutions is not worthwhile. The history of the term 'revolution' demonstrates that it has taken on important new dimensions since it first became politicized in Renaissance Italy. The taxonomy of revolutions can exclude upheavals that are not full revolutions and can distinguish among political, social, and socialist revolutions, or combinations of all three. The etiology of revolutions is particularly problematical because the conditions that occur vary widely, nevertheless the idea that disequilibrium of some kind precedes revolution seems a valuable one. In many cases revolutions occur when society is changing while the regime stands still, but in the case of the Iranian Revolution of 1979 the reverse seems true, disequilibrium resulting from a westernizing shah moving more quickly than powerful conservative groups, especially religious ones, were willing to accept. On the other hand the collapse of the satellite Communist regimes in eastern Europe after 1989 seems to be the result of the failure of those governments to satisfy the needs of their citizens and the weakness of systems imposed by external force. As for establishing a common pattern or morphology, the differences in the graphs which scholars have produced warn of the dangers in such attempts. Those historians, however, who steep themselves in just one revolution, are very unlikely to recognize what is unique about the particular upheaval in which they specialize.

Since revolution has been a recurrent phenomenon, and may be so in the future, social scientists will doubtlessly attempt to reach general conclusions about them. In such future attempts more attention needs to be given to the internal dynamic of revolutions once they have broken out. The idea of attempting to create a new citizenry by mobilizing all the available media, which has marked revolutions since 1789, deserves further study. So too does the use of symbols, allegorical figures, and political images which have distinguished revolutions in modern times. Moreover, graphs based on a left-to-right scale need to be modified because the meaning of left and right has shifted drastically over time. Finally, the comparison of revolutions must bring out the unique dimensions of each revolution instead of focusing mainly on similarities.

Revolutions of 1989–90 in Eastern Central Europe

1. A Deviant Type of Revolution

The revolutions in Eastern Europe were no conventional changes of the system that can be dealt with in the tradition of sequence models. There

was no uniform anatomy of the changes, though never in European history have so many regimes collapsed at the same time and for similar reasons. Revolution was traditionally linked to violent change that made it different from coups d'état. Nevertheless, the depth of change made the events between 1989 and 1991 a political and a social revolution at the same time. In this respect it was comparable only to the Bolshevik revolution of 1917 and its later repercussions in the 'people's democracies' after 1945 in the realm of influence of the Red Army. This double revolution made consolidation of the new 'revolutionary regime' so difficult.

No former system's change was as burdened with the same problems of institution-building as this one. Authoritarian and fascist dictatorships may have changed the political institutions, but they hardly touched the system of stock markets and banks. There was no need in post-authoritarian regimes to create offices to administer unemployment insurance nor institutions for social security.

This process of transformation was so unique that the old notions of revolution and reform tend to be inappropriate. Perestroika in the Soviet Union was frequently compared to the politics of Peter the Great, the Meiji Revolution, or the innovations of the Young Turks in the Ottoman Empire. Reform was defined as an eclectic un-ideological process of un-dogmatic actors. The consequence was contradictory measures and even 'messiness' of reform. *Ex post facto*, perestroika proved its messiness. But was it really not ideological? This author prefers to list perestroika under the type of reforms from above, steered by the ideological thrust of a great leader.

In Gorbachev's self-perception, perestroika was a revolution. The old Soviet Union under Brezhnev started to accept rather loose talk about revolutions. Revolution lost its connotation of a process intended by political elites and by political means. It was watered down to processes that the Central Committee and the Politburo of the party were no longer able to control, thus demographic, environmental, and technological revolutions entered the discourse in communist countries. Gorbachev tried to use revolution again in a more political way. Perestroika was dubbed a 'second revolution' and Gorbachev hinted at Lenin who had already envisaged several revivals of revolutionary activities in the tradition of the great French revolution that failed to implement its goals in one coup and had to be repeated in 1830, 1848, and 1871. Western analysts, on the other hand, never used the term revolution in describing the process of perestroika.

Only at the end of perestroika had the term system's change found universal acceptance. It lacked the connotations of violence and civil war implied in the term revolution, but is nevertheless aimed at a far-reaching change of politics, society, and economics. The minimal criterion is a break-down of the old

system. This does not need, however, revolutionary force.

The revolutions in Eastern Europe were different from former revolutions because—with the exception of Romania—never have so radical changes been achieved with so little violence from below and from above. Eastern Europe proved to be a deviant case in the history of revolutions for several reasons:

Political modernization was achieved in two different phases. The system's change was a second attempt at modernization after the socialist attempts in 1917 and 1945.

The collapse of socialism resulted from a threefold dissatisfaction of East European populations: dissatisfaction with a repressive political system, with an inefficient economic system, and with the dominance of hegemonic ethnic groups within a federation (Russians, Serbs, and Czechs) or within the socialist camp (the Soviet Union vis-à-vis its satellites).

There was not the same continuity of periods as in Southern Europe in the 1970s with phases such as liberalization, democratization, and consolidation.

The new process of transition was burdened with the unique double task of transforming the political and the economic system at the same time, something which has never before happened in world history.

The new transition process was hampered by ethnic strife, which occurred to an unknown extent. Spain had experienced some of it, but managed to solve the problem by various autonomy concessions.

In former transitions, a new elite was ready to take over power. There was no real preparation for the new task in Eastern Europe. Even non-Marxist scholars sometimes believed in Marxist periodization schemes. They held that a system needed to develop an economic basis and a recruiting ground for the new political elite. The old regime developed the preconditions of change. Revolution was only the last blow for the old system. The simplicity of this concept of transitions did not even work in the great French revolution. Historians have shown that the French revolution did not abolish feudalism or establish a market society throughout the country. This process of accomplishing a true market society was not successful before the beginning of the Third Republic (1875 ff).

2. Reasons for the Velvet Revolutions

First, in the history of changes of regimes the leadership groups have frequently disunited. One part of the power elite started mobilizing the masses. In Eastern Europe this model did not apply. The elites remained quiet until the last moment. The technical intelligentsia did not develop into an opposition to the 'strategic clique' in power, as had been forecasted. The technical intelligentsia increasingly de-ideologized and created more room for maneuvering in its own field,

independent of political leadership. It avoided conflict, however.

Reformist elites in those socialist systems where the regime eroded slowly and revolution was pacted in a corporalist mood also avoided the appeal to the masses. In Hungary, the negotiated revolution took place with complete discipline and there was no unified counter-elite. In Poland, Solidarity could have been the counterforce, but in the last stage it was pressed by the people rather than directing the masses into conflict with the 'nomenclature' leadership.

Only in Romania—in the third model of a collapse of the system, but under control of a middle-level elite of the old regime—was there conflict among elite sectors. The military, after some wavering, finally sided with the protest movement, not so much because of ideological sympathies with the revolutionaries, but because of its rivalry with the Securitate armed forces. The military played the role of a rear guard—blamed by Lenin as '*chvostizm*'—but apparently the capacity to wait and see and to grasp the right moment for action in the rear guard is not always a negative feature, as Lenin supposed.

Second, the European fascist dictatorships in 1945 collapsed because they were defeated in a war. In Southern Europe and Latin America external factors contributed to the collapse of a regime (Greece, Portugal, and Argentina). In Eastern Europe the changes of the international situation facilitated the peaceful velvet revolutions. The Soviet Union still existed as a hegemonic power, but Gorbachev had indicated that the satellites could no longer rely on Soviet help in a case of internal strife. It was less the active behavior of a superpower, than the non-decisions of the hegemonic bloc power that did not intervene, which caused the collapse of the whole alliance. Theoretically, each national elite could have followed the Chinese example of bloody suppression. Why did this not happen?

The most important reason is again the international factor: the 'Brezhnev doctrine' was meant to strengthen weak regimes within the bloc. But the bloc center at Moscow was not prepared for a situation where all the leaderships of her satellites entered into troubles at the same time. The Brezhnev doctrine proved its dysfunctional consequences. It had spoiled the satellite leadership because they were always able to rely on big brother's tanks. Only Romania was the deviant case which did not recognize the doctrine and therefore had to provide for her own security. All of the other governments were not accustomed to big actions for their own security and caved in as soon as the masses confronted them directly.

The old regime in its last defensive stage pretended that the turmoil was caused by subversion from the 'imperialist powers.' This was wrong, since the Western powers were so accustomed to détente that they avoided direct actions for destabilizing the communist systems. It was not international but rather transna-

tional policies which contributed to the destabilization of communism from outside. The protest movements in the streets of Leipzig did not receive weapons, but got information instead from the Western media about the situation in the country, the counter-reactions of their leadership, and the points of rallying for the protest movement.

The international factor could explain certain framing conditions of the development, but nobody would have dared to forecast that the Soviet Union was so occupied with her internal problems that she had no capacity for intervention abroad.

Third, the most complex explanation of regime breakdown is the loss of legitimacy. In socialist countries legitimacy could not be measured by surveys. The mass media in the West, such as *Free Europe* and *Liberty* have tried to measure legitimacy by the instrument of mail from the East, but results were unreliable. In the early 1980s, it was calculated that the communists in free elections would not get more than 3–5 percent of the votes, whereas they actually received 10–15 percent in the most developed systems and much more in the less-developed communist regimes in the southeastern parts of Europe.

Was socialism ever legitimized? Its foundation by force was not forgotten by large parts of the population in the satellite countries. Acceptance of the regime was concentrated on the cadres. With growing success and material benefits, however, legitimacy grew also under communist conditions.

Paradoxically, communism collapsed due to its partial success, especially in the sphere of producing intellectually trained elites. There was a mobilization for education, which hardly had an equivalent in the Western world. Communist systems produced a surplus of elites, whom they were unable to funnel into meaningful positions. Western democracies do the same, as periodical overproduction of elites seems to be as inevitable as the famous pig cycle, causing economic slumps in the economic and political conflicts. Western systems, though, can offer jobs for the new elites in the third sector of services when the elites cannot be integrated into the bureaucracy. This tertiary sector was chronically underdeveloped in socialist systems. Only the systems that were able to coopt the dissatisfied young elites, such as Hungary, experienced a slow transition to the new regime. Here the rebellion could be dubbed as the 'revolution of the deputy heads of administrative units.'

It would be unhistorical to look for a legitimacy of the whole life span of socialism. Legitimacy had also ideological foundations, and beliefs in legitimization are subject to change. In the early days of revolutionary socialism, the system claimed a kind of teleological legitimization because the party pretended to know the outcome of history. In the Soviet Union this was certainly combined with charismatic legitimization in the time of Lenin. As time went on, however, both withered away, charisma as well as the capacity to

predict the development of history. Quite frequently, the people experienced false prognoses that undermined the belief in the ideology. As Max Weber predicted, the personal charisma of the leader did not survive the founding father. *Veralltäglicung*, the erosion of charisma, was the necessary consequence. Stalin tried to substitute for his lack of charisma through organization and ideological leadership in all questions: from literature to biology. But this kind of mixed legitimization was increasingly built on force. With diminishing capacities of the regime for repression and mobilization, new forms of legitimization had to be found. Communist repression had to be substituted by more legal security. In the early days, huge groups of defeatists and subversive elements were discovered. After Stalin, nobody believed in this kind of singling out of groups any more. Only 'parasitism' and 'chuliganstvo,' spheres where the Soviet citizen felt endangered for his own security, was he ready to buy from the Communist propaganda.

Communism failed to establish a certain balance between the four basic principles of legitimization in Western systems. The legal state was violated by arbitrary decisions of special hierarchies in the party, in the security forces, and in the planning administration. The nation state was increasingly invoked by official propaganda in order to reinforce socialist ideology, but the hegemony of the Soviet Union prevented the development of authentic independent national states, even if more systems tried to embellish the socialist dogma by the national colors. The democratic state was proclaimed by state propaganda, but in reality, for the citizens it was only manipulated participation without alternatives in the political arena. Certain ultra-democratic requisites such as 'recall' and 'imperative mandate' were operating only with a hint of the party, never because of a free decision of the citizens. Thus, the welfare state was used to legitimize the late socialist systems. In the early days, communist propaganda thought that a social state was unnecessary, because a socialist state is socially minded *per se*. But the leveling down of all social differences was no longer accepted by the leadership. Stalin had already denounced *uravnilovka* (excessive equalization).

During the years of economic growth, Hungarian Goulash Communism or Polski Fiat Communism developed a certain legitimization of the system, but in the 1980s it became clear that the communist countries were falling further behind the West. Communication with Western countries grew, which contributed to a growing capacity of the people to compare East and West. During the 1980s, the system lost its legitimacy due to the economic crisis of socialism, which was felt in most of the countries.

Transition studies on a quantitative basis confronted us with the finding that democratization is impossible as long as the power resources of a regime are highly concentrated. This assumption was not

Table 1
Pathways to democracy

	Pragmatic piecemeal engineering	Ideological innovation
Control from above	Opening of the communist regime (Romania, Bulgaria)	Innovation of socialism (Perestroika under Gorbachev)
Pressures from below	Erosion of Socialism (Poland, Hungary)	Collapse of socialism and takeover by the opposition (GDR, CSSR)

even correct in the case of the communist countries. All of them had the power to suppress the opposition and had in the 1980s increased their service in both staff and technological equipment. Paradoxically, some of the socialist countries, such as the German Democratic Republic (GDR) invested most of their technological innovation in the social control of the population instead of investing it in production. Nevertheless, the system collapsed. The enormous security equipment did not help the system survive: as was the case with the Chinese Wall, Rome's Limes in the North of the Empire, or France's Maginot line in 1940. Unlike these cases, the fabulous equipment was not even applied in the last conflict. The index of power resources of the old regimes proved to be of minor importance in the fourth wave of democratization. On the contrary, the better equipped a communist regime was with repressive capacities, the more radical was the change.

Three models predominated in the system's change of 1989 (see Table 1):

The erosion of the regime by corporatist bargains between the power center and the opposition in a negotiated revolution. This type of transition caused a low rate of participation among the people, because the change was paced by elites without participation of the citizen. Many voters apparently did not even realize the amount of change and the voter turnout stagnated between 50 and 60 percent (Poland, Hungary).

The implosion of the communist regime (Czechoslovakia, GDR). In this model, the control of the ancien regime was least developed. A new elite took power. Continuity of elites and institutions was lower than in the first path to democracy.

System change was achieved by the old cadres of the second rank who kept control of the transition (Romania, Bulgaria (until 1991), Albania (until 1992), Serbia, Croatia, and most of the Commonwealth of Independent States (CIS) throughout the first part of the 1990s).

Change proved most complicated in all the multi-ethnic states. The disintegration of the Soviet Union and Yugoslavia showed elements of a 'bargained revolution.' Bargaining, however, was done not by functional groups but by territorially old and new governments. In no case did the old federation survive and in no case was a new federation feasible after the collapse of the old regime.

Transition theories—in the tradition of theories about the developments of the 1990s—were most interested in the dichotomy between pact and dictate. This dichotomy was confronted with reform and revolution in a matrix (Karl and Schmitter 1991). Most of these matrices only offered a realistic picture of the initial phase of transition.

3. Democratization and Consolidation of the Peaceful Revolutions

'Transitology' as a new branch of knowledge dealing with the peaceful revolutions since the 1970s and 1980s originally used a sequence model along the lines: liberalization, democratization, and consolidation. Only in the model of transition via erosion of the communist rule did a liberalization take place. The period of democratization is normally identified with institution-building (constitutional power and secondary institutions such as parties and interest groups). This process was successful in most Eastern European countries but hardly in the successor states of the Soviet Union. Consolidation of elite attitudes (the 'only game in town' criterion developed by Juan Linz) and the citizens is incomplete in most countries. The Vicegrad states, which formed a unit of economic cooperation, and those which entered negotiations with the European Union (Poland, Czechia, Hungary, Slovenia, Estonia) are fairly consolidated even in terms of economic indicators. But also other systems—outside the CIS—have consolidated by experiencing several free elections, by reducing the volatility of votes, by avoiding violence, and reducing the weight of extremist parties by practicing alternating governments that included even the acceptance of a comeback of the post-communists that turned in many countries to democratic socialism (Lithuania 1992, Poland 1993, Hungary 1994). Most countries have changed the composition of their governments from The Czech Republic (1998) down to Romania (1996) without turning the critical election into a crisis of the system.

Not all the processes of consolidation were successful, however. 'Consolidology' as a new branch in the study of democratization discovered various types of unconsolidated democracies that have been called 'delegated democracies' or 'defective democracies'. Most of these defective democracies have implemented

a rather democratic mode of participation, but fall short of consolidation in the sphere of the legal state and the treatment of minorities.

K. von Beyme

Revolutions, Sociology of

The modern concept of revolution comes out of one particular experience at the end of the eighteenth century, an experience that led some to hope for and others to fear similar occurrences. Reflections on the nature, causes, unfolding, and consequences of revolution were for a long time dominated by the French Revolution. As other cases came to preoccupy social scientists in the course of the twentieth century, and

particularly in the wake of the varied social upheavals after World War Two, scholarly reflection on revolution flourished as it developed in new directions.

1. An Old Word Takes on a New Meaning

'Revolution' (from Latin *revolutio*) initially had the sense of a return to a point of origin. In political discussion it might be used to characterize a dynastic restoration. By the seventeenth century it had also taken on the sense of an alteration in fortune and might be employed to describe some significant improvement or deterioration in political affairs. In this latter sense revolutions were often seen as frequent occurrences in the histories of states. For some eighteenth century writers, the installation of a new monarch in England in 1688 was a great singular revolution in the older sense of a return to an initial state of order after several tumultuous decades; for others it was but one of many revolutions that marked all of English history.

A century after this 'Glorious Revolution' in England, the geographic range and social diversity of French turbulence in 1789 and beyond (rural and urban insurrections throughout the country; military mutinies; elite challenges to royal authority; priests defying bishops; a tidal wave of legislative enactments) provided many revolutions (in the plural) for commentators to reflect upon. But as these upheavals continued to multiply and as various contenders sought to channel the dramatic events in one or another direction, participants began to speak of these many separate events as components of something singular, the French Revolution, that had a structure and causes, that was an ongoing process, and that rival contenders sought to understand and control. Some participants who were disappointed by specific events in France could even imagine that this particular process was but an instance of possible revolutions and look forward, as one radical group declared in 1794, to 'another, far greater, far more solemn revolution' of which 'the French Revolution is but the forerunner' (Furet and Ozouf 1988, p. 203). So some sought to make new (and perhaps differently constituted) revolutions and others to avert them; and theorists of either (or neither) persuasion sought to understand them.

Until 1917 the French instance was the central source of empirical evidence of what a revolution might be like. Much sociological reflection was profoundly stimulated by spectacular failures of radical causes to seize and hold power despite episodes of impressive popular mobilization such as the widespread European turbulence of 1848 or the Russian upheaval of 1905. But theorists were paying relatively little attention to social conflicts in lesser powers. Even well into the twentieth century, other revolutions, both imagined and experienced, were apt to be understood

with concepts derived from that French experience. Military terminations of popular upheaval were held to be 'Bonapartist'; Russian revolutionaries accused each other of being 'Thermidorians'; it has remained very difficult to think of political conflict without invoking notions of 'left' and 'right' (initially, spatial locations in revolutionary France's legislature).

The Russian Revolution of 1917 added some new possibilities to stimulate imaginations; the post-World War Two era, with its many anticolonial struggles, civil wars in which at least one party has claimed itself to be revolutionary, and regime transitions of many sorts, has provided even more food for thought about the causes, dynamics, and consequences of revolution. By the late twentieth century, the French dramas from 1789 on no longer stood as the central model for theoretical contemplation.

2. An Elusive Definition

Despite two centuries of reflection and an extremely vigorous body of comparative scholarship on revolution in the last quarter of the twentieth century, the very definition remained in dispute. First of all, to the extent that notions of revolution were abstracted from that singular French experience rather than from some sense of the commonalties of a large number of experiences, observers could readily differ on what they thought were defining features. Some of the elements that, in varying combinations, entered into various definitions might include:

- (a) Illegal seizure of national political power.
- (b) Extensive property transfers.
- (c) Radical alteration in the form of government.
- (d) Pervasive change in a wide variety of institutions.
- (e) Extensiveness of popular mobilizations.
- (f) Substantial violence.
- (g) New formulas for the legitimation of authority.
- (h) A new elite's claim to be effecting a radical break in the course of history.
- (i) A new elite's claim to be advancing forward to a new level of human progress.
- (j) Widespread sense of profound change.

Although scholars have never achieved consensus, this definitional debate opened up a whole host of fruitful questions about how these phenomena might be connected to one another.

Second, like many other concepts that are used by political actors, the term revolution has continued to be a term of legitimation and delegitimation rather than simply analysis. All sorts of things have been labeled (or not labeled) as revolutions in order to honor or dishonor them. This has been terribly confusing. A grammatically simple sentence, 'Revolutions entail considerable violence' might be any of at least four very different sorts of statement: part of a *definition* of revolution; a *proposition* about revolution

(when defined without reference to violence); an *exhortation* to violent tactics (when uttered among committed revolutionaries); a *condemnation* of revolution (when uttered among people who abhor violence).

3. Major Research Traditions

Divergent emphases fueled overlapping but distinguishable traditions of research on popular collective mobilization, regime overthrow, political violence, elite dissidence, governmental legitimation and delegitimation, institutional change, and class conflict, and a good deal of reflection on how such processes affected each other. Beginning in the nineteenth century, a well-developed Marxian tradition examined ways in which long-term economic transformations created new group identities and interests while altering political structures. Revolution was seen as a traumatic readjustment of power relations, at bottom driven by the shifting economic interests of rational actors. A theoretically more diffuse body of work looked for strains of various sorts produced by industrialization, urbanization, and secularization and tried to explain collective outbursts as responses to such strains. In such interpretations, revolutions were apt to be seen as 'moments of madness,' as frenzied and doomed responses to the forces of modernity, for example, in Durkheimian notions of 'breakdown' or in the 'collective behavior' research tradition (see *Collective Behavior, Sociology of*). Tocqueville's thesis linked the growing might of a rationalizing state with a broad array of cultural transformations that undermined the legitimation of aristocratic privilege by transferring to the state activities previously carried out by the lords; indeed the lords might themselves become oriented to serving the new state bureaucracy (see *State, Sociology of the*). This attack on the problem lay relatively undeveloped in twentieth century social science until revived by a renewed sociological emphasis on the state from about the 1970s.

Although abstract definitions of revolution continued to vary widely, the field of comparative studies of revolution developed despite varying notions of what relevant instances might be. Some scholars attempted to find processual uniformities and constructed models of the 'natural history' of revolutions. Others looked for some robust causal mechanism that could serve as necessary or sufficient conditions (or both). This latter research tradition was dominated by the search for sources of increased grievance, as in a variety of theories that stressed economic downturns. A very different research tradition, impressed by the role of revolutionary parties in the twentieth century, sought to examine the capacities of relatively small but organized groups, to take action, to catalyze changes in ideas, or to mobilize broad support.

4. *The Post-World War Two Era*

The social upheavals of the post-World War Two era brought many new instances of collective action, political violence, and regime overthrow into play. Anticolonial movements, some defeating great powers (as in Vietnam); long-term rural warfare with divergent outcomes (as in Guatemala and Nicaragua); and Third World state breakdowns (some leading to radically new regimes, as in Iran) all added new cases.

The vastness of human suffering so evident in the twentieth century increasingly suggested attention to opportunity as well as grievance in the genesis of revolt and the success of revolution. Since revolt was so much more scarce than misery, it was evident that something other than (or at least in addition to) misery was needed to explain dramatic struggle for change, and social scientists became adept at identifying structures and moments that furnished opportunities. If one peasant community rather than another supported a revolutionary movement, social scientists now sought an understanding of what resources in the daily lives of these (but not other) peasants might account for why these (but not other) peasants revolted. If one revolutionary party in a small, poor country (for example, Nicaragua) succeeded in coming to power, while another revolutionary party in another small, poor country (for example, El Salvador) succeeded only in sustaining a bitter, stalemated war with the government, social scientists began to explore the differential vulnerabilities of different kinds of regimes. Distinguishing long-standing differences in resources available to rebels from temporary opportunities, and distinguishing stable structures of elite domination from specific policies, became very important for this research tradition. A 'structural' school of explaining revolution was emerging.

But accounts of favorable structures soon seemed incomplete as well. The Iranian Revolution of 1979, in which many leading participants spoke a religious language at radical variance with the language of those who had come to power in previous, paradigmatic cases, brought many scholars to reconsider the role of cultural elements in revolutionary processes. The sudden breakdown of communist regimes in Europe were accompanied by extensive property transfers, but the victors claimed to be undoing revolution, even to be terminating the dream of revolution, which again raised important questions of culture as well as structure (see *Postsocialist Societies*).

Many of the instances in the second half of the twentieth century were occurring in lesser powers on the world stage, in places obviously subject to military, economic, or ideological domination by more powerful states, and whose upheavals often involved attempts (some partially successful) to throw off some of these forms of domination. One would hardly try to understand anticolonial revolutions without paying attention to the policies and institutions of colonial

rule, social upheavals in countries exporting tropical crops without paying attention to the world economy, and the resources available to governments and rebels in small, poor, and weak countries without paying attention to the capacities of both sides to elicit support from great powers.

Insights garnered in examination of the newer instances began to suggest different emphases in new examination of older cases. The French or Russian revolutions were looked at as cultural processes; the embeddedness of the 'great' revolutions of the past in transnational connections was noted; and conflicts beyond the few previously paradigmatic instances entered the comparativists' field of vision. The very variety of participants in the newer cases expanded the intellectual horizons of researchers. As varying combinations of participants in the newer cases became evident, comparative scholars were recognizing how multisided the conflicts were in past revolutions as well. Revolutions, both past and recent, were increasingly likely to be seen as complex affairs, in which governing authority failed in many different ways, elites divided in many different ways, and rebels mobilized in many different ways. Methodologically this meant that social scientists were likely to be looking at configurations: at complex intersections and interactions of processes that mobilized collective actions of varying kinds, produced elite conflict, and weakened governing institutions. Theoretically it means that the search for generalizable statements about necessary or sufficient conditions for revolution needed to be rethought.

5. *Emerging Directions in the Sociology of Revolution*

The issues engaging comparative scholars in the late twentieth century meshed with some of the large issues engaging macrosociology generally, indeed, were suggesting revolutions as a fertile terrain for engaging those issues. Among the issues generating much discussion:

(a) *How to integrate cultural accounts with structural ones.* Cultural issues were an emerging agenda in various ways. Social historians were making enormous advances in understanding popular culture in varied times and places. A new generation of scholars was examining the overt cultural politics of revolutionary elites. The direction of regime change in such places as post-Shah Iran and post-communist Eastern Europe seemed altogether impossible to discuss without considering legitimating ideas.

(b) *How to integrate accounts of individual action with macrostructural processes.* As elsewhere in sociological theory this constituted a major challenge. Proceeding from assumptions of individual rational actors, how could one account for the forms assumed

by collective action, especially in light of the often evident individual risk assumed in participation in revolutions in combination with their uncertain and often undesired outcomes? (see *Action, Collective*).

(c) *Adequate attention to the visions of revolutionary elites, the wellsprings of popular mobilizations, and the interaction of the two.* Some structural accounts seemed to make the visions and intentions of revolutionary leadership inconsequential; some other accounts seemed to make them everything and by implication ignored the motivations, intentions, and wishes of ordinary participants. Some urged us to consider how it was that some revolutionary parties managed to win the adherence of large numbers of followers; others urged us to see popular participation in revolution as rooted in the structures and culture of the popular classes and therefore quite separate from the concerns expressed by revolutionary elites. The empirical difficulty in getting these connections right remained a challenge in studies of particular revolutions, let alone efforts at comparative statement. Poorer, anonymous participants not only often lack the means to make their own wishes widely known (peasants seizing land are less likely to hold press conferences or write memoirs than revolutionary agriculture ministers), but are, also as usual, often highly motivated to conceal their intentions (especially in highly charged situations like revolutions). It is a major methodological problem that revolutionaries who claim to speak on behalf of, say, Central American peasants, are rarely peasants themselves.

(d) *Attention to the outcomes of revolutions.* The consequences of revolution for economic well-being, state power in the international arena, the rationalization of administration, national identities, citizenship rights, and democratization remain intensely controversial matters about which relatively little systematic investigation has been done by comparativists.

(e) *How to integrate accounts of revolution with other kinds of political conflict.* Scholars of revolution were increasingly making use of tools that resembled those used by other students of politics: attending to the play of threat and opportunity, the variety of resources, the forging of identities in struggle, the irony of unintended consequence, the gaps between elites and ordinary participants (and the interaction between the two). Increasing interchange with scholars of other modes of conflictual action (urged by Doug McAdam, Sidney Tarrow, and Charles Tilly) seemed a probable future direction (McAdam et al. 1997).

(f) *How to make superior use of comparative methodologies.* With increasing recognition of the complexity and diversity of revolutionary processes, the very logic of comparison was coming under heightened scrutiny. If revolutions are complex amalgams of multiple conflicts, some comparativists suggest that rather than searching for some single general cause, or some single general process, or some set of causes whose separate contributions to revolution

may be simply added together, there may be multiple configurations of causal processes which produce revolutions, which themselves unfold in a variety of ways. Some scholars sought to distinguish varieties of revolution about which valid generalization might be made. Others suggested that the way forward, theoretically, was to seek generalizations about much smaller processes, which were components of revolutions, but which combined together in so many distinct ways as to defy generalization on that concatenated level. That is to say, in this view 'revolution' is a complex made up of many components, and one revolution is made up differently from another; looking for uniformities in the class 'revolution' is hopeless, but there may be regularities in the causation or action of some of the components.

6. Conclusion

More than two centuries of reflection since 1789 have hardly exhausted the stimulation provided by revolution to the thinking of social scientists; if anything, the last quarter of the twentieth century saw a tremendous intellectual reinvigoration. This is likely to continue, for revolutions seem a particularly privileged terrain for many significant issues in macro-sociology, among which I indicate four:

- (a) the intermingling of change and persistence
- (b) the interplay of long- and short-run processes
- (c) the relationship of local, national, and transnational processes
- (d) finally, the collision of hopes for change and recalcitrant realities.

Revolution brings to the fore all the many issues that have swirled around the interplay of 'structure' and 'agency.' There are no other social processes which so strikingly juxtapose the capacity of human beings to construct for themselves previously unrealized and unexpected patterns alongside the incapacity of human beings to construct their world as they please.

Revolutions, Theories of

Theories of revolution are (or purport to be) causal explanations of revolution—they say that if certain sufficient conditions (the causes) occur, then revolution (the effect) will occur as well. But *revolution* has different meanings, and theories of revolution do not all explain the same facts—different theories explain different facts as well as cite different causes. Before analyzing theories of revolution and the problem situation they address, therefore, one must distinguish between the different facts that those theories would explain—the different events that *revolution* refers to.

1. Definitions

Some theories explain revolution mainly in the sense of a revolutionary movement—a concerted attempt to change government, regime, or society (or all three) by means of violence. Other theories explain revolution mainly in the sense of a revolutionary outcome—a successful change of government, regime, or society (or all three) by means of violence. Still other theories explain revolution mainly in the sense of a revolutionary situation—a contest for state power by means of violence that begins when insurgents claim sovereignty and ends when they overthrow, succumb to, or make peace with the government.

A revolution in one sense can occur without a revolution in the other senses occurring as well. A

revolutionary movement can occur without a revolutionary outcome occurring because revolutionaries can fail. A revolutionary outcome can occur without a revolutionary situation occurring because the government in power can make a 'revolution from above' *à la* Stalin and because revolutionaries can take power legally *à la* Hitler. And a revolutionary situation can occur without a revolutionary outcome occurring because the government under siege can win. But neither a revolutionary situation nor a revolutionary outcome can occur without a revolutionary movement occurring because they each entail revolutionary violence, which takes concerted effort to commit.

The above definitions of revolution overlap with common social science usage, which calls a change of government by means of violence a *coup d'état*, a change of regime (as well as of government) by means of violence a political revolution, a change of society (as well as of government and regime) by means of violence a social revolution, and a contest for state power by means of violence a civil war. Common social science usage can be misleading, however, especially when it suggests that the facts referred to are mutually exclusive. A *coup d'état* can become a political revolution, and a political revolution can become a social revolution—if the new government decides to make a 'revolution from above' (Colburn 1994). Indeed, a social revolution is a change of state and society by means of violence that the new government mainly commits (Walzer 1998). And a civil war that gives not only radical revolutionaries but also parochial rebels a fighting chance, and ends in victory for whichever side best combines what Machiavelli called *virtù* and *fortuna*, can start because conservatives revolt in order not to make a revolution but to prevent one.

In sum, theories of revolution that would explain a revolutionary movement or a revolutionary situation need not explain a revolutionary outcome, but theories that would explain a revolutionary situation, a revolutionary outcome, or both have to explain a revolutionary movement as well. And whatever the facts that theories of revolution would explain, those facts entail violence—the intentional infliction of physical harm. The Bolshevik theoreticians who ridiculed nonviolent revolution as a contradiction in terms conformed to social science usage: no violence, no revolution—by any definition. All theories of revolution converge on the *modus operandi*—revolutionary violence. The question they all have to answer is what motivates revolutionary violence and what intended or unintended consequences follow from committing it.

2. Theories

Theories of revolution in Western social science date back to the Greeks, who viewed revolution as the

worst kind of war. Thucydides blamed revolutionary situations (with or without revolutionary outcomes) on revolutionary movements or conspiracies, and blamed those conspiracies on hope of success. Plato agreed and blamed hope of success on weak government torn by faction, which he thought to eliminate from his ideal state by abolishing the family and private property among the rulers. Aristotle added (on the widest though not deepest comparative study) that since hope along with faction springs eternal, no regime is immune against revolution.

The theory that people attempt revolution because they have hope of success, and have hope of success because they think the government is vulnerable, lived on in classic political sociology as an explanation of what to avoid and how to avoid it. Machiavelli, who wrote in effect the first handbook on counterinsurgency, told new rulers who had just seized power how to use force and fraud in order to avoid being overthrown. Hobbes, trusting more to organization than to statecraft, designed a regime that would prevent revolutionary movements and revolutionary situations (which he called sedition and civil war) by repressing faction. *The Federalist* took Hobbes for granted, but held that checks and balances could avert faction and insurrection as well as tyranny. Burke—who excoriated the French Revolution already in its ‘liberal’ phase and predicted the regicide 2 years, the Terror 3 years, and the military dictatorship 9 years in advance (O’Brien 1993)—observed that the revolutionary parliament usurped a king busy making concessions. As Tocqueville summed up the whole line of thought: ‘The evil that one suffers patiently as inevitable seems unbearable as soon as one conceives the idea of escaping it.’

Not all theorizing on revolution was counterrevolutionary. ‘Violence is the midwife of every old society pregnant with a new one,’ wrote Marx, though his instant histories of revolutionary situations autopsied abortions, and his class-conflict theory of revolutionary movements and their abortionists proved false—street fighters on both sides of the June 1848 revolutionary situation in Paris, for instance, not only had the same class background, but were a cross section of the manual work force (Traugott 1985). The theory explained history no better elsewhere—industrial workers neither launched the revolutionary movement nor achieved the revolutionary outcome that the theory predicted. In Germany they did not try, and in Russia they acquiesced as a revolutionary movement of Marxist intellectuals achieved a revolutionary outcome in their name by a military *coup d’état*—the October Revolution was so low-profile that the author of *Ten Days That Shook the World* slept through much of it—followed up with Red Terror and Civil War (Moore 1978, Pipes 1991, 1995). But for the vicarious, posthumous prestige Marx got from that much-imitated revolutionary outcome, whose official ideology-cum-state religion made him a household word,

no one except social scientists might have heard of him today (Kolakowski 1978).

Whether counterrevolutionary or revolutionary, however, theories of revolution were handmaidens to political sociology and historiography before the twentieth century, when—after the revolutions attending World War 1, World War 2, and decolonization—they hived off as a cluster of answers to the why-question of revolutionary violence. The chief theorists were not activists but academics because activists (even successful ones) propounded only trite theories of revolution consisting mainly of prophecy and propaganda. Where activist theories rose above agit-prop to consider strategic means and ends, they rehearsed the classic wisdom in reverse—they advised revolutionaries to play on faction in order to weaken the government and thereby raise hope of success. Some activists became revolutionary dictators, but more academics became theorists of revolution and launched a social science growth industry (Rule 1988, O’Kane 2000).

Academic theories of revolution, in the standard pilgrim’s progress view, went through three stages of development since the 1920s. First there were natural histories explaining recurrent sequences of similar events in ‘great’ revolutions by the reasons that experts say motivated the people who made them, but not generalizing the reasons as a causal theory. Then there were general theories explaining revolutionary violence by discontent, but accounting for history ad hoc if at all. Now there are comparative-historical theories explaining social and political revolutions by ‘structural conditions’ of state and society cogently enough that older theories look *passé* (Skocpol 1979, 1994, Goldstone 1986, 1991, Goldstone et al. 1991).

The standard view is not far wrong, though it ignores continuities of theory and method. All theories of revolution cite a short list of sufficient conditions or explanatory causes and validate, or rather illustrate, the explanation with factual evidence consisting of case histories and statistics arranged to show by the comparative method that where the explanatory causes occur, revolution (by some definition) occurs as well, and that where the explanatory causes do not occur, revolution (by that definition) does not occur either.

Grouped by the explanatory causes they cite, theories of revolution form four families: psychological, functional, structural, and political theories. As a rule, psychological and functional theories explain revolutionary movements—they explain why people attempt to change government, regime, or society (or all three) by violence; structural theories explain revolutionary outcomes—they explain why people successfully change government, regime, or society (or all three) by violence; and political theories explain revolutionary situations—they explain why people fight civil wars for state power. Psychological and functional theories that explain revolutionary

movements mostly leave revolutionary situations and revolutionary outcomes over to historians, whereas structural theories that explain revolutionary outcomes also explain revolutionary situations and revolutionary movements along the way, and political theories that explain revolutionary situations also explain revolutionary outcomes and revolutionary movements at least in passing.

Psychological theories explain revolutionary movements by frustration (alias relative deprivation or discontent) defined as a discrepancy between what people want and expect and what they get. These theories all assume the frustration-aggression principle that people who are frustrated commit aggression against the perceived source of frustration, but they disagree about what social facts cause frustration—one blames steady improvement followed by a sudden setback that raises expectations and reduces attainments; another blames rapid social change that raises expectations beyond attainments; yet another blames whatever raises expectations, lowers attainments, or both. Few psychological theories explain revolutionary violence by frustration alone, however; most add insurgent strength and government weakness to their short list of sufficient conditions.

Functional theories explain revolutionary movements by dysfunction (alias strain or disequilibrium) defined as a discrepancy between socially prescribed ends, goals, or values, and the available institutional means or procedures for attaining them. When social change creates a gap between ideology and experience that the government omits to close with reform, people turn to revolutionaries for salvation. If the government looks weak or loses control of its armed forces, or if revolutionaries think they can overthrow it, revolutionary violence erupts.

Structural theories explain revolutionary outcomes piecemeal—they explain first why élites subvert governments, then why subalterns rebel, then why radical vanguards seize power, and then why new rulers reconstruct state and society. The first two events make up revolutionary situations; the last two make up revolutionary outcomes. Each event depends on the one that precedes it—no subversion, no rebellion; no rebellion, no power transfer; no power transfer, no reconstruction. All these events comprise collective actions and reactions, which the theories explain as rational efforts to satisfy interests under structural constraints like government weakness, subaltern community organization, vanguard politico-military organization, and geopolitical exigency. Ideology is a cover for interest—the motivating constraints are structural.

Political theories likewise explain revolutionary situations piecemeal—they explain first why insurgents claim sovereignty, then why certain people support them, and then why the government fails to repress the insurgency. Revolutionary situations do not all have revolutionary outcomes, but some do, and

political theories also explain these outcomes piecemeal—they explain first why government supporters defect, then why insurgents gain armed force, then why government forces waver or desert, and then why insurgents take power. All these events comprise collective actions and reactions, which political theories explain as rational efforts to satisfy interests under political and strategic constraints like organization, armament, threat, and opportunity. Ideology again is a cover for interest—the motivating constraints are political and strategic. Whether and to what extent new rulers reconstruct state and society is another question, which political theories mostly pass over.

These family portraits of theories of revolution are not just composite sketches, they are caricatures, though caricatures accentuate real features. Thankfully, competent accounts of the theories as well as internecine debates among the theorists are legion (Rule 1988, Goldstone et al. 1991, Skocpol 1994).

Theories of revolution are contentious. Advocates of structural theory point out that psychological and functional theories explain neither revolutionary situations that occur because élite infighting paralyzes the government nor revolutionary outcomes that see new regimes more bureaucratic and tyrannical than the old (Skocpol 1979, Goldstone 1991). Advocates of political theory point out that revolutionary outcomes depend on the fortunes of war in revolutionary situations—structural *virtù* proposes, political *fortuna* disposes (Tilly 1993). And skeptics add that since revolutionary outcomes owe to actions that vanguards take because they expect these actions to yield benefits that often do not materialize, no theory that downplays ideology can explain revolution cogently (Aya 1990). How else to explain strategic decisions like Lenin's based on false expectations of imminent world revolution, the rage for socialism in poor countries ruled by revolutionaries, and the resort to mass terror by revolutionary governments in proportion to the innovation they attempt (Pipes 1991, 1995, Colburn 1994, O'Brien 1993).

Though theories of revolution are contentious, few of them disagree with Thucydides that revolutionary movements owe to hope of success or with Plato that hope feeds on weak government torn by faction. The wisdom of the ages is no less wise for being ancient.

Rhetoric

'Rhetoric' has different meanings depending on the context and whether used abstractly or concretely. The word, found with slightly different spellings in modern European languages, is derived from Greek *rhêtorikê*, which first appears in Plato's dialogue *Gorgias*, written about 385 BC. It is used there of the art (*tekhnê*) of a public speaker (*rhêtôr*), and may be defined as the art of persuasive public speaking; it can refer to the theory of discourse, to the art of orators and writers, or to speeches, writings, or sometimes other art forms (painting, sculpture, architecture, music, and dance) when these are intended to influence an audience. In scholarly contexts 'rhetoric' is usually a morally neutral term, but it has had influential detractors beginning with Plato and continuing with Descartes and Locke, with the result that in modern popular language or journalism the term often describes empty or misleading verbosity.

From the fourth century BC until the nineteenth century AD rhetoric was an academic discipline taught

in most western schools and universities, following grammar and preceding dialectic in the liberal arts trivium. Its function was to teach and practice students in techniques of public speaking or written composition in prose and verse. Thousands of rhetorical handbooks, treatises, and model compositions were written from ancient to modern times; many have survived in manuscript or print, but many were ephemeral. The Romantic movement, with its rejection of rule-based composition and celebration of individual genius, and the development of science, with its assertions of objective truths, undermined study of rhetoric in the nineteenth century, so that it often came to be thought of as limited to identification of linguistic tropes, such as metaphor and metonymy. In the twentieth century, however, rhetoric experienced a renaissance in connection with new communication and media studies, new literary theories, and new forms of linguistic analysis. Confidence in objective truth was challenged, and some thinkers came to believe that all speaking and writing, even discourse about the natural and social sciences, is a rhetorical act and necessarily contains rhetorical elements. The extension of rhetoric from its traditional concern with public address to embrace discourse of all sorts is called 'globalization' (Gross and Keith 1997), a term perhaps better reserved for another recent development, the comparative study of the rhetorical traditions of western and nonwestern societies. In contrast, 'rhetoric' is sometimes the name given to introductory courses in composition at the college level. In these courses students are practiced in a variety of forms of writing, including descriptive, narrative, and argumentative compositions together with attention to spelling, word choice, grammar, arrangement, and the use of figures.

1. The Historical Development of Rhetoric in Europe and America

Systematic study of rhetoric in Greece resulted from the need for effective public speaking by ordinary citizens under democratic governments, especially in Athens, in the fifth and fourth centuries BC. In the Athenian democracy litigants were expected to plead their own cases before large juries of fellow citizens, thus putting a premium on rhetorical ability, and the functioning of the council and popular assembly was predicated on extensive debate among citizens. The first teachers of rhetorical techniques were the traveling lecturers known as 'sophists,' of whom the most famous are Protagoras and Gorgias. In Plato's dialogue *Gorgias*, in opposition to Gorgias and his followers, Socrates takes a very negative view of rhetoric, which he represents as a form of flattery of an audience and as lacking concern with truth, but in Plato's later dialogue, *Phaedrus*, Socrates is made to describe an ideal philosophical rhetoric that would use

knowledge of logic and psychology for legitimate ends. By the late fifth century BC rhetorical handbooks could be bought and studied. They seem to have included examples of introductions, narratives, probable arguments, and conclusions in the form of commonplaces that readers could adapt to specific situations.

1.1 Aristotle's Theory of Rhetoric

Plato's student, Aristotle, developed some earlier teaching in greater depth and added many practical observations in his lectures, embodied in the treatise *On Rhetoric* (ca. 336 BC). Although it was rather little read until modern times, through the work of his students many of Aristotle's theories became part of traditional rhetorical teaching. Major concepts and divisions of modern rhetorical theory are derived from Aristotle. He defined rhetoric abstractly as 'an ability (or faculty: *dynamis*), in each case, to see the available means of persuasion.' A speaker uses 'nonartistic' means of persuasion, such as witnesses or documents, and 'invents' artistic means of persuasion, of which there are, Aristotle said, three and only three: they are often referred to as *ethos* (presentation of the character of the speaker as trustworthy), *pathos* (the emotions of the audience as aroused by the speaker), and *logos* (rational argument). There are two kinds of logical argument: the enthymeme, or rhetorical syllogism, is a deductive, probable argument in popular form; it usually takes the form of a statement with a supporting reason or of an 'if ..., then ...' hypothesis. The other type of argument is the paradigm, or example; it is an inductive argument, supporting a proposition with examples from history or analogy.

Rhetoric as Aristotle understood it dealt with probable knowledge in the realm of politics (though it was found also in speeches in dramatic and narrative literature), not with scientific or philosophical knowledge. The sources of enthymemes are of two kinds: specific topics, that is, propositions drawn from other disciplines, such as politics, ethics, psychology, economics, or military strategy; and dialectical or 'common' topics, that is, techniques of reasoning, such as definition, division, argument from cause and effect, etc. Aristotle defined three species of rhetoric: judicial (sometimes called forensic) rhetoric, practiced in courts of law, is concerned with determining the justice of an action in the past; deliberative rhetoric, practiced in formal or informal political assemblies, is concerned with determining the benefits or expediency of a proposed future action; epideictic (or demonstrative) rhetoric, practiced on ceremonial occasions such as a holiday or funeral, is concerned with what is honorable or dishonorable and takes the form of praise or blame of a person or thing. Many of Aristotle's rhetorical concepts are universals, applicable to discourse in all cultures; some need modification to apply to discourse more generally. *Ethos*, for example, has come to refer

to any moral factor or any presentation of character used in a discourse for persuasive purposes, not just the credible presentation of the speaker's veracity, and epideictic is now viewed as ceremonial or ritual discourse concerned with instilling, transmitting, or reinvigorating cultural values.

1.2 Greco-Roman Rhetorical Theory

Aristotle was primarily interested in what came to be known as 'invention,' the aspect of rhetoric concerned with the use of topics and means of persuasion, but in the third book of his treatise he began with some remarks on delivery, followed by an extended discussion of prose style and finally an account of the structural parts of a public address. Subsequent Greek and Roman rhetoricians outlined a theory of rhetoric in five parts which recapitulate the process of planning and delivering a speech: invention, or the planning of the argument; arrangement, or division of the speech into parts; style (the choice of words and composition of sentences); memory (or preparation for delivery); and delivery. Greek and Roman teachers of rhetoric were especially interested in judicial oratory and had much to say about the definition of the question at issue, which is known as the *stasis* of a case. Three main categories of stasis were recognized, with numerous subdivisions and many variants. Stasis of fact (also called conjectural stasis) deals with the situation in which a defendant denies committing the act with which he is charged (e.g., I did not kill him); in a case of legal stasis (also called stasis of definition) the defendant admits the act but claims it was legally justified (e.g., I killed him, but in self-defense); in stasis of quality the act and its definition are admitted, but extenuating circumstances are alleged (e.g., I did not intend to kill him). A topic much discussed by the rhetoricians was argument about interpretation of the letter and intent of a law or document, something of continuing interest in modern jurisprudence.

Greek and Latin rhetorical handbooks, of which a number have survived, generally describe the arrangement of a speech into a series of parts, each with its own function. The *prooemion* or introduction should make the audience attentive, receptive, and well disposed, and specific suggestions were offered to effect this. A narration should follow, giving a clear, brief, and persuasive account of the facts of the case. There is then often a statement, or proposition, of what the speaker hopes to prove, with perhaps division, or partition, into a series of headings. Next comes the proof, supported by witnesses and other evidence when possible, but often largely a more or less probable argument based on the circumstances and the character of those involved. Finally comes an epilogue, or peroration, in which the speaker summarizes the argument and seeks to stir the emotions of the audience.

The subject of style was much developed by rhetoricians after Aristotle; it is found discussed in rhetorical handbooks such as *Rhetoric for Herennius*, in Latin and dating from the early first century BC, and also in a number of monographic works, of which the most famous is the Greek treatise *On the Sublime*, probably dating from second century AD (the authorship of both works is uncertain). Discussions of rhetorical style dealt with the choice of words, the composition of sentences, both simple and periodic, appropriate rhythms for spoken prose, tropes, figures, and kinds of style. A trope is a substitution of one word or phrase for another; among the most common are metaphor, metonymy, synecdoche, and hyperbole. Figures are divided into verbal figures, sometimes also called grammatical figures, such as alliteration and anaphora, and figures of thought, such as rhetorical question and antithesis. Style was divided by many authorities into three kinds: plain, grand, and middle; others, of whom the Greek rhetorician Hermogenes (fl. ca. AD 180) is the best known, sought to describe a series of qualities such as grandeur, beauty, sincerity, sweetness, subtlety, and vehemence, that could be blended into a harmonious and effective whole. The works of the orator Demosthenes (384–322 BC) were commonly taken as the best examples of eloquence in Greek, the speeches of Cicero (106–43 BC) in Latin, and students were encouraged to analyze and imitate these models.

The rhetoricians developed mnemonic techniques to help their students memorize speeches. The commonest system was based on identifying words or ideas with visual symbols and imagining these against a familiar spatial background. Discussions of delivery dealt with control of the voice and the use of gestures.

By the first century BC the study of rhetoric had been introduced into Roman schools, although after resistance from conservatives; it always kept close to concepts taught by Greeks. The turbulent conditions of the late Roman Republic provided the context for vigorous debate in the senate, popular assembly, and lawcourts, which were the venues of the rhetorical masterpieces of Cicero. He also wrote dialogs and treatises on rhetorical theory in which the orator is celebrated as the ideal figure of civilized society, to be achieved by a man learned in philosophy, law, history, literature, and rhetoric and applied in public life for the common good. Cicero recast the Aristotelian means of persuasion into what he called ‘the duties of the orator’: to teach, to charm, and to move, and he identified these with the plain, the middle, and the grand style respectively.

The establishment of the Roman Empire by Augustus after 30 BC led to a decline in opportunities for political oratory, but schools of rhetoric strengthened their dominance of the educational system. In these schools much of the students’ time went into the practice of ‘declamation,’ writing and orally delivering speeches on imaginary historical and

legal themes, often expressed in highly artificial prose. The most extensive account of classical rhetorical theory and rhetorical education is found in *The Education of the Orator (Institutio Oratoria)* in twelve books, published by Quintilian in 95 AD. Quintilian followed Cicero in regarding the orator as the highest civic ideal, and repeatedly insisted that only a morally ‘good man’ (*vir bonus*) can become a ‘good orator.’ Early Christians, Saint Paul among them, show ambivalent attitudes toward rhetoric, but preachers often borrowed techniques from classical rhetoric. About AD 426 Saint Augustine, a teacher of rhetoric before his conversion to Christianity, completed an influential treatise, *On Christian Learning (De Doctrina Christiana)*, which is essentially a handbook of Christian rhetoric, applying Ciceronian teaching to the training of a Christian preacher and teacher.

1.3 Medieval and Renaissance Rhetoric

Although freedom of speech and opportunities for public address were limited under autocratic governments in late antiquity and the Middle Ages, some understanding of rhetoric was transmitted in encyclopedias of the liberal arts compiled by Martianus Capella (fifth century), Cassiodorus (sixth century), and Isidore of Seville (seventh century). In the later Middle Ages rhetoric found new application in handbooks of letter writing (*ars dictaminis*), verse composition (*ars poetriae*), and thematic preaching (*ars praedicandi*). The recovery of a reading knowledge of Greek in Western Europe in the fifteenth century, and the rediscovery by Italian humanists of important manuscripts on rhetoric from the classical period were major contributions to the vigorous intellectual life of the Renaissance. Rhetoric as taught in schools and universities in the Renaissance was primarily based on writings by Cicero and Quintilian, but some dissenting voices were heard. In the sixteenth century Peter Ramus, lecturing in Paris, transferred the teaching of invention from the course in rhetoric to the course in dialectic and limited rhetoric to the study of style, primarily the use of tropes and figures of speech. His position proved especially popular with Calvinists and Puritans; rhetoric as first taught in America (at Harvard College, founded 1636) was based on Ramist teaching. Meanwhile, textbooks of rhetoric began to appear in the vernacular languages; the first in English was *The Art or Crafte of Rhethoryke* by Leonard Cox (1535). A more profound understanding of the subject is found in Francis Bacon’s *Advancement of Learning* (1605), where ‘the duty and office of rhetoric’ is defined as ‘to apply reason to imagination for the better moving of the will.’ A split between a narrow view of rhetoric as a linguistic or literary phenomenon, largely limited to the use of tropes and figures in written language, and a broader view of rhetoric as a persuasive tool of political speaking and discursive writing

has persisted. The linguistic-literary approach has often characterized the teaching of rhetoric on the European continent and in English Departments in schools and universities; the view of rhetoric as concerned with political issues and with discursive writing flourished in eighteenth-century Britain and America and has its modern home in Departments of Speech, Communication, or Media Studies.

1.4 The Relationship of Rhetoric to Poetics and Dialectic in the Western Tradition

Although the purpose of rhetoric was traditionally assumed to be persuasion, and the purpose of poetry to be pleasure and enjoyment, rhetoric overlapped with poetics in that both had a concern with artistic composition: word choice, tropes, figures, and sentence structure. In addition, traditional rhetorical handbooks regularly discussed narrative techniques, also applicable to narrative poetry; and rhetorical theories of the presentation of character, arousing emotions, and the effective use of humor had some application to dramatic and other poetic genres. Rhetoricians insisted that their students study poetry as a source of diction, compositional techniques, and inspiration. The close relationship between rhetoric and poetics can be well seen in Horace's Latin didactic poem *The Art of Poetry*, written toward the end of the first century BC, describing the task of the poet as effectively mixing useful teaching with sweetness of expression, a view that reappears in the medieval *artes poetriae*, and in renaissance and early modern literary criticism such as Boileau's *L'Art poétique* (1674).

Rhetoric traditionally overlapped with dialectic as practiced in schools in the treatment of logical argument, including definition, division of a question, and the use of topics. The two disciplines differed in that rhetoric was usually regarded as embodied in a continuous discourse, whether oral or written, whereas dialectic took the form of a question and answer dialogue. Moreover, rhetoric dealt with a specific question, primarily of a political or judicial sort, while dialectic dealt with general questions or philosophical universals, and perhaps most important of all, in its effort to persuade an audience rhetoric utilized the appeal of character and emotion as well as logical argument, while in dialectic only logical argument was regarded as legitimate. A good discussion of the traditional relationship of dialectic and rhetoric is found in the fourth book of Boethius' *On Topical Differentiations* (*De Topicis Differentiis*), written in the sixth century and used as a textbook in the Middle Ages and Renaissance.

2. The 'New' Rhetorics

The thinkers of the Scottish Enlightenment of the eighteenth century were much interested in rhetoric

and in their lectures and writings combined traditional elements from Aristotle, Cicero, and Quintilian with their new understanding of psychology and consideration of modern conditions. Among important figures in this movement were David Hume, Adam Smith, George Campbell, and Hugh Blair. Writings of Campbell and Blair were translated into several languages and used in the United States and elsewhere as textbooks of rhetoric well into the nineteenth century.

In the twentieth century many new studies of rhetoric were published, based on historical, linguistic, literary, philosophical, political, and psychological research and influenced by the growth of mass media, the use of propaganda and manipulation of audiences for economic or political advantage, and new research methods, both quantitative and qualitative. New professional organizations were founded for those interested in rhetoric, among them the Rhetoric Society of America and the International Society for the History of Rhetoric. *The Quarterly Journal of Speech* and other older journals published an increased number of articles on rhetoric, and new journals devoted to rhetorical subjects began to appear. These include *Philosophy and Rhetoric*, *Rhetoric Review*, *Rhetoric Society Quarterly*, *Rhetorica*, and *Rhetorik: Ein internationales Jahrbuch*. Several dictionaries and encyclopedias of rhetoric, listed below in the Bibliography, have also been published recently.

Among twentieth-century writers on rhetoric, two have had special influence. Kenneth Burke developed his theories of rhetoric in numerous writings over a long career. In *Grammar of Motives* (1945) he described his best known tool of rhetorical criticism, the pentad of act, scene, agent, agency, and purpose. In *Rhetoric of Motives* (1950) he defined the function of rhetoric as 'the use of language as a symbolic means of inducing cooperation in beings that by nature respond to symbols,' and he had much to say about 'identification' between speaker and audience as a rhetorical technique. Burke, an American, came to the study of rhetoric from an interest in language, literature, and political philosophy; Chaim Perelman, a Belgian and author with Lucie Olbrechts-Tyteca of *La Rhétorique nouvelle* (1958), approached rhetoric from study of argumentation and jurisprudence. He distinguished argumentation, which is always addressed to an audience, from formal proof, which is not, and explored topics of argument, divided into those of quantity and quality and those that help to identify and exemplify facts.

An example of a narrow linguistic approach to rhetoric is *Rhétorique générale* (1970), the work of six scholars at the University of Liège calling themselves *Groupe µ*. Here rhetoric was limited to the phenomenon of troping as seen in metaphor and metonymy. Of many modern studies of metaphor, one that is sensitive to rhetorical issues is Paul Ricoeur's *The Rule of Metaphor: Multi-disciplinary Studies of the Creation*

of *Meaning in Language*. Another new approach to rhetoric is included in *A Theory of Semiotics* by Umberto Eco (1979). Eco described rhetoric from the point of view of semiotics as 'over-coding,' that is, a network of associations invoked by linguistic usages or by the switching of codes.

3. *The Natural Sources of Rhetoric*

Many traditional features of human rhetoric have analogies in animal communication. Social animals in particular use a variety of oral, visual, and chemical signs to persuade others to do what they want, primarily in connection with mating and securing food. Animal communication shares elements of invention, arrangement, style, and delivery with human rhetoric. Many animals perform epideictic rituals, and honey bees engage in a kind of deliberation when swarming. Some intelligent animals learn to understand and even to use metonymy, but the use of metaphor, as well as logical arguments based on citation of examples, is a human development. Rhetoric in some form is a basic feature of human and nonhuman animal life, a tool in the survival of both species and individual. It can be viewed as a form of mental and physical energy, reacting to a challenge, need, or desire by producing and transmitting signs to a real or imagined audience. The simplest natural rhetorical techniques, exploited by animals and humans alike, are gesture, volume, pitch, and repetition of a message.

4. *Rhetoric Without Writing in Traditional Societies*

Ethnologists have collected much information about the forms and function of speech and techniques of persuasion in traditional societies in Africa, Australia, the South Pacific, and the Americas, although they generally use terms like 'political language' rather than 'rhetoric' to describe what they have observed. Formal deliberation is a regular feature of acephalous societies, where individuals gain reputations as orators, and in hierarchic societies recognized orators are employed as spokesmen for kings and chiefs. The goal of deliberation in traditional societies is usually consensus, real or imposed, and opportunity should be offered to opponents 'to save face' by seeming to compromise. Formal language is required of speakers on official occasions everywhere and is learned by imitation of earlier speakers. Such formal language often has archaic elements of diction and grammar, as well as conventions of etiquette and arrangement, and makes use of proverbs, examples, and traditional metaphors. Epideictic speech, as understood in the West, has nonwestern parallels in religious rituals, where extreme forms of formal language, often in-

comprehensible to the general audience, are employed, frequently accompanied by music and dance. As in official deliberation, formal ritual language seems to certify the authenticity or truth of what is said and helps to perpetuate conservative social control over the society on the part of chiefs and priests. Among many examples of oral discourse Aztec *huehuehtlahtolli* from Mexico show an unusually complex development or rhetorical artistry. Many examples of Aztec speeches were written down by Bernardino de Sahagún and others in the sixteenth century when the genre was still flourishing.

5. *Rhetoric in Nonwestern Literate Societies*

The invention of writing in Mesopotamia and in China, and its spread to Egypt, Greece, India, and elsewhere clearly had some effect on rhetoric, though definition and proof of that effect is controversial. Scribes in Mesopotamia and Egypt celebrated their craft and obtained considerable power as necessary intermediaries between illiterate rulers and the general populace. Writing made possible communication over distance, record keeping, scientific and historical research, crystallization of oral poetic texts, creation of textbooks, and standardization of grammar. It may have facilitated extended logical argument and the use of complex sentences with a variety of subordinate clauses.

6. *Comparative Rhetoric*

The study of rhetoric on a cross-cultural basis is a recent phenomenon. It attempts to identify what is universal and what culturally specific in rhetorical practice across linguistic and cultural barriers, with the aim of formulating a General Theory of Rhetoric as well as to improve cross-cultural understanding. One approach is to test the applicability of western rhetorical concepts, including those outlined earlier in this article, to discursive practices in other societies. Of particular interest to date has been study of rhetoric in China, where thousands of speeches, as well as handbooks of composition, rhetorical exercises, and critical, historical, and poetic writings, dating from antiquity to modern times, provide a rich source for comparative research. One remarkable early thinker was Han Fei-tzu (born about 280 BC), sometimes called 'the Machiavelli of China' because of his pragmatic, cynical teaching to rulers about how to employ rhetoric to solidify their power. In the early centuries of the common era Chinese scholars produced moralizing and allegorizing commentaries on the Chinese classics that employ an extensive technical terminology, sometimes resembling but often differing from rhetorical concepts in the West. Comparable developments occurred in ancient India, where the *Arthashastra* of Kautilya (about 300 BC) outlines the

rhetoric of power and provides extensive technical terminology for teaching and criticizing rhetoric. Poetic and dramatic theory was later developed in India to a high degree of sophistication.

In comparison with other traditions, western rhetorical practice, beginning with the Greeks, has been more tolerant of contention, personal invective, and flattery, less insistent on consensus, politeness, and restraint than elsewhere. The Greeks invented the counting of votes as a way of settling political and legal disputes, something unknown elsewhere until modern times. Although voting performs that function, its potential acceptance of a majority of one as determinative can sharpen disagreement. Artistic judicial rhetoric, with argument from probability and exploitation of circumstantial evidence in court, is largely a western phenomenon; elsewhere, judges have traditionally interrogated the principals and have usually demanded direct evidence or trial by ordeal. Handbooks of public speaking were composed in ancient China, India, and Egypt—the earliest known is the *Instructions* attributed to the Egyptian vizier Ptahhotep of which the earliest manuscript dates from the early second millennium BC—but outside the West rhetoric has always been taught as an aspect of politics, ethical philosophy, or literary criticism, and not as a separate discipline within a standard curriculum of liberal arts, as found in western schools and universities.

7. *The Defense of Rhetoric*

Rhetoric has often been denigrated; the traditional defense, originating with Aristotle, argues that it is in itself neither good nor bad; like the other arts, it is a morally neutral tool that can be used by good or bad purposes. This is sometimes now labeled the 'weak defense' in contrast to a modern 'strong defense' that seeks to justify rhetoric on the ground that ethical and political knowledge is not based in *a priori*, abstract truth but is culturally formed and reformed through rhetorical engagement in concrete situations. The strong defense works best in a liberal democratic society where the majority grant some measure of toleration to minorities. On the global level it seems to justify any values and beliefs in society that are rhetorically constituted and accepted by an audience. That includes fascism, anti-Semitism, misleading advertising, chauvinism, religious bigotry, and most of the ills of history. At this level of description, we then have to fall back to defend rhetoric as a neutral tool that can be used equally for beneficial or for exploitive purposes.

8. *Current Issues in the Study of Rhetoric*

Rhetoric, as practice, was affected by the invention of writing and both as practice and as theory by the

invention of printing. The rhetorical implications of the electronic revolution of the late twentieth-century are only now beginning to be assessed. Rhetoric is, almost by definition, an interdisciplinary study. Throughout western history it has had a love-hate relationship with philosophy, and modern students of rhetoric draw extensively from twentieth-century philosophy in their analyses of rhetorical practices and in their efforts to show how rhetoric can be said to generate knowledge. Ideas derived from the epistemology and hermeneutics of Martin Heidegger and Hans-Georg Gadamer have been influential on some scholars, and others show indebtedness to Ludwig Wittgenstein, Michel Foucault, Jacques Derrida, Richard Rorty, Jürgen Habermas, or other recent philosophers, most of whom do not specifically discuss rhetoric. Much rhetorical research at the end of the twentieth century was concerned with issues of gender as rhetorically defined and practiced. Long overlooked evidence for speaking and writing by women has been discovered and is now being studied for the first time. The evidence from the classical period is fragmentary, but medieval, renaissance, and early modern women developed distinctive rhetorical forms, and the contemporary women's movement has employed a variety of rhetorical techniques of its own as well as analyzing the repressive rhetoric of the past.

Rhetorical Analysis

Rhetoric, the *art of oratory*, was developed in ancient Greece and Rome. Both as a general communication theory and as a collection of practical advices on how to convince an audience, rhetoric exerted decisive influence on the history of Western civilization and culture. In the period from antiquity until the nineteenth century, rhetoric was the single most important subject taught in Western educational institutions. During these more than 2,000 years it changed both in scope and perspective. Corresponding with the growth in written communication, it was gradually transformed into an *art of writing*. In later centuries it became closely associated with the writing of literature while less emphasis was put upon argumentation and persuasion.

Rhetoric deals with communicative situations. Speeches and texts are always considered in their relation to the aims and intentions of the speaker/writer, the subject matter in question, the general mood and prior knowledge of the expected audience,

etc. Correspondingly, any kind of analysis which sets out to describe the ways in which a given discourse is determined or affected by its immediate communicative context could be said to be rhetorical in nature. Rhetorical analyses of this kind have always played an important role in literary studies, but during the few last decades similar methods have also been applied to nonliterary texts and even to nonverbal means of expressions, for instance in connection with studies of political propaganda, advertising strategies, as well as mass media in general.

1. The History of Traditional Rhetoric

1.1 Classical Antiquity

Some ground rules of oratory were developed and taught by Sicilians in 485 BC in connection with legal disputes about real estate. This rudimentary rhetoric quickly spread to Athens where a more comprehensive body of knowledge about the art of public speaking was developed from the mid-fifth century and onwards. Greek rhetoric was introduced in Rome in the first century BC as part of the education of older children.

In the Greek period, the so-called Sophists—persons who taught rhetoric, politics, and mathematics for money—played an important role in the development of rhetoric as a formal discipline. They were attacked by Plato for putting more emphasis on style than on substance. Plato's critique raises a question which has followed rhetoric ever since: Is rhetoric a method for discovering the truth, or merely an effective technique for manipulating an audience?

There is, however, no clear answer to this question. The old Greco-Roman rhetoric—as described by Aristotle (384–22 BC; see *Rhetoric*), Cicero (106–43 BC; *De Oratore*), and Quintilian (c. AD 35–c. 95; *Institutio Oratoria*)—was a complex social system of inter-related, and in some cases even contradictory, practices (cf. Barthes 1970, Vickers 1988). First of all, rhetoric was an art in the classical, Aristotelian sense of the word, i.e., *a craft or technique*, a collection of rules and advices for speakers who want to convince or persuade an audience. These rules were taught in and transmitted through strong educational institutions. Thus, rhetoric was also a discipline, a *subject*, a body of knowledge. In addition, this body of knowledge constituted a *theory*, or at least a semitheoretical field: it described and classified some important effects of verbal language.

1.2 The Rhetorical System

The old manuals divided rhetoric into five parts: *Inventio*, *Dispositio*, *Elocutio*, *Memoria*, and *Actio*.

Each part covers a specific field of knowledge and aims at training certain skills related to the field in question.

(a) *inventio* (finding what to say) is the part dealing with *argumentation*. Speakers learn to analyze a given subject matter, to find relevant information, and to determine which types of information are the most useful for their purposes. They also learn to convince an audience with quasilogical proofs (*logos*), and to move the audience by appearing to be good and trustworthy (*ethos*) or by stirring the audience's emotions (*pathos*).

(b) *dispositio* (organizing what one has found) deals with *composition*. Speakers learn to organize their speeches in clearly separated sections.

(c) *elucutio* (choosing the proper words) is the part that deals with verbal *ornamentation*. Some elementary rules are presented together with examples of striking images and other verbal devices which can be used to color a text.

(d) *memoria* (remembering what to say) is an introduction to *mnemonics*.

(e) *actio* (performing the speech) contains practical advices on how to *deliver* a text before an audience.

1.3 The Reduction of Rhetoric

The *memoria* and *actio* parts were rather sketchy in the old manuals, and because they were directly related to the practice of oratory, they disappeared as soon as rhetoric became a theory of written discourse. During the Middle Ages the tripartite system of *inventio/dispositio/elucutio* was taught together with grammar and logic. This system collapsed during the seventeenth century, and rhetoric ended up being a part of *poetics*. From now on it was further reduced: *inventio* and *dispositio*, the parts most closely associated with logic and argumentation, lost in importance and in the end all that remained of the old system was *elucutio*, the part dealing with questions of stylistics.

The *elucutio* sections of the old manuals taught the reader that significant persuasive or poetic effects can be obtained by selecting the proper words and combining them in the right manner. A flat statement of facts can be transformed into a strong, colorful, and convincing message by the use of *tropes* or *figures*, i.e., by substituting single words (*tropes*) or by manipulating phrases consisting of several words (*figures*). However, when eighteenth century linguists and literary theorists began to study and classify the many varieties of discursive ornamentation, they found that most of these poetic effects could be described as variations of two semantic relations, viz. *similarity* and *contiguity*. The similarity-relation finds its clearest expression in the *metaphor* while *metonymy* and *synecdoche* are well-known examples of ornaments based on causal and spatial contiguity-relations. From the eighteenth century and onwards, metaphor gradually became a kind of supertrope representing all the

other tropes and figures based on similarity-relations, while metonymy correspondingly became the representative of all the various ornaments based on contiguity-relations (Genette 1970).

2. Modern Rhetoric

2.1 Rhetoric and Semiotics

During the twentieth century several writers have sought to incorporate this reduced version of traditional rhetoric into a broader, more general framework. One of them is the Russian linguist Roman Jakobson who in 1956 presented a structuralist interpretation of *elocutio*, arguing that the metaphor/metonymy-dichotomy corresponds with a general bipolar structure in language (Jakobson 1956). All discursive production is the result of two fundamental linguistic processes based on similarity and contiguity. These metaphoric and metonymic poles in language can be observed in all normal linguistic behavior but, Jakobson argued, they are also manifest in any symbolic process, either intrapersonal or social (for a fuller discussion of the metaphor/metonymy-dichotomy, see the following section).

Jakobson thus opened the field of rhetoric towards sign systems other than language. His own examples were the dream work studied by psychoanalysts, the magic rites described by anthropologists, as well as nonverbal forms of art like cubist painting, the films of Chaplin and Eisenstein, etc.

Jakobson exerted decisive influence on French structuralists and semioticians during the 1950s and 1960s, among them Roland Barthes who in a seminal article, *Rhetoric of the Image*, proposed to rethink classical rhetoric in structural terms (Barthes 1964, see also *Semiotics*). Like Jakobson he argued that the immense variety of tropes and figures categorized by traditional rhetoric are merely surface manifestations of a few formal relations which can be shown to be the structural armature in all kinds of verbal discourse as well as in several nonverbal forms of expression. He predicted that it would be possible to establish a general rhetoric which would be valid for all types of discourses, for texts as well as for sound and images.

Since the 1960s there have been several attempts at implementing Barthes' project. The most comprehensive contribution is the work of the so-called *Groupe μ* , a group of Belgian researchers, who have presented a general description of rhetorical tropes and figures on a semiotic/structuralist basis (cf. Groupe μ 1970). In recent years the group has focused on the question of visual rhetoric (Groupe μ 1992).

The semiotic-structuralist interpretation of traditional rhetoric was mainly a theoretical project, but it had important practical and analytical consequences as well. In his 1964 article Barthes argued that there is

a close connection between rhetoric and *ideology*, a view supported by the fact that the classical manuals usually were more concerned with probabilities than with the actual truth of the matter. In order to be convincing one must know one's audience, know what people will or will not accept as probable, in short one has to respect *doxa*, i.e. public opinion, the stereotypical forms of thought which members of the audience rely on in their everyday lives. This means that the rhetorical devices used in a text can be understood as discursive expressions—or exploitations—of the dominant ideologies within a given society and that such ideologies can be brought to light by means of rhetorical analysis.

That rhetorical analysis can be used as a decisive critical tool had already been proven by the American critic Kenneth Burke who in 1939 wrote an influential article on the argumentative strategy in Hitler's *Mein Kampf* (Burke 1941, see also Burke 1962). From the 1960s and onwards Barthes and many other writers followed Burke's example and made rhetorical analysis a part of a general critique of ideology. Using the insights gained by the fusion of semiotics and rhetoric they made systematic studies of the patterns and systems of belief that are presented as 'natural' or 'evident' in newspapers, fashion magazines, popular films, television programs, etc. This form of analysis was particularly efficient in studies of advertising (for an overview see Dyer 1982).

2.2 Metaphor, Metonymy, and Mental Mapping

Elocutio was the only part that was left of the old rhetorical system by the beginning of the twentieth century. There was however a growing interest in this surviving part and particularly in metaphor. Not only did metaphor become one of the most studied subjects in literary theory, the interest spread to several other areas. At present the study of metaphor is one of the most fertile fields in the humanities and the social sciences. It plays a crucial role in academic disciplines as diverse as linguistics, film and media studies, constructivist psychology, anthropology, and cognition theory.

During the last century the conception of metaphor has changed dramatically. From being a poetic device producing a specialized type of discursive effect, it is now generally regarded as a very fundamental mental tool: 'the essence of metaphor is understanding and experiencing one kind of thing in terms of another,' as George Lakoff and Mark Johnson put it in their book *Metaphors We Live By* (1980). Metaphor is the kind of understanding which is produced when a set of relations is displaced from one kind of thing to another. Or to put it another way: Metaphor is a type of *mental mapping*. When people say that 'time is money,' they establish a simple relation of similarity between two elements but this process entails a further

mapping of a whole series of relations from the time-field onto the money-field: if time is money, then time must also be valuable, scarce, etc.

According to Lakoff and Johnson there are three major types of metaphor. One is the *structural metaphor*, the 'time is money' variety just mentioned: a restricted, almost local, structuration of one field in terms of another. Another one is the *orientational metaphor* which is used to give larger systems of concepts a spatial orientation. When for example happiness is described as 'being up' and sadness as 'being down,' a spatial relation (up/down) is mapped onto an emotional relation (happy/sad). Such orientational metaphors are clearly grounded in very concrete, physical experiences of the body and its position in space. According to Lakoff and Johnson all metaphors do actually have some kind of concrete experiential basis. One example is the third major type, the *ontological metaphor*, which is based on the everyday experience of handling physical objects. Ontological metaphors make it possible for an individual to understand—and thereby to deal with—events, activities, emotions, ideas, etc. as if they were objects, entities, or substances.

Metonymy, the other supertrope, does also have important cognitive functions. Its basic principle is that one entity *stands for* another. In the phrase 'sails on the water,' a part (sail) is used as a short hand reference to a totality (boat). Thus, a metonymy emphasizes or highlights certain aspects or features within a given totality. In the very act of referring, metonymy thereby serves some of the same purposes as does metaphor.

Metaphor and metonymy are mental tools which enable people to focus their everyday experiences and to understand the world they live in. They are, as Lakoff and Johnson point out, part of the ordinary way in which people think, act, and talk. Sometimes people use these tools in new and original ways, but most of the resemblances they perceive and most of the short-hand references they make in their everyday lives are the result of relatively conventional metaphors and metonymies that have become part of their conceptual system. In later years there have been a growing number of studies of such conventional metaphor/metonymy-based systems and the role they play in public debates and political communication. One striking example is George Lakoff's own analysis of the political rhetoric used by US politicians in the weeks before the war in the Gulf in 1991 (Lakoff 1991).

2.3 Rhetoric, Argumentation, and Thinking

Traditional rhetoric originated in relatively small, closed societies characterized by limited flows of information. Politicians and lawyers who should speak in public were faced with the task of convincing or

persuading uneducated and incompetent audiences. The manuals told them how to do that.

Communication today is still a question of finding and interpreting relevant information and presenting it in effective ways. Nevertheless, the general communicative situation has changed radically since the days of classical antiquity. The most important communication is mediated by radio, films, television, the Internet, etc.—media characterized by what has been called a new type of orality (Ong 1982). Information is distributed at an incredible speed, and the total amount of available information is growing rapidly. Even though the general level of education is considerably higher than anytime before in the history of the world, a modern mass audience is a rather heterogeneous phenomenon consisting of people with very varying degrees of knowledge and competence.

The fear that this complex situation with its rapid flow of information may result in massive manipulation of the audiences provides a significant background for many of the newer attempts at reviving rhetoric. One example is the so-called *New Rhetoric* which was developed in the mid-twentieth century (Perelman and Olbrechts-Tyteca 1958, Toulmin 1958). The New Rhetoric was initially an attempt at re-establishing the total rhetorical system in order to be able to cope with all aspects of the new, media-driven types of communication. However, from the very beginning the strongest emphasis was put upon *inventio*, and more specifically on *argumentation*, one of the parts of traditional rhetoric that more or less disappeared when rhetoric became associated with literature and poetics.

In the philosophical tradition argumentation has usually been associated with logic and the techniques of deduction and induction. What the New Rhetoricians have in mind, however, is not this strict, formal, and logical type of argumentation, but the ‘fuzzy’ thinking, the jumping-to-conclusions known from everyday life. Aristotle excluded this kind of thinking from logic proper but included it in his Rhetoric and actually considered it to be one of its most important parts.

Rhetorical argumentation is a ‘situated’ form of argumentation, it cannot be performed or understood without taking the total communicative situation into consideration. It is dependent on the subject matter, the level of available information, the pre-existing attitudes and prejudices of the speaker and the audience, the type of media which is used, etc. In short, what is at stake here and what the New Rhetoricians as well as many other, later writers (cf. for example Billig 1987) set out to describe and analyze are the various ways in which practical, everyday reasoning is determined by its immediate context.

Viewed like this rhetoric is much more than a theory of oratory or a collection of simple rules to be used by poets—it is a discipline which studies the underlying principles governing all human discourse, the way in

which people argue with themselves and with others, the way in which they make value judgments, etc. Rhetorical analyses of such arguments and of how judgments are made can provide a better understanding of how opinions and social attitudes are formed in complex modern media-driven societies.

Rheumatoid Arthritis: Psychosocial Aspects

1. Introduction

Rheumatoid arthritis (RA) is a chronic, disabling inflammatory disease with pain and stiffness in the joints. RA with its often unpredictable and painful course has a considerable impact on patients' lives. The disease has physical as well as behavioral and psychosocial implications for the patient and their family. On the other hand, behavioral and psychosocial factors may be determinants of disease development and of patients' ability to adapt to the condition. Over the last two decades there has been an increasing interest in psycho-educational interventions such as patient education or cognitive-behavioral therapies to help patients deal with the consequences of their disease.

2. Disease Characteristics

RA is a chronic disease characterized by inflammation of joints and joint tissues (Wegener et al. 1996). Some patients may experience remission of the disease without any noticeable damage. As the disease progresses and becomes chronic, the inflammation may lead to joint damage and disability. Cardinal symptoms are joint pain and swelling, morning stiffness, malaise, and fatigue. The course of the disease is highly variable. Patients experience periods of remission and exacerbation of the inflammatory activity. Sometimes patients feel very good and in other periods they feel worse.

The prevalence of RA is about 0.5–1 percent of the population in most cultures. The disease can affect people of all ages, including children, but the onset is usually between the ages of 40–50 years. Women are more affected than men; the overall ratio is 3 to 1.

3. Psychosocial Factors Related to the Onset and Course of RA

There has been much research into the role of personality characteristics ('arthritis personality') and stress in the onset and course of RA. However, there is no empirical evidence for the hypothesis that certain personality characteristics predispose individuals to get RA. More recent research shows that psychological characteristics in RA patients are reactions to the physical disease process rather than causal factors.

There are indications that stressful life events are related to the disease process in RA. The mechanisms through which stress exerts its influence on the disease process are still unclear. Recent developments indicate that stress influences physiological processes. Relationships have been found between minor stressors (daily hassles, such as car breakdowns, arguing with spouse) and disease exacerbation. Recent evidence suggests that major life events (e.g., death, divorce) are associated with RA improvement (Huyser and Parker 1998). It appears that physiological processes mediate the relationships between environmental stressors and disease activity in RA. Psychological factors (e.g., coping style, social support) appear to moderate these processes. A greater understanding of the complex relationships between stress and RA requires integrative studies that simultaneously consider environmental, physiological, and psychological factors (Huyser and Parker 1998).

4. Physical, Psychological, and Social Consequences of RA

For the patient with RA it is probably less significant that stress influences the process of his or her disease than it is that RA with its often unpredictable and painful course has a stressful impact on the life of the patient.

4.1 Physical Consequences

Disability and pain are major outcomes of RA. Many patients are restricted in their mobility, both inside and outside of the house, and have problems with activities of daily living such as dressing, bathing, housekeeping, or cooking. They often need the help of others to perform these activities. Most patients see not being able to do things and dependence upon others as the main disadvantages of their disease (Cornelissen et al. 1988, Taal et al. 1993). Pain is generally regarded as one of the most important consequences of RA and a major challenge for patients as well as healthcare providers. For many patients, however, it seems that pain is not their main concern, but the restrictions in daily functioning and the lack of independence, probably for a great deal caused by the pain (Taal et al. 1993).

Another significant problem for people with RA is fatigue. Studies have found that the prevalence of fatigue in adults with RA ranges from 80 to 93 percent (Riemsma et al. 1998). Fatigue has multiple causes that include physiological, psychological, and environmental factors.

4.2 Psychological Consequences

Feelings of depression and anxiety are often mentioned as psychological consequences of RA. Studies

among RA patients have found heightened depression scores on self-report questionnaires such as the MMPI and the Beck Depression Inventory (BDI). Using a structured interview (Diagnostic Interview Schedule), Frank et al. (1988) found that 42 percent of the patients with RA in their study met criteria for some form of depression, and 17 percent met criteria for major depressive disorder. These rates of depression are higher than those found in community populations, but approximate the rates found in other chronic diseases. An important methodological problem in the assessment of the psychological impact of rheumatic disease is that many instruments such as the MMPI or the BDI were originally validated in psychiatric patients. Depression scales may overestimate the prevalence and severity of depression among persons with arthritis due to the endorsement of somatically related items such as 'I felt everything I did was an effort' or 'I am about as able to work as I ever was' (Wegener et al. 1996). Questions about physical symptoms may be accurate to assess emotional distress among psychiatric patients, but in arthritis patients these questions measure symptoms that reflect their actual physical condition.

4.3 Family Relationships

RA has a considerable impact on the patient's family. Patients can no longer fulfill all their family roles such as household chores, maintaining family ties, or shopping. Limitations in family role function are related to a diminished psychological well-being among people with RA. The disease affects the relationship with the spouse (see *Family Health*). This relationship does not always deteriorate, often spouses grow closer to the patient (Revenson 1993).

RA patients may have sexual problems, mainly caused by physical limitations, pain, and fatigue (Van Berlo et al. 1999). Stiff and painful knees and limited range of motion can hinder sexual intercourse. It has been found that RA patients have a decreased sexual motivation, but no decreases in frequency of sexual activity and intensity of orgasm compared to controls. Patients with RA experience greater loss of sexual satisfaction over time than controls, and greater functional disability is related to greater sexual dissatisfaction (Van Berlo et al. 1999).

4.4 Social Contacts

A chronic disease such as RA can lead to diminished social contacts (see *Social Support and Health*). Reduced mobility, loss of work, or the inability to be involved in hobbies or sports may cause this. It has been found that RA patients have fewer opportunities for contacts with friends and acquaintances, and less satisfaction with these relationships. Cornelissen et al.

(1988) established that a reduction of social contacts was mainly found among patients who lived in cities and less in patients living in rural areas. A decrease in social activities among arthritis patients was found not to be strongly related to the severity of the disease (Cornelissen et al. 1988, Taal et al. 1993).

4.5 Work Disability

Many RA patients experience problems in their work and often become work disabled (Wegener et al. 1996). After 10 years of disease, between 25 percent and 50 percent of patients with RA have stopped working, and after 30 years of disease about 90 percent of patients are work disabled. The most important individual risk factors for work disability among patients with RA are poor disease status, greater job physical demand, and older age. Other risk factors are lack of control over work pace and other work activities, less education, less support from family members and co-workers, and depression.

5. Behavioral and Psychosocial Determinants of the Adjustment to the Consequences of RA

The impact of RA on physical and psychosocial functioning is not directly related to the severity of the disease, but there is considerable individual variation in adjustment to the disease.

Several studies have demonstrated relationships between the use of certain coping strategies and psychological adjustment (Manne and Zautra 1992). Coping can be defined as a patient's cognitive, behavioral, and emotional efforts to manage specific internal or external demands. RA patients' use of emotion-focused coping strategies, such as wish-fulfilling fantasies and self-blame, is associated with poor psychological adjustment, while the use of problem-focused coping strategies, such as information seeking and cognitive restructuring, is related to good psychological adjustment. From studies on coping with pain, it can be concluded that the use of active and problem-focused coping strategies (e.g., diverting attention from the pain, increasing activity level, ignoring pain) is related to less pain and less depression, while the use of passive and emotion focused strategies (e.g., restricting social activities, praying, catastrophizing) is related to more pain and worse psychological adjustment.

Perceptions of control over one's situation, such as self-efficacy or learned helplessness, influence the way people cope and adapt to the stresses of their disease (see *Control Beliefs: Health Perspectives*). It has been shown that self-efficacy and learned helplessness are related to pain, disability, and psychological well-being in arthritis patients (Taal et al. 1996). Self-efficacy refers to beliefs in one's capabilities to success-

fully execute the behavior required to produce a certain desired outcome. Learned helplessness refers to the experience of having no control over one's life, in general, and across different situations. The unpredictable nature of RA and the varying disease activity may cause patients to view their disease as uncontrollable. This often leads to low self-efficacy expectations about needed causes of action to cope with the consequences of the disease or to more generalized feelings of learned helplessness.

Social support, for example from family and friends, can also play a significant role in the adaptation to the disease (see *Social Support and Stress*). A distinction must be made between structural aspects of social support, such as the size of the social network, and qualitative aspects, such as perceived social support. Perceived social support refers to the perceived comfort, caring, esteem, or instrumental help a person receives from others. In several studies with RA patients, it was found that more perceived social support was related to improved psychological well-being (Revenson 1993). In most studies, however, the size of the social network did not seem to have a strong relationship with psychological well-being. An exception is a study by Evers et al. (1997) among recently diagnosed RA patients. They found that patients who have a smaller social network shortly after diagnosis showed an increase in depressed mood after one year. They concluded that an extended social network which probably offers broad sources of support seems to be more important for the psychological adaptation of a patient shortly after diagnosis, when usual patterns of life are disturbed and many life domains have to be reorganized, than at a more progressive stage of the disease.

Social interactions do not only have positive effects on well being: negative aspects of social interactions can decrease well-being. Manne and Zautra (1989) found in a study with female RA patients that critical remarks made by the husband were related to maladaptive coping by the patient, which in turn led to a worse psychological well-being. Problematic aspects of social support (for instance support that is neither desired, needed, nor requested, or when the type of support does not match the recipient's needs) were found to be related to psychological depression (Revenson 1993).

6. Psycho-educational Interventions

Psycho-educational programs can teach patients the knowledge and skills they need to manage the consequences of their disease (see *Health Education and Health Promotion*). This should eventually lead to an improved physical, psychological, and social functioning. A wide range of behaviors can be important in the management of RA. Among the behaviors that are thought to influence physical and psychosocial

health status are adherence to medication regimens, physical exercise, relaxation exercises, joint protection measures, rest, pain coping strategies, and problem-solving (Taal et al. 1996). A well-known and successful American educational program is the Arthritis Self-Management Program (ASMP; Lorig and Holman 1993). In this program self-efficacy enhancing strategies, such as skills mastery and modeling, were used. Participation in this course resulted in improved self-efficacy, more consistent performance of health practices, reductions in pain, and improved physical functioning and psychological well-being among patients with various rheumatic diseases (see *Health: Self-regulation*). Changes in self-efficacy were related to changes in health status. A Dutch self-management program, partly based on the ASMP, showed beneficial short-term effects on knowledge, self-efficacy, performance of learned skills, physical function, and joint tenderness (Taal et al. 1996). After 14 months, effects were still found on knowledge, self-efficacy, and the practice of physical exercises, but most effects had disappeared.

Next to self-management programs, cognitive-behavioral therapy programs have been developed that are mainly aimed at the teaching of skills to cope with pain. Examples of skills that are taught in these programs are relaxation exercises, active coping strategies, such as diverting attention from the pain, and problem-solving skills (Keefe and Van Horn 1993). These programs have shown promising effects on the performance of coping strategies, pain, and physical and psychosocial functioning. Parker et al. (1995) evaluated an individual stress-management program for RA patients that included relaxation training and instruction in cognitive-behavioral coping strategies for managing stress and pain. Significant improvements were found on measures of learned helplessness, self-efficacy, coping, pain, and disability.

Long-term effects of psycho-educational interventions on pain, disability, or psychological well-being of RA patients are not often found (Keefe and Van Horn 1993, Taal et al. 1996). It is necessary to look for ways to improve the long-term benefits of psycho-educational interventions, for instance by including booster sessions in educational programs, teaching patients skills for the prevention of relapse (e.g., learning to identify high-risk situations and early warning signs, methods for coping with setbacks), or the improvement of social support through the involvement of patients' family members in educational programs (Keefe and Van Horn 1993, Taal et al. 1996). Radojevic et al. (1992) showed that cognitive-behavioral therapy with active involvement of a family member led to greater health benefits among RA patients than cognitive-behavioral therapy without family support.

It can be concluded that psycho-educational interventions that teach patients with RA self-management

skills and strategies for coping with pain and stress show promising results, but ways to improve long-term benefits have to be looked for. However, it must be emphasized that psycho-educational interventions for patients with RA can only be supplementary to medical treatment.

Ricardo, David (1772–1823)

Among the educated public only a few names of economists stand out: Adam Smith, the spokesman for capitalism; (T.) Robert Malthus, who earned for economics the title of ‘the dismal science,’ by virtue of his belief that any temporary gain in well-being would self-destruct by inducing population explosion that would entail diminishing returns and a retreat back to a subsistence ration of real wages; Karl Marx, the prophet of capitalism’s doom and the exponent of allegedly scientific socialism; John Maynard Keynes, proponent of the Mixed Economy, who rescued capitalism from the post-1929 Great Depression by activist government macroeconomic policies and public regulation.

Within the economics profession, it is a different story. David Ricardo was the archetypical classical economist, the economist’s economist who supposedly improved upon Smith and spelled out with Euclidean logic the eternal behavior of the market system. In amiable epistolary debates with his friend Malthus, Ricardo used to be reckoned the hands-down winner: Malthusian fears of recurrent depression stemming from under-consumption spending were argued to be fallacies. Like poet Robert Frost, beloved by both highbrows and lowbrows, the self-made millionaire David Ricardo captured the respect of the Victorian devotees to *laissez faire* as well as socialistic critics of Marxian or romantic stripe.

Schooled only in the Darwinian jungle of speculative finance, the broker Ricardo wrote as an autodidact, often in an obscure style that impressed his limited number of readers as being profound. Since 1817 literally scores of articles have appeared in learned journals debating whether or not David Ricardo did believe in ‘a labor theory of value.’ This is the stuff of which PhD theses can be made.

Ricardo was also lucky in having the learned Piero Sraffa edit for the Royal Economic Society, over a period of 25 years, a magnificent and complete edition in 11 volumes of *The Works and Correspondence of David Ricardo* (1951–73). Although this brought Ricardo’s name back into the limelight, oddly it seems to have contributed to a revisionist erosion of his analytic reputation. Whereas the late-Victorian Alfred Marshall, pillar of post-1870 neoclassicism, had idiosyncratically argued that the good modern stuff was

already in Ricardo, and whereas Keynes had written in the 1920s that David Ricardo's was 'the finest mind that had come to economics'—neither Ricardo's late-twentieth-century admirers nor detractors could agree among themselves as to what his different virtues and vices actually were. A scholar who is much misunderstood cannot be acquitted of all responsibility for ambiguity.

Ricardo's parents were Sephardic Jews who migrated to England from Amsterdam in the mid-eighteenth century. His ancestors had gone from Spain to Italy and then on to Holland. They seem to have been for the most part successful dealers in finance, an occupation that young David took up at the age of 14. When he married a Quaker, he was cut off by his father with the proverbial shilling; but within a score of years, working as a broker in the City of London, he had by his early forties amassed a comfortable fortune—the period of the Napoleonic Wars offered windows of opportunity for an alert and nimble financier. During vacation, when he picked up by chance Smith's *The Wealth of Nations* (1776), Ricardo was hooked for political economy.

Reversing the usual order of study, Ricardo first made his mark in what has come to be called *macroeconomics*. His unqualified verdict typifies his non-eclectic style. To finance a very long war against Napoleon, Britain expanded its money supply of paper currency in order to procure goods at home and abroad for its armies. Price-level inflation, not surprisingly, was part of the economic history in that period. Eclectic Smithian theory would no doubt have predicted as well a worsening of Britain's terms of trade as she and other belligerents bid up the relative prices of needed imports. Had gold and silver been the sole money used then in England and elsewhere, the 1750 theories of David Hume would have predicted a drain of specie from London to pay for the war-induced trade deficit of exports compared to imports.

However, even in those distant times much of the money employed for purchase and sale transactions involved use of paper-money currency. And, as is customary in times of war, whatever the supply of domestic gold or silver, there ensued a considerable rotation of the printing press to finance government needs and accommodate the desire for the enhanced cash necessary to conduct the enlarged volume of goods transactions and their higher average prices. Under these circumstances, whenever a government chooses *not* to redeem paper currency notes into specie at their previous face value, those notes will depreciate in price relative to ounces of specie. The high price of gold is what the person in the street calls this phenomenon and passionate voices debated its cause(s). Young Ricardo attributed *all* of the rise in gold prices to over-issue of paper notes.

Today one can write counterfactual history. Somehow the British government might have taxed the populace more heavily to finance in a balanced-budget

fashion the enhanced war effort and the irreducible rise in relative import prices; imposed tightness in bank lending, enforceable only at higher interest rates, conceivably could have kept the stock of paper currency unchanged, at the same time almost certainly imposing unemployment and extra loss of consumption on the civilian populace. With heroic tightness, trade balances might even have been forced to cancel out to zero. (It is hard to envisage how normal peacetime unemployment levels could have somehow been made to prevail from say 1795 to 1810 in this contrafactual scenario.) An inflation-free war can thus be painfully conjured up in contrafactual history; and with no wartime increment of paper-currency issue.

In actual history, paper notes did depreciate and price levels did soar. As happened a century later during the 1920–23 German hyperinflation, economists lined up in opposing camps. Young David argued: over-issue in currency M explained virtually *all* of the rise in the price of bullion. Henry Thornton, practical banker and Bank of England authority, (at first) argued that the microeconomic phenomena of adverse trade balances and war-induced buoyant business activity explained a significant fraction of the observed appreciation of bullion.

Ricardo's 1809–10 strong assertion of what was called the 'bullionist view' won him instant celebrity, particularly with the dogmatic James Mill. But this economic debate was not really a zero-sum game in which Ricardo's gain had to equal Thornton's loss.

Both men agreed on the likely longest-run outlook. The price of gold in terms of paper would be the same in 1850 if, in the many preceding decades, the supply of paper currency was limited enough to permit free specie-currency convertibility at the old 1790 ratio. The so-called 'Ricardian vice' was his use of *long-run* true relations to characterize actual short-run patterns in economic history.

After the first decade of the nineteenth century, Ricardo concentrated mostly on *microeconomics*. In 1815 (and *not* prior to then), along with Malthus and Edward West he helped articulate the 'law of diminishing returns' and its consequences for land-rent determination. Society's product, call it corn, is produced by labor and by land, both working together. When you increase labor in two *equal* increments, working on fixed land, you acquire two successive increments of corn. But the second gain is presumptively *less* than the first—a technological law of nature. Thus the wage that the competitive market can pay to labor goes down when labor/land density increases; and the rent that the market will pay for land will go up. This is not a new idea—it is in Benjamin Franklin (1755) early in the eighteenth century and already in Smith (1776)—but it is an important insight that needed being made explicit.

Already Ricardo had perceived what he considers faults in Adam Smith. Posterity can be grateful that

this perception tempted Ricardo into economics, even though it can be argued convincingly that Smith is mostly the more correct thinker in the cases where Ricardo criticizes him. For example, in the capital-and-land-and-produced-capital models that both writers worked with, Smith was right to jettison the ‘labor theory of value’ as soon as the interest rate and/or the land rent rate becomes significantly positive.

As between the two tasks of political economy—(a) understanding how relative scarcities of factors of production constrain the alternative availabilities of different goods and their valuation relations; and (b) how society’s harvest gets *distributed* among and between the different social classes of workers and owners of property—Ricardo arbitrarily declared it to be distribution that was all important. Yet nowhere in the 11 volumes of his *Works and Correspondence* (1951–73) will the reader find a *complete* and satisfactory theory of distribution that goes beyond what is in Smith, Malthus, Mill or modern mainstream writers.

Perhaps Ricardo’s lack of a university education contributed to his methodological style. Frequently he asserts general ‘truths’ that do admit of important exceptions; repeatedly he fails to distinguish between *necessary* and *sufficient* conditions for an argument. He is a superb miniaturist but with an absence of coherence, particularly in his post-1815 textbook phase. (Ricardo’s theory of comparative advantage in international trade, similar to that of the contemporary Colonel Robert Torrens, is a brilliant example of his miniaturist virtuosity.)

If it be thought that, by use of hindsight, I am a bit harsh on 1810–23 David Ricardo, let it be understood that I am even harsher on Ricardo’s twentieth-century commentators: the brightest and the best of them—Piero Sraffa, George Stigler, Samuel Hollander, Mark Blaug and scores of others—while understanding that the positive interest and time-phasing of production do generically invalidate Ricardo’s championing of the *labor theory of value* (as, indeed, Ricardo himself intermittently admitted), at the same time seem blind to the parallel fact that positive rent(s) on scarce land(s) must similarly invalidate the labor theory of value. (Edwin Cannan, Knut Wicksell, Jacob Viner and Lionel Robbins are honorable exceptions to this indictment of blindness about how labor/land intensities do generically invalidate any labor theory of value in the same logical way that time-intensities are known to do so.)

Around 1815, between his macro works on gold and his *Principles of Political Economy and Taxation* (1817, 1819, 1821), Ricardo did puzzle over a simple scenario involving a farm good (corn) and one or more manufactured goods (cloth, ...), all produced by, say, homogeneous labor, homogeneous land and by one or more *produced* inputs (corn seed, raw materials from farming used for manufactures, durable tools). He may even have worked out, in an unpublished manu-

script that has not survived, a one-sector farm-only model. In it, a determinate model of distribution could have cogently defined long-run stationary-state equilibrium for (real corn wage rate, interest rate, real corn rent rate) = $(W/P_{\text{corn}} = \bar{w}, \bar{r}, \text{Rent}/P_{\text{corn}} = R^*)$. How would it have gone?

Like Malthus and other predecessors, Ricardo would have specified *exogenously* a classical ‘subsistence wage’ rate, $\bar{w}$, needed to keep population just reproducing itself. Like classical successors he would have specified *exogenously* a minimal interest rate, $\bar{r}$, needed to keep capital(s) just reproducing themselves. Land being a classical constant, $\bar{A}$, its stationary equilibrium rent rate he would *residually* determine once variable labor-and-capital stocks, L_t and K_t , dynamically converged to their long-run, asymptotic stationary equilibrium levels: $L_t \rightarrow L^*$; $K_t \rightarrow K^*$, when K is a single scalar. Finally, short-run determination of w_t and r_t would be market-clearing rates dependent on the relative transitional abundances of L_t and K_t .

Here is how in the spirit of Prokofiev’s ‘Classical’ Symphony, an ambitious neophyte in a 1932 Hicks–Wicksell *neoclassical* workshop might synthesize these classical insights into a coherent simplistic dynamic equation system, using the notational convention $dY_t/dt = \dot{Y}_t$:

factor supplies: $\dot{L}_t/L_t = |\bar{\alpha}|(w_t - \bar{w})$,

$$\dot{K}_t/K_t = |\bar{\beta}|(r_t - \bar{r}), A_t \equiv \bar{A} = 1 \quad (1)$$

factor demands: $w_t = \bar{\sigma} K_t^{1/3} / L_t^{2/3}$,

$$r_t = \bar{\sigma} L_t^{1/3} / K_t^{2/3} \quad (2)$$

where $\bar{\sigma}$ is an exogenous parameter denoting level of technical productivity.

When the modern crank of deduction gets turned, Ricardo’s (1) and (2) do lead convergently to a determinate classical stationary state. From any *initial* $(L_0, K_0, \bar{A})_0$, as $t \rightarrow \infty$,

$$(w_t, r_t; L_t/\bar{A}, K_t/\bar{A}; R_t) \rightarrow (\bar{w}, \bar{r}; \frac{1}{3}\bar{\sigma}/[\bar{w}^2\bar{r}], \frac{1}{3}\bar{\sigma}/[\bar{r}^2\bar{w}]; \frac{1}{3}\bar{\sigma}[r, w]). \quad (3)$$

One must commend the classical tradition for so subtle an accomplishment. (Note the version worked out here differs from the Samuelson (1978) ‘canonical’ model, which had more faithfully adhered to the conventional labor-capital ‘dose’ version.)

This above supply–demand equilibrium is definitely *not* independent of the problem of how consumers wish to allocate their earned incomes among the many goods, when there are many non-corn goods in the picture. Then in it there are no ‘natural prices’ definable independently of how consumers choose to spend their incomes.

Definitely goods’ relative price ratios do not remain close to proportionality with their respective embodied-labor contents, $P_t^i/P_t^j \neq (L_t^i/q_t^i)/(L_t^j/q_t^j)$.

Likewise embodied land contents $(A_t^i/q_t^i)/(A_t^j/q_t^j)$ and embodied capital contents $(K_t^i/q_t^i)/(K_t^j/q_t^j)$ similarly fail as approximations to empirical actual P^i/P^j ratios.

Since Ricardo did not coherently understand the intricacies of his own classical scenario, he never realized how unattainable was his hankering to have all relative prices determinable purely by *objective technology and cost data*. Subjective variabilities (a) of consumers' utilities and demand choices and (b) of intertemporal saving-and-consuming choices—which became central preoccupations of post-1870 neo-classical successors to the classical school—were thus *already* unavoidable in the classical school's own capital, land and labor models and in the competitive scenarios that Marx grappled with all his working life. This inevitability will come with pain for the small sect of Sraffian neo-Ricardians who proliferated after 1925 and especially 1960.

Ricardo was low-keyed and civil in argumentation, albeit firm in holding to his strong positions. The letters between Ricardo and Malthus, notwithstanding these scholars' deep differences, are a model of courtesy and affection. Despite Ricardo's typical unqualified dicta, he did not hesitate to change his mind and admit to previous mistakes. Marx, who abhorred classical authorities and for whom 'Parson' Malthus was a particular *bête noir*, was uncharacteristically soft toward Ricardo. Here is an illustrative incident. After Ricardo's first edition of *Principles*, but prior to its third edition, David, Humpty-Dumpty like, had declared that technical invention *must always* help *all* factors of production, including the working man. He encouraged disciples, like J. R. McCulloch, to affirm this strong view. However, on reconsideration, Ricardo came to realize that some inventions can assuredly *replace labor and reduce the demand for labor in the short and the long run*. Therefore, despite friends' warnings that this would weaken the case for *laissez faire*, Ricardo added a new chapter on Machinery to the third (1820) edition of the *Principles*, presenting exposition and numerical examples designed to show how labor's share of national income could suffer from certain possible inventions and how long-run equilibrium populations and gross-income levels could be permanently lowered. With virtually no exceptions, ancient and twentieth century authorities agreed that for once Homer had nodded. For once David must have invoked rigidity of wage rates with its resulting unemployment, thus for once denying J.-B. Say's sacred dogma that over-production is impossible in a capitalist system. Karl Marx praised the scholar for his honesty.

It is a story that casts discredit on virtually all. The Ricardo–McCulloch original sweeping position was gratuitously wrong. A new wind that raises an economy's *potential* for production and consumption most certainly can do harm to *some* competitors while helping others. (Ricardo did not, as J. S. Mill and

Vilfredo Pareto were later to do, argue that gainers could always bribe losers so that *with intervention all could gain*.) Nor did Ricardo's new understanding motivate him to abandon a dogmatic defense of *laissez faire*. His critics on Machinery, both then and in our time—including Knut Wicksell, Nicholas Kaldor, Joseph Schumpeter, George Stigler, ...—failed to see the absence in Ricardo's exposition of any denial of dogmatic Say's Law and its ruling out theoretical harm from under-consumption; instead his usual classical scenario of population decline dictated by the induced drop in the wage below an alleged equilibrium *subsistence* rate would, as the Machinery chapter alleged, call for an ultimate drop in population and gross product as a result of labor-saving invention(s). Just as the industrial revolution was beginning to raise wages by a genuine filter-down process, the philosophers of the Chair were getting first intimations of the complexity of how a market system metes out its distributive awards.

In that long ago age before antibiotics, David Ricardo in 1823, at the peak of his powers, died from an ear infection. Thus he never lived to see the 1836 Repeal of the Corn Laws, a vindication of his pamphleteering for free trade; and he did not live to witness Ireland's great famine of the 1840s, with its brutal confirmation of the laws of the free market.

In summary, David Ricardo, like the twentieth-century economists Friedrich Hayek and Milton Friedman, importantly pushed voters and public opinion toward libertarian *laissez faire*. Victorian England's Whig society and Manchester School owed much to him. In the modern debate about how a modern mixed economy can optimally compromise between market mechanisms and democratic rules of the road, Adam Smith and John Stuart Mill seem more subtle classical thinkers. From these two, rulers like Lenin, Stalin and Mao could have had the most to learn. But among the worldly philosophers, David Ricardo must be counted as an important shaper of the twenty-first-century mind.

Rights

No concept is more central to our moral and political thought than that of rights. We talk about our rights to life, liberty, and freedom of expression; we discuss the rights of children, animals, illegal immigrants, and prisoners of war; we wonder whether we have rights to health care, a decent wage, or physician-assisted suicide. We seem to make sense of a myriad of legal and moral rights, even as we debate their boundaries. Yet few concepts so central to our thought are more deeply puzzling. The clearest evidence for this is the persistent disagreement over the content of even the most basic rights. Is a right to a free press a basic human right? Many people around the world would deny that it is. Is there a basic or human right to health care? Who has the duty to provide it, and on what grounds? Do parents have a right to discipline their children? Do workers have a human right to ‘periodic

holidays with pay,’ as one United Nations document asserted? The problem is not simply that such assertions are controversial, but that we can feel so quickly at a loss about what to say next. Clearly, the concept of rights has been debased in recent years, as rights claims have become mere attempts to give rhetorical force to strongly held preferences, but the problem also lies in some deeper puzzles about the nature and justification of rights.

The least controversial rights are those created by laws and the shared norms of our institutions and practices, where rules allow us to coordinate and regulate our activities and to divide fairly the benefits and burdens of social cooperation. Any attempt to understand the concept of rights should begin here. If Smith gives tools to Farmer in exchange for a share of the grain Farmer will produce, then Smith has a claim to the grain after the harvest, and Farmer has a duty to turn it over. It seems natural to say that Smith has a right to the grain, and laws will respect and enforce such rights.

Governments have a right to tax their citizens to provide public goods, but laws also protect citizens by creating rights against other citizens and against the government itself. Civil society is founded on the concept of property, which is nothing more than a set of practices that allocate entitlements—in other words, rights to use and exchange things of value. Many of the functions of government create rights in this sense, by establishing entitlements and enforcing agreements.

1. Origin of the Concept

If it is possible to have a concept without having a word to denote it, as one view of rights maintains, then the idea of rights goes back to primitive societies and can be inferred from ancient texts. According to this view, any society with an institution of property understands the ideas of entitlements to use and claims against infringement, which are part of a theory of rights. Ancient laws also established other liberties and privileges. The Roman law of persons, for example, recognized different status for different members of society. The citizen, the resident alien, and the slave were all granted different powers and liberties, and the law determined when these people could change or lose their status. Romans thus had (and could forfeit) various personal rights.

A different view argues that rights did not exist until sometime in the late Middle Ages, when we first find a word to denote the concept (Tuck 1979). There is an important difference between the implicit, ancient understanding of practices that we regard as rights and this more explicit idea. According to this view, the ancient meaning is restricted to an objective sense of right, which refers to a state of the world. Ancient and medieval societies were dominated by ideas of the

natural differences between people. If someone was properly a citizen or a slave, or later a lord or a servant, their social rank determined their powers and privileges. Their status was meant to reflect the objective or correct natural order of the world. The concepts that come closest to describing this objective sense of right—*dikaiois* in Greek and *ius* in Latin—imply an idea of a proper natural order.

The modern notion of rights, as we might call it, developed as the idea that the natural or inherited differences in status could be justified was replaced by a belief in the fundamental moral equality of all people. Historians note that this idea of human equality was not new in the late Middle Ages. It appears in the writings of the stoics and early Christians, but these ancient philosophies did not attach much importance to earthly life. As traditional social orders began to crumble in Europe, the natural differences between people came to be seen as morally arbitrary. Justice required correcting these arbitrary differences with a more egalitarian distribution of powers and opportunities. As moral thought focused on the more worldly concerns of social and political interactions among people, the subjective idea of a right emerged, as something that belongs to individuals. Thus, where ancient and medieval philosophers would say that it is right that Smith controls some thing, modern theorists would say that Smith has a right to that thing (Dagger 1989, Tuck 1979).

Rights in the subjective sense express the moral importance of the equality of persons. They justify both the claims we make against others and the duties that arise in respect of those claims. But this idea of rights is no less puzzling than that of a natural moral order. Do rights exist? What is their content and justification?

2. An Analysis of Legal Rights

The revolutions in the USA and France in the eighteenth century were fought in part as a defense of the natural and inalienable rights of humans. Liberal republics and democratic governments based on these rights were established, first in the USA and Europe, and then elsewhere. By that time, the modern idea of rights had fully taken hold in law, morality, and political theory.

Early in the twentieth century, Wesley Hohfeld categorized legal rights in a way that has profoundly influenced subsequent moral and legal theories (Hohfeld 1923). He argued that an assertion of the form ‘Smith has a right to P’ is ambiguous and could mean any of four different things (or some combination of them). It could mean, first, that Smith has a *privilege* to do P, or that he is under no obligation not to do P. Smith’s right to find solace walking in a public park is a privilege, or as it is sometimes called, a mere liberty. It does not imply any corresponding duties on the part of others. The fellow on roller blades who

insists on circling Smith in the park, with his boom box blasting, is also exercising a privilege, even though his activity undermines Smith’s efforts to find solace. Hobbes’ claim that in the state of nature ‘every man has a right to every thing’ has been interpreted as a privilege in Hohfeld’s sense. Hobbes was asserting merely that in the state of nature a person could not be criticized as irrational for laying claim to any thing, although nobody else has a duty to provide him with any thing that he might claim (Waldron 1984).

Hohfeld’s second meaning of ‘Smith has a right to P’ is that Smith has a *claim* to P, which imposes corresponding duties, either positive or negative, on other people to allow or enable Smith to have P. Legal theorists following Hohfeld analyze claims further by distinguishing between rights *in personam* and rights *in rem*. This distinction has implications for the kinds of duties implied by a claim. Claim rights *in personam* impose duties on particular individuals. A contract is such a right. If Smith agrees to work for Miller, then when Smith completes the work, he has a claim that requires Miller to pay the agreed wage. Claim rights *in rem* impose duties generally on all others. Property rights are an example. If Smith owns a car, then every other person has a duty not to interfere with Smith’s use of the car. Each person’s right not to be assaulted is also a claim right *in rem*, which means that in respect of this right, each person imposes a duty on all other people not to harm him in certain ways. In order for such rights to seem plausible, the duties must typically be negative, i.e., duties to refrain from doing something. Unlike positive duties, the millions of negative duties we impose on each other in respect of our rights *in rem* do not create any unreasonable burden. We can fulfill all of these duties simply by minding our own business and not assaulting anybody.

Hohfeld’s two remaining categories of rights apply more specifically to legal contexts. ‘Smith has a right to P’ could mean that the law gives Smith certain *powers* to alter legal relationships, which do not entail corresponding duties. Smith exercises such powers, for example, when he sells or transfers property. Finally, ‘Smith has a right to P’ can mean that Smith has an *immunity* from certain kinds of legal change, i.e., he is protected from any or all other authorities altering his legal position. Constitutionally guaranteed privileges or inalienable rights are examples of immunities. Hobbes’ argument, that when humans enter into civil society and give up their rights to the Leviathan they nevertheless retain the right to defend their life under all circumstances, is a combination of a privilege and an immunity.

3. The Nature of Moral Rights

That legal systems and other institutions give rise to rights is unproblematic, but rights also play a more fundamental role in moral and political theory, where

they are often regarded as existing independently of and prior to social institutions. The Declaration of the Rights of Man and the Citizen in France states that 'the end in view of every political association is the preservation of the natural and imprescriptible rights of man,' and the Declaration of Independence in the USA asserts that all citizens have inalienable rights to life, liberty, and the pursuit of happiness. Natural rights constitute the moral basis and justification of government and laws. They express and give meaning to the belief that all people are morally equal.

Claims to natural rights have always been controversial, however. Jeremy Bentham (1834) famously dismissed them as 'pernicious nonsense,' and wrote that 'a natural right is a son that never had a father.' The controversy is about the nature of basic moral rights and their connection to duties, as well as about the justification of basic or natural moral rights. We will address these issues in order.

The defender of basic moral rights need not assert that all moral duties are correlated to rights. Kant, for example, discusses imperfect duties, such as the duties to be charitable or kind. No individual can claim the performance of such duties as a right, and governments may choose not to enforce them. We also have legal duties, such as a duty to pay taxes, which we are morally obliged to fulfill, but the performance of which no individual can claim as a right.

Whether moral rights must be correlated to duties is more controversial. Many theorists claim that they are, but Joel Feinberg (1980) has argued that moral rights may exist without any corresponding duties. Feinberg distinguishes between what he calls justifiable rights claims and valid rights claims. The former can exist when there are good reasons for a right to exist, even if nobody is in a position to provide what the rights-holder may claim. The idea of human dignity underlies some human rights, for example, which in Feinberg's view justifies claims that certain basic human needs should be met. But in some parts of the world today, nobody is in a position to meet those needs, so they cannot be required as a matter of duty. These rights should be interpreted as developmental goals, the fulfillment of which governments and other agencies must assign the highest priority. Feinberg calls such rights 'aspirational.'

A valid right in Feinberg's sense exists when the claim is justifiable and the corresponding duty can be specified and acted upon. In such cases, the right is logically prior to the corresponding duty. Thus, if Smith has a right *in personam* against Jones, then Jones has a duty in respect of this right. Smith's claim creates the duty for Jones, and if Smith forfeits the right or chooses not to claim it, then unless some other party has the authority to make the claim on Smith's behalf, Jones' duty does not exist.

We can thus interpret moral rights as valid claims, which can be created by law or else founded on the moral belief in human equality and dignity. In order to

explain rights in this way, however, we must be careful not to beg questions about the existence of rights in our understanding of claims. To claim a right is not merely to claim a truth, in the sense that to make a claim can be to assert the truth of a proposition. Claiming rights must be understood as involving a different kind of activity, more like claiming a patent for an invention or a site for a homestead in a newly settled territory. To claim something in this sense is to perform an activity different from asserting, which can create legal and moral consequences. To claim one's basic rights is to demand recognition of one's status as a moral equal, which imposes duties on others in respect of one's claims. Thus, following Feinberg (1980), we can say that a moral right is a claim, the recognition of which is called for by laws, moral principles, or an enlightened conscience.

4. Two Views of the Justification of Rights

This article has been describing rights by explaining their role in societies in which they are recognized. This argument might also count as a justification of rights or an argument, so to speak, for their normative existence. But to this point the argument sidesteps one of the most puzzling aspects of rights, which is about the nature of the values they promote or express. Are rights merely means for promoting other goods and preventing evils, or do they also have intrinsic value? This question has received considerable attention in recent philosophical literature, and most attempts to answer it are controversial. The following sections will consider defenses of each position.

The first approach argues that the value of rights is instrumental. Rights promote goods and prevent evils, the value of which can be explained without any reference to rights themselves. According to this account, rights provide people with certain social guarantees that are necessary for living happy and fulfilling lives. They are part of the institutional structures that give people power over their own lives and protect them from the abuses of governments or other groups.

In order for these guarantees to be effective, we may have to develop the strict prohibitions against doing certain things that rights typically require. We must refrain from treating people in certain ways, not only when the consequences would clearly be bad, but also when we believe in a particular case that the act would produce the best consequences overall. This is because deciding what to do on the basis of calculating the value of our actions in each case would produce consequences that are worse than those produced by institutions that rule out such calculations.

There is much to be said for an instrumental justification of rights. In a utilitarian theory, for example, intrinsic value is located in the aggregation of individual happiness or well-being, and rights play

an important role in promoting this value. Rights that establish property and legally enforceable contracts are effective ways to coordinate individual actions and foster ties of cooperation and trust. Rights that protect individual liberties give people the opportunity to promote their own happiness, which is generally a more effective way of achieving happiness than trusting the task to others. Rights that protect the freedoms of conscience and expression enable people to discover important truths that are necessary for reducing suffering and increasing happiness. In relatively affluent societies, a utilitarian might also defend positive rights to food, shelter, health care, a minimum income, and other basic needs, because the redistributive effects of recognizing such rights can increase social welfare. A utilitarian would thus defend most of the rights we take for granted, as well as many that are controversial.

Critics of utilitarianism may defend many of these same rights, but they will disagree about their justification. The utilitarian justification of rights depends on empirical assumptions that make it the case that rights are effective means for promoting happiness or welfare. But these assumptions may fail to hold, or the facts may be such that violating the rights of some would produce greater happiness overall. If rights are to have a more fundamental and secure role in political and moral thought, according to these critics, then they must be justified by appealing to other, more basic values.

Ronald Dworkin (1977) argues that the fundamental requirement of any legitimate political system is that it treats all people with equal respect and concern. Equality of respect means that, except in extreme circumstances, it is wrong to require some people to sacrifice their interests for the greater happiness of others. Rights play an essential role in securing equality, because they restrict the individual preferences that social and political decisions may legitimately consider, thus guaranteeing to all people a measure of independence from decisions aimed at promoting social welfare or the general good.

The kind of preferences that rights aim to restrict are primarily what Dworkin calls external preferences. These are preferences about how other people should be treated or what they should be permitted to do, because of who they are, because they have interests and desires of which others disapprove, or because their suffering is a source of happiness to others. Dworkin argues that unless a political system disallows these external preferences, it fails to show equality of respect. Under such conditions, a utilitarian concern simply to maximize the satisfaction of individual preferences lacks political legitimacy. Rights thus have a kind of lexical priority in Dworkin's system, which he expresses by saying that rights trump utility.

Another critic of utilitarianism, T. M. Scanlon (1977), argues that the basic values that a political

system should promote must include not only what happens to people but also factors that affect the ability of individuals to determine what will happen to them. People care about their ability to influence outcomes, and they want to be protected from interference or control by others. The goal of rights is to foster and protect this kind of autonomy.

If Scanlon's view is to be distinguished from a sophisticated utilitarianism, however, then the value of autonomy must be defended as an objective good that does not depend on the strength of the preference for it among the people that live in any society. Scanlon argues that moral values must be determined not merely by an aggregation of preferences but by an ethically significant objective notion of their importance. To value autonomy is 'to be concerned with the conditions necessary for people to develop their own aims and interests and to make their preferences effective in shaping their own lives and contributing to the formation of social policy' (Scanlon 1977, p. 85). Rights protect people from the paternalistic interventions of others, and they ensure an acceptable distribution of control over important factors in our lives. Rights would protect religious freedom, for example, even in societies where the majority of citizens care passionately about making their religious views mandatory, while the minority who don't share these beliefs also have tepid preferences about religion. A concern for autonomy implies that people must be free to make their own decisions about religion independently of the control of others.

James Griffin (1999) argues for a different but closely related non-utilitarian justification of rights. He appeals simply to the value of human agency. Griffin argues that a fundamental moral value, more important even than happiness, is the distinctly human ability to contemplate and plan a future. We deliberate, assess, and choose in ways that enable us to envision a good life and act to realize it for our self and others. This value of personhood or agency, however, rests on certain conceptual and empirical facts. One of these facts is the condition of autonomy, which Griffin interprets as the ability to choose a course in life free from domination or control by other forces. But the value of agency also demands that we be provided with some level of education, information, and the chance to learn what others think, so that our choices will be appropriate to our deepest interests. We must have the ability to follow the course of action we have chosen, which includes an adequate supply of material resources and capabilities, as well as protection from having our efforts blocked by others. The goal of rights on Griffin's account is to enable people by protecting and providing these conditions of agency. The basic right in Griffin's system is thus a right to *pursue* happiness, which is more important than maximizing happiness itself.

These three conceptions of moral rights are non-utilitarian, because they appeal to values such as

equality, autonomy, or human agency and claim that these values are more basic than happiness or well-being. But these theorists share with utilitarians the view that the value of rights is instrumental. Rights are part of the structure of institutions that aim to promote other basic values, and they can be overridden for the sake of promoting the values that justify rights in the first place. For example, if rights are justified because they promote equality of respect, then we would be justified in violating equality in some instances in order to produce greater equality overall. On any of these accounts, we presumably should still violate the rights of one innocent person if this is necessary to protect the rights of five other innocent persons.

While these implications might seem acceptable to many people who view rights as morally important but not absolute, they are unacceptable to theorists who believe that rights have intrinsic value. The belief that the value of rights is intrinsic lies at the core of the second approach to justifying rights. According to this second approach, all instrumental accounts of the value of rights fail to explain the way in which rights determine how a person may or may not be treated. Rights aim to secure for each person a realm of independence, not only from the will of the majority but more generally from pursuit of the best overall result.

In order to have this kind of intrinsic value, rights do not have to be regarded as absolute (Nagel 1996). If there is a right not to be tortured, for example, it may nevertheless be the case that some evils are great enough that they would justify torturing one innocent person to prevent them. The threshold for such justifications would have to be set high, however. Torturing one person may be permitted to save a thousand lives, but it would not be permitted to save one life or to prevent two other innocent people from being tortured.

This intrinsic justification of rights expresses requirements for how we may treat other people in a way that is relatively independent of the value of what happens to them. It tries to explain what we are *prohibited from doing* to others in respect of their rights, which it regards as different from what we must try to *prevent from happening* to them. Thomas Nagel, who defends this view of rights, explains that, 'It is this qualified independence of the best overall results... that gives rights their distinctive character' (Nagel 1996, p. 89).

Robert Nozick (1974) assumes the truth of an intrinsic account in his influential defense of natural rights. He insists that rights should be interpreted as side constraints, which mark the bounds of value-based deliberation and set limits to what we are allowed to do in pursuit of all other goals (see also Thomson 1990). But Nozick simply accepts the traditional view of natural rights and does not explain why they should have this character. Without appealing to something such as divine sanction for

natural rights, however, as did many of the traditional natural rights theorists, it seems *ad hoc* to posit rights as first principles of moral deliberation. It begs the question about why it would be wrong to torture one innocent person in order to prevent the torture of five others.

A different intrinsic account, which has been defended by Alan Gewirth (1981, 1982), tries to connect the justification of rights to the capacity for moral valuing, which human beings typically and uniquely possess. Rights express the conditions that make it possible for people to recognize and act on values, so respect for rights is necessary in order for things such as happiness or equality even to exist as moral goods. To violate a person's rights for the sake of some other value, therefore, undermines these conditions and thus makes the actions impossible to justify. While this kind of transcendental argument has drawn much interest among philosophers (see Hart 1955), many people do not find it convincing. If you kill one person in order to prevent five other people from being killed, you cannot then justify what you have done to the victim. But as long as the conditions necessary for him to recognize and act on moral values exist, it is not clear why a person could not comprehend why he might have to be sacrificed for the sake of others.

Another and currently popular intrinsic account of the value of rights appeals to our status as human beings. But rather than seeing human status as an objective moral value, this argument insists that status generates different kinds of moral requirements. Human status is a feature of each person that allows them to claim rights and demand to be recognized and treated in certain ways. Frances Kamm (1992) interprets this status as a kind of inviolability, which she identifies with the possession of rights. According to this argument, if one innocent person may be tortured in order to prevent the torture of five other innocent people, then not only have the rights of that one person been violated, but this acknowledgment of what *may* be done to someone undermines the inviolability of all people. Everyone's moral status is thus compromised by such an act (see Quinn 1993, Nagel 1996).

This argument for the intrinsic value of rights resonates with Feinberg's (1980) interpretation of rights as valid moral claims. He attempts to illustrate the significance of rights by imagining a society that is in every other way as good as possible but does not recognize moral rights. People in this imaginary society are virtuous, caring, and may even be motivated by a sense of duty, but without rights they can only receive beneficent treatment as a gift. If they fail to get what they deserve, they have no ground for complaint. What people lack in a society without rights is the capacity to claim their status as equals and to demand that these claims be recognized. Indeed, Feinberg suggests that the ability to claim rights may be necessary to having the minimal self-respect that

makes a person worthy of the love and esteem of others. A society without rights may be incapable of supporting the kind of love, compassion, and sympathy that we most esteem.

The moral importance of inviolability is thus different from the objective value of not being violated, and it is expressed in terms of moral requirements, the recognition of which each person can demand from all others. If this kind of argument could be made convincing, then it would have several important implications. First, it would explain why it is wrong to violate one person's rights, even to prevent similar violations of five other people. Second, it would explain another feature of rights that internal accounts regard as important, which is that rights imply that it is morally more important not to treat people in certain ways than it is to prevent identical harms from occurring to people. We value the reduction of harms, but rights express our idea of human dignity because they impose moral requirements that take precedence over what we value.

The justification of rights remains a matter of controversy. The difficulty is to defend a theory of rights that captures most of our deepest intuitions about them without making them seem mysterious or paradoxical in the ways we have been discussing. Most philosophers would acknowledge that much work remains to be done in defending an adequate theory of rights, just as most people would acknowledge that much more important work remains to be done to secure the protection of basic human rights for most of the world's population.

Rights: Legal Aspects

1. Definition and Background

1.1 The Basic Logic of Rights

The language of rights generally connotes claims of entitlement to certain goods. To assert that 'I have a right ...' is to articulate a normative claim that certain actions should or should not be performed by other individuals, agencies of the state, or intermediate social institutions. As such, rights are related to, but different from, preferences, interests, and needs. While rights are often invoked in the service of preferences and interests, only those rights which confer legal and/or moral authority that obligate others are enforceable by official power. Hence, whereas the assertion of a preference connotes merely that 'I want ...,' to assert a right is to declare that 'I am entitled to ...' Rights thus assume priority in the normative schemes of social ordering; they take priority—or 'trump,' in Ronald Dworkin's memorable phrase—over preferences and interests. Rights similarly take precedence over needs in much the same way—but with one major difference: needs, unlike preferences, convey an objective status that can be validated by persons other than the claimants themselves. Claims to rights, also, are subject to third-party validation, but are, unlike the identification of needs, typically initiated by individual agents acting on their own behalf (Waldron 1996).

Because rights constitute relationships between the

bearers of rights and other persons or institutions, each person's rights impose correlative duties on others. These duties may be negative in that they mandate noninterference or inaction by others, as in one's claim of a right to liberty, privacy, or autonomy. Conversely, the duties imposed by rights may be positive in that others are called upon for action and assistance—as, for example, to ensure the fulfillment of contractual terms or to provide accessible facilities for voting in political elections. Rights may be primarily negative or primarily positive, but they may also involve elements of both.

Rights not only correlate with duties, they also extend by implication to all other similarly constituted relationships in society and are, thus, inclusive. This inclusiveness is the source of the frequent claim that rights are universalistic—i.e., that they can be claimed by, and impose duties on, all citizens within particular sovereign domains. Similarly, the exercise of rights typically confers responsibilities on the rights-bearer. For example, a person may have a right to drink alcohol and a right to drive a car, but these rights imply responsibilities for not engaging in both activities at once. Finally, rights are intrinsically linked to remedies. Thus, for example, not only does the right to equal treatment oblige others not to discriminate, but should discrimination occur, the right to equal treatment requires a remedy to compensate for or to correct the denial of a basic entitlement.

1.2 The Origin and Evolution of Rights

The most widely recognized origin of rights is in European social contract theory dating back to the seventeenth century, and especially to *John Locke's* classic *Two Treatises on Government*. From this work, rights emerged as a moral imperative that is found at the very core of several of the most important political documents in the modern age—including the United States Declaration of Independence as well as the Bill of Rights, and the French Declaration of the Rights of Man and Citizen. While the concept of rights thus dates back several hundred years, and has provided a founding principle for several longstanding liberal republican orders, it is in the second half of the twentieth century that the moral ethos of rights took on widespread significance around the world. The persuasive power of rights developed, in part, in reaction to horrors of authoritarian states—Hitler's genocide, Stalin's purges, colonial repression and the like—and, in part, in recognition of deprivations suffered by ethnic and racial minorities, women, gays and lesbians, and other marginalized groups in nations throughout the world.

1.3 The Expanding Variety of Rights Claims

The evolution and diffusion of rights through the centuries and around the globe has been boiled down

by analysts to three separate stages, or generations, of rights claims.

1.3.1 First generation rights. These are closely linked to the rule of law and to liberal social contract theory; they are regularly found in the constitutions of liberal democratic regimes throughout the world, as well in such transnational legal orders as the European Convention on Human Rights. First generation, or classic rights, are embedded in the logic of both property ownership and in the law itself. On one hand, such rights tend toward the more negative pole, demarcate limits on interference by the state or other social actors, and turn on conceptions of liberty, privacy, due process, and the like. On the other hand, classic, first generation rights also include more positive rights to political participation—to free speech and association, to vote, to run for office, etc.—and to fair treatment by others according to the principles of due process and equal treatment. These rights claims are the most widely recognized and the least contested in general, although specific constructions vary greatly.

1.3.2 Second generation rights. These can be traced to the social democratic traditions of Europe and have during the last century gained currency elsewhere—although not, most notably, in the United States. Second generation rights have to do primarily with entitlements to economic and social wellbeing of the sort formulated in Articles 22–27 of the Universal Declaration of Human Rights (1948)—including, for example, basic education, health care, minimum income, secure employment, workplace organization, food, housing, social security, and the like.

1.3.3 Third generation rights. These are newer in conception, different in kind, and particularly controversial. Advocates of third generation rights seek to confer entitlements to collective or communal goods such as peace, security, a healthy environment, safe natural resources, animal welfare, and group self-determination or sovereignty, and thus seek to its rights to animal. The problematic posed by third generation rights will be addressed below.

2. Contemporary Philosophical Debates About Rights

The original conceptions of so-called liberal Western thinkers in the social contract tradition grounded rights in the theocratic logic of God's divine plan and natural law. Later versions downplayed the divine hand but continued the emphasis on rights as self-evident and inalienable features sewn into the rational

order of the natural universe or human nature. By the twentieth century, the philosophical foundations for rights became thoroughly secular—whether justified by various forms of moral rationality or appeals to proven historical efficacy. It is within the tensions among these legitimating logics that many of the most important philosophical controversies about rights have been waged. We identify just a few of such persistent debates.

2.1 ‘Nonsense Built on Stilts’

This critique, that can be traced back at least to Bentham and continues today among critical ‘neo-realist’ philosophers, turns on the recognition of rights indeterminacy. The core contention is that if rights are indeterminate and contingent, if they always are changing, and vary with context, then they really mean nothing at all and convey no real social power. Rights, it is argued, are simply moral fictions that possess none of the objectivity, coherence, independence, and universality that philosophers, state officials, and popular culture assign to them. At best, rights are epiphenomenal reflections and rationalizations for relations grounded in other types of causal forces. Respondents to this position acknowledge that rights are social constructions, but the very fact that people believe that rights matter and act accordingly in interpersonal relations, often in the shadow of official enforcement, demonstrates the power of rights. It is further argued that all moral discourses are indeterminate and that it is, therefore, inappropriate to dismiss rights discourses as meaningless because they are unstable and contestable. Indeed, according to this argument, the indeterminacy of rights discourse, as with moral discourse more generally, is desirable in providing a flexible, dynamic, and pragmatic tradition for ordering social relations in just ways.

2.2 Who Has Rights?

The debate over the qualifications for rights-bearing is as old as the concept itself and has expanded among moral philosophers as specific rights claims themselves have proliferated. From the start, rights typically have been understood to be properties belonging to all individual human agents capable of claiming them. But it has been precisely these qualifying properties of rights bearers as human agents that have been deployed to limit the reach, and some might say to betray, the promise of rights. Thus, paradoxically, the claim that rights apply only to rational, disciplined, educated, human agents capable of self-government has been invoked to deny rights to children, women, ethnic and racial minorities, religious adherents, immigrants, and the like in many societies that generally recognize individual rights. Similarly, the principle that rights inherently presume individual human

claimants has been central to contemporary arguments that third generation entitlements of animals and other nonhuman forms of life (e.g., trees), as well as nondivisible communal goods such as peace and a safe environment, are not suitable for rights claims. The philosophical skeptics argue that such claims lack theoretical coherence and might even undermine the social power of rights discourse itself. Such debates have generated extensive reconsideration about the very foundation of the meaning of rights as a social practice.

2.3 Do Rights Encourage Atomism, Egoism, and Selfishness?

The contention that rights practices encourage excessive individualism, egoism, and selfishness among citizens was perhaps most forcefully articulated by Karl Marx and is commonly asserted by moralists across the political spectrum today. Critics emphasize in particular the tendency of rights to celebrate the individual and thus to undermine citizens’ sense of responsibility for their actions, duties to others, and a shared commitment to ‘community.’

Theorists more favorably disposed to rights acknowledge that rights discourses presume, encourage, and protect individuals. Indeed, securing and advancing the exercise of individual citizen capacities for choice, action, self-development, and diversity against the harmful designs of other individuals, social groups, popular majorities, and the state has been the *raison d’être* of rights as a moral concept from the start. At the same time, however, most theorists understand the rights of individuals in relational rather than insular terms. Rights practices sustain particular obligations that are reciprocal among citizens as well as a general tolerance and even respect for the human dignity of others. In Kant’s (1948, pp. 95–6) famous words, ‘Act in such a way that you always treat humanity, whether in your own person or in the person of another, always as an end and never simply as a means.’ Defenders thus argue that, far from undermining a sense of duty, rights support and enforce dutiful interaction among citizens. According to this way of thinking, rights connote a particular vision of community where individual agency is respected but balanced with conceptions of fairness, justice, and equal treatment for all. It follows that it is precisely the disregard for basic rights that encourages or permits unjust or exclusionary acts that are corrosive of community.

There is also a middle position in this debate. To begin with, it is widely recognized that some rights are more self-regarding than others. Marx’s powerful indictment, after all, was that it is property rights that encourage selfishness, materialism, and competition for dominance through capital ownership. As a consequence, he argued, it was the positive communal promise of political rights which was overwhelmed, thus reducing the promise of political solidarity to an

illusion. The underlying point here is that critiques of rights that fail to distinguish among different types of rights—within the first generation as well as among the different generations of rights concepts—are unconvincing to many moral theorists.

3. *Jurisprudence and Legal Theory*

Contemporary discourse on rights within jurisprudence and legal theory is driven by an effort to identify a distinctively legal conception of rights. This discourse is organized around two foundational debates—pitting rights against democracy on the one hand, and natural law against legal positivism on the other. Historically, there have been profound and heated conflicts among the parties to these debates, but more recently a rapprochement has developed around the recognition that rights and law are mutually constitutive—that rights without the law are virtually unthinkable, as is law without rights. This convergence not only identifies the core common ground of legal theory; it also reveals the distance that separates the legal theory of rights from the understanding of rights that is found in moral and political philosophy. Whereas philosophical understandings of rights reach well beyond the law in search of universal moral meaning, rights in legal theory are much more constrained—principally by way of the intrinsic connection in legal thought between rights and the institutional processes in which rights under law are embedded. In particular, legal theories of rights seek to specify and to justify the responsibility of courts and judges for resolving disputes over rights, and for policing the boundaries of legitimate rights claiming.

3.1 *Legal Rights vs. Democracy*

The problem of the legitimation of rights claims is especially troublesome to legal officials in democracies and republics, where majority will is understood to carry considerable authority. We noted above that rights, by their very nature, are intended to protect and advance individual entitlements that restrict the actions of others, including those of popular majorities. As such, rights—both in general, and in specific instances—are often condemned as counter-democratic forces. Utilitarian theorists raise a parallel objection that begins with the assertion that rational public policy should provide the greatest good for the greatest number—thus giving considerable weight to the preferences of the majority. Rights are thus often challenged as costly obstacles to the development of democratic and efficient (see below) social policy.

Other legal theorists respond that rights do not thwart so much as give structure to utilitarian policy calculation, by assigning higher values to certain basic entitlements—especially those concerning protection for individual freedom and dignity—than to other

competing considerations. Consequently, securing rights may impose costs on particular social goals, but these costs are arguably incurred in order to sustain larger, enduring social commitments. Likewise, it is argued that rights claims do not absolutely throttle democratic majorities or elected officials; rather, rights claims tend only to place specific, limited restrictions on particular policy actions that defy core social values and protection for individuals. Moreover, it is important to underline that many types of rights advance—indeed, are actually essential to—the democratic process. Such entitlements include, at the least, protections for dissenting speech, political association, free elections, due process, and basic public education.

There is no simple way out of this debate. While it may well be true that rights in general provide sustenance to democratic polities, particular rights constructions certainly do, and indeed are intended to, defy the will of elected officials and popular majorities. Hence the enduring challenge for judicial authorities is to justify by legal argument their specific rights constructions.

3.2 *Rights and Justice*

Historically, a divisive debate in legal theory between positivism and natural law has pitted a theory of law that recognizes little in common between morality and law against a conception of law as being inseparable from morality. The latter is virtually indistinguishable from the moral philosophy of rights discussed earlier, and represented by the work of Locke and Kant among others. The former is rooted in analytic philosophy and in a logical positivism that eschewed the search for universal truths. During the late twentieth century the gap between legal positivists and natural law theorists narrowed (but was by no means closed) by the emergence of a widespread agreement on a least-common-denominator conception of justice as the ‘right to have rights.’ According to this way of thinking, the guarantees associated with rights are confined to assuring predictability, reciprocity, and impartiality in the application of the law. What remains unresolved in the debate between theorists of natural law and legal positivism is whether justice, as thus defined, is the differentiating element of legal right, or only a quality that tends to be closely associated with legal rights.

While many jurists have not reached out to the broader realms of political and moral philosophy, Ronald Dworkin, (Dworkin 1977) at the end of the twentieth century the most prominent legal theorist of rights, has done so. At the core of his analysis is the distinction between policy and principle. Whereas policy is driven by utility, principle, the defining element of law, is to be observed, not because it will advance or secure an economic, political, or situation deemed desirable, but because it is a requirement of justice or fairness or some other dimension of morality.

In thus linking law to principle, and principle to justice, Dworkin identifies himself with the relatively noncontroversial common ground between positivism and (neo)natural law. On the other hand, by introducing 'some other dimension of morality' he clearly breaks new ground. For Dworkin, it is constitutions and constitutional rights that 'fuse legal and moral issues' (Dworkin 1977, p. 185). Constitutions thus provide in addition to the right to have rights, particular substantive rights as well.

For Dworkin, then, rights are inextricably linked not only to the foundational elements of positive law but, at least in their political and constitutional incarnation, to the foundational elements of the state. In this sense Dworkin can be seen as a kind of transitional figure among legal theorists, reaching out as he does to moral and political philosophy and incorporating them into his analysis of rights constructions by judges and other state officials. But unlike those of moral and political philosophers, Dworkin's theory of rights is embedded in, and inextricably linked via principle to, what is distinctively legal. Moral philosophy thus becomes an adjunct to the law and is, in effect, put at the disposal of the law, as a source of principle. In this sense, Dworkin's theory of rights returns to the starting point and, indeed, to the cornerstone of jurisprudence and legal theory, that is, it is a search for what is uniquely legal, as opposed to moral, ethical, or political.

4. *Empirical Social Science Studies of Rights Practice*

Whereas philosophic and jurisprudential inquiries into rights tend to be normative and abstract, social science research regarding rights practices is explanatory and empirical. Moreover, in the social sciences rights are treated less as moral entitlements of historical persons than as contingent resources that are mobilized both by individuals in everyday life, and by organized interests in political advocacy. Rights are not viewed as 'above politics' and power so much as constitutive of political activity and power relations. The primary objective of the social sciences thus is to assess the value of rights as resources, and to explain variation in the value of rights from time to time and from place to place. To do so, social scientists shift the locus of rights inquiry from formal systems of logic and idealized institutions to inductively organized research on rights in actual institutional settings, everyday life, and political advocacy.

4.1 *Rights and Everyday Disputing*

There has been a rapidly expanding scholarly literature on the ordinary disputing practices of citizens, especially in the United States but increasingly around the world. Many studies of 'ordinary' (non-elite)

individual citizens in the US suggest that rights matter a great deal, and that these individuals are not hesitant to assert them. Indeed, some scholars demonstrate that lay people, more so than judges, clerks, police, and other legal authorities, act on the premise and the expectation that the legal system exists to protect rights. Studies from other polities around the globe have also found some evidence for this generalization. One of the most interesting findings of Ewick and Silbey (1998) is that ordinary, nonelite citizens in the US can, moreover, relate to rights in flexible, creative, and complex ways, entertaining several conflicting notions at once. Interviewees in their study could view rights instrumentally as malleable rules of a game, authoritatively as an objective source of valid law, and skeptically as a burden that must be endured, evaded, or resisted.

Other studies qualify or challenge assumptions about the salience of rights. Research on the disputes of individuals suggests, for example, that Americans and others often refrain from asserting their rights; many studies document a widespread reluctance to seek redress when rights are violated and entitlements denied. This is especially the case among lower-income and minority citizens. Moreover, some studies find evidence of considerable cultural biases and popular pressure against rights claiming, at least through formal adversarial channels, even in allegedly 'rights obsessed' cultures such as the US. Patterns of individual practice are thus complex, contradictory, counterintuitive, and often defy generalization within, much less beyond, the US context.

4.2 *The Politics of Rights: Mobilizing Rights in Political of Advocacy*

The value of rights as a political resource is heavily debated within the social science literature. The most stringent critics of rights strategies claim that to deploy rights is at best ineffectual, and at worst counterproductive. Some studies suggest that rights litigation had no more than negligible effect on policy outcomes. According to realist critics only political power built around electoral coalitions and influential interests can bring about changes in well-established policies and practices. Other scholars demonstrate that rights-based practices often do intrude into policy processes, but with the unfortunate consequence of making these processes rigid and inefficient.

There is, however, a substantial body of research that suggests rights strategies can make meaningful contributions to a transformative politics—albeit in complex, contingent, and unpredictable ways. This research does not so much invalidate the findings of critics as shift the focus and the standards by which rights strategies are to be judged. Instead of concentrating exclusively on the direct effect of court-articulated rights, their indirect and constitutive effects are explored and assessed. Moreover, in this research,

the criterion for judging rights strategies shifts from policy efficiency to social equity—with the salience of this latter criterion most compellingly articulated in the work of critical race and critical gender theorists.

Especially in the United States, where much of the available research has been conducted, the indirect and transformative potential of a ‘politics of rights’ (Scheingold 1974) has been persuasively demonstrated. Just as rights have a constitutive impact on individual disputants, so too have the connotations of entitlement associated with rights had a mobilizing impact on social movements for pay equity, disability rights, and animal rights. Insofar as a need or a grievance can be articulated as a legal or constitutional right, expectations can be altered, quiescence overcome, and a politics of rights generated. Note that this research focuses very much on the discursive power of rights to constitute social and political life. Moreover, despite their liberal connotations and associations, rights can also be deployed on behalf of substantive agendas that span the political spectrum.

Despite all of their persuasive power, however, rights alone secure very little. Nor is rights mobilization a matter of spontaneous combustion. The constitutive power of rights depends on deploying rights shrewdly, in conjunction with other political resources—including shrewd leadership working in combination with established organizations like churches (civil rights), labor unions (pay equity), and other kinds of social-action organizations. Even then a transformative politics does not necessarily follow. Political mobilization may, for example, generate countermobilization (the abortion rights vs. right-to-life movements). But as the struggle over abortion clearly demonstrates, rights do matter, and a well executed strategy of rights can at the very least destabilize the political arena—thus creating opportunities that were previously foreclosed. In sum, the increasing body of empirical research on rights advocacy in a variety of settings underscores the variable, contingent, and often-contradictory implications of a politics of rights.

Right-wing Movements in the United States: Women and Gender

Right-wing movements have existed since colonial times in the USA, yet the majority of studies have focused on either what is termed the ‘Old Right’ of the 1950s or the ‘New Right’ formed during the mid-1970s and 1980s. An explosion of interest in understanding right-wing movements occurred in the aftermath of WWII when attention turned to authoritarianism, McCarthyism, and the Old Right of the 1950s. During the 1960s and 1970s, particularly with the prominence of protest movements on the left, research on right-wing movements waned, but a resurgence of interest has focused on the New Right formed during the 1970s and 1980s. While little is known about women’s participation in the Old Right, recent studies have focused on understanding women’s role in the New Right. This article considers the affect of women and issues of gender in both the Old and New Right.

1. Women and the Old Right

Historically, right-wing movements in the US have been based on a crucial marriage of interests between two groups. First, members of less-educated, lower economic strata, who are highly religious and drawn to the non-economic issues of right-wing movements.

This sector is intolerant of ethnic and religious minorities, with particular antagonism expressed towards Blacks and towards immigrants, previously expressed against Catholics and Jews and more recently directed against Mexicans and Asians. The second sector includes those rooted in a more highly educated, higher-income strata, less religious, tolerant of minorities, and committed above all to economic conservatism. The Old Right of the 1950s combined these two sectors, one consisting of more affluent economic conservatives, particularly reacting to the expansion of government implemented by President Franklin D. Roosevelt during the New Deal of the 1930s, and a more devoutly religious and less educated, lower middle class following, fearful of communism due to strong evangelical and fundamentalist beliefs. Anticommunism held together the Old Right, spearheaded by the campaigns of Senator Joseph McCarthy.

In terms of women's role within the Old Right, the vast majority of research makes no mention at all of female activists. It is not clear whether the lack of attention to women in the Old Right is due to the small number of female participants in the movement or to the male bias of the researchers. Because of this lack of data, there is no way of knowing how women of the Old and New Right compare in terms of number of participants, degree of involvement, or social background.

2. Women and the Conservative Intellectual Movement

Cleavage within the popular movements of the Right in the US is also evidenced in the conservative intellectual movement, which is comprised of three main groups. First, classical liberals or libertarians promote the free market, private property, limited government, self-reliance, and *laissez-faire*, and resist the threat of the ever-expanding state to liberty and free enterprise. Second, are traditionalists who are dismayed by the erosion of values and the emergence of a secular society and who call for a return to traditional religious and ethical absolutes. Third are militant anticommunists, ex-radicals disillusioned by the left and who became alarmed by the despotism of the Soviet Union. With the emergence of the New Right, this third strand also includes 'neo-conservatives,' primarily academics and writers who rejected the politics of the Democratic Party during the late 1960s. Converts from the left, neo-conservatives are disillusioned liberals drawn heavily from Jewish, intellectual circles of the East Coast. As with mass right-wing movements, anticommunism has acted as the glue holding together the conservative intellectual movement.

Although nearly all of the influential conservative intellectuals are male, libertarian author Ayn Rand

has had a profound impact on generations of right-wing adherents. Through novels such as *The Fountainhead* and *Atlas Shrugged*, Rand introduced the philosophy of objectivism and celebrated unbridled individualism, rationalism, and *laissez-faire* capitalism. Rand inspired thousands of people, especially youth during the 1960s, to join the libertarian cause.

3. Women and the New Right

During the mid to late 1970s varied groups coalesced into the New Right. Much of the force behind this coalition was a counter-movement to the social movements of the 1960s, an organized protest against affirmative action, the welfare state, feminism, and gay and lesbian rights. Like the Old Right, the New Right also incorporated two distinct constituencies: social conservatism and economic or *laissez-faire* conservatives. Social conservatives are devoutly religious and are primarily concerned about moral issues and protecting the traditional family. The family represents the building block of society; it instills children with moral values and restrains the pursuit of self-interest. Implicit in this image of the family is the social conservative conception of human nature. Humans are creatures of unlimited appetites and instincts. Left on their own, the world would be a chaos of seething passions, overrun by narrow self-interest. Only the moral authority of the family and religion tames human passions, transforming self-interest into the larger good. The ideal society is one in which individuals are integrated into a moral community, bound together by religious faith and by common values. *Laissez-faire* conservatives or libertarians in contrast, aim above all to protect the economic and political liberty of the individual. Rooted in the classical liberalism associated with Adam Smith, John Locke, and John Stuart Mill, *laissez-faire* conservatives uphold the economic liberty of the free market and the political liberty based on the minimal state. The individual is viewed as an autonomous, rational, self-interested actor. Rather than viewing humans as creatures of unlimited passions, *laissez-faire* conservatives view humans as beings endowed with free will, initiative, and self-reliance. The larger good is not ensured through the maintenance of moral authority and the restriction of self-interest. Rather, the *laissez-faire* ideal poses a society in which natural harmony exists through the very pursuit of self-interest. The aim of the good society is to elevate the potential of humans by bringing their creative and productive nature to fruition.

Despite these fundamental differences, like the Old Right, these two constituencies of the New Right united in their virulent opposition to communism. The New Right is distinct from the Old Right, however, in the visibility of its female participants and leaders.

Increasingly women have taken a more active and visible role in right-wing politics. On a leadership level, such well-known figures as Phyllis Schlafly, who led the fight to defeat the Equal Rights Amendment (ERA), typifies the social conservative movement while Jeane Kirkpatrick, a professor of government, former United Nations representative, and newspaper columnist, embodies *laissez-faire* beliefs. Yet women of the New Right, like their male counterparts, are not a homogenous entity. They are drawn from different sociological pools. While the majority of activists are white, social conservatives tend to be somewhat less educated than *laissez-faire* women and are devoutly religious, primarily Catholic or Protestant fundamentalist, married with children, with many being full-time homemakers. *Laissez-faire* women tend to be younger, more secular in orientation, more likely to be single or divorced, and have smaller numbers of children, more postgraduate degrees, and typically have professional careers. In fact, in terms of social background *laissez-faire* women resemble feminist women.

3.1 Views of Gender and Feminism

Women of the New Right have contrasting beliefs regarding gender. Social conservative women believe in a strict division of gender roles as decreed by the Scriptures. Gender is envisioned as a hierarchical ordering with God and Christ at the top, followed by men, and then women. While male and female roles are each respected as essential and complementary components of God's plan, men are the spiritual leaders and decision-makers in the family. Women's role is essentially defined in terms of altruism and self-sacrifice: to support men in their positions of higher authority, and to care for the family. Because gender roles are delineated in such unambiguous terms, any blurring of these roles is viewed as a threat.

While social conservatives envision a man's world as distinct from a woman's world, no such distinctions are visible in the *laissez-faire* view of gender. There is a notable absence of commentary on gender, and particularly no mention of the need for male authority and female submission or of women's natural orientation to others. The social conservative vision of a hierarchical ordering of authority of men over women is antithetical to the *laissez-faire* conservative ethos. Faith in individual self-reliance and free will, and belief in the liberty and autonomy of every individual, extends to women as well as to men.

Clearly, there is a relationship between a woman's social location and her values and beliefs. It is not coincidental that a woman with a devout religious upbringing who is a full-time homemaker is likely to see the family at the center of the world and to adhere to a traditional ideology regarding gender. Nor is it a

coincidence that a single professional woman who is devoted to her career does not see the family as central and holds nontraditional attitudes about men's and women's roles. Traditional gender roles 'work' for social conservative women not simply because of ideology, but because they themselves are more likely to be in life situations which correspond to traditional roles. *Laissez-faire* women, on the other hand, are in life situations and have social resources outside of the traditional female sphere.

These varying perceptions of gender result in opposing views of gender discrimination. Because social conservatives adhere to a hierarchical ordering, they believe that positional differences between women and men do not imply inequality. Any positional differences between the sexes are attributed to 'natural' differences or to individual choice, not to gender discrimination. *Laissez-faire* women, on the other hand, are inclined to recognize and deplore the unequal treatment of women. Discrimination is denounced as interfering with the individual's ability to climb to the height of her talents. Both men and women must remain unconstrained by external interference, free to follow the dictates of their own initiative. Although *laissez-faire* women share recognition of discrimination with feminists, they react to such bias purely in voluntaristic terms. Women who are discriminated against at work should on their own initiative leave the job and enter the free market to choose another one.

These differences in views of gender extend to opposing views of feminism. While social conservatives view feminism as one of the primary forces of moral decay responsible for America's decline, *laissez-faire* women actually adhere to part of the feminist vision. Social conservative activism is a direct counter-movement to the feminist movement of the 1960s and 1970s, as well as to the changes brought on by the civil rights, student, and gay and lesbian movements. Social conservatives blame feminists for attacking the status of the homemaker and for promoting issues such as the ERA, abortion, gay rights, and childcare, all of which are viewed as eroding traditional notions of gender and the family. Calling themselves the 'pro-family' movement, opposition to these very issues tops the political agenda of social conservative activists. *Laissez-faire* women, on the other hand, support gay rights, a woman's right to abortion, and daycare, seeing them as private, individual matters that should not be legislated by the state. *Laissez-faire* women depart from many feminists, however, in the means to achieve women's equality. While feminists call for federal support in addressing women's needs, *laissez-faire* women oppose any reliance on big government, including government funding of daycare or abortion. Further, the top priority of *laissez-faire* women is not addressing women's inequality; rather, issues related to the economy and defense remain the objectives of these women.

3.2 The Paradox of Right-Wing Women's Activism

Given the social conservative woman's adherence to traditional gender roles in which men are breadwinners and protectors, and women are helpmates and caretakers, some analysts point to a seeming contradiction between these beliefs and her very role as a political activist. However, social conservative women do not see a tension between their political involvement and the traditional female role. Female activism is defined within the bounds of traditional gender ideology as women altruistically working for the benefit of a larger cause, acting as moral gatekeepers to bring purity to a world filled with sin. Nor is there any apparent paradox to *laissez-faire* women's activism. Because they do not see women as bound to traditional roles, there is no seeming contradiction between their beliefs and their own role as public leaders. They do not conceive of themselves as the caretakers of society, altruistically at work for the benefit of all. Instead, they see themselves as no different from men, self-interested actors working for a political cause.

Despite the prevalent assumption that anti-feminist women are 'brainwashed' or 'lackeys' of men, the actual paradox of right-wing women is that those women who are furthest from feminists in their beliefs actually do act in their own interests as women, while *laissez-faire* women, who actually share a portion of the feminist vision, do not act in their collective gender interest. Far from suffering from false consciousness, social conservative women are well aware of their interests and act to defend their status as women. To borrow a phrase from Marx, social conservative women act as women for themselves, while *laissez-faire* conservative women remain women in themselves. Gender identity is central to the political involvement of social conservative women; recognizing their commonality with other traditional women, they seek to protect women's place as a group. *Laissez-faire* women are not motivated out of concern regarding gender; they do not act in the collective interest of women and therefore remain women in themselves. They act as members of the marketplace, not as members of their gender group, in organizing to return America to strength and freedom.

Risk: Empirical Studies on Decision and Choice

Even though most people have an intuitive understanding of what is meant by *risk*, risk is a concept that defies precise definition. Ordinary citizens as well as scientific experts differentiate between choice options or courses of actions in terms of their riskiness, and such explicit or implicit judgments of perceived riskiness often affect their decisions. Some uncertainty about the outcome of a decision or action seems to be necessary to make it appear risky. This article describes three paradigms that define risk in different ways and that identify different types of variables that have been shown to affect people's perception of risk.

1. Risk Perception

The democratization of decision making and increased availability of information provide people with more choices than ever before. Economic globalization and faster social and technological change have, at the same time, introduced more uncertainty and unpredictability. Decisions under risk and uncertainty are abundant, and perceptions of risk affect those decisions. People pull their money out of financial ventures when they judge the risks to be too high or start a lawsuit when the risks of inaction outweigh the risks of litigation. The risk perceptions of individuals as citizens and consumers also affect decisions made by government agencies and corporations. Public perception that silicone breast implants put users at

risk of autoimmune disease, for example, resulted in bankruptcy for the manufacturer, despite clear scientific evidence of no silicone-related illnesses. Controversies about the licensing of technologies such as genetic engineering or the siting of facilities such as landfills or nuclear power stations tend to be fueled primarily by disagreements about posed levels of risk, rather than by disagreements about the acceptability of specific risk levels. While business or government experts have clear quantitative evaluations and definitions of the risks that products or technologies pose, based on objective data or models, members of the general public often seem to evaluate the same options very differently. Much of the early research on psychological risk dimensions (described in Sect. 2.2) was funded by the Nuclear Regulatory Commission to understand why and how public perception of the riskiness of nuclear technology could differ so dramatically from the estimates provided by nuclear engineers.

2. Measures of Perceived Risk

Risk perception has been studied empirically within three theoretical paradigms. Studies within the axiomatic measurement paradigm have focused on the way in which people combine objective risk information, that is, possible consequences of risky choice options such as mortality rates or financial losses and their likelihood of occurrence. Research within the psychometric paradigm has identified people's emotional reactions to risky situations that affect judgments of the riskiness of physical, environmental, and material risks in ways that go beyond their objective consequences. Studies within the sociocultural paradigm have examined the effect of group- and culture-level variables on risk perception.

Risk as an explicit or implicit variable in theories of risk preference is discussed elsewhere (see *Risk: Theories of Decision and Choice*; *Personality and Risk Taking*; Weber 1997).

2.1 Axiomatic Measurement Studies

The axiomatic measurement approach models perceived risk as a function of attributes of risky options that are described as probability distributions over possible outcomes. Much of this work derives from the definition of risk as variance in traditional models of risky choice (see *Risk: Theories of Decision and Choice*). Under this definition sure options carry no risk, since there is no variance around the guaranteed, single, known outcome. The wider the distribution of possible outcomes, the greater an option's riskiness becomes. Yet, studies that assessed people's judgments of the riskiness of financial gambles (see *Risk: Theories of Decision and Choice*) have shown that downside

variability of outcomes affects the perception of an option's riskiness much more than upside variability, an asymmetry that is not captured by variance measures.

As a result, other axiomatic measures of perceived risk were developed that differ in the assumptions they impose on judgments of riskiness (see *Risk: Theories of Decision and Choice*). These models capture both *similarities* in people's risk judgments (with a common functional form by which probability and outcome information about risky options are combined) and *individual and group differences* (with the help of model parameters that capture differences in the relative weight given to different model components).

Weber and Bottom (1989, 1990) submitted the behavioral axioms on which these models are based to empirical tests and found support for the assumption that risk judgments are transitive (if option B is judged more risky than option A, and C more risky than B, then C will also be judged more risky than A) and monotonic (if option B is judged more risky than A, then any combination of obtaining B with probability p and X otherwise should also be more risky than the combination of obtaining A with probability p and X otherwise). Some violations of the expectation principle for risk judgments in the gain domain (Keller et al. 1986) were shown to be the result of nonnormative probability accounting, similar to that observed for preferences. People, for example, do not think that a two-stage lottery carries the same risk as a mathematically equivalent single-stage lottery, even if the final outcomes of the two lotteries and their probabilities are identical. Weber and Bottom's (1989) results supported the additive combination of gain and loss components hypothesized by the conjoint expected risk (CER) model (Luce and Weber 1986; see *Risk: Theories of Decision and Choice*) and ruled out, at least as descriptive models of perceived risk, other risk functions that assume that losses and gains impact risk judgments multiplicatively. The CER model has been described as the most viable model to describe single-dimensional risk appraisal (Yates and Stone 1992) and is probably the most widely applied axiomatic model of risk, but other, similar models exist (see *Risk: Theories of Decision and Choice*).

Bontempo et al. (1997) fit the CER model to judgments of the riskiness of monetary lotteries made by business students and security analysts in Hong Kong, Taiwan, the Netherlands, and the US. Cross-national differences in risk judgments followed a Chinese–Western division, with respondents from the two culturally Chinese countries having model parameters that were similar to each other but different from those of the two Western countries. The probability of a loss had a larger effect on perceived risk for Western respondents, while the magnitude of losses had a larger effect on the risk perceptions of Chinese respondents. Cross-cultural differences in risk perception were greater than differences due to occu-

pation (students vs. security analysts), suggesting that cultural upbringing and environment seem to play a larger role in shaping the perception of financial risks than professional training or expertise.

2.2 Psychometric Studies

The psychometric measurement approach treats risk perception as a multidimensional construct and uses multidimensional scaling, clustering, and factor analysis to identify its underlying psychological dimensions (Slovic et al. 1986). Research within this paradigm has found that the perceptions of the risks of hazardous technologies or activities by members of the lay public have often little to do with possible outcomes and their probabilities. Compared to technical experts, ordinary citizens overweight risk associated with infrequent, catastrophic, and involuntary events, and underweight the risk associated with frequent, familiar, and voluntary events. The psychological risk dimensions identified by the psychometric paradigm fall into two categories. The first one, *dread*, is defined by a perceived lack of control, feelings of dread, and perceived catastrophic potential. The second one, *risk of the unknown*, is defined as the extent to which the hazard is judged to be unobservable, unknown, new, or delayed in producing harmful impacts. Cross-national comparisons show that risk perceptions in a wide range of countries are affected by the *dread* and the *risk of the unknown* factor. Risk perceptions between countries differ in where respondents place particular hazards (e.g., nuclear power) within this factor space, usually in ways consistent with national differences in exposures and socioeconomic development.

2.3 Sociocultural Studies

In Douglas and Wildavsky's (1982) cultural theory, risk perception is viewed as a collective phenomenon by which members of different cultures selectively attend to different categories of danger. Each culture selects some risks for attention and chooses to ignore others. Cultural differences in risk perceptions are explained in terms of their contribution to maintaining a particular way of life. The theory identifies five distinct cultures (labeled hierarchical, individualist, egalitarian, fatalist, and hermitic, respectively) that differ in their patterns of interpersonal relationships and argues that members of these cultures therefore differ in their perceptions of risk. Hierarchically arranged groups, for example, tend to perceive industrial and technological risks as opportunities, whereas more egalitarian groups tend to perceive them as threats to their social structure. The significance of this approach to understanding risk perception is that it provides a way of accounting for the effect of group-

and culture-level variables on the behavior of individuals. It suggests that culture teaches individuals where their interests lie and what variables and events pose risks to those interests and ways of life.

Implicit in this cultural theory of risk perception is the hypothesis that cultural differences in trust in institutions drive differences in perceived risk. Slovic (1997) summarizes empirical evidence for this hypothesis, for example, the fact that minority status (e.g., due to race) is associated with reduced trust in social institutions. The relationship between trust and risk perception seems to be mediated by an emotional pathway, with reduced trust resulting in stronger negative affective responses to potential hazards and increased perceptions of risk.

Weber and Hsee (1999) provide another culture-level explanation of cross-national differences in risk perception, based on differences in collectivism-individualism. Comparison of the perception of financial and other material risks by Chinese vs. American respondents supports their assumption (coined the cushion hypothesis) that social collectivism serves as mutual insurance against catastrophic losses, making the risks faced by members of the collective, in fact, smaller.

3. Relationships between Measures of Risk Perception and Applications

The axiomatic risk measures of Sect. 2.1 were developed to describe the perception of financial risks, whereas the psychometric risk measures of Sect. 2.2 were developed to describe the perception of health and safety risks. Holtgrave and Weber (1993) investigated how well either type of measure (a simplified version of the CER model and the psychometric model) would predict risk judgments for both types of risk. Respondents, who were MBA students, provided holistic risk judgments for a range of financial and health and safety risks. They also evaluated each risk on the variables used as predictors by the two types of models (probability of a loss or gain, and expected loss or gain for the CER model; dread, control, catastrophic potential, voluntariness, novelty, and equity for the psychometric model).

Regression results showed the CER model to be a better predictor of perceived risk than the psychometric model for both financial risks and health/safety risks. The predictor variables of the CER model seem to come closer to the way people evaluate risk in both domains. The psychometric model may need a dimension reflecting the probability of harm to provide a better fit, since this dimension is highly correlated with risk ratings. Another reason might be that people consider both the pros and cons of activities when judging their risks. The CER model assumes that the impact of positive outcomes can offset the impact of negative outcomes. The psychometric model, on the

other hand, focuses exclusively on the impact of the downside of activities.

The best predictor of risk perceptions for both financial and health/safety risks, however, was a hybrid model that added the dread variable of the psychometric model to the probability and outcome-based variables of the CER model. This suggests that the perception of both financial and health/safety risks has an emotional component that is not completely described by the 'objective' components of axiomatic models (see Loewenstein et al. 2000 for a summary of the role of affect in risk perception and risk taking).

Palmer and Sainfort (1993) applied the CER model in the context of genetic counseling to model the judgments made by members of a clinical population of dwarfs about the riskiness of different procreative alternatives available to them. Faulting the genetic counseling literature for equating the perceived riskiness of an adverse event (e.g., the birth of a child with a genetic disorder) with the perceived probability of the event's occurrence, Palmer showed that the perceived risk of different reproductive alternatives also reflects the severity of consequences. Therefore, measures of risk that combine both probability and outcome information (such as the CER model) are a better predictor of risk perception.

The CER model has also been used to test the prediction of Douglas and Wildavsky's (1982) sociocultural theory that individuals with different world-views differ in predictable ways in their perceptions of risk. Palmer (1996) elicited risk judgments for financial and health/safety risks from respondents who came from either a hierarchical, individualist, or egalitarian subculture in Southern California. Hierarchists who are comfortable with determining acceptable levels of risk for technologies (Thompson et al. 1990), a process that explicitly considers and weighs gains and losses, provided risk judgments that reflected all predictor variables of the CER model (gains as well as losses, outcome levels as well as probabilities). Egalitarians, on the other hand, who are suspicious of technologies and view nature as fragile and in need of protection, suggesting that they should see risk in terms of possible harm, provided risk judgments that reflected only the loss predictor variables of the CER model. Individualists, who view risk as opportunity, given their tendency to see benefits from most activities as long as they do not interfere with market mechanisms (Thompson et al. 1990), were the group that provided the lowest risk judgments for almost all of the risky investments and activities.

4. Conclusions and Future Directions

The empirical studies of risk perception reviewed in this article show that risk perceptions are shaped by three classes of variables: the negative and positive

outcomes of choice options and their likelihood; affective reactions such as dread or fear of the unknown; and social and cultural variables that influence the perception and interpretation of the consequences of risky choice options. These variables have mostly been studied in isolation. Future research should examine possible interactions. There is also need for further examination of the accuracy or appropriateness of people's perception of risk.

The fact that ordinary citizens perceive the risk of many activities and technologies in ways that fundamentally diverge from the way they are perceived by scientists moves the choice of a measure of risk onto which to base policy decisions into the political arena. Fischhoff et al. (1984) argue that such choice should not be the exclusive province of scientists, who have no special insight into what society should value.

Risk Screening, Testing, and Diagnosis: Ethical Aspects

The Human Genome Organization project has increased enormously the possibilities to predict disability or disease either for an individual or for his or her offspring. Information obtained from genetic testing raises ethical and legal issues that have been debated for several decades. New issues are emerging due to rapid advances in molecular genetics.

From an ethical point of view, risk screening, genetic testing, and diagnosis belong to the most controversial and contested areas in contemporary medicine. The new genetics will have a profound impact on our self-images and on our understanding of the relations between environment and heritage. Conceptual, normative, and empirical issues are here intertwined in a complex way. To begin with, a preliminary clarification of the key concepts will be necessary.

The expression 'risk' will here be taken to refer to an adverse or negative future event that is probable but not certain. Any risk can then be analyzed in two components: the probability of occurrence of an event and the magnitude of its negativity according to certain explicitly stated norms and values (including kind, degree, duration, and timing). Risk assessment accordingly analyzes these two components, while risk management proposes strategies for handling the risk in ways that minimize the negativity and probability.

However, risks involving probabilities are not the only sort of risks that are relevant in this context. The expression 'epistemic risk' has been coined to refer to risks due to ignorance, and in particular due to ignorance of what we are ignorant about (e.g., Sahlin and Persson 1994). This notion is particularly relevant to many clinical applications of molecular genetics, involving unknown factors. The ways in which these risks are communicated will then be important from an ethical point of view.

Testing should be distinguished from screening.

Harper has proposed the following definition: 'Genetic testing is the analysis of a specific gene, its product of function, or other DNA and chromosome analysis, to detect or exclude an alteration likely to be associated with a genetic disorder' (Harper and Clarke 1997). Testing refers to procedures performed at the request of individuals or families, and should always be voluntary. This holds also for genetic testing of members of families known to be at high risk, such as the siblings of persons with cystic fibrosis (Wertz and Fletcher 1989).

'Screening,' however, implies application to large population groups, to entire populations or subsets of populations (e.g., pregnant women, newborns, or job applicants). Screening is not performed at the request of individuals or families but rather based on policy or public health decisions. It may be mandatory or voluntary.

Both the expressions 'genetic information' and 'genetic disorder' are vague and ambiguous concepts (Zimmern 1999). The same holds for the key concepts of health, disease, and illness. The advances in molecular and clinical genetics may profoundly change our understanding of the latter concepts. They may have an impact on health care policy, on the patient–physician relationship as well as the way in which access to care is allocated (Murray et al. 1996).

Genetic information differs from other private information in that it reveals information not only about a particular individual but also about that individual's blood relatives. Genetic test results may also provide information about population groups. Moreover, genetic information can be obtained from any cell in a person's body, not just by examining, for example, particular malfunctioning organs or tissues.

The concept of genetic information is difficult to define and delimit in a clear and uncontroversial way. Just by asking for the age of a person's parents and grandparents, genetic information in a certain sense can be obtained. The necessary and sufficient conditions for a disease or disorder to be 'genetic' are far from clear. If these expressions 'genetic information' and 'genetic disorder' are to appear in legislative texts, they have to be made precise.

There are many kinds of genetic disorders, including (1) chromosome changes, like trisomy 21 or Down's syndrome, (2) monogenetic disorders which depend on a mutation in one gene, like Huntington's chorea, and (3) polygenetic disorders like diabetes which are due to mutations in several genes in combination with environmental factors.

These distinctions are important for several reasons. What holds for monogenetic diseases concerning genetic determinism cannot be generalized to genetic disorders of other kinds. Thus, presymptomatic testing can be done for disorders in group (2) but rarely and with much less certainty, if at all, for those in group (3).

1. Public Concerns

Genetic testing may be beneficial in those cases where early detection makes a difference, for example, makes it possible to prevent or cure the disease. The validity and the reliability of the test methods will then be of crucial importance. The background of many national screening programs, like the one launched in Ontario, Canada, in 1999, to detect risk of hereditary breast, ovarian, and colon cancers is that early detection can lead to medical interventions and surveillance. This can significantly reduce the risk of developing the disease and hence be cost-effective.

The concern expressed over genetic testing and screening, however, is that it may threaten privacy and civil rights and be the basis of genetic discrimination or stigmatization of individuals as well as of groups. Moreover, it has been feared that widespread use of genetic testing will help to foster intolerance of people with genetic variations. It may be difficult, too, if not impossible, for people with certain inherited disorders to obtain a life insurance. Finally, people may feel a pressure to be tested, as a result of cost-benefit analysis. In general, of course, the negative consequences of testing people and disclosing information about their test results to blood relatives will have to be weighed against the benefits of this, if any, for those concerned. However, this weighing operation is far from simple.

Guidelines for genetic testing and screening have been proposed in the attempt to maximize the beneficial consequences and minimize the adverse ones (by e.g., UNESCO 1997, Council of Europe 1992, 1996, Nuffield Council on Bioethics 1993, Danish Council of Ethics 1993). These guidelines include discussions of genetic counseling, informed consent, disclosure to individuals and family members, confidentiality, employment, insurance, as well as public policy. The commercial availability of genetic test kits raises both operational and ethical issues, dealt with in the principles and recommendations suggested by National Institutes of Health (1997). This report discusses the validity of genetic testing, deals with genetic counseling and the informed consent process, as well as recommendations on quality assurance measures for laboratories performing genetic tests and the need for a national body with the authority to review genetic testing procedures.

2. Ethical Issues

It has often been recommended that genetic information in health care should be acquired and used 'in a manner that respects the autonomy of individuals' (Institute of Medicine 1994), but it has proved hard to explain the precise meaning of this in a noncontroversial way. The autonomy of what individuals should be respected? Sometimes respecting the autonomy of

one individual may conflict with respecting the autonomy of another.

A general problem raised by all forms of genetic testing and screening is, first, how to give nondirective information, that is, information that makes autonomous decisions possible by individuals and couples, and then to obtain consent in a way that avoids exercise of pressure.

Why is nondirectiveness an important goal? In brief, the reasons are the value of autonomy and the importance for geneticists to dissociate themselves from the dark history of genetics, from abuse of genetics for eugenic purposes. But nondirectiveness in practice is not uncomplicated, and the goal is also controversial. There is now a debate on the process of genetic counseling beyond nondirectiveness (Clarke 1994, Harper and Clarke 1997).

Particular problems are raised by the testing of individuals or groups with reduced autonomy, like children, demented people, or immigrants who do not understand the language. The testing of a healthy child could arise in at least three different contexts (Chadwick 1998): predictive testing, to see if the child will develop a specific disease that runs in the family; carrier testing, to see if the child may be at risk of having an affected child; and a screening test unrelated to family history to identify children with increased susceptibility to some common disease such as diabetes or ischaemic heart disease. Children are vulnerable and their parents therefore have to be involved in the decision procedure. But how? The nature of parental consent and the degree to which children are to be involved according to their maturity need close examination. If relatives are to be informed, who should do this? The geneticist, the hospital, or those already tested? And in what way? How many relatives should be informed? How closely related to the person asking to be tested (the index person) should the relatives be for the clinical geneticist to be responsible for informing them?

Different consent models are available, each with their own pros and cons. One main alternative is called 'opt in,' which means that if you have not said yes, you have said no; another is called 'opt out,' which means that if you have not said no, you have said yes. The conditions under which any of these models may or must be used is an important ethical issue.

The challenge to genetic privacy concerns the control of personal genetic information. Privacy has two dimensions, according to the Canadian Human Rights Commission (1992): protection from the intrusion of others and protection from one's own secrets. Does this entail a right to genetic ignorance, a right not to know about one's own or one's relatives' genetic risk profile? Is there a duty for geneticists or tested persons to disclose such information to those who might benefit from it? What is the basis of such rights and duties, and what are the consequences for the various people concerned of accepting or rejecting

them? Opposite positions have been argued for by Rhodes (1998) and Takala and Hayry (2000). Several compromise positions have been put forward. Tested persons should be encouraged to share what they know about their genetic risk profile with their blood relatives, when this information would be of vital health interest to their relatives (Chadwick et al. 1997, Hermerén 2000).

The privacy and confidentiality of the information needs to be protected against third party interests, including other family members, employers, and insurers. It has been suggested that genetic information should not be given to unrelated third parties, without the explicit and informed consent of the tested persons. In many countries, access to genetic information is regulated by law. The conditions or criteria under which medical confidentiality may or must be breached are bound to be controversial (Harper and Clarke 1997).

The practical problems raised by genetic testing also have to do with how to estimate and evaluate risks, communicate them in an understandable way, and decide which risks are acceptable and which are not. This includes the risk that a person will have an increased risk for a genetic disorder and the risk that the test result is not accurate. Communicating risks is obviously an important part of the genetic counseling process.

The accuracy of the tests—their validity and reliability—and the predictive value of the test or the screening method is another important issue in this context. To estimate the predictive value, one has to be able to compute the number of false positives and false negatives as well as to know about the prevalence of the genetic disorder.

Finally, there are issues of justice and fair access. If testing and screening is to be done on an equitable basis, it should not be available on the basis of such accidents as in which geographical region a person happens to be born.

These ethical problems arise in somewhat different ways, according to the type and purpose of testing or screening. The difficulties are not the same in all cases. In particular, certain forms of screening and presymptomatic testing for late onset genetic disorders present problems from an ethical point of view. Some of the most common types of genetic testing and screening will therefore be described below along with a brief indication of the particular ethical problems they raise.

3. Types of Testing and Screening

3.1 Presymptomatic Testing

Individuals may be tested for monogenetic disorders (of which there are many though each is fairly rare) by

DNA analysis before any symptoms are shown. If an early diagnosis is of value, because the disease can be prevented, presymptomatic testing is fairly uncontroversial. If the disorder cannot be prevented, the value of presymptomatic testing is more difficult to judge. This holds also in cases where there is a method of prevention but it is nevertheless impossible to guarantee that the person tested positively will not get the disease (for example, breast cancer).

In addition to the obvious difficulty of informing people in such a way that they can make autonomous decisions, presymptomatic testing raises problems about how the information obtained from the tests should be handled, and who should have access to it. Likewise, it is controversial whether blood relatives should be contacted and who should contact them in that case (the person tested, the hospital, the clinic, the geneticist, etc.). Moreover, in many countries there is great concern about how to prevent certain external third parties, like employers or insurers, from getting access to information about the test result.

3.2 Prenatal Diagnosis

Prenatal diagnosis can be regarded as a special case of presymptomatic testing. By prenatal diagnosis it is possible to discern whether a fetus is at risk for various disabilities or diseases.

There are several methods for prenatal diagnosis. Some are visual—either noninvasive, like ultra-sonography, or invasive, like embryoscopy or fetoscopy, which uses a camera on a needle inserted in the uterus to view the fetus. Other methods are based on analysis of fetal tissues (like amniocentesis or chorionic villus sampling). By ultrasound tomography it is possible to create fetal images on a screen.

The indications of when prenatal diagnosis should be offered include advanced maternal age, a genetic history of abnormalities in the family, repeated miscarriages, or previous infants with birth defects. Then a prenatal diagnosis may be offered to provide information to couples about what they can expect. A normal result is found in most cases. If not, prenatal diagnosis may make it possible for them to adjust and may also influence the way in which the baby is delivered.

There has been great concern about the risk of spontaneous abortion induced by the use of amniocentesis or chorionic villus sampling. This is a problem one does not have with ultrasonography. On the other hand, ultrasonography may give information that is unexpected or not wanted, for example, that some organs or limbs are malformed. With other methods, too, one may make unexpected or unwanted discoveries, for example, that the social father is not the biological father.

All this serves to underline the necessity of careful counseling before the diagnosis, so that the woman or

the couple knows what the test may show and how certain the result is. Informed consent is crucial, and the difficulties of nondirective counseling should not be underestimated.

Other ethical issues raised by this type of diagnosis are concerned with how to preserve the confidentiality of the information obtained. Since prenatal diagnostics sometimes leads to abortion, it may be controversial in the eyes of some people for the same reasons that abortion is controversial. The impact of prenatal diagnosis on our views of people with handicap has also been a matter of concern.

3.3 Preimplantation Diagnosis

Preimplantation diagnosis means that the diagnosis is carried out before (in connection with *in vitro* fertilization) the pre-embryo is implanted in the woman's uterus. If there were a history of sex-linked diseases in a family, it would then be possible to prevent a child with such a disease being born. Thus the resulting pregnancy could be normal and the woman would not have to abort the fetus at a later stage or give birth to a child with a very serious or lethal disease. Preimplantation diagnosis is becoming an established medical practice in many countries.

The first serious ethical problem that arises is to whom these tests should be offered. Usually, they are limited to severe illnesses and to persons in specific 'high risk' groups. But both these criteria are value laden, and the indications may be narrowed down or widened. There are also considerable variations not only between lay people but also between geneticists over the severity of different genetic conditions (Chadwick 1998).

Preimplantation diagnosis at the beginning of the twenty-first century is thus limited to sorting out fertilized eggs carrying genes associated with severe diseases for which there is no cure at present, like Huntington's chorea and certain X-linked diseases. Concern has been expressed that the practice may be extended to diseases that are less serious (Shenfield 1997). Obviously, there is a risk of a slippery slope in this area.

Preimplantation diagnosis also, at least theoretically, opens up possibilities for a shift of power from the woman to the geneticist, as well as for cloning and manipulation of human pre-embryos that many people find too risky or simply ethically unacceptable. In some countries, like the UK, manipulation of human pre-embryos is illegal.

3.4 Prenatal and Neonatal Screening

Newborn screening involves the analysis of blood or tissue samples taken in early infancy in order to detect inherited diseases where early intervention can mini-

mize or eliminate the risk of later serious health problems or premature death.

In screening, a group of individuals is examined directly with DNA, RNA or biochemical analysis to find those who will later in life have an increased risk of developing a particular genetic disorder. A good screening method is reliable and valid, with a minimum of false positives (who are worried unnecessarily) and false negatives (who are lulled into false security).

The best-known example of uncontroversial neonatal screening is screening for phenylketonuria (PKU), a genetic disease. The reason is that PKU, if undetected, can lead to serious mental retardation. Moreover, it can be discovered easily and prevented through early intervention. For many other conditions, such as cystic fibrosis and galactosemia, the benefits of early detection are more controversial. Screening programs for newborns also raise the issues of freedom of choice and informed consent by parents (Hermerén 1999).

Newborn screening raises several ethical issues, among them the nature of informed parental consent and how it is obtained, confidentiality and privacy, and the interests of third parties, as well as issues of justice such as equal access to testing and treatment. Moreover, it is clear that more research needs to be carried out on the psychological responses to newborn screening, particularly when the health benefits are disputed (Harper and Clarke 1997).

People with certain genetic disorders have had difficulties in getting a life insurance. In some countries the right of insurance companies to ask for genetic information has been regulated by law. In Norway, it is forbidden. In other countries—The Netherlands and Sweden, for instance—there has been a temporary voluntary moratorium during which the insurance companies will not ask for genetic information, provided that the life insurance asked for will not exceed a certain amount. This is still a very controversial area (Sandberg 1996).

3.5 Carrier Screening

Carrier screening identifies individuals with a gene or chromosome abnormality that may cause problems either for offspring or for the person screened. The testing of blood or tissue samples can indicate the existence of particular genetic trait changes in chromosomes or changes in DNA that are associated with inherited diseases in asymptomatic individuals. Carrier screening exists for sickle cell anemia, for Tay Sachs disease, as well as for cystic fibrosis, Duchenne muscular dystrophy, hemophilia, and Huntington's chorea.

Carriers have one normal copy of a gene and one copy that varies from the normal gene. Since one gene is normal, the carriers ordinarily do not exhibit symptoms of a genetic disorder. A woman who is a

carrier of an X-linked disease such as Duchenne muscular dystrophy or fragile X syndrome, has a variant gene on one of their two X (sex-determining) chromosomes. Her risk of transmitting the variant gene to each child can be estimated accurately.

The purpose of carrier testing is to inform potential parents of their genetic risk profile so that they can make informed reproductive decisions. National screening programs are usually justified by cost-benefit analysis. The question is then which costs and whose costs are taken into account, and how the benefits are defined and evaluated. The importance of cultural differences as to what constitutes benefits, and how benefits are ranked, should not be underestimated.

The right to autonomous choices is an important issue also in this area. Whether the choices open to people found to carry a disease gene are acceptable or not, may depend on their life plans, their ethical views, the laws of their country, as well as their culture and social customs. Before a carrier screening program is decided on and implemented, these questions need to be considered. In practice there may be subtle coercion, even if a carrier screening program is formally voluntary.

Screening the subset of a population at risk rather than the entire population makes sense from a medical and economic point of view, but selecting target groups for such screening programs also creates ethical problems. For example, there have been in the past controversies over whether these screening programs in effect had a eugenic purpose, particularly when the diseases screened for are over-represented in certain ethnic groups.

3.6 Testing in the Work Place

Susceptibility screening can be used as a form of presymptomatic testing, but is also used to identify workers who may be susceptible to toxic or carcinogenic substances such as benzene in their workplace (Van Damme et al. 1997, Surrallés et al. 1997, Jarvholm et al. 1999). This susceptibility may lead to occupational health problems and future severe disabilities.

Van Damme et al. (1995) have proposed a conceptual model of the complex interactions between exposure, acquired and inherited susceptibility, and risk for disease. The validity of tests for determining genotype and phenotype and their relevance for the disease must be evaluated critically to provide an objective basis for ethical discussions. The acceptability of such tests is related to a number of issues which Van Damme et al. identify and discuss.

Genetic testing of employees and job applicants is controversial. The first basic question concerning testing in the work place is simple—for whose sake is the test performed? Is the test performed in order to protect persons with increased (inherited) suscepti-

bility to hazards at the workplace? Or is the test in the interest of the employer, so that the employer can avoid improving the working conditions and avoid hiring people who would be damaged by the work they do? Here it is essential to separate the situation of the job applicant from the situation of the person already with a job. The latter could be monitored for exposures and early effects of, for example, toxic substances on the genes.

There are methods of detecting inherited predisposition to cardiovascular diseases as well as to adverse effects from otherwise well-tolerated exposures related to the job. Clearly, with widespread use of genetic testing in the workplace there is the obvious danger of discrimination and stigmatization of individuals or groups. It may be tempting for employers to use tests to select only workers who will be able to work in the present working conditions, instead of improving the working conditions. The result could be that large groups of people would be barred from the job market.

3.7 Forensic Testing

A comparatively new use of genetic testing is to examine a possible genetic linkage between, for example, alleged fathers and their children, or between suspects and evidence discovered in criminal investigations, like hair, blood, sperm, saliva, or skin. The idea is to use genetic methods of analysis to clear the innocent and identify the guilty. However, concern has been expressed that mistakes can be made. Critics argue that it is necessary to improve the quality control of the test laboratories. Another problem is the confidentiality of the DNA profiles obtained from criminal investigations and stored in national police databanks. For how long time will they be stored? Who will have access to them and for what purpose?

4. Concluding Remarks

Genetic testing and screening should be done for 'health purposes.' This is sometimes stated as a necessary condition for genetic testing (Council of Europe 1992, 1996). Health purposes could include diagnostic and therapeutic purposes as well as medical research and health care planning. Moreover, 'health' can be defined in several ways. It is important to state more precisely what this means.

Careful counseling remains crucial. One of the present concerns is that do-it-yourself test kits for genetic disorders may be bought via the Internet or over the counter without any professional counseling to explain what the findings mean, how certain the test is, etc. There is an urgent need to find ways of regulating the economic interest of commercial biotechnological companies in order to minimize the harm of premature use and overuse of genetic testing.

G. Hermerén

Risk, Sociological Study of

That the world is punctuated with uncertainty, danger, hazards, disasters, and threats to what humans value has been recognized since the beginning of human life on earth. Risk is the conceptualization of that recognition—providing a means for anticipating and avoiding or adapting to untoward outcomes. By 3200 BC, ancient Babylon had the first recorded risk assessors, and in 1700 BC, the Code of Hammurabi included a classification of risk matters. Despite these

ancient beginnings, however, and despite subsequent refinements accompanying the rise of the insurance industry during the age of exploration, the centrality of risk is the child of advanced industrialization, particularly since World War II. With advanced industrialization came technologies that were larger, more sophisticated, and potentially much riskier, having the capacity to affect far greater numbers of people, as well as the things they value and the areas they occupy. At the same time, scientific and technological advances have led to remarkably increased sophistication and precision, in many cases, in the ability to detect unwanted side effects or risks.

The notion of 'risk' has evolved over the last decades of the twentieth century to become the key analytical lens for anticipating our actions' consequences for the environment and ourselves. It includes an analytic orientation and a suite of evaluation methodologies, but it is also a new consciousness—a way of looking at a world of technological and environmental uncertainty. Attention to risk is a consciousness born of vast uncertainties over the durability of nuclear peace, the resilience of the ozone protecting us, threats of global warming, the growing extinction of species and the possibility of creating new ones, and more broadly, threats of technological disasters both large and small. It is a consciousness entirely foreign to the optimistic beginning of the century just ended.

The first significant body of sociological work on risk can be traced to the 1940s, with the work on natural hazards by Gilbert White (a social geographer), gaining momentum in the 1950s with White's collaboration with a number of sociologists, and evolving into the sociological specialty of natural disaster research. A key focus of this specialty has involved the social impacts of hazard events—how did structures and individuals respond to natural disasters such as storms, floods, earthquakes, wildfires, or droughts? One of the most consistent findings from this literature was the emergence of what has become labeled a 'therapeutic community': contrary to the self-focused maximizing predictions of utility theory, citizens typically engaged in acts of altruistic aid and community building (for reviews, see Drabek 1986, Kreps 1984).

Particularly in the United States, a significant fraction of the ongoing interest in natural disasters was motivated by the concerns of the early atomic age, including the prospect that a nuclear attack could wipe out a significant fraction of a community's population; given that much the same could be said for natural phenomena, such as floods, fires, or hurricanes, these and other 'natural disasters' came to be seen as useful 'natural experiments' for studying community responses. Particularly after the accident at the Three Mile Island nuclear power plant in 1979, however, it was a different form of nuclear activity that came to provide what is in many ways the prototypical 'risk' issue.

Although the point is often forgotten today, nuclear power facilities once enjoyed widespread support, even in the communities where they were constructed. Still, even before the 1979 accident, there were early signs of rising public concern. One response of nuclear power supporters (including those who controlled some of the most powerful branches of government) was to characterize the concerns as being ill-founded or 'irrational,' doing so by demonstrating that the 'real risks' were instead quite small. The earliest efforts, however, indicated that the consequences of a plausible 'worst-case' disaster could have been quite serious, indeed. These early efforts led to little publicity, but to a change of focus—an emphasis on what soon came to be called 'probabilistic' risk assessment, or PRA, a reductionistic engineering technique that estimates the risk of a plant mishap by estimating the probability of failure of all the plant's parts and subsystems and then aggregating these probabilities. The conclusion from the first systematic application of this technique to nuclear power plants, which was stated particularly forcefully in the executive summary for the multi-volume effort that is still remembered as 'the' reactor safety study (US Atomic Energy Commission 1975), was that citizens were more likely to be killed by a falling meteorite than by a malfunction at a nuclear power plant.

Four years later came the accident at Three Mile Island, near Harrisburg, the capital city of the state of Pennsylvania—an accident that by technical analysis virtually could not happen. The accident brought to public and sociological attention an incipient schism between the state, its technological experts, and citizens. European sociological interest in risk was similarly intensified by the far more serious nuclear accident at Chernobyl in April 1986. While at one level of analysis these accidents and the vast media coverage surrounding them offered dramatic signals to publics of the risks of nuclear-generated electricity, at a deeper level they revealed conflicts between expert and lay knowledge, and between 'top-down' and 'bottom-up' strategies for managing large-scale, risky technologies.

The 1979 accident, in particular, generated a number of legacies. First among them was the further institutionalization of what soon came to be known as the field of risk analysis: the Society for Risk Analysis was established in the United States (with subsequent affiliates in Europe and Asia), as was the Division of Risk and Management Science at the US National Science Foundation, along with a number of new professional journals and a substantial outburst of published literature. That outburst included a significant increase in sociological work, with much of the initial increase paralleling the three general theoretical levels in sociology—the micro, the meso, and the macro, or in simpler terms, the social psychological, the organizational/community level, and the societal.

At the micro level, much of the work was conditioned by what soon became the dominant social

science research tradition in risk studies: the psychometric tradition (Slovic 1987). A growing body of work in cognitive psychology was brought to bear in examining the extent to which lay perceptions of risk differed from actuarial data and from experts' views. Key among the findings from this work, replicated in a variety of cultures, is the idea of heuristics—cognitive rules of thumb that provide shortcuts to risk estimation. One example is the so-called 'availability heuristic,' or the tendency to judge a risk on the basis of its cognitive 'availability,' or the ease of imagining or recalling examples; such a tendency increases the perceived riskiness of a low-probability but sensational risk, such as death from botulism, relative to more probable but more prosaic risks, such as deaths from asthma.

In political circles, the early psychometric findings were sometimes taken as reinforcing the argument that the 'irrational' public should be excluded from risk decisions, but the evidence proved not to be so clear-cut. Sociological work on technological controversies, for example, had already drawn attention to the lack of unanimity among experts (see e.g., Mazur 1980), and further research showed that experts relied on similar heuristics—even in the contexts of their own expertise, and even when the experts were studied with the same protocols used to study lay perceptions. Work from a social constructivist perspective (e.g., Wynne 1992) further challenged the tendency to equate expert risk estimates with 'real' risks, with Clarke (1999) eventually going so far as to argue that many official proclamations were little more than 'fantasy documents'—efforts to deal with ultimately uncontrollable risks through ritualistic proclamations of rationality. At the same time, psychometric work pointed to the importance of a number of broader issues, such as trustworthiness and fairness, that were omitted from technical risk analyses. Hence, from the psychological literature emerged a reaffirmation of sociology's first principle: context matters.

Sociologists responded with three sustained research efforts—one that contextualized the individual actors, a second that aligned risk choices with the most powerful technological decision-makers, namely organizations, and a third that examined the consequences of technological accidents in the contexts where people live, namely communities—as well as with broader and more conceptual work at the macrosocietal level.

At the individual level, the work showed that a social actor's perception and responses to risk are shaped not just by heuristics, but also by an entire set of social, political, and institutional forces. Perhaps the most comprehensive effort to capture this wide variety of psychological and social forces is the 'social amplification' framework, a conceptualization adapted from formal communication theory (Kasperson et al. 1988), and emphasizing that, when signals are sent

from a source to a receiver, those signals often flow through intermediate transmitters that 'amplify' or attenuate the message. Similarly, individuals can receive risk signals either directly, through personal experience, or indirectly, through information provided by institutions (e.g., the media) or social networks (e.g., opinion leaders). These 'amplified' interpretations can then produce behavioral responses, resulting in secondary impacts that, in turn, are often themselves amplified, producing tertiary impacts. Partly because of its interdisciplinary orientation and its capacity to integrate the cumulative psychological findings with other factors that have been shown to influence risk perception and response—social, organizational, institutional, political—the framework has generated a considerable body of generally supportive empirical research.

With mesolevel work on organizations, meanwhile, sociologists began to point out the inherent metamethodological bias of early PRA work—the Cartesian reductionism of assuming that one can understand risk by understanding its underlying fundamental elements. A counterpoint to this methodological individualism was provided by the sociological holism of organizational sociology, treating organizations, not individuals, as the key risk decision-makers in contemporary societies.

The landmark contribution to this orientation is Perrow's *Normal Accidents* (1984), which argued that certain technological systems were complicated beyond our understanding of them—and beyond our ability to make them safe. Key factors included complexity and 'tight coupling'—essentially the lack of room for error—meaning that even attempts to improve safety, such as the introduction of redundant parts and backup systems, could result in further complication of these systems, thereby increasing risk. The book argued that some of our technological systems—nuclear power plants, nuclear weapons, and perhaps others—were predictable 'system' accidents, or 'normal accidents,' waiting to happen.

A counterpoint to this argument emerged in subsequent work on 'high reliability organizations' (LaPorte and Consolini 1991). Building on a set of fieldwork-based case studies—e.g., an air traffic control system, a large electric utility system, aircraft carrier operations—this school of thought argues that complex systems can be made safe with proper component, system, and organizational design, with specialized, sometimes variable, management structures, and through the development of a corporate culture of safety. Given that a great many of society's complex technological systems do indeed operate daily without incident, but also that other empirical tests appear to support normal accident theory, the jury remains out over which of these two schools of thought offers the deeper purchase on this key problem of advanced industrialization. The issue is only likely to be resolved with further refinement of the conditions

under which 'normal' accidents or 'high reliability' operations are more likely.

Another body of mesolevel work focused on community contexts. Particularly after Erikson's study of a so-called 'man-made' or 'non-natural' disaster (1976), a growing number of studies found that the impacts of technological or non-natural disasters proved to be far more severe and long-lasting than those associated with natural disasters. In contrast to the 'therapeutic community' of natural disasters, numerous studies of technological disasters have encountered what Freudenburg and Jones (1991) call a 'corrosive community,' typified not by offers of help, but by efforts to avoid responsibility or affix blame. Similarly, while the long-term social, economic, psychological, and cultural impacts of natural disasters have generally been found to have been surprisingly small, the long-term impacts of technological disasters have been found to be far greater than would be expected on the basis of the immediate physical destruction. At Three Mile Island, for example, most observers have concluded that only small amounts of radiation escaped, but careful studies found increased reports of 'intense distress symptoms'—that is, levels of distress symptoms that are characteristic of hospitalized mental patients—with later studies finding that stress levels were actually higher some six years later than they were in the immediate postaccident period. The symptoms were not merely self-reported, but included physiological measures such as elevated catecholamine levels in blood—a form of medical measure that is generally considered 'real' even by observers who question the legitimacy of people's own reports on stress and well-being. More broadly, several studies indicate that distress levels may actually be highest among the citizens afflicted not by the worst levels of disaster, but by an *ambiguity of harm*—cases where not even the best scientific work can clearly demonstrate whether people have been seriously endangered or not (Freudenburg and Jones 1991).

At the macro- or societal level, finally, a growing body of work has responded to the call of Short (1984), in his presidential address to the American Sociological Association, to examine the importance of risks to the social fabric itself. In the early days of the twentieth century, Weber had pointed out that the 'rationality' did not mean that the citizens of modernity would know more about their surroundings and tools than the citizens of a premodern age; instead, Weber emphasized, the modern citizen would see the tools and technologies as being 'knowable,' in principle, rather than being in the realm of magic. A century later, Weber's point is, if anything, more clearly true. Collectively, we know far more about our world and tools than did our great-great-grandparents, but individually, we actually know far less about the tools and technologies on which we depend; instead, we literally 'depend on' them to work properly. In turn, that means that we depend on whole

armies of specialists, most of whom we will never meet, let alone be able to control. Even if we find that we can usually depend on the technologies, and on the people who are responsible for them, the rare exceptions can be genuinely troubling. The risks to the social fabric, in other words, include what Freudenburg (1993) has termed 'recreancy'—cases where an organization or an individual entrusted with a specialized task fails to perform in a way that fulfills the responsibility and upholds the trust.

Still more broadly, while differing in ontological and epistemological assumptions, and while differing in orientation and research method, the various perspectives share the view that risk is an identifiable feature of the world, whether real or constructed, that risks are consequential in many facets of social life, and accordingly, the topic is worthy of sociological examination as well as policy attention (Rosa 1998). In addition, the pragmatic importance of new approaches to risk management reflects the growing recognition that the modern world has generated risk problems that demand scientific understanding, but that are too complex or too ambiguous to be 'answered' by science alone. Both the scientific examination and the policy making must take place in a context that is permeated by values, and also by unknowns—both those that can be recognized in advance and those that cannot. Owing to these conditions, democracies may have entered an era of postnormal risk (Funtowicz and Ravetz 1992), an era demanding better procedures for managing growing technological risks, procedures that require scientific inputs, but that broaden the scope of peer evaluation and integrate citizen involvement. A variety of social experiments have been undertaken to refine and implement these analytic-deliberative procedures, potentially reshaping not only technology policy but also democracy itself.

Risk is the unavoidable companion of a growing technological complexity. Managing large-scale technological risks has therefore become a central challenge for all societies—perhaps even the key basis for distinguishing contemporary from past societies (Beck 1986, Giddens 1990). It is this challenge that raises the fundamental and daunting question: are contemporary societies capable of generating technological complexity, technological interdependence, and pervasive risks at a more rapid pace than our growth in knowledge of these complexities and risks—and more rapidly than we can manage them safely? Whether a form of cultural lag, an inherent paradox of technological sophistication, an epiphenomenal feature of what we currently call postmodernity, this question will remain a focal point of discourse and decision making in the coming era, both for sociology and for society more broadly.

Risk, Sociology and Politics of

Risk and chance have long been held to be key elements of the human predicament; but risk aware-

ness besets whole cultures as well as individuals. Social scientists typically have been interested in risk, from both the social-psychological stance of particular actors and in terms of cultural responses to collective exposures. At one level, sociologists have discerned a historical trend towards the taming of risk, both in the sense that risk and probability have become better understood, and that certain forms of exposure to risk have been reduced. Nineteenth- and early twentieth-century confidence in progress and control over nature suggested both that risks were diminishing—diseases could be controlled, dangers to food supply countered through scientific farm management, and so on—and that better understanding of risk and chance was possible. But this modernist confidence about the prospects for the control of risk has been moderated and to some extent undermined by subsequent developments. As an example, twentieth-century technologies were associated with new forms of risk, including risks to the whole ecosystem. It seemed that the forces of progress could lead to novel hazards as well as to enhanced security. Furthermore, the legal frameworks and intellectual tools developed for the regulation of risk made it possible to elaborate arguments about risk in ever more sophisticated ways, ironically engendering a more vivid appreciation of risk. Finally, the complexity of social development fostered distinctively social risks, related to crime and the increasing uncertainty of social life. This discussion will begin by focusing on the regulatory treatment of risk before moving on to consider the broader social experience of risk.

1. Risk Assessment: Regulators and Risks

One systematic and extensive literature on risk grew out of concerns to make policy and to legislate for risk; this literature can be categorized as concerned with 'risk assessment.' Given the ubiquity of risks, the question for regulators was customarily thought of as: 'how safe is safe enough?' Governments and official agencies recognize that, regrettably, train crashes occur, that drivers are daily involved in automobile collisions, that leaks will sometimes happen even from well-managed chemical plants, and that farm chemicals may impact the environment, agricultural workers, or even occasional consumers. Given that no complex system can be guaranteed to be perfectly safe, the leading approach was to ask about the price of additional safety. From this consequentialist world view, risk is thought of as the mathematical product of the likelihood of a hazard occurring, and the costs to which that hazard gives rise. The policy maker's art is then to minimize risk within the budget that society is willing to spend on safety.

In practical terms, this task was always much more difficult than might be supposed, and certainly more

intractable than economists routinely implied. In part, difficulties arose because of the inherent problems of trying to harmonize risk data across various fields. It may be possible to compare the costs and risks of various railway signaling systems, but (in the absence of a super-ministry of risk reduction) transport, industrial, medical, and agricultural risks cannot be brought within the same calculus. Worse still, both the likelihood of the problem and its consequences commonly defy exact specification. While there are good data on the medical and related risks of typical motor accidents on US and European freeways, the probability and the consequences of nuclear power station incidents can only be calculated in hypothetical ways. Similarly, the risks and costs of 'mad-cow disease' (bovine spongiform encephalopathy, or BSE), an unprecedented form of infection apparently spread through the food chain, could not be subjected to the risk calculus in the standard way. Further, the only way to obtain quantitative measures of many risks to humans is to extrapolate from indirect observations, such as rodent bioassays, thereby introducing additional sources of distortion into risk assessment. Without good data, all calculations will be 'rough and ready.' Nor is it even clear that there is a single 'currency' into which all sorts of harms can be converted for the purposes of cost-benefit calculations.

Despite these persistent difficulties, one line of the literature about risk has been devoted to exploring what are thought to be the public's shortcomings in relation to risk understandings. Lay people appear to make irrational and statistically unsupported assessments of the relative risks of different hazards, and to demand high levels of risk reduction without being aware of the costs. In the extreme, the public appears unwilling even to accept the cost-benefit approach, but has no systematic alternative with which to replace it. As an added complication, despite frequent public protestations of anxieties about risk, market mechanisms seem to imply that people are not necessarily very risk averse: The automobile market has tended to sell on aesthetic and performance criteria rather than on safety; and consumers continue to eat fatty foods and to avoid exercise despite well publicized links to heart disease.

The apparent discrepancies between public and expert versions of risk have given rise to a series of psychometric studies (Slovic 1992). For example, researchers have shown a tendency by people to undervalue systematically the risks to which they are routinely exposed (because of their lifestyle or occupation), and to overvalue the seriousness of risks that are novel or could be catastrophic. Moreover, there appear to be significant differences between people's assessment of the risks to which they expose themselves and those to which they believe they are subjected by others. These perceptions translate into corresponding pressures in policy. People seem

more likely to demand that automobiles be engineered to lower traffic fatalities than they are to constrain themselves to drive those automobiles more cautiously.

The resulting tension between public and expert interpretations of risk has caused a problem for policy makers. If they base regulations on expert judgments—that is, keyed only to the statistical probability of harm—policies may be unpopular or even subverted, whereas basing policies on the public's apparent preferences threatens to make regulations arbitrary, unscientific, or too costly (Breyer 1993). If the citizenry really is more tolerant of self-imposed risks than of risks visited on them by others, then there is an argument for reflecting this in public policy, whatever the 'actual' exposure to risk. Similarly, if, as Slovic and colleagues report (Slovic 1992, p. 121), the public is more concerned about certain 'dread' risks than other risks which experts hold to be of equal hazard, then maybe the cost-benefit equation has to be widened to take into account people's manifest preferences. Regulators find themselves confronting a tension familiar to liberal democracies: That between people's 'revealed' preferences and the recommendations supported by expert opinion.

2. Risk Expertise: The Reflexivity of Risk

These problems have become amplified in particular institutional contexts in ways that social science research has sought to explicate. Risk assessments have been developed, particularly by official regulatory agencies, so as to apply to statistically representative, or in some other sense, 'average' people (Jasanoff 1990). Calculations of how long it takes to evacuate an aircraft, and thus of the requisite number of emergency exits, the width of aisles and so on, are supported by evacuation trials, but these in turn depend on notions of what is a typical passenger cohort. Similarly, arguments about exposure to pollutants have had to construct some notion of the average person as the unit for measuring the at-risk population (with, in many cases, the need to substitute the average risk animal for the average human). Yet this ideal type hardly exists in reality and may obscure threats to specific subpopulations. Women may be different from men; pregnant women are more clearly different. The young may differ from the elderly, the housebound from the active, and so on. These differences may prove to be far from 'academic' in particular contexts of exposure. For example, people who live near one of the UK's most controversial nuclear power plant sites, Sellafield, and who happen to favor a shellfish-rich diet may be exposed to a greater nuclear hazard than the average person, because of the way in which shellfish filter material from sea water. In this case, a behavioral choice exacerbates other risk factors. In other cases, however, numerous background

factors may act in synergy for the poor or socially disadvantaged, as in the case of American inner-city minority populations, who may be exposed to toxic pollutants from multiple sources (Bullard 1994). In neither the UK nor the US cases would standard risk-assessment methodologies, based on average characteristics, compute adequately the risk to specially vulnerable populations. Indeed, technical risk assessment has tended to obscure the distributive implications of risk production. It is, in this sense, a social technology that reinforces existing structures of power (Winner 1986).

Ironically, the great increase in formal examinations of risks has not so much diminished as contributed to the exacerbation of risk concerns (Beck 1986). Given the complexities of risk assessment and the high stakes involved, it is understandable that risk assessment methodologies have been subject to legal and other formal challenges (see Jasanoff 1990). These proceedings have subjected risk assessments to critical deconstruction, questioning the precise basis for the choice of methodologies. Where these methods have had consequences injurious to some but not all sections of the population, the procedure has been made to appear discriminatory. Environmental justice movements have formed to press the point that risk assessments of individual chemicals are not equivalent to a demonstration of the impact of a cocktail of pollutants. Communities experiencing extensive hazardous exposures—each element of which may be deemed not to be unduly risky on its own—argue that the overall impact of multiple sources is not well gauged by standard methodologies.

Furthermore, as Jasanoff (1990) has demonstrated, particularly in the US, the combination of adversarial cross-examination with the separation of powers and scope for judicial review of executive agencies, has meant that extensive financial and intellectual resources have been directed at deconstructing risk assessments. Given all the complexities outlined above (the hypothetical nature of many risks, the difficulty of identifying an average case, the impossibility of most human experimentation, the need for surrogate measures, and so on), there has been no prospect of finding an incontestable scientific basis for defending particular risk assessments.

Sociological research has focused also on the strategic constructions of certainty and uncertainty associated with risk assessments. Thus, Wynne (1992) has argued that risks and probabilities are made up of many kinds of not-knowing, only a fraction of which (e.g., uncertainties of extrapolation from rodent bioassays) may be acknowledged openly in formal risk assessment processes. In some cases, it is possible to establish a hierarchy of uncertainty, as between 'risks' and 'uncertainties': With risks one knows the odds, but with uncertainties, only the general parameters of the problem. Most practical questions which science-in-public has to face, however, involve an additional

kind of noncertainty. This Wynne terms ignorance. Ignorance refers to aspects of a problem which are consciously or unconsciously bracketed off, and commonly not further investigated. These may be issues which lie outside the disciplinary paradigms of the sciences and are thus in a sense necessarily, rather than perniciously, excluded from day-to-day research. Nonetheless, ignorance in this sense is a different form of not-knowing than mere uncertainty; it is not adequately captured by being treated simply as extreme uncertainty.

In principle at least, more knowledge might assist in handling these kinds of not-knowing. Uncertainties might be turned into risks. New understandings might clarify specific areas of former ignorance, though, of course, there is no prospect of ignorance being overcome in general. But, in addition, Wynne argues that there is a fourth consideration, 'indeterminacy,' resulting from 'real open-endedness in the sense that outcomes depend on how intermediate actors will behave' (Wynne 1992, p. 117). In other words, the safety or reliability of systems with an organizational or human component are deeply dependent on how the systems are operated. By treating most systems as determinate, conventional risk-assessment practices typically adopt tacit, unexamined and untested sociological hypotheses about those social practices that are central to the risk-producing activities. Thus, evaluations of risks from potentially hazardous technologies do not depend only on the behavior of physical and biological systems (difficult to model though they may be) but every bit as much on the behavior of plant managers, operators, and even those exposed.

Several insights into the sociology of expertise follow from these claims. First Wynne (1992) observes that experts, when faced with the need or chance to regulate in an area of noncertainty, are tempted to treat all forms of not-knowing as statistically treatable uncertainty, even though things of which they are ignorant cannot, by definition, be quantified. Second, he argues that the public may be significantly more expert than the scientists in relation to some of the matters covered by indeterminacy. His view, as expressed with Irwin, is that 'science offers a framework which is unavoidably social as well as technical since in public domains scientific knowledge embodies implicit models or assumptions about the social world' (Irwin and Wynne 1996, pp. 2–3). In other words, insofar as expert assessments depend on assumptions about particular social, cultural, or occupational practices of lay groups, it is likely that these publics will be more expert in these matters than technical 'experts' more distant from the relevant experiential insights.

A related body of research ties this manifestation of hazard within complex sociotechnical systems to features of organizational practice and culture. Thus, Perrow's discussion of 'normal accidents' (1984) makes the case convincingly that many hazardous occur-

rences are a routine (if often unpredictable) outcome of the interaction of the manifold technical and organizational components of modern power stations and production plants. Accidents are to be expected even if no particular accident is predictable. More recently, Vaughan has applied associated insights to understanding the decision to launch the ill-fated Challenger mission (Vaughan 1996). Of course, questions still remain about the extent to which organizational arrangements give priority to concerns for production, or for safety (Clarke 1989), and many recent case studies show corporations placing the most value on production and profitability.

In sum, though risk discourse has been promoted by scientists and by scientific attitudes to the valuation of the natural world, it is clear that public experience of risk assessment has encouraged successful challenges to the official orthodoxy, as in the emergence of an environmental justice agenda, and that 'scientific' risk assessment has been undermined dialectically by the advance of legal-rational reflection. In response to such difficulties, official agencies commonly are left with no alternative but to demand 'more and better' science; yet there are few grounds for thinking that further research or rationalization will resolve the problems outlined above. Ironically, social movement campaigners find themselves confronting a similar impasse. In opposing the establishment they commonly produce counter-claims about health or environmental risks, yet find related difficulties in underpinning their risk claims. Such experiences often generate an ambivalent attitude toward scientific expertise (Yearley 1992). These phenomena serve as a good example of what Ulrich Beck (1986) has termed 'reflexive modernization.' The institutions of modernity, notably the traditions of scientific analysis and legal fact-finding, have been turned upon themselves with deconstructive consequences. For Beck, this reflexive modernization is just one facet of the 'risk society' thesis, which portrays late-millennial industrialized societies as being unusually and overwhelmingly concerned with the distribution of risks and other 'bads.' In this view, social scientific interest in risk consists not so much in the study of societal responses to particular hazards; rather it is the key to characterizing the dynamics of society as a whole.

3. *Risks and Cultures*

Beck's thesis in its widest form asserts that the most modern risks (termed by others 'late' or 'high' modern (Giddens 1991)) are reflexive in the sense that they are self-induced. Risks in the early modern period were external to the self-conscious control of social actors. Diseases would spread, bad weather would damage harvests, fires would consume urban areas as though under the influence of external, natural forces. Even if some of these risks were exacerbated by human

interventions, the contemporary perception was that they were uncontrollable. In high-modernity, by contrast, risks such as the threat of disastrous nuclear reactor incidents are plainly the consequences of human activities (Beck 1986). In this view, Victorian and early-twentieth-century confidence about the progressive diminution of risk marks, in an ironic fashion, the transition from apparently external to societally-induced risk. Scientific and technological developments are caught up in this reflexive pattern because modern risks are typically the result of technological ventures (nuclear power, ozone-depleting chemicals in the earth's atmosphere); science and technology are involved in the cause, the diagnosis, and, with luck, eventual rectification of the problem.

Beck's overall analytical claim has been greeted with widespread enthusiasm by many social scientists, and the term 'risk society' has popularly been adopted. However, the details of his analysis have not met with the same welcome. For one thing, it is unclear how 'modern' all present-day risks are. The incidence of 'mad-cow disease'—eventually apparently transmitted to humans—is thought to have arisen from the low-technology business of producing cattle feed from animal protein, specifically in the context of energy-saving, low-temperature process innovations. More significantly, Beck's favored examples—such as the risk of fall-out from the Chernobyl reactor explosion—have a primitively 'democratic' quality. On the face of it, the fall-out may descend upon the poor and wealthy alike. In that sense, the 'risk society' is everyone's problem (Beck 1986). But as the environmental justice movement, particularly in the USA, has made clear, environmental 'bads' are still often distributed quite unequally along ethnic, gender, and class lines (Bullard 1994). The risks of the risk society may not be shared as evenly as Beck implies. Finally, Beck has rather little to say about the reasons for cultural differences in the salience of different kinds of risk, although it is clear, for example, that the framing of, and policy responses to, risks vary widely even between socially and economically comparable regions, such as Europe and North America (Jasanoff 1986).

The relationship of risk and culture has been explored by the anthropologist Mary Douglas and several of her colleagues. Developing Durkheim's celebrated suggestion that religious cosmologies reflect social structures, Douglas proposed that cultural views of the characteristics of nature indicate as much about the reflected character of society as about the underlying features of nature itself. Carefree, individualistic, dynamic cultures tend to view nature as resilient and able to look after itself, while cultures which are precarious or worry about protecting their boundaries tend to view nature as fragile and in need of protection. Douglas subsequently developed this approach for the examination of risk in advanced industrial societies. A society's risk anxieties, in her view, relate as much to

the cultural 'insecurities' of that society as to the actual extent of hazards (Douglas and Wildavsky 1982). Douglas' 'cultural theory' has proven difficult to test (but see Marris et al. 1998) and it raises a host of theoretical problems, such as the unit of cultural analysis and the sources of cultural change. However, her approach does serve to underline the extent to which a culture's awareness of risks may be an imputation on to nature of more general cultural anxieties.

Finally, it is clear that not all modern risks arise from human interventions in nature. Though concerns about medical and environmental risks have increased conspicuously since the mid-1970s, worries about crime, immigration, internet security, financial markets and global social dislocation have also characterized the networked and industrialized world (see also *Science and Social Movements*). Risk anxieties can thus be inscribed not only to nature and to the human body, but also to the self-understanding of modern societies.

Risk: Theories of Decision and Choice

Risk is a central concept in everyday life as well as in many theories of the social and behavioral sciences. People have an intuitive notion about what is meant by risk. We are able to make risk judgments and we are able to compare the riskiness of alternatives. We might agree that it is riskier to invest in stocks than in bonds, and it might seem riskier to eat mushrooms which we have collected ourselves than mushrooms bought in a supermarket. Nevertheless, some people choose to buy stocks and others choose to eat mushrooms which they collected, i.e., they are willing to take the risk.

The examples demonstrate that risk can be analyzed as a primitive and that risk can be analyzed in the context of choice. Theories which model risk as a primitive usually start from the assumption that for each individual there exists a meaningful risk ordering of alternatives which can be obtained directly by asking the individual. Theories that consider risk in the context of preference start from choice as a primitive. A definition of risk or riskiness of an alternative is then derived based on models of choice.

Throughout Sect. 1, the leading model of choice, expected utility, is considered. Based on this model, concepts of risk and riskiness are analyzed. Section 2 investigates theories that take risk as a primitive. In Sect. 3, risk value models are presented. They model choice in a way that explicitly considers risk, i.e., they combine the ideas of Sects. 1 and 2.

Throughout the article, only theories for the risk of random variables are presented. Random variables will be denoted X , Y , etc. and they will also be called lotteries or gambles. See *Risk: Empirical Studies on Decision and Choice* for what is known about the public's judgments of the riskiness of physical, environmental, and material risk in ways that go beyond modeling these risks as random variables. An overview on risk-taking behavior can be found in Yates (1992).

1. Risk in the Context of Expected Utility

The most widely used model of preference is von Neumann and Morgenstern's (1947) expected utility model:

$$X \succsim Y \text{ if and only if } E[u(X)] \geq E[u(Y)]$$

where $u(\cdot)$ is the utility function of an individual and E stands for expected value. The binary relation $\succsim$ denotes 'preferred or indifferent to.' As expected utility results in an ordering of risky alternatives, it is called a theory for decision making under risk. However, utility theory offers no direct definition of risk or riskiness.

1.1 Risk Premium

One measure of risk in the context of expected utility could be the risk premium (RP), which is defined by the following equation:

$$E[u(X)] = u(E[X] - \text{RP})$$

The difference $E[X] - \text{RP}$ is also called the certainty equivalent of the lottery X . For reasons of simplicity, in the following only increasing utility functions are considered. If the risk premium is negative (positive), the expected utility of the lottery is larger (smaller) than the utility of the expected value of the lottery, i.e., the decision maker does (not) like the risk of the lottery, i.e., they behave in a risk seeking (risk averse) manner. A decision-maker with a risk premium of zero is labeled risk neutral. All risk premiums for nondegenerate lotteries (lotteries where no single consequence has a probability of one) are positive (negative, zero) if and only if the decision-maker's utility function is concave (convex, linear).

Can the risk premium be used to define a risk ordering on lotteries, i.e., a binary relation $\succsim_r$, where $X \succsim_r Y$ means that lottery X is at least as risky as lottery Y ? Unfortunately, the answer is no. The risk premium depends on the initial wealth of the decision-maker. If W and W' denote two initial wealth levels, it is quite possible that $\text{RP}(W+X) > \text{RP}(W+Y)$ and $\text{RP}(W'+X) < \text{RP}(W'+Y)$. To define risk unambiguously, one must place restrictions on the utility function, or on the random variable.

1.2 Restrictions on the Utility Function

A classic restriction on the utility function is to assume that it has a quadratic form

$$u(x) = x - \beta x^2, \beta > 0, 0 \leq x \leq 1/(2\beta)$$

where x denotes possible outcomes of the gamble X . In this case, the expected utility of a gamble X is given by

$$\begin{aligned} E[u(X)] &= E[X - \beta X^2] \\ &= E[X] - \beta E[X^2] \\ &= (E[X] - \beta E[X]^2) - \beta \text{Var}(X) \end{aligned}$$

Thus, the expected utility is a function of expected value and variance. An increase in risk (measured by variance) implies a decrease in expected utility and vice versa. The coefficient β reflects the trade-off between risk and expected value. The risk ordering of lotteries implied by variance is independent of the decision-maker's wealth level. For further cases where variance is a reasonable measure of risk, see Levy (1992). The general question to what extent expected utility can be interpreted as a risk value model is discussed in Sect. 3.

1.3 Restrictions on Random Variables

A classic restriction on the random variable is to compare only those that have identical expected values. For this case, Rothschild and Stiglitz (1970) were able to provide a definition of the risk of gambles. For $E[X] = E[Y]$, we can say that X is more risky than Y if and only if the following three statements, which are equivalent, are true

- (a) Every risk-averse decision maker prefers Y to X .
- (b) X is equal to gamble Y plus noise, i.e., some random variable with expected value zero.
- (c) X is obtained by a mean preserving spread of Y . A mean preserving spread takes probability weight from central parts of the distribution and puts it into the tails of the distribution while holding the expected value constant.

This definition of riskiness is convincing, but it is only applicable to lotteries with equal expected value, and thus yields a partial ordering of the space of gambles. To overcome this limitation, Jia and Dyer (1996) define a risk ordering on lotteries for concave utility functions u as follows

$$\begin{aligned} X \succsim_r Y \text{ if and only if } & -E[u(X - E[X])] \geq \\ & -E[u(Y - E[Y])] \end{aligned}$$

This definition of riskiness is able to order all lotteries. However, it is not clear to what extent this definition captures what people intuitively think about risk and how an ordering in terms of risk is related to an ordering in terms of preference. We will further investigate these questions in Sect. 3.

1.4 Relative Risk Aversion

All the results in this section are based on expected utility theory. However, it should be pointed out that utility functions not only measure decision-makers' risk attitude, simultaneously they measure the marginal value of the good to be evaluated. An example should illustrate this point.

Suppose one has to evaluate a lottery which gives eight oranges if on a coin flip head comes up and zero oranges if tail comes up. Assume that the certainty equivalent is three oranges, i.e., the risk premium is one orange and thus the decision-maker is considered risk averse. Now, it could well be that this positive risk premium has nothing to do with any 'intuitive' notion of risk aversion. For instance, if the decision-maker likes three oranges half as much as eight oranges, then the average value of the lottery is equal to the value of three oranges, i.e., the risk premium can equally well be explained by some strength of preference considerations. The notion of relative risk aversion, introduced by Dyer and Sarin (1982), helps to disentangle strength of preference from utility. The concept of relative risk aversion defines risk aversion relative to the strength of preference. The above example shows a decision-maker who is relatively risk neutral.

2. Risk as a Primitive

In this section we start out with the assumption that subjects are able to meaningfully order lotteries with respect to their riskiness, i.e., that a risk ordering $X \succcurlyeq_R Y$ exists. In *Risk: Empirical Studies on Decision and Choice* it is demonstrated that individuals are able to give consistent risk judgments. In this section we investigate how these judgments can be modeled. One has to look for a function R defined on the set of gambles with the property

$$X \succcurlyeq_R Y \text{ if and only if } R(X) \geq R(Y)$$

Every such function R will be called a risk measure. Note that we take subjects' risk judgments (risk perception) as a primitive without giving an abstract definition of risk and without relating it to preference (see Brachinger and Weber 1997 for an overview).

2.1 Naive Measures of Risk

The first class of risk measures to be discussed are so-called naive risk measures. Most of them are special cases of the following formula

$$R(X) = E[|X - x_0|^\alpha | X \leq x']$$

where x_0 is a benchmark (reference level of wealth) defining gains and losses, x' defines the range parameter that specifies what deviations are to be included in the risk measure, and α is a measure of relative impact of large and small deviations. Risk measures

such as variance, semivariance, shortfall measures, probability of ruin (loss), etc., are all special cases of this risk measure. Some of these measures are quite popular, e.g., shortfall measures in the insurance and banking industry; nevertheless, they do not capture what individuals perceive as risk (see *Risk: Empirical Studies on Decision and Choice*).

The fact that risk perception is not captured by variance, the measure most popular in economics and finance, can be demonstrated by a simple example. Consider the three two-outcome gambles $X = (10, 0.5; -10, 0.5)$ —this is a gamble with a 50–50 chance of receiving 10 or -10 —, $Y = (20, 0.2; -5, 0.8)$, and $Z = (5, 0.8; -20, 0.2)$. Empirical studies find that subjects consistently judge each of Z and Y to be more risky than X (Coombs and Bowen 1971), but expected value and variance are the same for all three lotteries. Higher moments of the distribution, e.g., skewness, have an influence on risk perception too.

2.2 Axiomatic Measures of Risk: I

For a while it was quite popular to axiomatically derive measures of risk. Similar to what is done in modeling preferences, simple axioms of risk judgments were presented and measures of risk were derived mathematically. Pollatsek and Tversky (1970) were the first to use the axiomatic approach. Besides some technical axioms, they require a risk measure to be additive, i.e., the risk of the convolution of two lotteries should be equal to the sum of the risk of each lottery. This property implies, e.g., that the risk of a lottery played twice is equal to twice the risk of the lottery played once, and the risk ordering of two lotteries is not changed if they are both convoluted with the same lottery. Finally, they require that the risk of a lottery is reduced if a constant is added to all outcomes. From these conditions they derive the following risk measure

$$R(X) = \alpha \text{Var}(X) - (1 - \alpha) E[X], \quad \alpha \in (0, 1]$$

Thus, according to Pollatsek and Tversky (1970), the risk ordering is generated by a linear combination of expected value and variance. This model does not fit risk judgments since, for instance, the example given at the end of Sect. 2.1 demonstrates that subjects' risk perception can not be explained just by expected value and variance.

Fishburn (1982, 1984) explored risk measurement from a purely axiomatic point of view. He considered gambles separated into gains and losses and did not specify functional forms, thus his theory remains rather general and is not considered further here.

2.3 Axiomatic Measures of Risk: II

Luce (1980) was the first to derive risk measures from functional equations characterizing the effect of resca-

ling on perceived risk. His most prominent models consider the α -transformation X_α in which each outcome of the gamble X is multiplied by $\alpha > 0$. He assumes that there exists an increasing function S (with $S(1) = 1$), such that $R(X_\alpha) = R(\alpha X) = R(X) S(\alpha)$ for all X and α . He also assumes that the risk of a gamble X is the expectation of a transformation T of that gamble, i.e.,

$$R(X) = E[T(X)], \text{ with } T \text{ some non-negative function with } T(0) = 0$$

These assumptions imply the following risk measure

$$R(X) = b_1 E[|X|^\delta \mid X < 0] \text{Prob}(X < 0) + b_2 E[X^{\delta^+} \mid X > 0] \text{Prob}(X > 0)$$

where δ is a positive real number, b_i are weights on the components, and $\text{Prob}(X > 0)$ denotes the probability that the random variable has outcomes greater than zero. This risk measure is a linear combination of the conditional expectation of negative and positive outcomes, where all outcomes are raised to the power δ .

Luce's model was extended by Luce and Weber (1986). Influenced by empirical work and based on a system of axioms, they proposed the Conjoint Expected Risk (CER) model that has the following form

$$R(X) = a_1 \text{Prob}(X = 0) + a_2 \text{Prob}(X < 0) + a_3 \text{Prob}(X > 0) + b_1 E[|X|^{\delta^-} \mid X < 0] \text{Prob}(X < 0) + b_2 E[X^{\delta^+} \mid X > 0] \text{Prob}(X > 0)$$

with a_i and b_i being weights on the components, and δ^- and δ^+ being coefficients of power functions. Empirical research has demonstrated that the CER model describes risk judgments reasonably well, admittedly at the cost of a rather large number of parameters in the model.

Sarin (1987) chose another way to extend Luce's measure of risk. Instead of the α -transformation, he used a β -transformation, which just adds a factor β to all outcomes of the lottery. He then assumes that $R(X_\beta) = R(X + \beta) = R(X) S(\beta)$, with S a strictly decreasing function, $S(0) = 1$ and $\beta > 0$. This assumption mirrors the fact that the risk of a gamble appears to decrease when a β -transformation is applied. In conjunction with the expectation principle (see Luce's approach), Sarin derived the following risk measure

$$R(X) = k E[e^{cX}]$$

with $k > 0$, $c < 0$ or $k < 0$ and $c > 0$. This risk measure gives higher weight to a gamble's potential losses than to its potential gains. Both Sarin's model and the CER model are able to capture the effect that subjects strongly dislike the possibility of large losses (potential catastrophes).

All the risk measures presented in Sects. 2.2 and 2.3 have the property that adding a constant (applying

the β -transformation to the gamble) changes the risk, i.e., they are not location free. This property is supported by a lot of empirical work. However, on theoretical grounds, in quite a number of applications, e.g., in capital market theory, risk should be location free. Since nearly all the models proposed in Sect. 2.1 are location free, for certain applications it might be useful to combine the ideas of Sects. 2.2 and 2.3 with the concept of a location free risk measure. Weber (1990), therefore, advocates extending Sarin's measure of risk to the following form, giving the risk measure some normative flavor

$$R(X) = k E[e^{c(X - E[X])}]$$

with $k > 0$, $c < 0$, which can be used in a capital market framework.

Recently, Jia et al. (1999) modified the model of Jia and Dyer (1996) presented in Sect. 1.3 to make it descriptively appealing. In Sect. 1.3, risk was defined as $R^*(X) = -E[u(X - E[X])]$ which is location free. To heal this deficiency, they propose the following measure of risk

$$R(X) = f(E[X]) (R^*(X) - R^*(0))$$

where $f(E[X])$ is a decreasing function of the expected value and $R^*(0) = -u(0)$ a constant. Thus, an increase in expected value leads to a decrease of risk—as in Sarin's model. Their model is rather general as it only specifies that $R^*(X)$ depends on the decision-maker's utility function, but no specific form of the utility function is required.

3. Risk Value Models

Clearly, risk is related to preference (see also Sect. 1). To further investigate this relation, one could propose a general risk value model for evaluating gambles such that a gamble X is preferred to a gamble Y , i.e.,

$$X \succcurlyeq Y \text{ if and only if } f(V(X), R(X)) \geq f(V(Y), R(Y))$$

where V measures the value of a gamble, R measures the risk, and f reflects the trade-off between these two components (see Sarin and Weber 1993 for a more extensive review). Clearly, a greater value is more preferred and a lower risk is more preferred. Therefore, f is increasing in V and decreasing in R .

Risk value models have an intuitive appeal, as people like to talk about the risk and the value of alternatives. There are two ways to use risk value models:

(a) Starting from expected utility, the EU model can be reformulated as a risk value model.

(b) A measure of risk as a primitive and the expected value can be the components of a risk value model.

Both ways still have their disadvantages. If one starts with expected utility (case (a)), in most cases it is not possible to find a straightforward decomposition into risk and value. It was shown in Sect. 1 that in

order to do this one has to considerably restrict the utility function or the probability distribution. In addition, the risk measures derived from expected utility might not be descriptively correct. If one begins with a risk measure as a basis for a risk value model (case (b)), one has to first define a trade-off function f . It is by no means clear that the resulting risk value model will be prescriptively appealing. Future research hopefully will shed more light onto the relation between preference and risk.

Ritual

For Durkheim (1964), ritual is social activity falling within the domain of the sacred. The sacred is opposed to the profane, which does not contain ritual action. Leach (1954), however, rejects Durkheim's hard and fast distinction between sacred and profane, preferring to see these as aspects of social actions lying along a continuum. At one end are those actions that are largely technical and profane, while at the other are those which have no technical functions and are largely symbolic, aesthetic, and sacred. Most actions in between these two poles have aspects which are both sacred and profane. Ritual in Leach's sense is, then, by no means confined to ideas of the sacred. By removing ritual as exclusively to do with the sacred, Leach is able to broaden the definition of ritual. He thinks of it as a message-making kind of activity, and so as an aspect of any kind of behavior in which repetitive or customary acts signal messages. Handshakes or wearing a tie in the office are as much forms of ritual as a priest praying to ancestors at a shrine. So-called magical and secular acts are therefore both communicative and both are examples of ritual action.

Ritual for Leach is, then, a way in which humans communicate with each other different aspects of their social structure. Thus, we may be perfectly aware of social class or status differences and even be able to talk about them discursively. But we still signal or symbolize these differences in a number of short-cut ways, through distinctive accents, differences of dress and life-style, and even bodily movement and gesture. Sometimes we are not so conscious of the differences our ritual behavior communicates, and sometimes the differences exist simply through lack of knowledge of how to behave on, say, a formal occasion. In other words, the sociostructural approach argues that ritual action does not occur in a political and economic vacuum: politicoeconomic interests are always involved to some degree, even if sometimes minimally.

A second approach to the study of ritual emphasizes its logical qualities. Here, ritual communicates fundamental ideas that may be specific to a particular culture, or that may even be universal. It is an approach that owes much to structuralism in anthropology, which is predominantly associated with the work of Lévi-Strauss. It runs very much from the idea of culture as organized through binary oppositions. Thus, Needham (1961) has suggested that, when a male diviner or shaman uses his left hand to throw the cowrie shells which he or his possessory spirit will interpret in order to understand the cause and course of an illness or misfortune, he is reversing a kind of natural order. For men are normally associated with the right hand and women with the left. But since diviners fall outside the realm of normal human capacities, being able to see what other humans cannot, it makes logical sense to reverse the equation

of maleness with the right hand. There is no functional explanation for these kinds of ritual reversal for they are governed by proclivities of the human mind. That said, local political and economic circumstances can sometimes take up these proclivities and harness them to a cause. Thus, prophets leading religious movements may communicate their power and distinctiveness through rituals which reverse normal expectations. Many other kinds of ritual behavior, like some beliefs and myths, achieve their communicative effectiveness by reversing what is otherwise considered natural.

Now, while it is true that ritual may be thought of as communicating messages about status or about the way the human mind works or how the world is, it varies enormously in the degree to which it is elaborated. After all, a handshake can hardly compare with a full-scale ritual investiture of a monarch spread over days and involving thousands of people and lavish expenditure. To call both these kinds of activity 'ritual' clearly leaves out much of what is special to the latter. Similarly, some hunting and gathering peoples such as the African Mbuti forest dwellers do not perform elaborate rituals, while other African groups noted for their masquerades do. Peoples do, then, seem to differ in the relative amounts of ritual which they perform; although, in making this claim, there is a dangerous Eurocentric qualitative assumption that the significance of ritual is measured by the amount of time, materials, and people involved. Who is to say that an apparently slight activity, taking only a moment and few resources, may not in fact 'say' much more than a drawn-out ceremony of great proportions whose influence on people is in fact limited? Nevertheless, it is a useful if provisional starting point of analysis to try and understand how variations in the complexity and lavishness of ritual reflect those of social organization and cultural logic. Arising from this approach is another, which recognizes that as well as communicating messages about the current social structure or about fixed properties of the human mind, rituals also change things or enable changes to take place.

We may call this third, the transformational approach to ritual. For Van Gennep (1965), the rites of passage as marking changes of status in the human life cycle—for example, birth, puberty or adolescence, marriage, first child, first grandchild, and death—could be broken down into three phases: separation, liminality, and incorporation. In other words, the individual undergoing the ritual must first be separated from the community of which they are a member, perhaps by removal of the head hair or some other bodily alteration. They then enter the liminal phase in which they are regarded by members of the community as outside and beyond normal human society. This is the phase in which there is transition from one status to another, for example from child to adult, bachelor to husband, etc. Van Gennep saw this as a period of

death, i.e., of the child, and of rebirth, i.e., of the adult. It is a theme elaborated in many later studies that showed the ritualization of death as the condition of new life or regeneration. The third and final phase is when the individual is reincorporated in the community, now no longer a child, but an adult with the rights and duties expected of this new status.

Van Gennep saw these features of rites of passage as also typifying other kinds of transition in addition to those of the life cycle, such as the seasonal or other movements of groups, fertility rites, and entering and leaving dwellings, special days or months, and cult societies. Victor Turner (1967) made the notion of liminality central to his work on ritual, extending to the idea of antistructure, by emphasizing the rejection of society on the part of people undergoing transition or in a marginal state, and also *communitas*, by which he meant the way in which people on ritual occasions temporarily transcended their normal, everyday social conflicts and cleavages and emphasized their common humanity. In addition to the life crisis rites of Van Gennep, Turner further distinguishes rites of affliction, which are held to reverse the effects of, for example, women's infertility, crop failure, sickness, and other misfortunes adversely affecting the lives of people living together in a single village or other dwelling. They also enable people to move from one state to another, although not as part of the human life cycle, but more as part of the unpredictability of the human and social condition in which conflicts and contradictions are not so much represented in ritual as presented, addressed, and then redressed, an approach which thus builds on and advances that of Durkheim.

A subset of this approach might conveniently be called Marxist in the sense that social inequality and exploitation of a working by a ruling class is presupposed. A Marxist approach would, for instance, claim that the official, media, and public ritual attention devoted to the British royal family evokes ordinary people's unquestioning compliance and loyalty, to the extent that they cannot see that the institution of royalty in fact underpins the system of landed privilege that defines an aristocracy and provides an imitative model for other ruling and bourgeois classes. The 1990s in the UK saw an extraordinary rise in the degree to which the media and many of these same ordinary citizens began to question the worth-whileness of royalty. Was this an example of royal rituals losing their capacity to retain subjects' loyalty, a kind of demystification of ritual? Or is this a case of the different interpretations of ritual enabling social change to occur?

Royal rituals have been a common focus of anthropological analysis, in which their transformative power has been highlighted. Gluckman (1963) was dissatisfied with studies of royal and other rituals which saw them as simply affirming the sovereign's authority and the solidarity of the society under his rule. Using the example of the Swazi *Incwala* royal

ritual in southern Africa, Gluckman claimed instead that its socially cohesive function was only possible after it had revealed the society's internal conflicts: such conflicts had to be addressed before they could be accepted as part of the normal social process. Beidelman (1966) criticizes Gluckman's over-reliance on social conflict as needing to be expunged through royal rituals, and argues for a view of them as marking out the divine or mystical properties of kingship, so providing the king with legitimate recognition to reign over his subjects.

This example moves us on to a fourth approach to ritual, which is to see them not necessarily as achieving a particular social or logical function, but as expressive in and of themselves. Beattie (1966) attacked attempts to explain rituals as practical and intellectual attempts to solve problems. Rituals draw instead on people's human predilection to engage in creative thinking, sometimes through culturally enjoined associations of ideas, and were thus closer to art and drama than to technology or science. Rituals in this sense do not 'do' things so much as express human dilemmas, symbolically and often under some kind of duress. They cannot be reduced to questions of whether they are rational or irrational, or true or false propositions, any more than aesthetics can be explained in these terms.

In many respects this explanation of ritual as expressive rather than functional, reproduces Leach's distinction between technical and aesthetic acts as occupying two extreme poles of a continuum between which they are both aspects of any activity. Nevertheless, expressed in the way that Beattie did, it freed anthropologists from having to seek practical explanations for a particular form of ritual behavior. If a ritual appeared to perform a particular function in society, this could better be regarded as an unintended consequence of an activity whose participants did not have such consequences in mind. Thus, it may well be that the British royal rituals for a long time had the effect of persuading the public to accept the stratified status quo as rightfully headed and legitimized by the monarch and the monarch's family. It may well be, moreover, that politicians and members of the ruling elite recognized, seized on, and developed this effect, so turning consequence into purpose. The expressive here becomes instrumentally effective. However, not all that which we understand as ritual behavior can be interpreted in this way. People throughout time do not normally calculate in advance what might pass as effective ritual, nor indeed separate ritual as a social category from nonritual; nor may we assume that what we define as rituals always have significant social and intellectual consequences.

Approaches to the study of rituals are not exhausted by the above, and indeed overlap in part. They represent, as much as anything, the discipline's decision to divide up its findings in this way. An alternative method is to ask how anthropologists define ritual on the basis of their own ethnographic data. A recent

example is a study of the Indian Jain rite of worship by Humphrey and Laidlaw (1994). Their intriguing starting point is the fact that in some societies people may distrust ritual practices as being empty or false, and yet continue with them. Similarly, noting that for many people, religion and ritual are seen as going together, they also refer to the way in which practitioners of some religions turn on their rituals as unworthy and even frightening. The European Reformation attempted to strip off from Christian religious belief what were regarded as some unacceptable ritual practices, as Wahabi reformers in Islam are doing today. By contrast, some argue that ritual is good for religion and humanity. Mary Douglas (1973) drew some of her own ideas from trying to understand the rejection of ritual in the Catholic Church by many of its senior adherents who also, for good measure, dispensed with the Latin language as if transparent clarity was all that mattered, over and above the expressive power of faith.

The disjunction between religion and ritual led Humphrey and Laidlaw (1994) to suggest another disjunction, which is that between the intention of actors in ritual and the ritual actions themselves. Sometimes intention and act fit, and sometimes they diverge irretrievably, but sometimes they are aligned. Such lack of fit is not to be understood as the result of mistakes in intention and performance, but as evidence of the way in which ordinary actions may become endowed with the quality of ritual. For these authors, ritual is a quality that actions take on: they become ritualized. While everyday actions are intrinsically intentional, ritual acts enter a kind of phenomenological space freed of such everyday intentions, and, paradoxically, are 'intended' to do so. There is here a 'ritual commitment,' a notion close to that expressed in a classical study of ritual by Gilbert Lewis (1980). Humphrey and Laidlaw (1994), moreover, oppose the idea that ritual is necessarily communicative and expressive of messages and beliefs. One is here reminded of Sperber's (1975) view that symbols do not intrinsically mean anything. Rather it is people who interpret a symbol as such, and who thereby give it meaning. The concept of communication here has to be established. It may mean one person making an assertion and expecting a response from the hearer. Or it may simply mean making a gesture or uttering a conventional phrase ('It's hot today'), for which no response is expected and which is therefore really a form of what has been called phatic communion, a device to secure solidarity with another person. Rituals may sometimes communicate but, as Rappaport (1979) points out, so do many other kinds of phenomenon, and by privileging its expressive functions we miss what is otherwise distinctive of ritual.

The view that ritualization is a process by which actions become endowed with a ritual quality, shares something with Gerholm's (1988) notion that ritual is, so to speak, partly made up as it proceeds. That is to

say, there are at least some kinds of ritual for which precise textual rules do not exist or which have been forgotten, with the consequence that participants have little more than a sense of ritual occasion or commitment and endeavor to convey that sense in actions and words, inventing and borrowing as much as they can. This ushers in a query as to how much ritual depends on precise wording as well as actions. A Christian prayer depends heavily on personally composed as well as prescribed verbal forms, and is firmly regarded as ritual. But rituals are also organized through spatial orientation and bodily positioning. The many different kinds of Islamic prayer are also personally or formulaically verbal, but crucially require orientation to Mecca, while a particular class of prayer or devotion called *salat* is made up of a complex sequence of prostrations as well as recitations (Bowen 1989). In the event of the mosque imam taking on the recitations on behalf of the congregation, the prescribed bodily actions become the individual worshipper's ritual responsibility and must be repeated if they are performed incorrectly. Parkin (1992) has argued that it is not always the case that the verbal is important in ritual, while set spatial directions and orientations, and bodily gestures, movement, and positions are what mark off and so fundamentally characterize ritual.

A challenge is to avoid essentialist definitions of ritual which seek to set up criteria which must be met before this label can be applied to an activity. Phenomenologically, ritual is to do with the paradox of being both the agent of an action, but also being taken along by this same action. It presupposes being able to move within an action from citing its purpose to having no need, wish, or clear idea of what it is about, and yet valuing it. Nevertheless, ritual must have some kind of structure, the most elemental of which is that individuals alone or with others take up positions with regard to each other or with regard to objects, experiencing such positioning as unlike any other.

D. Parkin

Ritual and Symbolism, Archaeology of

Ritual (repetitive sequences of actions related to beliefs) and symbolism (the representation of one thing, often more abstract, by reference to another, often more concrete) have been subjects of archaeological study since the origin of the discipline. Individual artifacts, locations within archaeological sites, and even entire sites or landscapes have been used as archaeological evidence of ritual and symbolism. Archaeologists have varied in their assessment of how difficult it might be to study these subjects, with some expressing doubt that accurate information about such nonmaterial topics could be produced, and others noting that symbols are polysemous, requiring multiple interpretations. Contextual analysis and an emphasis on the active role of social agents characterize the contemporary archaeology of ritual and symbolism.

1. From Ritual Objects to Symbolic Archaeology

Archaeologists have always identified some deposits as evidence of ritual, and ascribed symbolic meanings to some artifacts. Where texts were available, as in Egyptian archaeology, they were employed to validate early interpretations. Beginning in the 1950s explicit concern was addressed to the methodological status of

archaeological inferences concerning belief and meaning. Interpretation of ideational systems, including symbolism and ritual, was viewed as more problematic than other topics, such as economics and subsistence. As early as the 1960s, some archaeologists argued that ritual and symbolism were no more difficult of access than more apparently materialist topics, questioning the analytical separation of material and ideational aspects of society. Since the 1980s, archaeologists influenced by practice theory have attempted to demonstrate that the archaeological analysis of symbolism and ritual benefits from attention to human agency. Despite changing theoretical perspectives, throughout the history of professional archaeology similar empirical materials have served as the basis for the archaeology of ritual and symbolism.

1.1 Early Archaeological Research on Ritual and Symbolism

Early fieldwork recovered material interpreted as evidence of ancient ritual and belief. Contemporary texts were sometimes available that sketched out beliefs and, as in the case of Egypt, even provided details of ritual actions.

Such early research established assumptions underlying much subsequent archaeological investigation of symbolism and ritual. First, the symbolism of material remains ideally was to be explained by reference to explicit texts, assigning material culture to the role of a container of a formalized and generally accepted singular meaning. Second, specific kinds of archaeological deposits came to occupy a central place in discussions of ritual. These included formal structures identified as the locations of rituals (temples); human burials, viewed universally as occasions for mortuary ceremonies; and 'offerings': deposits of selected objects, especially those encountered in ritual structures and burials.

1.2 The 'Ladder of Inference' and Processual Archaeology

In 1954, Christopher Hawkes proposed that in the absence of texts, archaeologists were constrained by a 'ladder of inference' which governed the probable reliability of their explanations (Hawkes 1954). According to the ladder of inference, some topics were more closely tied to material manifestations, which were more tightly circumscribed by pragmatic considerations. As a result, archaeologists were likely to recover a greater proportion of the evidence necessary for understanding these topics, and their explanations were likely to suffer less from crucial missing data or from variability in the nature of the evidence. Areas

such as religion and belief were less tightly tied to materiality, and thus archaeologists were likely to lack crucial pieces of evidence to support explanation, or they might recover material that could be explained in multiple ways and have no basis to choose between explanations. In contrast, in initial programmatic statements for the processual archaeology of the early 1960s, Lewis Binford explicitly argued that all aspects of culture were open to scientific archaeological analysis if questions were properly framed. Neither symbolism nor ritual was excluded from archaeological investigation.

Important contributions to the archaeology of ritual and symbolism were developed in processual archaeology. Drawing on information theory, symbols could be treated as messages intended to communicate clear meanings (Wobst 1977). Information theory provided a means to support some of the assumptions necessary for archaeologists to treat ancient symbols as if they had a single consistent meaning. If symbols were media to convey messages, then there would have been strong social pressures, and even adaptive advantages, to having shared interpretations of their meaning. The application of communication models to the archaeological study of symbols facilitated the development of an archaeological theory of style, the definition and interpretation of sociopolitical 'status badges,' and the interpretation of differences in material culture as markers of ethnic boundaries and cultural identities.

Robert Drennan (1983), employing processual systems theory, developed an explicit set of expectations for ritual subsystems, which could be linked to specific characteristics of archaeological remains to create predictions for the material correlates of ritual. Following social anthropologist Roy Rappaport, Drennan operationally defined ritual as specific sequences of repeated action directed at intervening in relations between humans and supernatural forces or beings. Among the key features he and others used to attempt to objectively identify remains stemming from ritual were associations between otherwise rare items, and the recovery of such rare items from public spaces. The systems approach assumed a separation between an everyday sphere of activities and a separate sphere, the domain of ritual, detectable by distinctive location and unusual artifacts.

Processual approaches required external bodies of information for the formulation of models of ritual and symbolic systems. Specific ethnographic analogy, the 'direct historic approach,' drew on the study of living societies believed to be descended from the archaeological population. General analogies were made from comparative ethnographic samples such as those contained in the Human Relations Area Files. (These were abstracts of ethnographic samples selected to provide a cross-section of known variation in human activity. They provided a beginning point for statistical generalizations about human behavior, including ritual.) The power of explanation rested on

the strength of arguments linking the analogies to the test case, requiring extremely broad uniformitarian generalization. The level of generalization required made explanations of ritual and symbolism employed extremely vague, and tended to substitute the operations of superorganic entities for individual actions.

1.3 Postprocessual Directions in the Archaeology of Ritual and Symbolism

In a series of edited volumes, Ian Hodder (1982a, 1982b, 1989) and colleagues initiated a range of challenges to the processual analysis of ritual and symbolism. Critiques of the information theory models embedded in processual analyses were central to these analyses. Demonstrations of diversity *within* cultural traditions, based on historical and ethnographic documents, highlighted problems with uniformitarian and normative assumptions shared by processual and preprocessual archaeologies.

While there is variation among scholars participating in the postprocessual critique, they share a fundamental view of the nature of symbolic meaning. Rather than seeing archaeologically recovered objects as vehicles carrying pre-existing meanings, they argue that symbolic meaning was negotiated through the use of cultural forms, including the permanent ones recovered by archaeologists. This view of symbolism requires attention to contextual relations in order to understand how symbolic meaning was negotiated. Even when archaeologists operating under this model express uncertainty about their ability to understand the specific meanings symbols had for past actors, they routinely make arguments about the deployment of symbolism as part of strategies of actors and factions within past societies.

The meaning of symbols and their social effects are seen as mutually constituted. Contrasts within and between contexts are required to argue for a relationship between symbolism and any specific form of meaning under these assumptions. The constitution of symbolic meaning is seen as a constant feature of social life. Rituals provided marked settings in which the meanings of symbols were negotiated, but they were not the only or even the most significant settings in which symbolic meaning developed.

2. Archaeology of Symbolism

Relations of substitution are fundamental to the definition of symbols. Archaeologists commonly use specific objects as signs of categories, for example, the identification of Clovis stone points as markers of a Palaeolithic population in the Americas (see *Ethnic Identity/Ethnicity and Archaeology*). This basic archaeological operation rests on the assumption that the

makers and users of these points would have recognized a commonality among themselves and a dissimilarity from others, albeit on a largely non-discursive level (see Gardin and Peebles 1992). Ethnoarchaeological research has demonstrated that the degree to which the use of common material forms conveys either a conscious or unconscious identification is highly variable (Hodder 1982a).

Some symbolic relations of substitution by past populations are treated as more conscious (see *Pre-historic Art*). The embedding of symbolism in concrete things has been a focus of extensive empirical and theoretical debate (e.g., Robb 1999). For example, some artifacts have been interpreted as 'status badges' created as deliberate signs of rank. Some archaeologists seek to understand the specific properties of materials which lend themselves to being used in symbolic transactions, or to reinforce culturally accepted meanings. Others are concerned with the way that symbolic meanings are interpreted. The latter approach includes a consideration of the experiential contexts within which objects with symbolic significance were used, including rituals.

3. Archaeology of Ritual

The archaeology of ritual has moved away from an early history of identification of specific material objects, settings, and representations as evidence of the presence of a separate ritual or symbolic sphere or system, to the use of contextual associations to identify repeated sequences of action like those that are recognized as ritual in living societies. Certain classes of artifacts have been described as 'ritual' objects: examples include ancient Chinese bronze vessels, North American copper and shell objects, and ceramic figurines in many areas of the world. The identification of objects as ritual objects has been criticized as a facile means to defer our understanding of unusual objects. Recently, Ruth Whitehouse (in Wilkins 1996) has argued that 'ritual objects' can be a real category of material with unique potential for informing about ancient belief and action.

What distinguishes ritual contexts in recent work is not simply their separation from presumed household locations. Historical archaeologists specializing in the study of the African diaspora have recovered assemblages of artifacts arguably used in healing rituals on the household level. In place of defining specific objects and places as inherently associated with ritual, contemporary approaches emphasize the repetition of activity that is central to the definition of ritual. Archaeologists working on the British Neolithic proposed the concept of 'structured deposition' as a way to recognize specific archaeological deposits that were likely to be the result of ritual action (Richards and Thomas 1984).

4. The Material Base for an Archaeology of Ritual and Symbolism

Remarkably, despite theoretical differences, the specific material bases for an archaeology of ritual and symbolism have remained fairly stable and have been constantly under investigation. Offerings or caches, burials, particular spatial locales, and visual images have consistently provided the subject matter for archaeological analyses.

4.1 Caches and Offerings

Caches, hoards, or 'offering deposits' figure as primary evidence of ritual in several regional traditions in archaeology, particularly North America, Central America, the eastern Mediterranean, and Neolithic Europe (e.g. Bradley 1991). Interpretations of caches vary from purely materialistic to ideational. Some analysts stress the economic effect of the withdrawal from circulation of a large quantity of specialized goods at one time. Others propose structural-symbolic interpretations in which materials employed worked to create specific associations between ideas about the supernatural world and the locale of the offering, consecrated by the deposit. Explanations of both kinds have been offered for the same deposits, and indeed, they are not mutually exclusive, since a ritual action can have both pragmatic and symbolic effects.

4.2 Burials

Mortuary analysis, the study of sites and artifacts related to human burial, has occupied a central place in the archaeology of ritual and symbolism (e.g., Chapman et al. 1981). Studies conducted under the normative assumptions of culture history described burial customs, including the laying out of the body according to symbolic beliefs (such as the eastward orientation of the head), and the inclusion of artifacts as 'grave goods.' Among mortuary activities, the removal of skeletal elements and the practice of secondary burial have been seen as unambiguous evidence of ritual practice. The deliberate burial of animals has generally also been regarded as evidence of ritual activity.

Processual archaeology directed attention to the generation of covering laws or assumptions that could link the forms of burials, and particularly, diversity among them, to social differences. Burials were seen as reflecting the social identity of the deceased. They operated as mechanisms to assert claims for territory. Postprocessual archaeologists examine burial assemblages as the material media of ancient rituals, and demonstrate that mortuary remains can mask social relations as easily as they can reflect them (e.g., contributions to Hodder 1982b).

4.3 Temples and 'Sacred Landscapes'

The identification of temple sites through spatial segregation, specific construction, or a combination, characterizes much archaeology addressed at understanding ritual and symbolism. While buildings denominated temples may sometimes be unambiguously identified, usually through written documents, such as ancient Egyptian and Maya inscriptions, in other cases the identification of 'temples' may be challenged. Other architectural settings that are assumed not to have seen use in everyday life, such as the ball courts of Central America, the Caribbean, and the US Southwest, are also viewed as sites of ritual.

Spatial locales that can be viewed as nonordinary by nature are sometimes treated as effectively unproblematic locales for an archaeology of ritual. Caves and natural springs are prominent foci for some definitions of 'sacred geographies.' In contrast, the investigation of entire landscapes, such as those of megalithic Europe, emphasizes the social marking of space through ritual action (see *Settlement and Landscape Archaeology*).

4.4 Visual Images

Artistic representations of artifacts and buildings recovered archaeologically have been a staple in reconstructing ritual. They have been approached in two complementary ways. On one hand, researchers have argued that scenes represented mythologies or beliefs about the supernatural. Some scenes have been identified as models for ritual enactment. For example, the elaborately-dressed individuals buried at the coastal Peruvian Sipan site have been identified with the clearly nonhuman figures depicted in supposed mythological scenes on pots of the Moche kingdom. The implication that such acts as ritual decapitation and mountaintop sacrifice actually took place within ancient Peruvian society has been supported by the recovery of caches of skulls and of frozen bodies on the high Andes.

In other cases, representations have been interpreted as scenes recording ritual practices. For example, Classic Maya *stelae* have been identified as showing members of the ruling class engaged in ritual blood-letting and the sacrificial burning of paper and resin. The availability of written texts in societies like those of the ancient Maya and Mesopotamia has led to ambitious attempts to reconstruct specific ritual practices from an emic perspective.

4.5 Animal Remains

Analysis of faunal assemblages is a relatively recent addition to the repertoire of methods used to reconstruct ancient ritual practices (Anderson and Boyle

1996). Ritual studies begin with the assumption that the use of any materials in unusual proportions within a site may signal the location of activities different from those oriented toward the practical demands of day-to-day life. With faunal remains, an additional criterion can be added: the identification of parts of animals that cannot have been used for subsistence.

5. Future Directions

Contextual analysis has become a fundamental part of archaeological investigation of ritual and symbolism. Through contextual analyses, specific suites of artifacts are identified that can be interpreted as evidence of ritual action. Continued emphasis on combining data to produce multifaceted arguments for ritual, and on placing active social agents at the center of reconstructions of meaning, can be expected.

For example, archaeologists in many regions have converged on the concept of feasting as a means to interpret particular assemblages of artifacts, animal bone, and plant remains. While feasting itself need not be seen as a ritual, it is often described in those terms, and is always interpreted as of symbolic significance. Studies of ritual feasting employ remarkably similar language and concepts. Drinking, the ingestion of drugs, and dancing have all been identified as part of ritual feasts. This is leading to the identification of specific categories of material remains that provide evidence of presumed ritual activities. Attention is also being directed to the experiential effects of ancient ritual practices on the development of forms of subjectivity.

Archaeologists are otherwise less inclined to propose specific meanings for symbols, except in literate traditions where texts continue to serve to validate interpretations. Continuing debate will focus on how to create interpretations of symbols that incorporate multivocality and capture the recursion between practice and meaning.

R. A. Joyce

Robinson, Joan (1903–83)

Joan Robinson was born on October 31, 1903, in Camberley, Surrey, into an upper middle-class English family characterized by vigorous dissent and independence of mind. Her great-grandfather was F. D. Maurice, the Christian Socialist who lost his Chair of Theology at King's College, London, on a point of principle; her father was Major General Sir Frederick Maurice, the victim of the infamous Maurice debate in 1918 and subsequently Principal of what is now Queen Mary College in the University of London. Her mother was Helen Margaret Marsh, the daughter of Frederick Howard Marsh, Professor of Surgery and Master of Downing at Cambridge. Joan Robinson was born into a milieu of controversy. She was educated at St. Paul's Girls' School in London, where she read history, and from 1922 to 1925 at Girton College, Cambridge, where she was Gilchrist Scholar. There she read for the Economies Tripos, searching for rational argument and hoping to understand poverty and its cures. She graduated in 1925 with second-class honours ('a great disappointment'—her words) although it was not until 1948, when women

were given full membership of the university, that she was admitted to the degree. In 1926, she married Austin Robinson, the Cambridge economist, and the couple sailed for India for what was to become the first of many visits. They stayed for over two years and returned to Cambridge in 1929, making it their intellectual and domestic base for the rest of their lives. They had two daughters and five grandchildren. Joan joined the Cambridge Faculty of Economics and Politics as a Faculty Assistant Lecturer in 1934, becoming part of an outstanding group of scholars in Maynard Keynes, A. C. Pigou, Dennis Robertson, Austin Robinson, Maurice Dobb, Richard Kahn, Gerald Shove and Piero Sraffa. She became a University Lecturer in 1937, Reader in 1949, and Professor in 1965. She was elected to a Professorial Fellowship at Newnham and made Honorary Fellow of Girton in 1965, and Honorary Fellow of Newnham in 1971; she was the first woman to be made an Honorary Fellow of King's (in 1979). From 1958 to 1971 she was an FBA. She 'retired' from her Chair in 1971, remaining as active as ever in Cambridge and abroad, until her death in Cambridge on August 3, 1983.

Early in her career Joan Robinson set out her views on methodology for economics, (Robinson 1932a, Harcourt 1990a). Her procedure was to identify and make explicit her assumptions and to develop a 'box of tools' for understanding and exploring the analytical object, to construct a logically sound analysis of the processes concerned: these successive stages she saw as independent of each other. Extending these views, she suggested (1937b, pp. 99–102) that controversy could result from lack of understanding, lack of knowledge, errors of logic, from working from different assumptions but, most commonly in economics, from differences in (political) objectives: the goals of a theory could direct its analysis as well as its policy conclusions. Throughout her life she argued that economics is not neutral, it is always ideologically driven. Nevertheless she believed that it was possible to develop pure analysis independently of dispute.

Her early contributions to economic theory were mainly in the realm of value theory (microeconomics, as it is called now) and *The Economics of Imperfect Competition* (1933), her first book, generously acknowledged her debts to Marshall (via Pigou), Kahn, Austin Robinson, Shove, and Sraffa. It was a controversial and much celebrated success, revealing her great clarity of thought and exceptional analytical powers. It was her interpretation, within a Marshallian context, of several contemporary theoretical issues. In particular, it was a response to the heretical claims about decreasing costs and increasing returns being made in the *Economic Journal*, especially Sraffa (1926), Symposium (see Robertson et al. 1930), and including Robinson (1932b). Robinson replaced an analytical basis in Marshall's free competition with one in imperfect competition, where free competition became a special case. She also moved the focus from Mar-

shall's long period to a short period. Within that context the book also presented new concerns. On the basis of the downward sloping demand curve for each firm, Robinson introduced the marginal revenue curve as an integral analytical construct. She showed how the response of relative factor shares to a change in demand depended on whether you used her partial analysis of the elasticity of substitution or Hicks', aggregate. She reconceived Marshall's 'representative' firm as an 'equilibrium' firm where each such firm faced a less than infinitely elastic demand curve for its product in a monopolistic market. What then became 'the industry' in such a market? And was the simple profit-maximising rationale too reductionist to depict the firm? How was a monopolist to be identified theoretically? Or a duopolist? How indeed was imperfect competition definable?

The Economics of Imperfect Competition provoked; each stage of the theoretical process, even her geometrical method, incited reaction. More controversial than her analysis were its implications for policy. She represented perfect competition theory as demonstrating that the economy left alone would generate the optimal outcomes: it suggested a political philosophy of *laissez faire*. Imperfect competition showed that left alone the economy could become stuck at a position of unemployed capacity and labour and indeed, at that time, this was the case. The debates on the elasticity of substitution further illustrated what the emerging critique of perfect competition theory could mean for the status quo. The issues raised in this book were to fill the journals for decades to come. She herself came to reject its analyses (postwar) as a 'shameless fudge.'

Robinson's interests were not confined to microeconomics. During this time she was a member of a group of economists who met to discuss John Maynard Keynes's *Treatise on Money* (1930) and his emerging new theory. His ideas appealed to her, they represented a break from the orthodox and they were focused on the pressing problem of the persistence of high levels of unemployment. As a member of the Circus, with Meade, Kahn, Austin Robinson, and Sraffa, Robinson contributed to the critical scrutiny of drafts of Keynes's *The General Theory* (1936). A formidable group, but they were persuaded by the dissenting view of the behaviour of investment and of saving in Keynes's new theory of output and employment. Immediately following the book's publication, she wrote to develop its themes and analysis. *Essays in the Theory of Employment* (1937a) and the popular *Introduction to the Theory of Employment* (1937b) were both published in the year following *The General Theory* (and in the same year that her second daughter was born). She sent Keynes drafts of the two books as well as the proofs, and the related correspondence reveals his respect for Robinson in her role as his interpreter. *Introduction* is still one of the best guides to *The General Theory*.

During the interwar years, Michal Kalecki had a major impact on Robinson's thinking. His preemptive version of the theory of effective demand, which interwove imperfect competition with a macro-economic theory of distribution, was based on Karl Marx's schema of reproduction and his analysis of the realisation crisis. She integrated his double-sided relation between investment and profits and his short-period theory of income distribution to develop her theory of employment and output. Kalecki provided a structural base to Robinson's theoretical explorations and extensions of Keynesianism and later of growth. During the war Robinson wrote *An Essay on Marxian Economics* (1942). Her interest was partly attributable to Kalecki's and Sraffa's Marxist-based work, and partly to the structure of society portrayed by, and fundamental to, such classical and Marxist analysis; her continued dissatisfaction with orthodox theory was also reflected in her essay which compared Marxian with mainstream ideas.

Robinson's interpretation of Marx again illustrates her approach to constructing theory. Responses to her book were to her methodology, as well as to her critical remarks about both Marxian and neoclassical economics. She extracted from Marx's writing the circuits of deductive logic with their attendant assumptions and political implications. The methodology of her censorship was not so inclusive as to embrace Marx's theory of history and of the processes of change. Yet it was these elements—the centrality of historical analysis to Marx's method and of class to understanding effective demand—that attracted Robinson to Marx's writings. The pervasive implications of time and history underlay her vision of capitalism and informed all of her subsequent economic research even though she ultimately was to abandon the classical method. Her book was a challenge to her colleagues to read and learn from Marx, if selectively and from a Keynesian perspective. It remains a useful introduction to Marxist economics.

In the early postwar years Robinson became committed to developing a dynamic analysis of capitalism. Inspired by Harrod's (1939, 1948) studies of long-period growth, *The Rate of Interest and Other Essays* (1952) was a collection in preparation for this project, in particular. The generalization of *The General Theory* attempted to extend Keynes into the long period. This essay was an interpretation of Keynes in terms of the Marshallian short period, characterized by uncertainty, incompatible decisions and unrealizable expectations, by a new definition of equilibrium. The elements of Robinson's growth theory were coming together in a non-neoclassical and long-period framework.

Integral with Robinson's exploration of long-period accumulation was an increasing dissatisfaction with the conceptual and logical foundations of neoclassical theory and its method, for which she became most well known, if not best understood. She prefaced her

constructive contributions to dynamic theory with the critique of the neoclassical production function, Robinson (1953–4). This article fired a debate that continued for more than two decades. The implications of these exchanges were for the legitimacy of the very concept of capital and hence of the aggregate production function, fundamental to neoclassical theory. In particular, Robinson targeted its distribution analysis and its corollary, value theory. Ultimately, she criticized its method, that 'the neo-neoclassics still refuse to understand the difference between a comparison of timeless equilibrium positions and the effects to be expected from a change taking place at a particular moment' (1978a, p. xix). That particular moment was characterised by its own inherited structure of decisions, expectations, and uncertainties. She rejected the neoclassical method of long-period equilibrium as a point towards which the actual economy is moving; the implied stationarity of that theory meant that the movement towards it, and the rest point were logical, not historical. Her own account would not be in equilibrium terms but would take into account the actual features of the economy, the existence of uncertainty, and disappointed expectations. Her understanding of capitalism was based on classes and relations of conflict, while the neoclassicals begin with technical factors and harmonious distributive shares. What she wanted to put in the place of neoclassical theory was not a rival complete theory, which she considered would be only another 'box of tricks,' but an approach that started from institutions, history, and the 'rules of the game' (Harcourt 1990b). Robinson's optimism about the power of economic debate was continually frustrated, yet she determinedly defended what seemed to her to be right and just arguments. Her conservative colleagues, she felt, treated new ideas 'like heresies.'

The Accumulation of Capital (1956) continued the 'generalization' within a classical framework. The questions she set out to explore were: what are the conditions for cumulative long-term growth of income and capital (Golden Age) and what is the outcome of this process in terms of growth of gross and net output and the distribution of income between wages and profits, given a certain evolution through time of the labor force and technology? Inspired by Harrod's 'fruitful provocation,' *The Accumulation of Capital* brought together Marx's historicism, Harrod's economic dynamics, and Wicksell's capital theory. True to her methodology, she started out by presenting her most basic model and then devoted the rest of this remarkable book to relaxing the 'most severely simple' assumptions and tracing out the implications. 'The whole argument,' she proposed, 'is set out ... as an analytical construction, with the minimum of controversy' (1956, p. x). In contrast to the mathematical style endemic to American economics, Robinson wrote her entire work of pure theory in literary form. It was a difficult book to assimilate and several years

later she followed it up with a hands-on guide. *Exercises in Economic Analysis* (1960) fills in the gaps, clarifies obscurities, and extends the arguments from *The Accumulation of Capital*. Its object, Robinson stated, was ‘to sort out questions’ (1960, p. xx). It offers readers an opportunity to formulate for themselves the analytical examples she derives in *The Accumulation of Capital*. This book (1960) was immediately followed by *Essays in the Theory of Economic Growth* (1962) which presents a retrospective introduction for the ‘too terse’ earlier (1956) book. Although there was a hint of re-switching in Robinson (1953–4) as well as in *The Accumulation of Capital*, Robinson dismissed the phenomenon at the time and saw it as a distraction from the main methodological point of her critique of neoclassical capital.

Dissatisfied with her quest for a long-period theory of growth, Robinson looked more to Kalecki’s theory of cycles as a depiction of capitalism. She was a pioneer in the development of what was to become post-Keynesian theory, its bases in Sraffa’s interpretation of Ricardo and in Kalecki’s interpretation of the theory of employment. To this she brought ‘a general framework of long- and short-period analysis which will enable us to bring the insights of Marx, Keynes, and Kalecki into coherent form and apply them to the contemporary scene’ (1978b pp. 1, 18). Within this framework, post-Keynesian theory offered a ‘method of analysis which takes account of the difference between the future and the past’ (1978b, p. 12). Here was a broad conceptual structure that brought together Robinson’s major theoretical concerns. From this analysis, post-Keynesian theory is evolving in several, not always compatible, directions, establishing its authority in the body of economic theory.

Robinson was a charismatic teacher; she inspired successive generations of students to develop their own ideas from her methods of analysis and brilliant insights, to think critically and for themselves. She spent many years demonstrating that ‘mainstream teaching has been inculcating defective methodology’; she wanted to provide a logically sound, historically based dynamic approach to first-year economic analysis. *An Introduction to Modern Economics* (1973) with John Eatwell was a response to the ‘fashionable textbooks [of] mainstream’ economics. It presented a history of thought, a classical-cum-Kaleckian/post-Keynesian analysis. It was an ambitious, presumptuous book, at once a critique of neoclassical theory, and a terse introduction to the alternative. Robinson overestimated the intuitive powers of her audience and it proved too difficult for beginners; it remains a challenge for more advanced students.

Throughout her life Robinson pursued an active interest in the Third World, in India and China in particular, and in the Soviet Union. Her initial writing on development was based on the growth models developed in *The Accumulation of Capital*. Kalecki influenced this book. Development, she argued,

should proceed by appropriate land reform and industrialization in both agriculture and manufacture, mindful of the balance of payments constraint and a minimum real wage or its equivalent. Socialist development, she continued, could mobilize savings and enable the state to organize the investment of the surplus, so achieving faster if not more efficient accumulation and growth than under capitalism; socialism, furthermore, led to a more equitable distribution of income (although the standard of living she saw as a political decision). She was less enthusiastic about the Soviet-style socialism of Eastern Europe than she was about China. Her mission to eradicate poverty and to meet basic needs always guided her judgements. She leaves a body of work; some reprinted in her *Collected Economic Papers* as well as Robinson (1979), on development planning and socialism that is relevant and provocative.

Joan Robinson depicted her work as an agenda for discussion as well as formulating the questions. Yet she has left an important legacy in her substantial literary output. She wrote for colleagues, students, and for the general, interested reader. As well as her many books, there is a stream of challenging evaluative essays written through the 50 years of her career. Her writing includes a theoretically rigorous critique of neoclassical economics that as yet goes unanswered; the questions she has raised present a formidable program for further research. She leaves an exacting methodology, a theoretical structure, and significant analytical details of a new, unified system of political economy.

G. C. Harcourt and P. M. Kerr

Robustness in Statistics

Robust statistics is concerned with the description and the correction of problems caused by a discrepancy between attributes of the data being analyzed and the implicit or explicit assumptions used in modeling the data. But, of course, robustness is a word used frequently and in diverse situations. In statistics, it also conveys various meanings, always involving the stability of the method under study. The arithmetic mean, for example, is an optimal estimator of the expectation if the data follow exactly a normal

distribution. Tiny deviations of the actual distribution of the data from the normal ideal, however, destroy the optimality and the arithmetic mean can be an arbitrarily bad estimator even though the data has a very nearly normal distribution. The robustness of estimators may also be defined without reference to a model. The arithmetic mean of the three observations (14, 13.7, 26.3), for example, is equal to 18.0 and the lack of stability is expressed through the large effect of the single observation 26.3 on the estimate.

Implicit and explicit assumptions in statistics are of various types. In a generalized linear model, for example, they include the link function, which determines the scale on which the relationship between the response and the explanatory variables is of the form of a linear combination of terms. Another assumption concerns the cumulative distribution for the response, which determines certain aspects of the inherent randomness of the data, such as the form of the relationship between the standard deviation and the expectation of the response variable or the rate of growth of the extreme $(1 - \alpha)$ quantile of the response variable as α tends to zero. The best-known phenomenon observed in the data concerns the so-called *outliers*. This is a term used in describing various incidents in a data base. It may refer to *gross* errors in observations due to faulty transcription, mistakes in the manipulation of a measurement instrument, errors in the preparation of a particular experiment, confusion as to which experiment should have been performed, or some other such mistake. The frequency of such gross errors is much higher than one would expect at first thought. We will also use the term *wild value* for a distinct outlier. The term ‘outlier’ may also refer to the effect, that a sizable proportion of the data seems to behave differently from the rest. In a linear regression, for example, it is sometimes observed that any one regression surface fits only part of the data. This might be due to an overly simple model for the surface, or to the fact that the data is a mixture of cases that cannot be separated into more homogeneous pieces based on the available variables.

Of course, the data can be used to check assumptions and it is certainly good statistical practice to do so. To check details of a model, however, requires huge amounts of data and it is misleading to suggest that diagnostic checking of model assumptions can solve the robustness problem. Good practice in statistics requires the use of methods that do not suffer the drawbacks of the arithmetic mean of loosing performance under tiny violations of the idealistic assumptions. This is especially true in routine and less thoroughly scrutinized applications of statistical methodology. Robust methods retain very good performance, while being less sensitive to assumptions.

Robustness seems similar to nonparametric or, more precisely, distribution-free statistics. This is a superficial and even wrong view. Converting data to ranks, for example, in order to liberate the statistical

analysis from distributional assumptions, does not give particularly good protection from the deleterious effects of atypical observations.

1. Indicators of Robustness

1.1 Sensitivity Functions

Let $T(y_1, \dots, y_n)$ be an estimator of a real parameter, calculated with n observations, $(y_1, \dots, y_n)$. The sensitivity function is a simple idea leading to a better understanding of the estimator. The question being asked is: 'How would the estimator have come out, if the data had not been exactly the ones I observed?' To answer it, one considers the *sensitivity function*

$$SC(y) = (n+1)(T(y, y_1, \dots, y_n) - T(y_1, \dots, y_n)) \quad (1)$$

that is the change in the estimate induced by an additional observation at an arbitrary value y . The multiplier $(n+1)$ in this formula provides a natural scaling of the size of the change.

Examples. For the arithmetic mean $T(y_1, \dots, y_n) = \bar{y} = (y_1 + \dots + y_n)/n$ one finds

$$SC(y) = (n+1) \left(\frac{y + y_1 + \dots + y_n}{n+1} - \frac{y_1 + \dots + y_n}{n} \right) = y - \bar{y}. \quad (2)$$

Even in this easy case, the sensitivity function is of interest. It shows that the arithmetic mean is sensitive to the distance of the additional observation y from the average of the remaining data. The larger this distance, the larger the change.

For the trimmed mean, $T(y_1, \dots, y_5) = (y_{(2)} + \dots + y_{(4)})/3$, obtained by deleting the largest and the smallest observation, the sensitivity depends on the position of the additional observations y . If y is between $y_{(1)}$ and $y_{(5)}$, it will not be trimmed from the sample and $SC(y) = 6((y_{(2)} + y_{(3)} + y_{(4)} + y)/4 - (y_{(2)} + y_{(3)} + y_{(4)})/3)$. If on the other hand, y is larger than $y_{(5)}$, then y will be trimmed and the sensitivity becomes $SC(y) = 6((y_{(2)} + y_{(3)} + y_{(4)} + y_{(5)})/4 - (y_{(2)} + y_{(3)} + y_{(4)})/3)$, which is independent of y . The same reasoning applies in the case where y is smaller than $y_{(1)}$.

For the least-squares estimate of a regression coefficient, the algebra is a bit more difficult, partly because the data is of a more complex structure. Suppose we observe the couples of explanatory variables and responses, $(x_1, y_1), \dots, (x_n, y_n)$, and that we add an observation at (u, v) . The least-squares estimate of the regression coefficients is $T(y_1, \dots, y_n) = (X^T X)^{-1}$

$X^T y$, where X is the design matrix. After some algebra, one has

$$SC(u, v) = (v - u^T T) \frac{(n+1)(X^T X)^{-1} u}{1 + u^T (X^T X)^{-1} u}. \quad (3)$$

Again, this is a revealing formula, because it makes it clear that the estimated regression coefficients are sensitive to the size of the residual, the first factor, but also to the position of u among the explanatory variables as expressed by the second factor.

In practice, it is not really necessary to do the computations illustrated in these examples. The sensitivity function can easily be computed numerically for any given estimator and underlying data set and one can thus construct the plot of $SC(y)$ against y , which in most cases will serve as a good basis for judging the robustness qualities of the estimator. From such a plot one can deduce several indicators, the simplest one being the *maximal sensitivity*

$$g^* = \sup_y |SC(y)| \quad (4)$$

where $|SC|$ denotes the absolute value of SC . In the above examples, the maximal sensitivity is equal to ∞ for the mean and the least-squares estimate of the regression coefficient—the first and the third example. It is finite for the trimmed mean. An estimator with infinite maximal sensitivity is necessarily *non-resistant* in the sense that a single wild observation that behaves differently from the rest can destroy the estimate and lead to rather arbitrary conclusions.

1.2 Influence Functions

The sensitivity function has a more formal counterpart in the *influence function*, which is defined as a kind of derivative of a statistical functional. In many cases it is simply the limit as the sample size n tends to infinity of the sensitivity function computed for a sample generated from a fixed model.

Examples. Let $y_1, \dots, y_n$ be a sample from some distribution F with expectation μ_F . As n increases, the sensitivity function of the arithmetic mean converges to the influence function of the expectation, which is $IF_F(y) = y - \mu_F$. The influence function of the trimmed mean obtained by trimming a fraction of α at each end is

$$IF_F(y) = \begin{cases} (y - \mu_F)/(1 - 2\alpha), & \text{for } y \leq F^{-1}(1 - \alpha); \\ \text{sign}(y - \mu_F)F^{-1}(1 - \alpha)/(1 - 2\alpha), & \text{otherwise} \end{cases} \quad (5)$$

where F is any distribution symmetric around μ_F . In the regression case, one can choose an arbitrary error distribution F with finite variance and an arbitrary true regression coefficient θ . The influence function is

$$\text{IF}_F(\mathbf{u}, v) = (v - \mathbf{u}^T \theta) (\text{ave}(\mathbf{x}\mathbf{x}^T))^{-1} \mathbf{u} \quad (6)$$

where the matrix $\text{ave}(\mathbf{x}\mathbf{x}^T)$ denotes the average design matrix.

The influence function is very similar to the sensitivity function and can thus be interpreted similarly. In particular, the *gross error sensitivity* is

$$\gamma_F^* = \sup_y |\text{IF}_F(y)|. \quad (7)$$

The squared influence function is directly linked to the asymptotic variance of an estimator. Let $Y_1, \dots, Y_n$ be independent and identically distributed with distribution F_θ for some real parameter θ . One can show that most estimators of θ satisfy the following approximate relationship:

$$T(Y_1, \dots, Y_n) \approx \theta + \text{ave}(\text{IF}_{F_\theta}(Y_i)). \quad (8)$$

If this approximation is sufficiently precise, it implies that the asymptotic variance of the estimate T is

$$\text{Var}_{\text{asy}}(T) = E_{F_\theta}((\text{IF}_{F_\theta}(Y))^2) = \int (\text{IF}_{F_\theta}(t))^2 F_\theta(dt). \quad (9)$$

In this case, one can also apply the central limit theorem to conclude that

$$P(T \leq t) \approx \Phi \left(\frac{\sqrt{n}(t - \theta)}{\sqrt{\text{Var}_{\text{asy}}(T)}} \right) \quad (10)$$

where Φ denotes the normal distribution function with density $\varphi(t) = \exp(-t^2/2)/\sqrt{2\pi}$. This in turn shows that

$$[T \pm 1.96 \sqrt{\text{Var}_{\text{asy}}(T)}/\sqrt{n}] \quad (11)$$

is an approximated 95 percent confidence interval for θ .

1.3 Breakdown and High Resistance

A limitation of the influence function is its local nature. It is based on the change of the value of the estimator from one sample to another one that differs by adding a single small ‘contamination.’ The *breakdown point* is the simplest global measure of ro-

business. It is the largest percentage of wild values in a data set that an estimator can tolerate without giving wild estimates. This notion is inspired by the trimmed means, computed as the mean of a sample after deleting 100 α percent of the largest and of the smallest data points. This estimator has a breakdown point of 100 α percent, since any contamination by wild data below this fraction is being trimmed. A special case of the trimmed means is the median, which for an odd-sized sample ($n = 2k + 1$) has a breakdown point of $k/n \approx 50$ percent. This is so, because the median is computed as the $(k + 1)$ st value in the sample and anything less than k wild values will not lead to a wild estimate. More generally, global indicators describe the properties of an estimator under contamination of a sizeable portion of the data.

The distributions used in modeling data sets containing outliers are *heavy-tailed*. One can, for example, model a sample containing a sizeable portion of outliers with a *contaminated distribution*. A sample generated from $(1 - \varepsilon)F + \varepsilon H$ is a mixture of one part, $(1 - \varepsilon)$, of a ‘good’ distribution F and another part, ε , of a ‘bad’ distribution G . The *contaminated normal distribution*, $(1 - \varepsilon)\Phi(y) + \varepsilon\Phi(y/\sigma)$, describes observations that can either result from a standard normal distribution, or from a normal distribution having a larger variance $\sigma > 1$. As ε grows from 0 to 50 percent, a larger and larger fraction of the data is expected to exhibit a distinct behavior. A global robustness indicator for estimators is based on behavior under positive fractions ε , whereas local properties, such as the influence function, merely consider limits as ε tends to zero.

An estimator with a breakdown point of 50 percent is called *highly resistant*. Such estimators can be very revealing when applied to data containing a large proportion of outliers, because they lead to a clear separation of the ‘good’ and the ‘bad’ data. The median is an example of a highly resistant location estimator. The residuals from the arithmetic mean of the three observations (14.0, 13.7, 26.3) are equal to $(14.0 - 18.0 = -4.0, -4.3, 8.3)$, whereas the residuals from the median are $(14.0 - 14.0 = 0.0 - 0.3, 12.3)$. The highly resistant median produces residuals that make it immediately evident that the third observation is a wild value. The ability of estimators to reveal hidden outliers is explained by the fact that they have bounded sensitivity with regard to single observations, but also, and more importantly, that even a largish fraction of outliers does not exert an undue influence on the estimate. The median absolute deviation (MAD) is a highly resistant scale estimator. It is defined as

$$\text{MAD}(y_1, \dots, y_n) = \text{median}(|y_1 - m|, \dots, |y_n - m|) \quad (12)$$

where m denotes the median, $\text{median}(y_1, \dots, y_n)$.

2. Robust Estimators

2.1 Least-squares, maximum likelihood, and M-estimators

Least-squares estimators,

$$T(y_1, \dots, y_n) = \arg \min_{\theta} \sum_{i=1}^n (y_i - \mu_i(\theta))^2 \quad (13)$$

have an unbounded influence function and a breakdown point of 0 percent. Maximum likelihood estimators (m.l.e.) for independent data,

$$\begin{aligned} T(y_1, \dots, y_n) &= \arg \max_{\theta} \sum_{i=1}^n \log(f_i(y_i, \theta)) \\ &= \text{solution of } \left(\sum_{i=1}^n \partial \log(f_i(y_i, \theta)) / \partial \theta = \mathbf{0} \right) \end{aligned} \quad (14)$$

can be robust, depending on the properties of the densities f_i . Generalizing either of these two concepts, one obtains *M-estimators*, defined by

$$T(y_1, \dots, y_n) = \arg \min_{\theta} \sum_{i=1}^n \rho_i(y_i, \theta) \quad (15)$$

where the choice of ρ_i is in principle quite free. The corresponding estimating equation is of the form

$$\sum_{i=1}^n \psi_i(y_i, T(y_1, \dots, y_n)) = \mathbf{0} \quad (16)$$

where $\psi_i(y, \theta) = \partial \rho_i(y_i, \theta) / \partial \theta$.

Example. For illustration, we consider here briefly the linear regression case, where $\mu_i(\theta) = \mathbf{x}_i^T \theta$, $f_i(y_i, \theta) = f(y_i - \mathbf{x}_i^T \theta)$, $\rho_i(y_i, \theta) = \rho(y_i - \mathbf{x}_i^T \theta)$, and $\psi_i(y_i, \theta) = (\psi(y_i - \mathbf{x}_i^T \theta) \mathbf{x}_i)$ with $\psi(t) = \rho'(t)$. The M-estimator with $\rho(t) = t^2/2$ (rho-function) and $\psi(t) = t$ (psi-function) is nothing else but the least-squares estimator, which is the same as the m.l.e. for Gaussian errors. Any m.l.e. can be thought of as an M-estimator with $-\rho(t) = \log(f(t))$, but thinking in terms of M-estimators is an advantage and an important conceptual step since it frees us from any artificial constraints. The influence function of the M-estimator at the error distribution F and the true regression parameter θ is

$$\text{IF}_F(\mathbf{u}, v) = \frac{\psi(v - \mathbf{u}^T \theta)}{\int_{-\infty}^{\infty} \psi'(t) F(dt)} (\text{ave}(\mathbf{x} \mathbf{x}^T))^{-1} \mathbf{u}. \quad (17)$$

The first factor in this influence function involves the residual at the contaminating point $(\mathbf{u}, v)$. It is

bounded whenever $\psi = \rho'$ is bounded. The deficiencies in the stability of the least-squares estimator are therefore best explained by the fact that the derivative $\rho'(t) = \psi(t) = t$ is unbounded.

M-estimators are defined by a rho-function and an associated psi-function. As shown above, boundedness of the psi-function is a necessary condition to achieve robustness. Careful tuning of the shape of the psi-function permits both robustness and efficiency. It is well-known that the least-squares estimator, which has psi-function $\psi(t) = t$, is optimally efficient when the error distribution is exactly Gaussian. To preserve this Gaussian efficiency as much as possible, the linearity of the psi-function in a neighborhood of the origin $t = 0$ should remain unaltered. The *Huber estimator* is based on

$$\begin{aligned} \psi_H(t) &= \min(1, \max(-1, t)) \\ &= \begin{cases} -1, & \text{if } t \leq -1; \\ t, & \text{if } -1 < t \leq 1 \\ 1, & \text{if } t > 1. \end{cases} \end{aligned} \quad (18)$$

The reader should draw this function to note that it does indeed preserve the linearity near the origin, while at the same time enforcing a bound. In this definition, the interval $[-1, 1]$ plays a special and undeserved role. It goes without saying that in any practical use of the estimator this interval must be adapted to the data.

Example. The Huber regression estimator is defined as the solution to the estimating equation

$$\sum_{i=1}^n \psi_H \left(\frac{y_i - \mathbf{x}_i^T \theta}{k \times S} \right) \mathbf{x}_i = \mathbf{0} \quad (19)$$

where $S = S(r_1, \dots, r_n)$ is a scale estimate based on residuals and $k > 0$ is a further tuning constant. Consider S as known and computed before solving the estimating equation (19). Dividing the argument of the psi-function by a multiple of a residual scale achieves the adaptation we were looking for. It is quite evident that the tuning constant k introduces a trade-off between robustness and Gaussian efficiency. For sufficiently large values of k the estimator is equal to the least-squares estimator because all scaled residuals $(y_i - \mathbf{x}_i^T \theta) / (k \times S)$ will lie in the interval $[-1, 1]$ and thus in the linear part of Huber's psi-function. For small values of k , the Huber estimator loses Gaussian efficiency but gains in robustness. In the limit, as $k \rightarrow 0$, the scaled residuals are either exactly zero, smaller than -1 , or larger than 1 . In this case, the function ψ_H returns as values either 0 , -1 , or 1 and the above estimating equation turns into

$$\sum_{i=1}^n \text{sign}(y_i - \mathbf{x}_i^T \theta) \mathbf{x}_i = \mathbf{0} \quad (20)$$

which corresponds to the so-called L_1 -estimator defined by $\psi(t) = \text{sign}(t)$ and $\rho(t) = |t|$ = absolute value of t . A good compromise choice for the denominator $k \times S$ is $1.3 \times \text{MAD}$ (residuals).

2.2 Theoretical Justification of Huber's Estimator

A concise discussion of many of the topics discussed in this entry can be found in the two books by Huber (1981, 1996). Huber's location estimators T_k in the case of known scale ($S = 1$) are solutions of

$$\sum_{i=1}^n \psi_H \left(\frac{y_i - T_k(y_1, \dots, y_n)}{k} \right) = \sum_{i=1}^n \psi_k(y_i - T_k(y_1, \dots, y_n))/k = 0 \quad (21)$$

where

$$\begin{aligned} \psi_k(t) &= \min(k, \max(-k, t)) \\ &= \begin{cases} -k, & \text{if } t \leq -k; \\ t, & \text{if } -k < t \leq k \\ k, & \text{if } t > k. \end{cases} \end{aligned} \quad (22)$$

The corresponding rho-function is

$$\rho_k(t) = \begin{cases} -k(t + k/2), & \text{if } t \leq -k; \\ t^2/2, & \text{if } -k < t \leq k \\ k(t - k/2), & \text{if } t > k, \end{cases} \quad (23)$$

that is quadratic in the middle and linear in the tails. These M-estimators are m.l.e.s in the sense that $\exp(-\rho_k(t))$ can be standardized to become a density, $f_k(t)$. From the form of $\rho_k(t)$ it follows that $f_k(t)$ is like a Gaussian in the center and has tails that decrease exponentially, i.e.,

$$f_k(t) = \begin{cases} (1 - \varepsilon_k) \exp(-t^2/2)/\sqrt{2\pi}, & \text{if } -k \leq t \leq k \\ (1 - \varepsilon_k) \exp(k^2/2 - k|t|)/\sqrt{2\pi}, & \text{if } |t| > k \end{cases} \quad (24)$$

where $0 \leq \varepsilon_k \leq 1$ decreases as k increases. These distributions were discovered by Huber and have been discussed in his seminal paper (Huber 1964). The above formula shows that $f_k(t) = (1 - \varepsilon_k)\phi(t) + \varepsilon_k h_k(t)$ is a *contaminated density* with contamination fraction ε_k . Huber showed that f_k is in some mathematical sense

the worst among all contaminated densities with a contaminating fraction of ε_k . As a consequence, the corresponding Huber estimator T_k is the estimator that best protects against a contamination of 100 ε_k percent of the data. The sets of possible error distributions considered in Huber's paper contain a positive fraction $\varepsilon_k > 0$ of an unspecified 'bad' density. The Huber estimator is therefore the best one in a global sense. Even if a sizeable portion of the data are not of any real use, this estimator will perform as well as possible under the circumstances. All of this, however, is only true for the simplest case of a location parameter with known scale. In more general regression models Huber's result no longer holds.

Indicators of robustness such as the breakdown point and the gross error sensitivity lead rather naturally to optimality problems. One is interested, for example, in finding an estimator that satisfies the two conditions of consistency and bounded gross error sensitivity and which, given these conditions, is most precise. This problem is of a local nature, because we do not consider sizeable fractions of outliers, but rather limits for very small fractions. The problem is again solved by the Huber estimators, which shows—not very surprisingly—that a globally best estimator is also locally best. The estimators T_k form a family of least variable estimators with gross error sensitivities that increase as k increases. In other words, they provide a bridge between the median ($k = 0$) and the mean ($k = \infty$) and between a minimal value of the gross error sensitivity and an infinite gross error sensitivity. Considering only local properties defined by the influence function has the advantage of being more easily generalized. Thus, it is possible to solve a variety of problems of this type. The book by Hampel et al. (1986) provides a detailed discussion of related results.

2.3 Redescending M-estimators

The form of the Huber estimator comes as a surprise because it never entirely rejects gross errors among the observations. In order to completely reject such outliers, the psi-function $\psi(t)$ would have to be equal to zero for sufficiently large $|t|$. The *biweight estimator* proposed by Tukey is a convenient example. It is based on

$$\psi_T(t) = \begin{cases} t(1 - t^2)^2, & \text{if } -1 \leq t \leq 1 \\ 0, & \text{if } |t| > 1. \end{cases} \quad (25)$$

Such an estimator is called *redescending*, because the psi-function remains roughly linear near the origin, reaches a bound, and subsequently redescends towards zero. The reader is invited to draw Tukey's biweight

psi-function in order to appreciate these qualities. The biweight regression estimator solves the same estimating equation (19) as Huber's estimator, except that we replace ψ_H by ψ_T . This small change has important repercussions. Because ψ_T is not an increasing function, the estimating equation of the biweight estimator may have multiple solutions. The estimate is therefore not well defined. However, among all the solutions of the estimating equations, an appropriate one can usually be picked out by looking at the resulting residuals. Also, when multiple solutions do exist, several of them may be of interest. An appropriate choice for the denominator $k \times S$ when using the biweight is $7 \times \text{MAD}$ (residuals). The rho-function of the biweight estimator,

$$\rho_T(t) = \begin{cases} (1 - (1 - t^2)^3)/6, & \text{if } -1 \leq t \leq 1; \\ 1/6, & \text{if } |t| > 1 \end{cases} \quad (26)$$

is shaped like an vase with a flat rim and the solutions of the estimating equation are local minima of the criterion function

$$\text{criterion}(\theta) = \sum_{i=1}^n \rho_T \left(\frac{y_i - \mathbf{x}_i^T \theta}{k \times S} \right). \quad (27)$$

Redescending M-estimators such as the biweight are of interest in the quest for highly resistant regression estimators. Inspection of the influence function (17) of the regression M-estimator reveals a weakness, namely the unboundedness of the second factor. In cases where one observation is far from the other observations in the sense that $\mathbf{u}$ is distant from the other observations taken at $\mathbf{x}_p$, the influence of this distant observation on the estimated regression parameter will be considerable. Redescending estimators for which the first factor in the influence function can be equal to zero correct this problem. Whenever the data give support to several regression equations, the redescending M-estimator can be of great value in pointing out the different solutions, each one as a separate local minimum of the criterion.

Rousseeuw's *least-median-of-squares* (LMS) estimator is another highly resistant regression estimator. It is defined by the criterion

$$\text{criterion}(\theta) = \text{median}\{(y_1 - \mathbf{x}_1^T \theta)^2, \dots, (y_n - \mathbf{x}_n^T \theta)^2\}. \quad (28)$$

The LMS is a useful, often revealing, estimate. It is, however, quite unstable, not with regard to outliers, but with regard to other features of the data.

2.4 Finite Samples

A robust data analysis must be valid and efficient beyond a narrow set of circumstances. The classical

regression estimator, for example, is chosen to be the best possible for normally distributed observations

$$y_i = \mathbf{x}_i^T \theta + \varepsilon_i, \quad \varepsilon_i \sim \text{normal}(0, \sigma^2). \quad (29)$$

Robustness demands joint optimality for a broader set of error distributions. One way in which this can be achieved, is by choosing a finite number of challenges, in the simplest case a couple such as {normal, Student's t_2 }, the idea being that the estimator would have to perform well, whether the errors were generated by one or the other of the distributions. For such a set of challenges, the performance of an estimator is determined by a set of efficiencies, one for each challenge. Typically, an estimator that is highly efficient for one of the challenges will have a low efficiency for all the others. In the example of a couple of challenges including the normal distribution and the heavy-tailed Student's t_2 distribution, the least-squares estimator, for example, has optimal efficiency for the Gaussian but is inefficient for the t_2 . Robust estimators on the other hand must have a high efficiency for all challenges. How to compute estimators that maximize jointly the whole set of efficiencies is discussed in Morgenthaler and Tukey (1991).

2.5 Iteratively Re-weighted Least-squares

The computation of the least-squares estimator is straightforward because the estimating equation is linear. A program for computing the weighted least-squares solution is all that is needed to find the values of M-estimators. To illustrate the idea, we consider the solution of (21). Rewriting the estimating equation as

$$\sum_{i=1}^n \left[\frac{\psi_k(y_i - T_k(y_1, \dots, y_n))}{(y_i - T_k(y_1, \dots, y_n))} (y_i - T_k(y_1, \dots, y_n)) \right] = 0 \quad (30)$$

an algorithm immediately suggests itself. We could start with a reasonable guess T_k^0 for the value of T_k , such as the median of the observations. Next, we compute weights

$$w_i^0 = \frac{\psi_k(y_i - T_k^0)}{y_i - T_k^0} \quad (31)$$

and then solve the estimating equation, $\sum_{i=1}^n w_i^0 (y_i - T_k(y_1, \dots, y_n)) = 0$. From this, we obtain the next guess for T_k , i.e.,

$$T_k^1 = \sum_{i=1}^n w_i^0 y_i / \sum_{i=1}^n w_i^0. \quad (32)$$

With this new value for T_k we are back at the start of the loop, ready to recompute the weights, and then

the next value for T_k . Repeating the loop a fixed number of times or until convergence leads to practical values for M-estimates.

3. Robust Inference

The sampling distributions of robust estimators can often be approximated sufficiently well by their asymptotic normal distributions. For the regression M-estimator the following formula gives an estimated variance matrix of the estimated regression coefficients

$$\frac{\frac{1}{n} \sum_{i=1}^n (kS)^2 \left(\psi \left(\frac{r_i}{kS} \right) \right)^2}{\left(\frac{1}{n} \sum_{i=1}^n \psi' \left(\frac{r_i}{kS} \right) \right)^2} \quad (33)$$

where $r_1, \dots, r_n$ are the residuals. Using the approximate normality of the estimate, this equation allows one to compute robust confidence intervals for individual parameters. The robustness in the context of confidence intervals means that the coverage of the parameter is equal to the nominal coverage rate even under deviations from the model. Furthermore, the interval should not achieve this feat by being overly long.

Distribution-free tests are very resistant in one respect. Their size, that is the probability of falsely rejecting the null hypothesis, is stable. The power, however, depends, of course, on the distribution of the observations and need not be stable under changes to this distribution. Robust tests must have both, stable sizes and good power under a variety of circumstances. This point illustrates once more the fact that robustness and distribution-freeness are two quite distinct aspects of statistical inference.

S. Morgenthaler

Rogers, Carl Ransom (1902–87)

Carl R. Rogers was arguably America's most influential psychotherapist and one of its most prominent psychologists. His therapeutic approach, known most often as 'client-centered therapy,' was validated through voluminous scientific research and taught widely, profoundly affecting the fields of counseling and psychotherapy throughout the world and permeating many other helping professions. A leader in the humanistic psychology movement of the later twentieth century, Rogers' writings and personal example influenced individuals personally and professionally in many continents.

1. Education and Influences

Rogers was born on January 2, 1902 in suburban Oak Park, Illinois, where he spent his childhood with four brothers, a sister, and conservative, Protestant

parents. Spending teenage years on the family farm in Glen Ellen, Illinois, he developed a love of nature and serious working knowledge of scientific method, conducting agricultural experiments on a plot he and his brothers managed. He majored in agriculture at the University of Wisconsin, Madison, but switched to history after experiencing the call to religious work. Motivated by the 'social gospel' as much as religious conviction, he eschewed his parents' dogmatism and attended liberal Union Theological Seminary in New York City, also taking courses at adjoining Teachers College, Columbia University. There, religious doubt combined with fascination with psychology. Influenced by instructors Leta Stetter Hollingworth, Goodwin Watson, William Heard Kilpatrick, the leading proponent of John Dewey's progressive education philosophy, and others, Rogers transferred to Teachers College to pursue a doctorate in clinical psychology.

At Columbia, exposure to the testing and measurement movement of E. L. Thorndike was balanced by his experiences in clinical work and fellowship at the Institute for Child Guidance, where he encountered Freudian thought, a lecture by Alfred Adler, Rorschach testing, and other psychoanalytic and psychiatric approaches. Seeking to integrate these influences, Rogers came to appreciate the importance of attending to and honoring clients' inner experience while also striving to assess objectively any changes which resulted from treatment. His doctoral dissertation, *Measuring Personality Adjustment in Children Nine to Thirteen Years of Age* (1931), combined both subjective and objective measures. Rogers' 'Personality Adjustment Inventory' was subsequently published by YMCA Press and used for over 50 years.

His next major learning experience was the 12 years working with thousands of troubled children and adults in Rochester, New York, where he gradually developed his nondirective approach to counseling and psychotherapy. During this period, he was influenced by students of Otto Rank, especially Jessie Taft whose 'relationship therapy' shifted emphasis from past content to a focus on the patient's self-insight and self-acceptance within the therapeutic relationship.

2. Positions Held

In Rochester, Rogers worked at the Society for Prevention of Cruelty to Children (1928–38), where he directed the Child Study Department, then became director of the Rochester Guidance Center (1939–40). Based on his practical experience and first book, *Clinical Treatment of the Problem Child* (1939), he was offered a full Professorship at Ohio State University, where he taught from 1940 to 1944. After an interim year training United Service Organization (USO) workers to counsel returned servicemen, he moved to

the University of Chicago, where he developed and ran the internationally renowned Counseling Center and taught in the Psychology Department from 1945 to 1957. He held joint appointments in the Departments of Psychology and Psychiatry at the University of Wisconsin from 1957 to 1963 before leaving academic life and moving to the Western Behavioral Sciences Institute in La Jolla, California (1963–72). He and others then formed their own organization, Center for Studies of the Person, where Rogers remained until his death in 1987.

3. Client-centered Therapy

Rogers' approach to counseling and psychotherapy was based on a core hypothesis about human growth and personality change, which he summarized in 1950:

Client-centered therapy operates primarily upon one central and basic hypothesis which has undergone relatively little change with the years. This hypothesis is that the client has within himself the capacity, latent if not evident, to understand those aspects of his life and of himself which are causing him pain, and the capacity and the tendency to reorganize himself and his relationship to life in the direction of self-actualization and maturity in such a way as to bring a greater degree of internal comfort. The function of the therapist is to create such a psychological atmosphere as will permit this capacity and this strength to become effective rather than latent or potential.

While other therapies might profess similar belief, Rogers' method of creating the therapeutic psychological atmosphere was radically different from other approaches commonly employed. Avoiding questions, interpretation, or other directive techniques, Rogers' initial 'nondirective method' relied exclusively on careful listening and skillful 'reflection of feelings,' leading to client insight and positive action. Although he always remained primarily nondirective in his practice, Rogers soon recognized that the counselor's *attitudes* were more important than his particular techniques. Still later he clarified that it was the therapeutic *relationship*, which the attitudes helped create, that was growth producing. Rogers called this therapeutic relationship 'client-centered' and described three key 'conditions' in the relationship that bring about positive change in clients.

First is to accept the client as he or she is, as a person of inherent worth possessing both positive and negative feelings and impulses. Rogers called this acceptance and prizing of the person 'unconditional positive regard.' Second is 'the therapist's willingness and sensitive ability to understand the client's thoughts, feelings, and struggles from the client's point of view ... to adopt their frame of reference.' Third is to be 'genuine, or whole, or congruent in the relationship ... It is only as [the therapist] is, in that re-

lationship, a unified person, with his experienced feeling, his awareness of his feelings, and his expression of those feelings all congruent or similar, that he is most able to facilitate therapy.'

When a counselor communicates this unconditional positive regard, empathic understanding, and congruence so that the client perceives them, the 'necessary and sufficient conditions for therapeutic personality change' are present. Rogers argued and demonstrated that clients have within themselves the ability and tendency to understand their needs and problems, to gain insight, to reorganize their personality, and to take constructive action. What clients need is not the judgment, interpretation, advice, or direction of experts, but supportive counselors and therapists to help them rediscover and trust their 'inner experiencing' (a concept borrowed from Gendlin), achieve their own insights, and set their own direction.

4. Recording Therapy

Rogers was able to demonstrate these propositions cogently, in part because he was the first person to record and publish complete cases of psychotherapy. This was a remarkable achievement before the invention of tape recorders, requiring a microphone in the counseling room connected to alternating phonograph machines in an adjoining room, which cut grooves in blank record disks that had to be changed every three minutes. With graduate student Bernard Covner, Rogers and his team recorded thousands of disks, involving scores of clients. These recordings were pivotal in the clinical training of psychotherapists which, in the 1940s, Rogers may have been the first to offer in an American university setting.

Beyond audio recording of therapy sessions, Rogers was among the first to make cinematic recordings of counseling and psychotherapy. The American Academy of Psychotherapists became a leading distributor of training tapes and movies, with Rogers the most frequent therapist portrayed. A still widely distributed set of training films showed Rogers, gestalt therapist Frederick Perls, and rationale-emotive therapist Albert Ellis each demonstrating his method with the same client.

5. Scientific Research and Theory

Recording actual therapy sessions also provided the data with which Rogers and his colleagues conducted more scientific research on one therapeutic approach than had ever been undertaken before. Rogers devised and used numerous instruments for measuring the variables of client-centered therapy and its outcomes: therapist acceptance, empathy and congruence; client expression of feelings, insight, self-concept, self-acceptance, self-ideal, level of experiencing; clients'

positive actions, social adjustment, and numerous other variables. In 1959 the American Psychological Association awarded Rogers its first 'Distinguished Scientific Contribution Award' for developing an original method to objectify the description and analysis of the psychotherapeutic process, for formulating a testable theory of psychotherapy and its effects on personality and behavior, and for extensive systematic research to exhibit the value of the method and explore and test the implications of the theory.

As the award citation suggests, Rogers was interested in psychological *theory* and in the effects of therapy on *personality* as well as behavior. Building upon the Gestalt and phenomenological movements in psychology, and work of his students Victor Raimy and Arthur Combs, he developed a 'self-theory' of personality which is still included in many textbooks (Rogers 1959). The theory describes how an individual's concept of self emerges, how the process of socialization causes individuals to distrust their feelings and sense of self, how experiences which are inconsistent with the concept of self become denied and distorted causing personal distress and psychological problems, and how the therapeutic relationship can help the individual restructure the sense of self, allowing previously denied and distorted experience into awareness, leading to reduction in stress and openness to new experiencing.

6. Impact on the Professions

More than anyone, Rogers helped spread professional counseling and psychotherapy beyond psychiatry and psychoanalysis to other helping professions. While not the first to use the term 'client' for the recipient of therapy, he popularized it, emphasizing that 'a person seeking help was not treated as a dependent patient but as a responsible client,' and that those in psychological distress were not necessarily 'sick,' requiring treatment by medical specialists. Rather all people could be helped by the growth-producing conditions of empathic understanding, unconditional positive regard and congruence, and professionals from many fields could be trained to provide these conditions. Thus counselors, social workers, clergy, medical workers, youth and family workers, and other helping professionals could employ counseling methods and client-centered attitudes in their work. Rogers' books *Counseling and Psychotherapy* (1942) and *Client-Centered Therapy* (1951) described the principles of effective therapy and presented ample case studies from recorded sessions to illustrate his points. In 1982, surveys in the *Journal of Counseling Psychology* and *American Psychologist* still ranked Carl Rogers as the most influential author and psychotherapist.

Rogers also impacted the helping professions through leadership in many professional associations. He served on the executive committee of the American

Association of Social Workers, was Vice-President of the American Association of Orthopsychiatry (social workers), and President of the American Association of Applied Psychology, the American Psychological Association, and the American Academy of Psychotherapists, among other distinguished positions.

7. Applications to Other Fields

Through teaching, writing, and personal example, Rogers continually applied his theory and method to other fields—education, parenting, group leadership, and the health professions, to name a few. In each instance he demonstrated how the facilitative conditions of empathy, positive regard, and congruence could unleash growth, creativity, learning, and healing in children, students, group members, patients, and others. Applied to education, his views on ‘student-centered learning’ coincided with and contributed to the ‘open education’ movement in the USA, Great Britain, and elsewhere. His book *Freedom to Learn* (1969) went through two new editions over 25 years.

He expanded his theory and practice into the areas of group leadership and group facilitation over several decades. In the 1940s Rogers, Thomas Gordon, and colleagues had experimented with ‘group-centered leadership,’ whereby the leader’s acceptance, understanding, genuineness, and willingness to let the group set its own directions stimulated great energy, creativity, and productivity among group members. In the late 1950s and 1960s, Gordon, Richard Farson, Rogers, and associates extended this approach to what Rogers called the ‘basic encounter group’—an unstructured group experience in which ‘normal’ group members came to greater self-understanding, spontaneity, improved communication, and genuineness in relationships. Rogers led scores of encounter groups in professional, business, religious, medical, academic, personal growth, and organizational settings. *Look* magazine called Rogers an ‘elder statesman of encounter groups.’ *Carl Rogers on Encounter Groups* (1970) was a major seller, and his and Farson’s filmed encounter group, ‘Journey into Self,’ won an Academy Award (Oscar) for best full-length feature documentary.

Recognizing the ever-widening applicability of the client-centered, student-centered, group-centered approach, Rogers increasingly used a broader term, ‘person-centered,’ to describe his work. In the 1970s and 1980s he experimented with a person-centered approach to resolving intergroup and international conflict. Through workshops and filmed encounter groups involving different races, generations, and political persuasions—including Catholic and Irish protagonists from Northern Ireland—Rogers demonstrated how the same growth-promoting conditions useful in all helping relationships can enhance communication and understanding among antagonistic

groups. He and colleagues led person-centered workshops for groups of 100 to 800 participants in Brazil, Mexico, South Africa, Hungary, Soviet Union, other newly emerging democracies, and other countries. They organized a gathering of international leaders in Austria, about resolving tensions in Central America, which vividly demonstrated the potential of the person-centered approach for resolving international conflict. Testimonials suggested these efforts in professional development and citizen diplomacy helped foster democratization in several countries.

8. Humanistic Psychology

Rogers was a leader in what Abraham Maslow described as a ‘third force’ in psychology, which became prominent in the latter half of the twentieth century. ‘Humanistic psychology,’ as it came to be known, differed from psychoanalysis and behaviorism in at least three ways. (See *Freud, Sigmund (1856–1939)*; *Psychoanalysis: Overview*; *Skinner, Burrhus Frederick (1904–90)*; *Behaviorism*; *Allport, Gordon W (1897–1967)*.) First, this psychology gave more emphasis and credence to the individual’s *phenomenal field*—e.g., the client-centered therapist empathizes with the client’s frame of reference rather than evaluating or diagnosing from the outside; the existential psychotherapist helps the patient find ‘meaning’ in his life. (See *Lewin, Kurt (1890–1947)*.) Second, this psychology focused not just on remediation of psychological problems, but on psychological *health, creativity, self-actualization*—what Rogers described as ‘the fully functioning person.’ The goal was more than ‘adjustment,’ rather helping people experience their full human potential. Third, it was a psychology interested in what distinguishes human beings from other species. Choice, will, freedom, values, feelings, goals, and other *humanistic* concerns were all central subjects of study.

As Rogers’ career and that of leading behavioral psychologist B. F. Skinner were parallel in timing, productivity, and influence, their views were inevitably contrasted. Meeting on several occasions, including a six-hour debate–dialogue in 1962 (Kirschenbaum and Henderson 1989a), one of their exchanges on *Some Issues Concerning the Control of Human Behavior* (Rogers and Skinner 1956) became one of the most reprinted articles in the behavioral sciences. Rogers became a leading spokesperson for the humanistic psychology movement.

9. Enduring Influence

Major factors in Rogers’ impact on psychology and the helping professions were his personal example, longevity, and prolific writings. He presented a vivid role model of the person-centered approach for almost

six decades, demonstrating his theories through teaching, lecturing, live demonstrations and workshops, and audio-visual recordings. By all accounts, he embodied his theories by being an exceptional listener and communicator and a decent, honorable person. He wrote 17 books and over 200 professional articles and research studies. Millions of copies of his books have been printed, in over 60 foreign language editions. His most popular book *On Becoming a Person* (1961), written for both a professional and general audience, continues to spread his ideas.

Critics of Rogers' work have argued (sometimes fairly, sometimes not) that client-centered therapy is superficial, unworkable with some populations, and unmindful of recent advances in behavioral, drug, or alternative therapies; that Rogers' views on human nature are unrealistically optimistic and underestimate human evil; that encounter groups and humanistic psychology have fostered widespread selfishness, narcissism, and moral permissiveness; and that Rogers' experiments with organizational change were naive and counter-productive. Nevertheless, in the USA, although no longer a central figure in popular psychology, Rogers' influence endures. In 1972, he was awarded the American Psychological Association's Distinguished Professional Contribution Award, becoming the first psychologist to receive the organization's highest scientific and professional honor. The citation read:

His commitment to the whole person has been an example which has guided the practice of psychology in the schools, in industry and throughout the community. By devising, practicing, evaluating and teaching a method of psychotherapy and counseling which reaches to the very roots of human potentiality and individuality, he has caused all psychotherapists to reexamine their procedures in a new light. Innovator in personality research, pioneer in the encounter movement, and respected gadfly of organized psychology, he has made a lasting impression on the profession of psychology.

After Rogers' death in 1987, the greatest new interest in his work has been outside the USA, including Russia, Eastern Europe, and Latin America. As a Japanese counselor explained in the 1960s, Rogers helped 'teach me ... to be democratic and not authoritative.' His life's work demonstrated how supportive, growth-producing conditions can unleash healing, responsible self-direction, and creativity in individuals and groups in all walks of life. As countries strive to resolve intergroup tensions and practice self-government and self-determination, many have recognized in Rogers' work not only useful methods for helping professionals, but a positive, person-centered, democratic philosophy consistent with their national aspirations. Rogers eventually recognized the political implications of his theories and methods and explored these in *Carl Rogers on Personal Power* (1977). At Rogers' memorial service, Richard Farson eulogized him as 'a quiet revolutionary.'

10. Personal Life

Upon college graduation, Rogers married childhood friend Helen Elliott (1901–79), an aspiring commercial artist. Their two children, David (1926–94) and Natalie (1928–), distinguished themselves professionally, David in medicine (e.g., Dean of Medicine, Johns Hopkins; President, Robert Wood Johnson Foundation) and Natalie in art therapy and 'client-centered expressive therapy.' For many years the Rogers spent the academic winter quarter in the Caribbean and Mexico, where Carl read widely and developed a number of his theories, Helen painted, and both snorkeled. They regularly traveled to visit their children and six grandchildren. Carl pursued life-long hobbies of photography, making mobiles, and gardening. When Helen became ill in her seventies, Carl cared for her until her death in 1979. Thereafter he remained involved in work, cultivated old and new friendships with both men and women, and traveled widely. He was active until his death at age 85, on February 4, 1987 in La Jolla, California.

H. Kirschenbaum

Rokkan, Stein (1921–79)

Stein Rokkan was one of the world's leading social scientists after World War II. He played a unique role in organizing international social science cooperation in the 1960s and 1970s, and was the driving force in the development of infrastructure services for comparative research. But he was also a prolific writer, and it was the combination of all his contributions to comparative research, international cooperation, and infrastructure development that made him the comparativist of his time.

1. Stein Rokkan, the Norwegian

Rokkan was born July 4, 1921 in Vågan on the Lofoten Islands, on the northern periphery of Norway, and grew up in Narvik. Between 1938 and 1948 he attended the University of Oslo, where he first studied philology and then political philosophy, in which he received his doctorate with a dissertation on David Hume. From 1948 to 1951 Rokkan continued his studies in the USA and England: at Columbia University, where his work with Paul Lazarsfeld acquainted him with the methods of modern social research, and at the London School of Economics, where he met T. H. Marshall, whose historical-sociological research profoundly influenced his own.

Rokkan's educational career already contained the seeds of a rare combination of highly diverse talents: above all his great openness towards the 'new' social sciences while maintaining a firm grounding in the 'old' cultural sciences. His extensive linguistic, philosophical, and historical studies gave him a keen eye for the significance of cultural differences in international comparison, and thus for the often misleading simplicity of purely quantitative approaches. At the same time he recognized the potential of such approaches in comparative research and became one of their most important supporters. Rokkan's thought was interdisciplinary from early on. His scholarly interests included the entire spectrum of the social sciences, and this characterized his core scientific work: a political sociology in the tradition of classic macrosociology, the historical-comparative analysis of whole societies and polities.

From the very beginning, Rokkan combined a genuine international orientation with a deep devotion to his homeland that shaped his comparative approach. From his intimate knowledge of Norway he developed concepts (e.g., the center–periphery dichotomy) and questions (e.g., on the interaction of mass movements and institutional change) that he then applied to comparative research. This made him aware of the complexity of each single 'case' and led him to assess realistically the possibilities and limits of international comparisons.

Rokkan developed his system of thought, which was rooted in his origin and education, systematically throughout his entire scholarly career until his early death on July 22, 1979 in Bergen. From 1951 to 1958 he worked at the Institute of Social Research in Oslo, where he soon became engaged in various comparative research projects. In the same period he initiated, together with Henry Valen, the Norwegian Program of Electoral Research which was oriented on the work of the Survey Research Center in Ann Arbor, Michigan, but already showed Rokkan's signature in its emphasis on context variables.

In 1958 Rokkan became research professor at the Christian Michelsen Institute in Bergen, where in 1966 he was awarded a university chair and founded a new department of comparative politics. During this time he was also engaged in efforts to increase cooperation between the Scandinavian countries, which resulted in the publication of *Scandinavian Political Studies* since 1966, and in the founding of the Nordic Political Science Association in 1975.

2. Rokkan and the Internationalization of the Social Sciences

Rokkan was active at the international level from the very beginning of his professional career. Developing international research programs, organizing international projects and conferences, and building institutions and infrastructures for comparative research became the focus of his activities from the early 1960s. Three contexts of these activities can be distinguished: UNESCO and the International Social Science Council, the International Committee on Political Sociology, and the European Consortium for Political Research.

Rokkan, then Secretary-General of the International Sociological Association, participated in the founding of the International Social Science Council (ISSC) by UNESCO in 1952. In 1961, he proposed to the ISSC a broad program in cross-national and cross-cultural research which he then directed for over 15 years. He became a member of the Executive Committee of the ISSC in 1965 and served as president of the ISSC from 1973 to 1977.

The 1961 program led to a broad spectrum of activities to develop infrastructure services for com-

parative research and to promote concerted interdisciplinary research. Whole series of conferences were organized on comparative survey research and aggregate statistical comparisons of nations in the first half of the 1960s. Some of the further work was channeled into the European Coordination Centre for Research and Documentation in Social Sciences, set up in Vienna in 1963; other activities were headed up by two ISSC standing committees for data archives and comparative research established in 1966–7. Rokkan remained the driving force behind most of the subsequent activities, which in the 1970s also included summer schools and workbooks for training on comparative analysis and the promotion of an International Federation of Data Organization.

In the late 1960s, with the support of UNESCO Rokkan launched another series of conferences on national developments, asking what conclusions could be drawn from the early European experiences of state formation and nation-building for developmental processes outside Europe. Rokkan here developed his basic ideas about a macromodel of European political development. This work was also linked to the International Committee on Political Sociology that Rokkan, together with Shmuel Eisenstadt, Morris Janowitz, and Martin Lipset, had founded in 1960 and for which he served as Secretary from 1960 to 1970. Originally affiliated only with the International Sociological Association, in which Rokkan was vice-president from 1966 to 1970, it became a joint ISA/IPSA committee in 1970 when Rokkan was elected president of the International Political Science Association. During the 1960s the committee was an exclusive group of international scholars with a common interest in studying major historical changes. It was in this second context that Rokkan developed his ideas on democratization, cleavage structures, and party systems.

The third context was the European Consortium for Political Research. Rokkan was one of its founders and its first Chair from 1970 to 1976. Here too he pursued his central goals of developing joint research programs and improving infrastructure in the broadest sense: from bibliographic tools, research documentation, and data archives to computer applications (including cartography), and the training of the next generation of social scientists.

Rokkan's decisive role in the internationalization of the social sciences and the promotion of comparative research resulted from a congruence of personality and historical situation. In the 1960s the social sciences were expanding rapidly in Western Europe, but they suffered from national fragmentation. International cooperation was needed, and succeeded first via the USA. Only later did a genuine 'Europeanization' begin. Rokkan's broad education and international orientation proved invaluable in building bridges between the USA and Europe and reconciling different European traditions. His enormous talent for com-

binning personal networking and institution-building was a crucial asset in this start-up phase and the close linkage he saw between programmatic conceptualization, cooperative organization, and infrastructure-building gave this endeavor a cohesiveness that seems to be lacking today.

Rokkan's historical role has somewhat overshadowed his scientific contributions, apart from a few famous single hypotheses and typologies. His lasting contribution will be his attempt to develop a macro-model of the political development of Europe. In particular, his comparative studies on the structuring of European mass democracies, and his analyses of the processes of state formation and nation-building in Europe, but also his general approach to comparative research.

3. *The Structuring of Mass Politics in Western Europe*

Rokkan's work on the democratization of the European nation-states concentrated on the institutional and organizational variations in the structuring of mass politics up to World War II. Here he developed his well-known ideas of four institutional thresholds of democratization and of historical cleavage structures which in the process of democratization are transformed into party systems via the formation of alliances and oppositions.

In institutional terms, democratization for Rokkan meant the successive lowering or removal of four thresholds: the threshold to political opposition (legitimation), to political participation (incorporation), to access to parliament (representation), and to participation in government (executive power).

The lowering of the first two thresholds, through the recognition of civic rights and the extension of suffrage, ushered in the age of mass politics with mass parties and mass election campaigns. For Rokkan, an unbroken tradition of representation, a history of continuous center building, and a Protestant nationalization of territorial culture were the main factors favoring an earlier, more gradual, and stable democratization.

The lowering of the third threshold implied a transition from majoritarian to proportional representation, easing the access of minorities to representation in the legislature. In his view, the pressures for proportional representation were higher in the ethnically and/or religiously heterogeneous countries, and in general in the smaller nations with their greater international dependence.

The introduction of universal (male) suffrage in all Western European countries at the end of World War I and the transition to proportional representation in most of them tended to stabilize the party systems of the 1920s for a long time, in most cases until the 1960s (Rokkan's famous 'freezing' thesis). In Rokkan's view,

the party systems of the 1920s reflected older cleavages that had emerged in the earlier processes of state formation and nation-building and became politicized and organized in the process of democratization.

Cleavages are understood as strong and enduring conflicts that tend to polarize a political system. Rokkan distinguished between four or five basic cleavages that emerged at different critical junctures in European history. The *National Revolution* (1789 and after) produced two cleavages, with even older roots in the early state formation processes and the Reformation:

(a) the *center–periphery cleavage*: conflicts between the central nation-building culture and ethnically linguistically distinct subject populations in the peripheries;

(b) the *state–church cleavage*: conflicts between the aspirations of the centralizing, standardizing, and mobilizing nation-state and the corporate claims of the church.

Two further cleavages were produced by the *Industrial Revolution* in the nineteenth century:

(c) the *land–industry cleavage*: conflicts between the landed interests and the rising class of commercial/industrial entrepreneurs; and

(d) the *worker–employer cleavage*: conflicts between owners/employers and tenants/workers.

The class cleavage was overlaid by a fifth cleavage between proletarian internationalism and nation-accepting socialism as a result of the *International Revolution* (1917 and after).

According to Rokkan, the differences between the European party systems largely were produced by the first three cleavages, reflected in the presence or absence of regional, Christian, or agrarian parties. Whereas Christian parties emerged mainly in the religiously mixed and some of the Catholic countries, agrarian parties are found only in Protestant areas. The class cleavage, by contrast, produced working-class parties in every country, but their strength and unity differed greatly due to the socialist–communist split.

4. State Formation and Nation-building in Europe

In analyzing the historical development of the different cleavage structures, Rokkan took a decisive step beyond traditional comparative research: he no longer regarded the units of comparison, the nation-states, as given, but rather thematized their development itself. In these later works, Rokkan was influenced greatly by Hirschman's concepts of exit, voice, and loyalty, which he used in his analyses of the development of the nation-state in terms of boundary-building, internal structuring, and system-building.

Rokkan distinguished between four basic processes of loyalty-producing system-building: state formation and nation-building; two processes mainly of

boundary-building and two processes of mainly restructuring, the establishing of political citizenship by equalizing the rights to participation and the establishing of social citizenship by redistributing resources and benefits. In the older countries these processes tended to follow each other in time, whereas in the newer countries the problems associated with them often cumulated.

In the European context, according to Rokkan, these processes were influenced by six givens: first, the heritage of the Roman Empire (law and citizenship); second, the tradition of the Germanic kingdoms (legislative/judicial assemblies); third, the crucial role of the supraterritorial Catholic Church; fourth, the growth of a central city belt; fifth, the development of feudal and manorial agrarian structures; and sixth, the emergence of literatures in vernacular languages.

The European world of states and nations emerged from the disintegration of the Western Roman Empire, after centuries of territorial fragmentation and retrenchment, followed by processes of expansion and reorganization. For Rokkan, 'the alphabet and the city decided the fate of Europe' (Rokkan 1999) in these processes. As a result of various waves of migration, a new 'ethnic-linguistic infrastructure' arose in the Middle Ages. The alphabet made it possible to turn spoken into written standards of communication, and this vernacularization provided a basis for the later nation-building.

The city belt in turn was a decisive factor in center formation and early state building. The revival of trade between the Orient, the Mediterranean, and the North Sea had produced a belt of independent cities from Italy to Flanders. The polycephality of the city-state Europe either delayed state formation (Germany, Italy) or led to confederations (The Netherlands, Switzerland). By contrast, monocephalic city structures conducive to centralized state development formed at the western and later also at the eastern end of the city belt. The rise of Atlantic capitalism, however, brought with it a European division of labor that strengthened the Western states, while the Eastern states largely became incorporated into empires.

The variations in city structure and thus the tripartite division of Europe into a Western Europe of unitary, centralized nation-states, a federalist Central Europe, and an Eastern Europe of multi-ethnic empires constitute the 'west–east axis' in Rokkan's well-known typological–topological model or conceptual map of Europe. It helps to explain the great paradox of European development: that the strongest and most durable systems emerged at the periphery of the city belt and the old Empire.

While the 'west–east axis' defines differences in economic conditions of state formation, the 'south–north axis' denotes differences in cultural conditions of nation building, depending on the geopolitical distance northward from Rome. Rokkan interpreted the Reformation as the first major step in defin-

ing territorial nations in Northern Europe, whereas in Catholic Europe the Church remained supra-territorial.

The conditions for successful center-building and territorial consolidation as well as for cultural standardization and identity-building, therefore, varied across Europe in a typical and topological way. The easier these processes of territorial and cultural boundary-building, Rokkan generalized, the more gradual and less violent were the internal restructuring of the nation-states through the establishment of citizenship rights.

Towards the end of his life Rokkan attempted to integrate his comparative studies into a comprehensive model of Europe spanning the entire history of state formation, nation-building, and mass politics in Europe and identifying the crucial variables in the long and complex process that led up to the current constellations of territories, economies, and systems of political alignment. This macro-model remained a sketch exemplifying the nature of most of Rokkan's studies, which were essentially research programs.

5. Rokkan's Comparative Approach

Rokkan defined the decisive challenge of cross-cultural, cross-societal, and cross-national research as follows: 'We propose to direct our attention to one single, central set of issues: the possibilities of translating "grand theory" into empirically workable "typologies of macro-settings" for variations in human behaviour, and the consequences of such typologies for decisions on the cultural and the geographical range of comparisons at the level of communities, households, and individuals' (Rokkan 1970b).

From this fundamental orientation, Rokkan developed a series of basic elements that characterize his comparative approach: the need for context-specific comparisons, the multi-dimensionality of contexts, the twin concepts of structuring and boundary-building, the dynamics of freezing and unfreezing at critical junctures, and finally the method of retrospective diachronics.

For Rokkan model-building always had to be context-specific: 'No single explanatory or intervening variable can be linked up with a dependent variable in isolation from the context, whether across systems or across stages' (Rokkan 1999). Because such macro-contexts are comparable only to a certain degree, Rokkan was skeptical of universalizing comparisons and instead preferred region- and period-specific models, particularly in his cleavage model and his conceptual map of Europe.

The macrocontexts are in principle multidimensional, since for Rokkan they always resulted from interactions between three different systems, the political, economic, and cultural systems. Due to their

relative autonomy, he started in his macromodel from configurations, rather than hierarchies of factors: 'There is no economic determinism in the model, nor a geopolitical, nor a cultural: in this sense it seeks to combine the traditions of Karl Marx with those of Max Weber and Emile Durkheim.'

While all three systems have a territorial dimension, only the political system is ultimately capable of controlling territory. Territory is a crucial concept in Rokkan's comparative analysis of political systems. It is a starting point for his most basic twin concepts of structuring and boundary-building in the formation of territorial systems. Such systems essentially are structured through the formation of political, economic, and cultural centers and the incorporation of peripheries. Their consolidation presupposes a process of political, economic, and cultural boundary-building which in turn contributes to the emergence of territory-wide cleavages. Center-periphery relations and cleavage structures are the two dimensions that for Rokkan underlay the institutional and organizational structuring of political systems.

With his twin concepts, Rokkan went beyond traditional comparative research that was limited to comparing structures and focused on the formation of systems as a process of structuring and boundary-building. In this historical process critical junctures are crucial. This concept of Rokkan's refers to political, economic, and cultural 'revolutions,' historical events and processes which he used to distinguish between periods: between 'critical junctures' when basic new decisions are taken, structures are 'unfrozen' and boundaries are 'opened,' and periods in which the institutional and organizational structures remain 'frozen' and the boundaries 'closed.' This attempt at periodization underlies Rokkan's basic method of retrospective diachronic analysis which addresses the question: 'given an observed contrast in the values of variables at time t_i , what combinations of variables for earlier phases t_{i-1} , t_{i-2} , and so on, can best account for these differences?' (Rokkan 1999).

In this way, Rokkan attempted to explain systematically current structural differences between the European societies and polities as arising from their long-term development. In many cases, his efforts to do so took the form of research programs. With his contributions to developing a social science infrastructure, he wished to create a basis for carrying out these programs. In both respects, Rokkan has left us an important legacy.

Romanticism: Impact on Social Thought

Romanticism was a broad intellectual movement within modern Enlightenment that aimed at bringing the arts together with philosophy, history, and religion and attempted to aestheticize life. The central objective was a philosophico-political reconciliation of the fundamental connectedness of life, which was seen as damaged in the present, with the individual, with love, and with beauty. Although it was a wide European movement, it was in particular German romanticism that significantly influenced art and literature as well as the philosophy, psychology, and history of modernity. The key participants in the circles of Berlin and Jena as well as of Heidelberg, as the most important groups, were August Wilhelm Schlegel (1767–1845), Dorothea Caroline Michaelis/Schlegel/Schelling (1763–1809), Friedrich Schlegel (1772–1829), Brendel Mendelssohn/Dorothea Veit/Dorothea Schlegel (1763–1839), Friedrich von Hardenberg (Novalis, 1772–1801), Friedrich Schleiermacher (1768–1834), Rahel Antonie Levin Markus/Varnhagen von Ense (1771–1833), Henriette Herz (1764–1847), Karoline Günderode (1780–1806), Sophie Schubart/Merlau/Brentano (1770–1806), Clemens Brentano (1778–1842), Bettina Brentano/von Arnim (1785–1859), Achim von Arnim (1781–1831), Friedrich Wilhelm Joseph Schelling (1775–1854), Johann Gottlieb Fichte (1762–1814), in the broader environment Friedrich

Hölderlin (1770–1843); as well as Johann Joseph Görres (1776–1848), Jacob Grimm (1785–1863), and Wilhelm Karl Grimm (1786–1859).

The impact of romanticism on the emerging social sciences can be demonstrated across the following areas: (a) knowledge and hermeneutics; (b) culture and society; (c) critique of modernity; and (d) reason and aesthetics.

1. Knowledge and Hermeneutics

Whereas Enlightenment thought starts out from the assumption of the intelligibility of the world and lets its knowledge of the world predetermine its view of the arts, romanticism turns this relation around and—with reference to Kant's critique of reason—denies philosophy's primacy with regard to knowledge. Science (*Wissenschaft*) was to be 'beautiful'; analogies and metaphors were to enrich and complement scientific-scholarly practices; and the 'novel of life,' in which all arts and sciences unite, should unfold from an ever-open, progressive concept of form. 'The absolute,' 'freedom,' and 'nature' become key concepts of philosophical debate. Within such core of romanticist perspectives, however, important differences and contradictions co-exist. Friedrich Schleiermacher, for insistence, turns against Friedrich Schlegel's progressive universal poetics (*progressive Universalpoesie*) and insists on the boundaries and relative separateness of the diverse aspects of reality (religion, science, art, aesthetics). In addition, the new mythologization appears to him as an unwarranted intervention of human action into the absolute. He contradicts Schlegel's characterization of infinity with its inclination towards dissolving ethics, since under conditions of achieved finite freedom the autonomy of the other needs to be respected. Even though he rejects any ahistorical contractual thinking, he thus combines an ethics of obligation with an ethics of virtue.

Within this framework, the task of hermeneutics according to Schleiermacher (see *Hermeneutics, History of*) emerges from the following movement of thought. If thinking occurs in intersubjective individuality, then there needs to be an art of understanding, which compares that which is one's own critically with that which is of the other. Thus, such art can approach the infinite spirit that is always already at work in everything individual. Schleiermacher's hermeneutics—which can well be seen as part of an aesthetics, of a 'theory of artistic activity' (Schleiermacher 1984, p. 154)—investigates writing and speech under the following aspects: with regard to general grammar, in psychological-subjective perspective with regard to the genesis of authorship and work, by comparative procedure and, finally, by divinatory procedure. Understanding occurs in a historical process that encompasses both reader and author. Although understanding aims at agreement, this process can nevertheless not be closed (see Frank

1977). Not least Walter Benjamin (1991) has demonstrated that it is only the reader as the extended author who completes the work of art. Thus, he showed that the romantic way of 'raising reflection in the work to a higher power' contained a 'more modern' theory of art than can be found in Goethe. The impact of hermeneutics continued through Wilhelm Dilthey to Hans-Georg Gadamer (Ferraris 1998).

Beyond hermeneutics, theology, the study of religion, classic studies, and philology, psychology and psychoanalysis show signs of a romantic heritage. Early romanticism showed a particular interest in phenomena at the margins of reason, such as magnetism, occultism, somnambulism, and telepathy (Johann Wilhelm Ritter 1776–1810, founder of electrical chemistry). Late romanticism—Gotthilf Heinrich Schubert (1780–1860)—was concerned with the analysis of the human unconscious and systematic studies in the symbolism of dreams as a linguistic system (*Symbolik des Traums*, 1814), in particular, can be considered as predecessors to Freud and his cultural criticism (*Das Unbehagen in der Kultur*, 1912). Themes of the split I (the motif of the *Doppelgänger*), trauma, loss of identity, melancholy, and delusion as well as, in particular, the imagery world of sentiments in, for example, the works of Johann Ludwig Tieck, Jean Paul, Heinrich von Kleist, or E. T. A. Hoffmann were well known to Freud.

2. Culture and Society

There is a clear impact of romanticist thinking on Jacob Grimm and Wilhelm Grimm (1785–1863 and 1778–1859), whose historically and empirically comparative research on language opened the space for the identity-constituting role of the emerging *Germanistik* (German studies) and at the same time already separated the natural sciences from the human sciences.

Romanticist impact, though, is particularly evident in that problem area that is currently discussed under the denomination of 'identity' (Frieze 2001). Johann Gottfried Herder (1744–1803; *Über den Ursprung der Sprache*, 1772; *Ideen zur Philosophie der Geschichte der Menschheit*, 1784–1791), whose work connects Rousseau to romanticism, already meant what is now called 'collective identity' when he spoke of the inalienable 'character' (*Geburtsstamina*) of a people. Following up on Herder and relating to motifs in Friedrich W. Schelling—motifs that found their continuation in the theory of archetypes as developed by C. G. Jung and Mircea Eliade, Aby Warburg but also in Ruth Benedict's work—the search was for universal and constant features of culture that found regionally diverse expressions. These concepts have in common that they postulate a universalism in terms of the laws of the human psyche on the one hand, while working with a particularism in terms of the variety of different 'identities' of peoples on the other. The assumption of

'collectively shared' representations was also one of the conceptual pillars of the 'psychology of peoples' (*Völkerpsychologie*) and of the emerging sociology. It was Wilhelm Wundt who provided the most comprehensive view of psychology and the cultural sciences. His late writings (*Grundrisse der Psychologie*, 1898, *Völkerpsychologie*, 1917) focused on those psychic phenomena that are significant for the social life of human beings and that are at the roots of community and of the emergence of creations of the collective spirit. The reference to Herder's 'spirit of the people' (*Volksggeist*), which describes the supra-individual features of the members of a people, is as evident as the one to Wilhelm von Humboldt whose comparative linguistic investigations entailed a comparison of 'people's characters.' The impact of Wundt—whose writings were known by Franz Boas, Bronislaw Malinowski, but also by Emile Durkheim—extended as far as Lucien Lévy-Bruhl.

Next to the emphasis on linguistic and psychical factors for the formation of identities, the distinction between *Gemeinschaft* (mostly translated as 'community') and *Gesellschaft* ('society'; see Schleiermacher, *Theorie des geselligen Betragens*, 1799) as well as the particular relations between society and state (Fichte, *Beiträge zur Berichtigung der Urtheile des Publikums über die französische Revolution*, 1793), that were established in romanticism and reaching from republicanism to a thinking in terms of natural rights to a skepticism towards the state, lived on in the emerging social sciences (see *Community/Society: History of the Concept; State and Society*). Even though they were considerably altered, these conceptual oppositions had an echo in virtually all dualisms between 'traditional community' and 'modern society' that were established by 'classical' sociology and maintained from Max Weber, Georg Simmel, Emile Durkheim onwards to the present day.

3. A Modern Critique of Modernity

The crisis of the modern subject was made a central literary topic in romanticism (and was continued, *inter alia*, in Robert Musil or Franz Kafka). Friendship and love (Schlegel 1988) were counterposed to modern loneliness, loss of self, and the break of the individual with the icy machinery of society (as presented in Ludwig Tieck or E. T. A. Hoffmann). At the same time, forms of sociality were theorized as well as practiced in which an unadapted, anticonventional subjectivity mediated between the romantic individualism and the freedom of the subject on the one hand and the exchange with others on the other. Such forms of sociality were considered as the ideal of education (*Bildung*) in a comprehensive humanistic sense. Romanticism thus created an intellectual space in which women in particular, who were excluded from the university as an institution, occupied a central place.

The crisis of the modern subject, the romantic-enlightened cultural criticism and its dream of the 'noble savage' were in the background of the emerging field of anthropology (Georg Friedrich Creuzer, 1771–1858) and in the 'imaginary ethnography' of the nineteenth century (Kramer 1977, Said 1979). It continues to be effective as the escapism into the exoticism of the other as well as in the current constructions of (cultural) identity and 'difference' in the era of 'globalization.' The modern critique of modernity, as prefigured by romanticism, is taken up in a variety of quite different strands of thought. Karl Marx states the human alienation under conditions of capitalism; Friedrich Nietzsche celebrates the 'great separation' against both Christendom and bourgeois morality; Max Weber condemns the 'iron cage', Martin Heidegger the being 'fallen to the they' (*Verfallenheit im Man*); Theodor W. Adorno denounces the administered world and the culture industry and Walter Benjamin laments the 'loss of aura'. The (social) philosophy of the early twentieth century reclaims 'authenticity' and 'emancipation' and all these perspectives share in the critique of the Modern world as developed in romanticism and they point to a—indeed often denied—romantic heritage (in which, in particular, the connection between aesthetic experience and renewed religion, characteristic of early romanticism, is visible; see *Eudaemonism*). The romantic critique of modernity, however, is an integral moment of the Enlightenment, and not its subjective-irrational counterpart. This latter verdict has often been cast, and peculiar intellectual alliances can be found sharing it. It stretches from Hegel and the Left-Hegelians to Heinrich Heine's rejection of romanticism to Nietzsche and Carl Schmitt's critique of 'romanticism as subjective occasionalism' as well as to George Lukács. It finally culminates in the reproach that the modern-bureaucratic mass annihilation is a result of the romantic critique of modernity—a modernity that precisely created such horror.

4. Reason and Aesthetics

For August W. Schlegel, formulating the program of romanticism in his lectures on 'arts and literature' (*Schöne Kunst und Literatur*, 1801/04), reason is founded not just on empirical perception, and the autonomous validity of poetry is thus emphasized. Romanticism, however, never abandons the concept of reason. Even when the technical-instrumental use of reason against nature is opposed, a comprehensive concept of reason is sustained. Despite all criticism of idealist systemic thinking, romanticism moves within the path of Kantian philosophy, behind which there is no falling back, and it shares in Kant's rejection of the utilitarian grounding of morality in selfishness. Schlegel knows perfectly well the distinction between concepts of the intellect, which refer to the world of appearances, and concepts of reason, which refer to

ideas and states that since ideas can be judged only by a reason that has enlightened itself about the limits of the possibility of knowledge.

In this context, early romanticism reacted to a situation in which the Enlightenment attempts to deal with the question of religion were difficult to sustain. Kant's critique made the argument for belief on the basis of reason impossible. Lessing intervened into the enlightened criticism of the bible by publication of the Reimarus papers; the dispute over this inheritance culminates in F. H. Jacobi's reproach of Spinozism (The dispute over atheism, 1789–99). Fichte justified his 'Attempt at a critique of revelation' (*Versuch einer Kritik der Offenbarung*, 1792) with the argument that revelation constrains the moral freedom of the human being. For Schleiermacher, the bible is a historical expression in the ever-incomplete path of Christendom, in the infinite perfectability of the world.

At the same time, romanticism addresses the problem of Enlightenment after the unity of reason and the tangible world could be cast only as the telos of action in the sense of a regulative idea, which never becomes real. Kant's critique of reason had demonstrated that the claim that nature is the bearer of moral norms could not be justified. Nevertheless, human action in the process of history can provide experience as to whether reality is constituted by the actualization of regulative ideas. Such a concept of Enlightenment in which the relation between ideas and the world of appearances can be sensually experienced in the course of an infinite rapprochement has been expressed by Novalis and F. Schlegel by means of infinitesimal calculus, which lets the tendency towards the infinite be grasped within finitude.

A different path towards the unity of idea and world of appearances is provided by imagination and the arts. Fichte described productive imagination as 'the faculty that is suspended in the middle between determination and nondetermination, between the finite and the infinite' (*Grundlage der Wissenschaftslehre*, 1794, II, 360). The objective is here not reconciliation, but rather the insistence on remaining within a space of contradictions.

Fichte exerted decisive influence on Friedrich Schlegel's aesthetic conceptions such as the 'progressive universal poetics' and infinite irony as poetic reflection (see *Imagination: History of the Concept*). Such poetes can 'remain suspended in the middle on the wings of poetic reflection and free of all real or ideal interest, it can ever again produce such reflection and multiply it as in an infinite row of mirrors; [...] the romantic art of poetry is still in its becoming; it is even its authentic being that it can ever only become and can never be completed' (F. Schlegel 1988, II, pp. 114–15; *Athenäums-Fragment*, p. 116; see also *Lyceum-Fragment*, p. 108). The concept of infinite irony reassumes such a moment of infinite reflexivity, a reflexivity that is not limited by any fixation. Hegel—in the *Phenomenology of Spirit* and in the

Aesthetics—attacked such conception, just as he criticized the transfer of Fichte's philosophy into the arts.

F. Schlegel referred here to Socratic irony, as presented by Plato (see Plato, *Symposium*, 216e), which according to Quintilian (*Institution oratoria*, IX, 2,44) brings the opposite of what is said to understanding. Irony is, in a dialogical reference, a double negation. It reflects on the possibility of things being different from what they seem to be and thus opens an 'ironic space of play' (Allemann 1956, p. 10). In contrast to allegory and metaphor (see *Metaphor and its Role in Social Thought: History of the Concept*), irony demands a principled and reflective understanding of the ambiguity what is meant and what is said, of essence and appearance. Friedrich Schlegel develops irony in particular in the Lyceum and Athenaeum fragments and explains it in his essay 'On unintelligibility' (*Über die Unverständlichkeit*, 1800): 'The French Revolution, Fichte's *Wissenschaftslehre* and Goethe's *Meister* are the grandest tendencies of the age' (Fragment 216)—'I wrote this fragment with the most honest intention and almost without any irony' (237). The 'system of irony' (239)—in the plural forms of irony, from the raw to the fine, dramatic and double irony to the 'irony of irony' (239)—is turned here from a rhetorical trope into a basic element of philosophical reasoning. Irony becomes the infinite play back and forth between opposite moments, none of which can be led into univocality. Infinite irony is thus distanced from any kind of identity or mediation—as, for instance, in the sense of Hegel's dialectic. When 'idea' is characterized as 'a concept completed to the level of irony [...] the change, ever again recreating itself, between two thoughts in dispute' (Fragment 121, 115), then it is not a conceptually mediated identity that is at issue, but the persistent creation of difference. 'Irony of irony,' however, contains infinite regress, namely 'when one speaks without irony about irony, as it has just been the case' (239), thus when irony can no longer be mastered, 'when one is no longer able to step outside of irony, as it appears to have been the case in this essay about unintelligibility; [...] when irony, so to say, ironizes the poet [...] when irony has to be made against one's will [...] when irony turns wild and lets itself no longer be governed' (239–40).

Schlegel's writings on irony have been received as well as criticized by, among others, Schelling, Schleiermacher, Novalis, Karl Wilhelm Solger (1780–1819), and Søren Kierkegaard (1813–55). Even though Solger (*Vorlesungen über Ästhetik*, 1819) remains with the negativity of irony that excludes absolute mediation, irony, originally thought of as infinite, is turned by him—and by Hegel—into a dialectically conceived moment of artistic activity. Following up on both Solgers and Hegel, Kierkegaard (*Über den Begriff der Ironie mit ständiger Rücksicht auf Sokrates*, 1841) regarded the infinite irony of ro-

manticism as a subjective moment, seeing itself capable of separation from the positivity of reality. 'For irony, everything turns into nothing' (Kierkegaard 1993, p. 263)—and therefore Kierkegaard counterposes a controlled, limited irony to the infinite romantic irony.

Although the recasting of romantic irony thus appeared to have reached its end, recent attempts at rehabilitating irony refer back to this heritage, multiply broken and rewritten as it may be. Richard Rorty (1989, p. 123) attempted 'to cleanse romanticism of the last traces of German idealism'—but 'he overlooks that German romanticism has no need for him, since the inventor of theoretical irony had already taken his distance from early German idealism himself' (Bohrer 2000, pp. 11–12). Rorty (1989, p. xv) then designs a liberal society in which irony has become universal, thus reducing irony to a plain liberal principle. The idea here is that a plural society with its variety of life-projects, language-games, and contingencies can no longer be determined or mastered from an allegedly superior viewpoint.

Beyond such political thinking, the heritage of romanticism has a particular current significance in theories of language. The determined opposition between what is meant and what is said, between the authentic and the inauthentic is, once it has been separated from its foundation in transcendental philosophy, dissolved in 'infinite suspense' and deconstructed as the vertigo of infinite recombability in Paul de Man and as the emphasis on principled 'undecidability' in apparently fixed semantic orders of meaning in Jacques Derrida. The recent theoretical approaches, however, can hardly be considered a continuation of romanticism, but rather as the rewriting of romanticism, Enlightenment, and modernity as an inextricable philosophical complex, as 'the rewriting of some traits that had been claimed by modernity' (Lyotard 1988, p. 43).

H. Friese

Rousseau, Jean-Jacques (1712–78)

1. Life and Work

Rousseau was born on June 28, 1712 and raised in Geneva, the center of Calvinism. Jean Calvin, not a native of Geneva, published his magisterial *Christinae Religionis Institutio*, the central work on education, in 1536. Its final version, dated 1559, justified general priesthood by way of the doctrine of predestination. Calvin dissolves the ‘two empires’ of laymen and ecclesiastical office in favor of a parish without differences, one which sees itself as an elected body (Calvin 1957). Clergymen are chosen teachers whose sermon is intended to educate without the possibility of it being associated with primacy or hierarchy (Calvin 1958). Rousseau’s life and work is, in many ways, a manner of dealing with Calvinism. The concept of *equality* determines *The Social Contract*, the theory of education, and Rousseau’s natural theology. Calvin’s doctrine of grace is translated into the predestination of nature, along with a rigorous inwardness which has the only true form of education on its side. Virtue becomes a model for society given the education of man’s nature. Calvinistic rigor fascinated Rousseau. Following the banning and public burning of his books, he dispensed with the citizenship of the Republic of Geneva in 1763, but not his membership in Calvin’s church, which he had renewed in 1754.

Rousseau’s dramatic life (Cranston 1991a, 1991b, 1997, Incoprom SA et al. 1999) is characterized by

ascent outside the elite and by being an outsider. The young Rousseau completed an apprenticeship as an engraver and in terms of his education he was largely self-taught. His constantly intermittent, restless, and wavering career ran between Geneva and Paris, later included Switzerland, and England. Rousseau himself attempted to gain control over his biography with the writing of his *Confessions* (Rousseau 1961), which was published posthumously in 1782 and have determined the image of Rousseau ever since then. In 1740, after various wanderings and low-level activities Rousseau took up a position as a private tutor in Lyon, where he wrote his first text on education (*Mémoire à Mr de Mably*: Rousseau 1969, pp. 1–32). In 1742 Rousseau went to Paris, publishing his *Dissertation sur la musique moderne* in 1743. In 1749 Rousseau wrote the articles on music for Diderot’s *Encyclopédie*. His first major literary success came a year later with the *Discours sur les sciences et les art*, which was awarded a prize by the Academy of Dijon. From 1756 on, Rousseau, living now in the *Eremitage* of Montmorency, concentrated on his three major works, the *Nouvelle Héloïse* (1761), a successful, widely read novel throughout Europe, the *Contrat social* (1762), Rousseau’s theory of society, and *Emile ou de l’éducation* (1762), the theory of ‘new education.’ The latter two books were banned directly after publication and publicly burned in Paris and Geneva.

From then on Rousseau was on the run. He was granted asylum by the Prussian governor in Neuchâtel soon after his flight from Paris. At his place of refuge in Môtiers he was subjected to attacks by such differing authors as the general procurator of Geneva, Tronchin, and his arch-enemy Voltaire (‘Sentiment des citoyens’, Voltaire 1961, pp. 715–18). At the same time Rousseau became the idol of the generation of ‘Sturm und Drang’: young *litterati* from all over Europe visited Rousseau in Môtiers and made him famous. In January 1766, his flight having taken him to various places, Rousseau made for England following an invitation from David Hume. Both had different preconceptions of each other and their relationship soon broke down. Rousseau returned to France and worked, with increasing paranoia, on his autobiography, which can be viewed as an attempt at self-therapy. His precarious financial situation was revived at short notice in May 1778, when Rousseau and Thérèse Levasseur, whom he had married in 1768 following a long-standing affair, moved to Ermenonville into an estate owned by the Marquis de Girardin, Rousseau’s final benefactor. His sudden death on July 2, 1778 ended a very unlikely literary and philosophical career which was intended to be *à rebours*—contrary to convention.

2. Education and Society

The archbishop of Paris, Christophe de Beaumont, justified the banning and burning of Rousseau’s *Emile*

primarily because of its denial of original sin. Rousseau assumes that human nature is not tainted. 'There is no original sin in the heart of man' 1969, p. 322). In his statement of defense against Beaumont, printed at the beginning of 1763, Rousseau formulated a far-reaching dualism which has dominated political and educational conceptions ever since. The two aspects of this dualism are *nature* and *society*, which are treated as contradictions. The present social order contradicts human nature in every respect, society is the alienation of nature, and this explains the vices of men and the evils of life. The assumption of original sin then is superfluous: man could live without sin if nature and society corresponded and harmonized (Rousseau 1969, 966ff.). In this respect Rousseau had a post-Augustinian concept of education in mind, and this is developed in *Emile*.

Essentially, the theory has three axes: the political difference of *homme civil* and *homme naturel*, the assumption of phases of 'natural development,' and the anthropological difference of *amour de soi* and *amour propre*. Rousseau's concept of education is constructed from these axes. This concept is peculiar *not* because it stresses 'natural education,' a term that was established in educational discourses long before Rousseau (Mercier 1961), but because of its paradoxical attempt to solve the contradiction between nature and society by way of education. To this end, Rousseau, as early as in the draft of *Emile*, the *Manuscrit Favre*, draws a distinction between two contrary types of education: that of *nature* and that of *society* (Rousseau 1969, p. 58). These refer to two ways of life—the life of natural and of civil man—both described contrary to Hobbes, who, in his *Leviathan* (1968, originally published 1651) distinguished between natural and social condition. Society, for Hobbes, tames and cultivates nature, and thus repression of nature is unavoidable. Rousseau reversed this argument. For him, the social condition is that of ongoing civil war (*bellum omnium contra omnes*), while the natural condition is considered to be of presocial peaceableness. Education for 'public business,' as suggested by Hobbes (1968, 289ff.) is completely ignored.

Rousseau justified his fundamental thesis in the second *Discours*, dated 1765, which was devoted to the evolution of inequality (Rousseau 1964, pp. 109–94). Rousseau explains *inegalité* in the form of society's corruption of human nature, which was originally in a position to live harmoniously with people's own needs. *Homme sauvage* ('savage man'), as he terms it, is considered to exist on the basis of his own strengths, while *homme civilisé* ('civilized man') develops social needs which render him dependent and weaken his nature (Rousseau 1964, 135ff.). The division of labor, the development of knowledge, and connected social differentiation (Rousseau 1964, p. 143ff.) forcefully brought about a progressive inequality among men. Leave is taken of the condition of innocence and

natural freedom (p. 152), and the invention of the *first* society irresistibly causes all those following (p. 178) for the prize of alienation of mankind from its own nature. In this respect *society* is the fall of men, not nature.

The theory of education in *Emile* picks up the evolution thesis and elaborates it with regard to the development of the child. This forces a reversal: the social condition does not follow the natural condition. Moreover, the social condition is led back to the natural condition, given that education can develop nature on the basis of its own potentials. Rousseau's risky experiment of thought goes as follows: if children are seen as the *homme sauvage*, education would have to apply to this condition entirely, provided that the social condition can be excluded for the duration of education. This assumption leads to *Emile*'s basic scenario: an *élève imaginaire*, described in greater detail merely as an 'orphan,' is exclusively educated by a 'governor' outside any society. The scene is anonymous countryside far away from corrupt cities and raw villages i.e., independent from the social condition as Rousseau viewed them (Rousseau 1969, pp. 264, 267, 279). The place in which the story is told is described simply *as au milieu des champs* ('in the middle of fields') (p. 277) without any details of the origin and personal history of the two protagonists. As such, the tale is not a novel of education but a treatise which is intended to describe the paradigm of true education. The name 'Emile' is presumably reminiscent of Plutarch (Shanks 1927), as it has no biographical meaning. Accordingly, the governor is not given a name and is thus not distinguishable. Both are paradigms, not persons.

'Natural' is *negative* education. Rousseau largely draws on the phases of human development from the *Histoire Naturelle* by Buffon and de Leclerc Comte (1989, pp. 1–114). Again it is not the schema of 'development,' formulated at the beginning of the *Manuscrit Favre* (Rousseau 1969, p. 60) that is original, but the linkage with the axes of educational theory. Rousseau understands the entire childhood as the 'age of nature,' which must take place outside the social condition. Thus the entire first education is negative. It does not consist at all of teaching virtue or truth, but in avoiding vices and errors in order to grant innocence of heart and integrity of mind (Rousseau 1969, p. 323). The concept of negative education is aimed against Locke (317ff.), whose *Some Thoughts Concerning Education* had been available in French in a translation by Pierre Coste since 1695 and had had considerable influence. Locke's central idea (1989, p. 142), that 'Children are to be treated as rational creatures,' aroused passionate contradiction in Rousseau. For him 'Reasoning with children' (Locke 1989, p. 142) was nothing other than the reversal of nature's plan. Reason (*raison*) is the end of education, but the end cannot determine the beginning: 'If children could understand reason there would be no need to educate

them' (Rousseau 1969, p. 317). Childhood must have its own manner (*manière*) of seeing, thinking, and feeling, which is not that of adults (p. 319). Locke's concept of reason is that of adults outside the world of children.

It is above all this idea of the separate world of childhood, that justifies Rousseau's fame in education—along with the paradisaical metaphor of pure education outside society and the spontaneity of children led by immediate interests (*intérêts présents*) (Rousseau 1969, p. 358). Rousseau seems to be the originator of modern education, which stresses the 'new' image of child and childhood. In this respect, however, the fact that *Emile* clearly has a theological center is overlooked. The treatise ends by giving preference to republic, not to nature, and the whole theory presents two concepts of education with differing gender forms. The center of *Emile* is the concept of 'natural religion,' justified in the *Profession de foi du Vicaire Savoyard*, a treatise within the treatise (Rousseau 1969, pp. 565–635). Rousseau takes the role of the vicar, who, against the materialism of the Parisian philosophy, announces a supreme being or an active creator who is assumed to be 'King of Earth' (Rousseau 1969, p. 382). Being in unison with creation cannot mean anything sinister: 'Where everything is good nothing can be unjust' (p. 588). The good can be seen in creation, justice emanates from the good, only a just person can live happily (p. 589), but the enthusiasm for virtue (p. 596) is an inner principle (p. 598)—that of the heart and not of reason (p. 627). Consequently, the key to the profession of faith is as follows: 'We can be men without being scholars' (p. 601).

What Rousseau called 'natural religion' (Rousseau 1969, p. 607) is a theology of the heart (Osterwalder 1995, cf. Chevallier 1994), it does not require any positive dogma. Moreover, inner enlightenment needs no teachers (*pasteurs*) (Rousseau 1969, p. 609), only the inspiration of belief in seeing God's creation. Rousseau radicalizes the Calvinistic doctrine here: the metaphor of 'heart' signals independence even from the community of belief. 'Equality' is therefore not a social construction which would require comparison with others, but a sovereignty in solitude. 'Sovereignty' or inner strength presupposes identity and distance. Rousseau justified this difference with the relation between two instances of the soul called *amour de soi* and *amour propre*. The fact that two instances are mentioned violates again a convention of literature. In French virtue literature such as La Rochefoucauld's *Maximes* (1665) or Blaise Pascal's *Pensées* (1670), 'amour propre' is the formula for egoism and self-love that has to be restrained by education. Rousseau used the formula in a new way: he took over the negative meaning of *amour propre* but added a second, positive, instance—that of *amour de soi*. The positive instance suggests that man looks only for himself and is content with the satisfaction of his own true needs. The

negative instance, *amour propre*, leads to comparison with others; man is never satisfied because no man will give preference to others more than to himself (Rousseau 1969, p. 493).

Loving and tender passions occur in *amour de soi*; hate and temper, i.e., from comparison with others, occur in *amour propre*. Thus, man is all the happier the fewer needs he has and the more he can avoid comparisons with others; in contrast, the factors which make man suffer ills and evils (*méchants*) are *too many* needs and *too many* opinions i.e., the dependency on others. Consequently, Rousseau develops the concept of *éducation solitaire* (Rousseau 1969, p. 341), which isolates the fictitious Emile throughout his childhood, totally controls learning (*la liberté bien réglée*: p. 321), and stipulates the didactic scenario on the theory of natural requirements and needs. Therefore Emile does not receive lessons, is not provided with any written works, and is excluded from all forms of cultural education. Only the *age de raison*—youth—requires formal lessons; all of childhood should apply exclusively to nature, which, of course, is only experienced in a didactic manner i.e., extremely artificial. The governor (and he alone) arranges the entire experience, and it is not by chance that *Robinson Crusoe* is the only literary evidence that Emile is given to read (Rousseau 1969, 455ff.).

The concept of *éducation solitaire* refers to the education of man (*faire un homme*: Rousseau 1969, p. 248). However, in the beginning of the fifth book Rousseau introduces 'Sophie ou la femme' i.e., he is forced to react to the difference in sex. The education of 'the woman' is given treatment as generalized as was previously the case with 'the child.' But now 'the child' is recognized as a *male* child and not as a sexless 'person' in general. Rousseau's *homme sauvage* is stated as male, namely 'strong,' 'sovereign,' and 'independent.' Sophie, the generalized woman, is educated in a manner that she can see herself as being in complementary dependence on males. The education of the sexes is therefore not equal, it is dissimilar (Rousseau 1969, 700ff.). This is subject to the precondition of sexual difference that cannot be dissolved or harmonized (p. 697). Because men want to seduce, they are dependent in the crucial moment, but women have to agree and thus can say 'yes' or 'no.' This female strength can only be compensated by virtuousness publicly. The 'mutual dependency' is therefore not symmetric: men are dependent on women because of their *désirs* (*desires*), women are dependent on men as a result of their wishes and needs (*besoins*). Accordingly, 'by the law of nature itself women are at the mercy of men' (Rousseau 1969, p. 702), not vice versa.

Rousseau's treatise about true education ends with a grand tour (Rousseau 1969, pp. 826–55) which is intended to introduce Emile to basics of government theory (p. 833) i.e., the doctrines of Rousseau's own *Contrat social*. Endeavors are made regarding 'le

dernière perfection' (p. 799): it is envisaged that the well-educated *man* now is to become a respectable *citizen*. The citizen's know-how is taught with the theory of the 'social contract' (839ff.); *Emile* has to learn what defines the status of citizens (*citoyens*) and thus the constitution of society (p. 840). The small *republic* is given preference—one which can create an ideal relationship between population and government (p. 840). Obviously the Republic of Geneva, idealized by Rousseau during his lifetime, is the paragon for this thesis. The ideal republic is rare and thus hard to find. The governor concludes his teachings on government as follows: the obligations of the citizen presuppose a true country (*patrie*), and a country is true insofar as it can be considered a model of political virtue. Those who do not find their *patries* will not face political abysm, 'car qui n'a pas une patrie a du moins un pays' (Rousseau 1969, p. 858).

The connection of education and society fails. Rousseau had two views on society: first the ideal of the *contrat social* creating a model for social order that is mainly granted by the concept of *volonté générale*—the general will behind all singular wills (Rousseau 1964, 361ff.); and second the polemical description of general decadence within existing society. In no place does society comply with the ideal; therefore the grand tour ends without result. The couple *Emile* and *Sophie*, educated differently, are not released into society as citizens but led to marriage and family (p. 867). More is not possible: the ideal society, inspired by the *volonté générale* and thus safe from the corruption of power, is not realized anywhere. The social ideal has no social place. Decadent society, on the other hand, is morally unacceptable; real society has its place but not a legitimate form. Thus, loneliness (*solitude*) is in the end stronger than sociality (Starobinski 1971), because education will not change society but can only develop man's nature. The great project of 'humanization' though natural education (as stated by Ravier 1941) fails because of its own ambitions and contradictions. 'Nature,' in the framework of Rousseau's *Emile*, is an artificial experience, learning is bound by didactic parameters, control is total, and sentiment for the children's *separate* world arises from the fiction of a good and equal nature that does not mirror any child's individuality.

3. Reception and Enduring Influence

The reception of Rousseau's work demonstrates the often dramatic and always radical conflict between convinced supporters and equally convinced adversaries. Rousseau divides his readers into the twenty-first century, not least because he wrote against reality. His ideals of antiquity, especially those of Sparta and Athens, suggest an *âge d'or* (Terasse 1970, Leduc-

Fayette 1974), which can be understood as an anticipation of the future, the renovation of the 'true society' that has been lost in history. It is therefore not by chance that Rousseau is the hero of the Jacobins; his cult was established in the French Revolution (Barney 1986) against all conservative theories that negate revolution in favor of the long-term development of society without the sentiment of decadence. Rousseau's *Social Contract* represents the new society that conservatives can only deny. The tension between freedom and equality attributed to, and paradoxically and provocatively described by, Rousseau characterizes one major part of political theory up to John Rawls's reformulation of the *Contrat social*. The same applies to the theory of 'natural education': Rousseau's *Emile* is a key source for Tolstoy and the reform movements of the nineteenth century, a central inspiration for Piaget (Oelkers 1996) and the development of child psychology, and a milestone for progressive education.

Of central importance are Rousseau's dualisms and thus his language. He stresses contradictions and paradoxes between nature and society, men and citizens, children and adults, and, not least, male and female. Even John Dewey, who rejected dualism, accepted that Rousseau—and only Rousseau—was the founder of the theory of 'natural development' (Dewey 1985, 211ff.) as opposed to artificial schooling, and was thus to be read in a dualistic manner. Educational theorists are irritated by Rousseau, who is regarded as a 'classical writer' of education (Rorty 1998) *because* of the unsolved paradoxes. Rousseau's concept of education makes no attempt at solving the paradoxes and dilemmas, but leaves them open, thus puzzling readers with keen contradictions which are right and wrong at the same time. What counts for Rousseau is not logic but the heart, and this seems to be part of his success. His radical conclusions seem to be obvious: politics within a new society following the education of 'new man' according to his own true nature. The famous ascription to 'return to nature,' which was part of the nineteenth century's reading of Rousseau and nowhere stated by him directly, was regarded as the emancipation from alienation, and thus a project of the left. But Rousseau was at the same time radical *and* conservative—stating that society should return to the golden age, education should leave schooling for true nature, man should be first man and then citizen. It is this rigor without reality that fascinated Rousseau's readers—disciples as well as opponents.

Rousseau's theory of education is provocatively puzzling: 'negative education' has no objective, and nature develops itself. However, the learning process is subject to extreme regulations (Rorty 1998, p. 248). The present should not be made a victim of the future (Rousseau 1969, p. 309), but every form of education is a deal with the future, and this is true for Rousseau's theory too: the ages of childhood and of youth are

clearly defined, as are the phases of education, so nature is not chance but necessity, aiming at the future. Children should be educated in a manner solely dependent on *things* (p. 311), yet the governor dominates the whole of Emile's education. Nature should lead the way (p. 259), but every effort possible must be made to avoid the first wrong step (p. 317). Children stand like savages outside the law and are completely natural (p. 320), but education must take everything in hand so as to exclude chance (p. 342) without being able to act solely on the basis of the necessity of nature. The first education should be that of the senses alone (p. 380), but that requires a rational plan of education which cannot simply be drawn from nature. In consequence Rousseau's educational scene is one of extreme regulation: Emile does not play, he does not develop anything of his own and is not allowed to listen to music, and his learning differs in every way from 'amusement' (p. 407). According to Rousseau, education should be 'realistic' (p. 418) and this is possible only when undertaken in an extremely artificial manner. Because society is excluded, educational rigor can rule. The basis for this is nature in the sense of self-love (*amour de soi*). Self-love is always good and always in compliance with the natural order (p. 491)—which begs the question why education does not concentrate fully on this *amour de soi*.

Rousseau wrote the counterclaim to sensualistic educational theory, which dominated the pedagogy of the eighteenth century. Children, according to Rousseau, should not be viewed as empty vessels or *tabulae rasae*, but instead as parts of nature which develop of their own accord. Children cannot simply be influenced, and education is not merely the establishment of habits and customs; moreover, it is the child's nature that limits all education. This fundamental concept is weakened by the implicit sensualism, the education of the senses (Rousseau 1969, 415ff.) that is necessary because education is inconceivable without any influence. But the provocation remains, and it defines Rousseau's standing as an educational author. Education is limited by nature, nature has nothing to do with sin, the child is innocent because of nature's original goodness, thus education can take place without any of the burdens of history and society. It is a renewal of mankind with every new child. This is the fundamental basis of Rousseau's theory, which is still read and discussed today because it provokes and stimulates educational thought without attempting to solve the puzzles. Rousseau is read today because he defines the problems, not their solutions.

Rule of Law

The rule of law is commonly understood in contrast to arbitrary exercise of power, which is, above all, the evil that the rule of law is supposed to curb. The rule of law, though not always the specific verbal formulation, embodies ideals that have been central to political and constitutional discourse at least since Aristotle, who contrasted 'the rule of the law' with 'that of any individual.' In any of its many versions, the meaning of the rule of law is contested; all, however, share the idea that law can and should contribute in salutary, some say indispensable, ways to channeling, constraining, and informing—rather than merely serving—the exercise of power, particularly public power.

The antagonistic juxtaposition of rule of law and arbitrariness has led many jurists to view the rule of law as a purely negative ideal (Raz 1979), devoted to 'damage control' (Shklar 1998a, p. 5), particularly damage done by government. However that view is not universal. Several writers (e.g., Allan 1993, Dworkin 1985, Selznick 1999) offer a more affirmative, morally ambitious account of what is required to govern according to the rule of law. Negatively, constraint by clear legal rules is central. Positively, space needs to be made to include underlying principles of morality and purpose in legal systems. The differences between these views go deep, involving larger differences over the nature and the point of law. This account begins with the better known negative conception, but seeks to point beyond it.

1. Elements of the Rule of Law

1.1 Scope

Central to most conceptions of the rule of law is the conviction that there should be no privileged exemptions to it. Everyone comes within the scope of the law, even those who make it. This has a political and a social aspect.

1.1.1 Government under law. The political aspect of rule of law is that governments and public officials are subject to the existing law. Legislatures can of

course change law, but even 'sovereign' legislatures must comply with existing law so long as it remains in force, and can only change it in conformity with existing higher-order legal rules. To make this subjection effective, there must exist legal ways of challenging and forcing the government and political officials, even the very highest, to submit to the law.

There have been many polities in which the ideal of subjecting government to law was unknown and would seem outlandish. Even where the idea exists, the extent to which it is realized within a political order will vary markedly between polities and over time. It is, after all, a complex ideal even more complex to realize, not a faithful description of a state of affairs. Where the ideal is professed or understood, differences in attainment are crucial indicators of the sway of the rule of law. To the extent that the idea or the practice is lacking, so is this crucial element of the rule of law.

1.1.2 Equality before the law. The social aspect of the rule of law is the equal subjection of all citizens to the law. This, it was traditionally thought, required that law should take the form of an 'abstract rule which does not mention particular cases or individual nominated persons, but which is issued in advance to apply to all cases and all persons in the abstract' (Neumann 1986, p. 213; see also Hayek 1960, Oakeshott 1983). This is to prevent the use of law against specific groups or individuals, by making all equally liable, in advance, if they come within its terms. A corollary is that adjudicators should then weigh, impartially and impersonally, legal issues that come before them on the basis of such laws. They should be 'blind,' as the bearer of the scales of justice is classically represented, to inequalities of status, power, wealth, and other resources.

These conditions are the source of much controversy. Contemporary law associated with the welfare and regulatory activities of modern governments is frequently neither general nor abstract but targeted, detailed, and specific. A matter of continuing controversy is whether these forms of law are compatible with the rule of law (Hayek 1973–1979, Kamenka and Tay 1975, Neumann 1986, Oakeshott 1983, Unger 1976, but see Selznick 1992, 1999); if so, how, and if not, what should be sacrificed to what. A matter of even longer dispute is whether such formal equalization counts for much if it merely leaves substantive social and economic inequalities to play themselves out with more significant effect, and even if the legal arena allows or ensures that the 'haves come out ahead' (Galanter 1974). Liberals have commonly believed that the existence of social inequalities does not cancel out the worth of the rule of law, and may even make its impartiality more significant; precisely because inequalities confer advantages in the world,

they should not do so before the law. Many on the political left disagree, arguing that differences in the world render the 'blindness' of the law false or inconsequential, or both.

1.2 Character

A second element of the rule of law has to do with the character of laws. It can be expressed with minimal and deceptive simplicity: 'the law should be such that people will be able to be guided by it' (Raz 1979, p. 213). Reflection on that simple condition can generate tomes; it has certainly generated lists (see Fuller 1969, Raz 1979, Walker 1988). In order that law guide behavior, it must exist, that is, it must take the form of general requirements, typically rules, that people can consult before they act. Even where it exists, it will not guide behavior unless its requirements can be known. Therefore it must be public, understandable (by someone—it might take a lawyer), and relatively clear and determinate in its requirements. These requirements must be possible to perform. So the law cannot be internally contradictory (more accurately, the legal system must provide ways to resolve contradictions which inevitably occur). It must be prospective, for if it is retrospective people will neither know it, nor be able to rely on what they do know for fear of it being retrospectively changed. It must be relatively stable, for if it were constantly to change people would be reluctant to trust any present incarnation. Exercises of public power made unannounced, or announced in peremptory or arbitrary decrees, retrospective in effect, in ignorance or in violation of existing law, defy the rule of law.

Of course, whatever the character of the laws, the rule of law will amount to little unless laws are taken seriously, and enforced. So the law must be authoritative, that is, taken as binding by those whom it claims to bind. To make it so, it must be treated so, at least by the legal institutions that administer it, and it must be administered in ways that conform to its publicly announced terms.

1.3 Institutions

In the most influential English account of the concept in the last several centuries, Dicey (1961) took the rule of law to be a peculiarly English virtue associated with peculiarly English institutions, unavailable across the Channel but successfully implanted across the Atlantic. From what Judith Shklar aptly describes as this 'unfortunate outburst of Anglo-Saxon parochialism,' the rule of law emerges, 'both trivialized as the particular patrimony of one and only one national order, and formalized, by the insistence that only one set of inherited procedures and court practices could sustain it' (Shklar 1998b, p. 26).

As an ideal of some degree of generality, longevity, and abstraction, however, the rule of law is tied neither to any one national experience nor to any set of institutions. Rule-of-law regimes have often embodied different judgments about how to implement rule-of-law ideals, and have been realized within different legal and other histories and traditions that have influenced the particular shapes of the institutions that emerge. Institutional variety and possibility are too rich, and local traditions often too dense and particular, for it to be fruitful to identify the rule of law with just those particular institutions and arrangements which seem to work at home. Moreover, even within one society, problems change, and so do the solutions most appropriate to solve them. These differences are not automatically fatal, since the rule of law is not a recipe for detailed institutional design. It is rather a value, or an interconnected cluster of values, which might inform such design, and which might be—and have been—pursued in a variety of ways (see Selznick 1999).

This is not to deny that the ideal has been better served in some nations and by some institutions than by others. Institutional learning can and does occur. Some arrangements have been shown to work well in many contexts; others less so or only in some contexts. It is, therefore, appropriate to ponder the relationship between particular, realized, institutional forms, and rule-of-law ideals. Success does not, however, depend upon faithful mimicry (for even if whole institutional complexes could be duplicated, it is another job to graft them), and it often thrives on innovation, even misinterpretation. Montesquieu understood the English to have prospered because of the institutional separation of powers he mistakenly attributed to them. Even though this was not quite so, the Americans were so impressed with the philosopher's account that they institutionalized a strict institutional separation of powers embedded in that other American innovation in aid of the rule of law, a binding, written constitution. They have been widely copied. The details vary, but there is a rather simple and generalizable institutional insight at the bottom of this: at the very least, those who judge the legality of exercises of power should not be the same as those who exercise it; and they should be shielded from interference. This is why the separation of the judiciary from other branches of government is seen as central in rule-of-law states, even where they do not follow America in other aspects of the separation of powers. It is also why the rule of law is thought to depend on measures to secure the independence of the judiciary from political and other pressures. Further resources, often institutional traditions and conventions as much as written laws, are important in order to ensure that judicial decisions are grounded within plausible interpretations of existing laws. Institutional measures to guarantee litigants a fair hearing are also crucial. Access to legal institutions should be available to those who would make use

of them. The details can go on forever, but it is better not to amass them aimlessly, as though such means, rather than the values that inspire them, were the point. Rather, it is preferable to think to them in their particular contexts, from the stand point of the idea of the rule of law, and of the values it is thought to serve, together with close, but not slavish, attention to stories of institutional success and failure.

1.4 Legal Culture

As lawyers often forget, but social scientists never should, the rule of law depends upon more than the scope, character, and institutions of the law. It also depends upon a host of—apparently ‘soft’ but actually crucial—cultural supports, among them socialization into the values of the rule of law, at least of the professionals who have to administer it, and assumptions more or less widespread in the society that laws do and should count. Such assumptions are commonly revealed in the degree of willingness to use laws ‘on the books’ to protect and advance one’s interests, in demand for law as much as in supply as well as in levels of unreflective but routine law abidingness in a society. These crucial aspects of legal culture and practice are variable among and within societies and we know little about how to affect them in ways that might advance the rule of law. Lawyers give more thought to laws and institutions than to what might be necessary to make them count, but if no one is listening it does not matter too much what the law is saying. And who listens, why and how, and with what effects are empirical questions to which the law offers few answers, though the sociology of law might. If the answer is ‘only lawyers,’ the rule of law is not in good (see Örkény 1999).

2. The Value of the Rule of Law

Though the rule of law carries the patina of age and the danger of congratulatory cliché, what it expresses are not truisms. Neither the goal nor the means of the rule of law are self-evident goods. Many have thought that what mattered was who had power, not whether or how that power might be constrained. Indeed, if the right people had power, they should be unconstrained. Charismatic leaders, as Weber points out (1968, p. 243) are the sort who say ‘it is written ... but I say unto you ...’; often they have been happier when ‘it’ was not written at all. Nor was it, for example, a Russian tradition that the ruler, whether Tsar or Party, should be constrained, either by laws or to produce laws.

For anarchists, on the other hand, constraint was not enough. Institutions of public power had to go; this was Marx’s long-term view too. In the meantime,

like many radicals, he considered fraudulent those claims that law significantly restrained the power of the powerful within capitalist societies. In bourgeois societies, many Marxists have alleged, the rule of law is an ideological mystification which masks the truth: that the bourgeoisie rules, typically with aid of the instruments of law (see Krygier 1994). Many subsequent ‘critical’ thinkers, Marxist or not, have tended to agree on this point.

In the modern world, it is the liberal tradition that values the rule of law most highly. Liberty being central to liberalism, liberals are concerned with ways of averting threats to it and with securing it. An overarching source of such security is taken to be the rule of law. What is at stake here?

2.1 Freedom from Fear

According to Thomas Hobbes, fear of others is what drives people to agree to subjection to a political sovereign, and in turn justifies that subjection. The sovereign, by being empowered to issue and enforce laws, saves us from others, and them from us. Moreover, and therefore, it saves us and them from a major reason to fear each other. When we all are equally subject to known laws, both we and they have assurances which would otherwise be unavailable.

Many thinkers who agree with Hobbes on little else agree with him that this is a necessary and salutary work for states to do. But as John Locke observed, if we have reason to fear our neighbors who are just individuals, how should we avoid terror of that ‘mortal God,’ the state, which Hobbes called Leviathan? The solution is to arrange an institutional order which both consolidates power, and then curbs it, so preventing its arbitrary exercise; the challenge is to achieve such a solution. One very old attempt to achieve it—suggested by liberalism though not its invention—is to require rulers to operate under law, and by means of laws of a character that conforms to the rule of law.

The stakes on this view are high. According to those belonging to the tradition Judith Shklar calls the ‘liberalism of fear,’ we have a simple and stark choice,

a very basic dichotomy. The ultimate spiritual and political struggle is always between war and law. ... The institutions of judicial citizen protection may create rights, but they exist in order to avoid what Montesquieu took to be the greatest of human evils, constant fear created by the threats of violence and the actual cruelties of the holders of military power in society. The Rule of Law is the one way ruling classes have of imposing controls upon each other (Shklar 1998b, p. 25).

Reflecting on the blood-stained twentieth century, the eminent Marxist historian E P Thompson voiced similar sentiments, in the process scandalizing many

other Marxists, who traditionally had little time for law. He insisted that

the rule of law itself, the imposing of effective inhibitions upon power and the defence of the citizen from power's all-intrusive claims, seems to me to be an unqualified human good. To deny or belittle this good is, in this dangerous century when the resources and pretensions of power continue to enlarge, a desperate error (Thompson 1977, p. 266).

What Shklar, a lifelong liberal, and Thompson, a somewhat rueful Marxist or ex-Marxist, share is the insistence that the value of the rule of law lies primarily in what it shields us against. When they warn complacent beneficiaries of the rule of law to value what they have, it is by comparison with the perils that they believe to flow from its lack.

2.2 Coordination and Cooperation

Fear is not, however, the only reason for the rule of law, nor is government its only subject. We all are. Madison wrote that if we were angels we would not need any laws. Unfortunately, so the familiar argument goes, we are not, so we do. However, even angels and indeed all but the omniscient, particularly if there are a lot of them about, might benefit from the rule of law. We can all become confused and lose our way, not necessarily due to our or others' evil but merely to the superfluity of possibilities in an unordered world. All the more when that world is, as ours is, one of large and mobile societies full of strangers, where ties of kinship, locality and familiarity can only partially bind, reassure, or inform.

The predicament of a member of such a 'civilized' society, identified by Adam Smith in the eighteenth century, is that he 'stands at all times in need of the co-operation and assistance of great multitudes, while his whole life is scarce sufficient to gain the friendship of a few persons' (Smith 1981, Vol. 1, p. 26). The rule of law can provide crucial information and security, 'a basis for legitimate expectations' (Rawls 1971, p. 238), without which the 'co-operation and assistance of great multitudes' will necessarily be a more chancy affair. It enables fellow citizens to know a good deal about each other, though many of them are strangers, to coordinate their actions, and to feel some security and predictability in their dealings with them. For though it does not make everything predictable, it ties down much that would otherwise be up for grabs. It establishes fixed and knowable points in the landscape, on the basis of which the strangers who routinely interact in modern societies can do so with some security, autonomy, and ability to choose.

To the extent that a legal system approximates the ideal of rule of law, citizens have, or can obtain, in advance, clear understanding of their and others' legal obligations, and they can reasonably have faith that

the law will constrain other citizens and officials of state in ways that they can predict. Rules of the road are an example; everyone has to obey them, and everyone suffers from confusion, or a good deal worse, if they do not apply to all, are retrospective, secret, incomprehensible, contradictory, require the impossible, or are corruptly administered. If laws do not suffer from these defects, citizens share intersubjective cues as to the rights and responsibilities of people they might know little else about. These are invaluable cues (and clues) to have.

3. Justice

On the account so far, and according to many writers, the rule of law might provide certain basic conditions for a society to exist free of certain fears and informed of certain things, but it has little to do with the moral quality of what goes on there. According to one prominent interpretation, there is no special connection between the rule of law and higher values such as justice. The former merely sets out principles of legal efficacy, such as those one might address to a knife-maker: 'make it sharp'; or to a poisoner: 'make it kill quickly and quietly' (see Hart 1965, p. 1286). What it is used for is a quite separate question. Moreover, proponents of this view point out that the rule of law is perfectly compatible with iniquity in the content of laws. The Republic of South Africa, prior to 1989, is a common example in this connection. On the other hand, it is common for there to be a 'general and drastic deterioration in legality' (Fuller 1969, p. 40) when despots do their worst, and there is no surprise in that. There is nothing in the logic of despotism that inclines it to respect the rule of law, and there are many costs in doing so for which there is no despotic rationale. So at the very least one might claim a strong empirical inconsistency between horrific government acts and the rule of law.

Many writers might concede this, but still agree with Joseph Raz that 'the rule of law is a purely negative value. It is merely designed to minimize the harms to freedom and dignity which the law may cause in its pursuit of its goals however laudable these may be' (Raz 1979, p. 228). However, as we have seen, the rule of law has a horizontal function—in facilitating interaction and cooperation among citizens—which is as important as its vertical one—in relation to governments. To the extent that it performs the former role, it goes well beyond the merely negative virtue that Raz allows it.

By contrast to this negative conception, another tradition has it that the rule of law is altogether more, and more morally charged, than mere formal or procedural regularity. For Ronald Dworkin, the rule of law 'is the ideal of rule by an accurate public conception of individual rights' (Dworkin 1985,

pp. 11–12). That will often involve formal regularity, but not only, and not always. For Philip Selznick, the constraints emphasized in the formal conception are precious and need to be respected for what they secure. Yet the weight given to formality in the rule of law might generate vices of its own—particularly that of blindness to particularity—that subvert the doing of justice that the rule of law might otherwise be thought to support.

Even apart from the high price of exaggerated ‘legalism,’ legal systems are not always or only threatened by unrestrained power. There are other sources of arbitrariness in social life, and among them can be a refusal to take account of particulars to which rules are being applied. Moreover, in well established legal systems, with strong rule-of-law institutions, traditions, and legal expectations, there might well be room to vindicate larger values carried within the principles, traditions and purposes of law, in the service of a ‘higher instrumentalism’ which is not limited to, but need not necessarily subvert, a legal order whose injunctions overall are clear, predictable, and obeyed.

According to this view, formal regularity should not be the limit of one’s ambitions for the rule of law. Rather, it should be supplemented by a

thicker, more positive vision [that] speaks to more than abuse of power. It responds to values that can be realized, not merely protected, within a legal process. These include respect for the dignity, integrity, and moral equality of persons and groups. Thus understood, the rule of law enlarges horizons even as it conveys a message of restraint (Selznick 1999, p. 26).

The move from negative to positive conception, on Selznick’s view, is not merely a matter of normative expansion. It has a sociological basis and plausibility, for

we cannot really separate the negative and positive aspects of the rule of law. Indeed it would be highly unsociological to try to do so, for we would then miss the moral and institutional dynamics which create demands for justice, and which induce rulers to accept accountability (1999 p. 25).

One objection which the first, agnostic, interpretation has to the second, justice-impregnated one is that it threatens to do away with the specificity and usefulness of the concept:

[i]f the rule of law is the rule of the good law then to explain its nature is to propound a complete social philosophy. But if so the term lacks any useful function. We have no need to be converted to the rule of law just in order to discover that to believe in it is to believe that good should triumph (Raz 1979, p. 211).

Yet there is a space between a purely procedural account of the rule of law, whose only connection—if

any—with virtue is external, and one that wipes out the distinction between the rule of law and the rule of good law. Legal orders typically embody and generate certain values, both in their animating principles and in the complaints they provoke when their practices flout the values that give them legitimacy. These include values such as due process or natural justice and, in particular legal traditions, much more. The rule of law might well be argued to be incomplete to the extent that such values are not honored. Attempts to vindicate such values, often implicit in legal principles and traditions if not in rules, might be considered a service to the rule of law, even if it goes beyond purely procedural fairness and notwithstanding that it might fall short of justice more globally conceived.

4. *Tensions and Challenges within the Rule-of-law Ideal*

Like most important ideals, the rule of law contains internal tensions and can lead to conflict with commitment to other social ideals, because the ideals themselves are under strain, or because different interpretations of the same ideal, or attempts to realize different ideals, have different institutional logics. Thus, whether one thinks it an assault on the rule of law, or a vindication of a particular vision of it, the law generated by an active welfare state sits ill with some of the procedural conditions mentioned earlier. The simplest ways to deal with such tensions is to hold fast to one interpretation of one ideal and reject whatever might compromise it in another (Hayek 1973–79, Walker 1988). Another is to minimize the conflict and pretend that no price is being paid. More complex, but perhaps more realistic, is to acknowledge that the rule of law is not consistent with every value that one holds dear, and that, consequently, compromises in one or other direction might be unavoidable. We ask many things of law, as we do of life, and not all of them are consistent with each other. The rule of law is a mighty source of good in large modern polities, but not the only source, nor one which is automatically better the more you have of it. If power in a polity is unconstrained, the negative conception of the rule of law speaks to precious virtues, the absence of which can be vicious. But if power is already substantially constrained by law, the rule of law might tolerate, even on occasion require, that some space be made for wisdom, judgment, particularity, and substantive justice.

All the more is this the case, if one amplifies the lawyer’s and philosopher’s understanding, of what law does and how it does it, with what might be gleaned from other social sciences. Sociology of law does not suggest any linear connection between the rigidity and precision of laws and their real-world

reliability (see Bardach and Kagan 1982). Social causation is too complex, and the mediation and supplementation of formal by informal institutions, norms, and social practices too pervasive, for such a connection to be plausible, or for the extrapolations of legal dogmatics to carry much explanatory or predictive weight.

Yet those who sought the protection of the rule of law against abuse of power and social disorganization were onto something precious. Our experience of despotism, and of rule-less chaos, gives us good reason to take their exhortations very seriously indeed. Our experience, however, of incompetence, legalism, and arbitrary manipulation of hard-edged rules, even by non-despots, gives us reason to be suspicious of too narrow an understanding of the rule of law, or, if that understanding appeals, not to exaggerate its proper reach.

Rules in the Legal Process

The ancient Romans had two words for law: *lex*, the specific rules written in statute books, and *ius*, enduring principles of justice. Contemporary 'legal positivists' view *lex*, the legal rules made by legislatures, courts, and administrative agencies, as the essence of law, and those legal rules are the focus of this article. Yet the idea that law also includes a body of principles, in some sense superior to the rules written by the current political regime, persists in many modern languages, in legal theory (Dworkin 1967, Fuller 1964), in popular consciousness (Ewick and Silbey 1998), and in the recurrent political effort to entrench 'higher law' principles in written constitutions.

To distinguish rules from principles, legal scholars emphasize the specificity and binding quality of legal rules. Thus, Lawrence Friedman (1975, p. 26) defines a legal rule as 'a proposition of law couched in general terms,' consisting of a statement of facts and a statement of the legal consequences which follow from those facts, for example, 'Any person who drives a motor vehicle through a red light is guilty of a violation and shall be fined \$50.' Social scientists, on the other hand, focus on the distinction between legal rules and customary rules or social norms. Thus Max Weber

defined legal rules as norms which have some likelihood of being enforced coercively by an officially-designated staff of legal officials (Rheinstein 1954, pp. 1vi, 14–15), a definition that emphasizes the political origin of legal rules and the contingencies surrounding their actual use.

1. Types of Legal Rules

Legal rules can be unwritten, as in preliterate societies (Hoebel 1964), or written and published, as in larger, literate political systems. Some legal rules are specific, such as those which prohibit driving over 60 miles per hour, while others, such as those that impose liability for accidents caused by driving ‘unreasonably dangerously,’ articulate vague standards. Highway speed limits are primary rules, designed to regulate ordinary citizens and businesses. Secondary rules, in contrast, guide the making and application of primary rules by government officials and judges (Hart 1961). Thus secondary rules—often stated in constitutions as well as in statutes—prescribe which officials have authority to make speed laws (and other laws) for a particular territory, who has authority to enforce them, who has authority to adjudicate disputes about their proper application, and who has authority to build the roads and install traffic lights. Other secondary rules govern the making of rules by legislatures, while ‘procedural rules’ govern the process of litigation and adjudication. In political systems that value the rule of law, one fundamental secondary rule is that legal officials must be guided in their decisions and actions by pre-existing, publicly accessible primary and secondary rules.

From a sociolegal perspective, it is useful to distinguish ‘high consensus’ legal rules (such as statutes condemning theft or breach of contract) from rules that are politically, morally, or economically controversial. Controversial rules are generally much harder to enforce than high consensus rules, and they pose more difficult moral dilemmas for officials and judges who are expected to enforce them.

2. The Political, Social, and Institutional Functions of Legal Rules

The most obvious function of legal rules is to serve justice, increasing the likelihood that different decision-makers will treat like cases alike. Political scientists, however, emphasize the political control function of legal rules (Farber and Frickey 1991): political authorities entrench their policy choices in statutes and administrative rules to increase the odds that those policies will be implemented uniformly by far-flung bureaucrats, law enforcement officials, and judges. For political authorities, legal rules also serve a broader communicative function, informing citizens

and businesses about their obligations and the decisions they might expect from government administrators, law enforcers, and judges. A tax code provides a familiar example. In consequence, legal rules often are said to have a constitutive function, shaping citizens’ conceptions about what is fair, permissible, and proper (Sarat and Kearns 1993, Edelman and Suchman 1997, pp. 503–6, Kagan and Skolnick 1993).

By imposing controls on administrative officials, police, and judges, legal rules tend to serve a useful function for the citizenry: restraining official power, at least in the sense of making it more predictable. Published legal rules provide criteria for holding officials accountable via judicial review or public criticism. For this reason, legal rules, when combined with a credible governmental commitment to adhere to them, serve yet another function: adding legitimacy to governmental and judicial authority—which helps explain their ubiquity in the governance of nation-states. To Karl Marx and to contemporary ‘critical legal theorists’ (Kennedy 1997, Kairys 1982), this legitimating function has an ominous side, shrouding repressive policies (and, one might add, nonrepressive policies) and coercive penalties in the language of neutrality and restraint of power.

In contemporary democratic countries, legal rules are not infrequently remade in response to popular political movements, litigation by public interest law firms, and electoral competition. Hence they have still another function: protecting individual rights. Partly because legal rules lend a graspable concreteness to general ideals and notions of justice, ordinary citizens can brandish them as shields and swords against government officials, businesses, and fellow citizens, both in and outside of court. This is the function referred to by the ancient Greek playwright Euripides in *The Suppliant Women* when he has Theseus praise the development of written codes of law:

Once written laws exist
People of few resources and the rich
Both have the same recourse to justice. Now
A man of means, if badly spoken of,
Will have no better standing than the weak;
And if the less is in the right, he wins
Against the great.

Many sociolegal scholars would argue that Euripides praised written legal rules too fulsomely. For as rules accumulate within a legal system, acquiring complicated subsections and qualifying clauses, they make the legal process so complex that it becomes inaccessible unless one can afford a lawyer. Rather than guaranteeing equality, therefore, contemporary legal systems tend to provide an advantage to sophisticated, better-financed litigants (Galanter 1974). Many sociolegal scholars might have Thrasymachus (the legal cynic of Plato’s *Dialogues*) respond to Theseus by saying something like this:

All written laws are parchment words

Whose import shifts in each man's mind.
Thus Justice is tossed this way and that from
Judge to judge, and advocates with clever minds
Oft bend the law to serve their wealthy friends.

After communist revolutions in Russia and Cuba, new regimes established 'people's courts' in which lay judges, freed from 'bourgeois' legal rules, were to 'do justice' based on the community's sense of fairness and social good. But the unhappy experience of 'socialist justice' (Markovits 1986, Hendley 1996, Krygier 1990) reminds us that written legal rules have an important political function: preserving judicial autonomy and blunting the risk of tyranny. Moreover, the 'peoples' courts' experience suggests that Theseus was probably more correct than Thrasymachus. Except in homogenous, slow-changing societies, an adjudicatory system based on written legal rules, however imperfect, is likely to approach predictability and even-handedness more closely than systems that eschew fixed rules.

Finally, legal rules enhance the efficiency of legal processes. When legal rules are clear and predictably applied, they become weighty 'bargaining chips' in negotiating settlements before or during litigation (Mnookin and Kornhauser 1979) and hence most disputes can be resolved without adjudication, while litigation is more costly when legal predictability declines (Priest 1993).

3. The Dilemma of Rules and Discretion

Because human activity is varied and changing, legal rule-makers suffer from relative ignorance of fact and indeterminacy of aim (Hart 1961, p. 125). Rules, therefore, are often underinclusive and often over-inclusive—that is, covering activities that are irrelevant or marginal to the primary evil that the rulemakers wished to deal with. Thus, if a motor vehicle code states 'Any person who drives a motor vehicle through a red light is guilty of a violation and shall be fined \$50,' it ostensibly compels punishment of a motorist who proceeds carefully through a malfunctioning traffic light which is stuck on red, or an ambulance driver rushing a patient to the hospital (Goffman 1971 p. 102). To apply the rule in such cases is disparaged as legalism (Friedman 1975, pp. 247–8, Nonet and Selznick 1978). Rule-based decision-making can lead to legalism because rules, in their quest for neutrality, often disregard individual litigants' special attributes and circumstances; this makes it easier for officials to apply law's coercive powers, but blunts their sensitivity to justice claims not embodied in the written rules (Noonan 1976).

Many governments seek to prevent the anger generated by legalism by granting legal officials some discretion to make exceptions. American criminal prosecutors, for example, can generally decline to prosecute violations of the law 'in the interests of justice.' Juries, by virtue of the secrecy of their

deliberations, can decline to convict when they feel justice requires it (Kadish and Kadish 1973). Another antidote for legalism is to substitute general standards for very specific rules; for example, requiring custody decisions to be based on 'the best interests' of the particular child, taking all relevant facts and considerations into account. Yet granting scores of frontline decision-makers discretion to suspend rules or use their own judgement in implementing vague standards recreates the risk that legal rules were invented to reduce; that is, decisions that vary across different individual decision-makers or erode official policies.

Most legal institutions, therefore, employ a mix of rule and discretion (Mashaw 1983). Some, such as tax collection agencies, may be instructed to emphasize rule-based decision-making, while others, such as juvenile courts or patent offices, may be allowed to rely on experienced legal decision-makers to apply general standards sensibly and consistently. Generally, an institution's legal rules are more prescriptive when lawmakers and politically potent interest groups do not trust it to make acceptable decisions. Thus American regulatory statutes, regulations, and permits often contain more prescriptive legal rules than their Western European counterparts (Rubin 1997, Kagan and Axelrad 2000, Rose-Ackerman 1995, Vogel 1986).

4. Can Legal Rules 'Decide Cases?'

Beginning with the American 'legal realists' of the 1920s and 1930s (Ackerman 1974, White 1972, Twining 1973), some scholars have contested the assumption that judges can be 'bound' by pre-existing legal rules. In political science, adherents to the 'attitudinal model' hold that each judge's own political values are the best predictors of individual decisions (Rowland and Carp 1983, Spaeth and Segal 1999). More fundamentally, legal philosophers refer to the 'indeterminacy' of legal rules, arguing that no matter how long one stares at the words of a constitutional bill of rights, a statute, or a set of judicial precedents, the words alone cannot determine which of two conflicting interpretations (and legal outcomes) in a particular case is 'correct.' Moreover, in complex legal systems, it is argued, decision-makers inevitably use their own judgment in deciding which of many rules or precedents 'applies' to a case. The implication is that all legal decisions are policy decisions, rationalized only after the fact by reference to one particular rule or rule interpretation.

Other scholars, however, argue that within any particular legal institution—a national judiciary, an administrative agency—legal professionals reduce indeterminacy by assigning mutually understood meanings to the rules they work with. They learn to do so through social interaction: in law school classes and legal argument; by explaining and defending their rule

interpretations to others; by absorbing institution-specific conventions concerning the purpose of particular rules; and interaction with senior officials or higher authorities who resolve disputes about particular cases. Conventional methods of rule application become part of the socially constructed role of 'judge,' 'regulatory inspector,' or 'police officer.' Legal officials are socialized to regard adherence to their institutions' processes or rule interpretations as obligatory, as essential to their legitimacy as power wielders and their identity as legal professionals (Fuller 1958, Dworkin 1967, Kagan 1978, pp. 88–90, Feeley and Rubin, 1998, p. 338, Kennedy 1997). Indeed, in complex, pluralistic societies, legal officials often find adherence to rules a comforting practice, relieving them of the sense of personal responsibility for decisions which disappoint claimants or impose harsh penalties. Legal officials who stray from their institution's conventions learn that their decisions can be criticized or reversed; thus even judges who wish to maximize their policy preferences must act strategically, avoiding decisions that cannot be linked to plausible interpretations of existing rules (Epstein and Knight 1998).

Conventional rule interpretations do not dictate the result in every case, or totally suppress the individual decision-maker's inclination to decide each case as the decision-maker personally thinks best, but they substantially restrain those impulses. The amount of constraint depends on the degree of homogeneity and hierarchical supervision in particular legal institutions, and on whether the legal rule in question is highly specific (as in highway speed limits) or is complex, requiring the weighing of many facts (as in a standard demanding payment of 'compensation' for accidents caused by 'negligent' driving). Yet even in the US Courts of Appeals, where politically appointed Republican and Democratic judges usually divide on party lines in the 20 percent of cases that generate dissenting opinions, in the other 80 percent judges with different political preferences agree on which legal rules and precedents are controlling (Gottschall 1986). A stark illustration of the constraining effect of 'interpretive communities' and socially constructed judicial roles is provided by Cover's (1975) account of American judges in Northern states in the 1850s; they returned escaped slaves to Southern 'slave-catchers,' notwithstanding the judges' (and their communities') moral opposition to slavery, because a recently enacted federal statute seemed so clearly to require that painful action.

5. *Styles of Rule Application*

For many judges and administrative officials, decision-making is a two-step process: the decision-maker first 'looks backwards' to pre-existing rules to discern what they seem to require, but then 'looks forward' to

assess the consequences of the rule-based decision in terms of the decision-maker's understanding of fairness or good public policy (Cardozo 1921, pp. 19–25, Wasserstrom 1961, Kagan 1978). Even if he feels the rule-based decision would not 'make sense,' he might nevertheless feel bound to follow the rule; that would be a legalistic decision-making style. In another style—unauthorized discretion—decision-makers ignore the rule and follow their own judgment (Kagan, 1978, p. 93). A third style, retreatism, is to temporize, push the parties to settle the dispute, or find other ways of avoiding hard decisions. Finally, in what has been called legal policymaking, the legal decision-maker reinterprets the pre-existing rule, adopting innovative readings or principled exceptions which support the preferred outcome (Feeley and Rubin 1998).

Which of these four modes of rule application predominate in a legal institution is influenced by the political system and the legal tradition in which it operates. Common law systems appear to allow judges more scope for creative rule interpretation than Western European judiciaries, which are more closely bound by statutory codes and legal treatises (Damaska 1986). Yet judicial policymaking does occur in civil law judiciaries, such as France's (Lasser 1995), and common law judges in Great Britain tend to feel more tightly bound by existing precedents than their counterparts in the United States—partly because American legal training encourages a more policy-oriented mode of legal reasoning, and partly because the fragmentation of lawmaking power in the United States makes judges less vulnerable to prompt 'overrides' by the legislature than are judges in parliamentary systems (Atiyah and Summers 1987, Damaska 1990).

Rule application styles also vary across legal institutions in the same legal system. Variations in local political culture produce different rule enforcement styles in different police departments (Wilson 1968), criminal courts (Levin 1972), and regulatory agencies (Hutter 1988). Variations in rule application also arise from the personality, role conceptions, and political commitments of individual decision-makers; from the skill and persistence with which particular parties or their legal advocates present their arguments; and from the likelihood that the decision will be reported in the news media or subjected to professional review and criticism. US Court of Appeals judges are less likely to decide cases on the basis of their political values when they serve on panels with judges from another political party (Cross and Tiller 1998). Regulatory agencies tend to enforce rules legalistically when they are subjected to public criticism for perceived laxity (Bardach and Kagan 1982) and to adopt a retreatist style when potential complainants remain silent or violators enjoy the backing of political authorities (Gunningham 1987). Legal officials are more likely to bend the rules when they confront individual subject face to face, as in 'streetcorner

bureaucracies' (Lipsky 1980) than when decision-making is based on paper dossiers or occurs in highly formal settings (Kagan 1978, p. 152). Overall, the way that legal rules are employed is shaped by the interaction of a legal institution's political environment, its clientele, its legal culture, and its mode of recruiting, training, and evaluating its personnel.

Rumors and Urban Legends

Rumors may be defined as unverified or false brief reports (*rumors*, strictly speaking) or short stories (*urban legends*) with surprising content. They are passed on among a social milieu as true and current and expressing something of that group's fears and hopes.

1. Mythology and Ethics of Rumor

Ancient civilizations bequeathed us a mythological and ethical concept of rumor. In *The Aeneid* (IV, 173–197), Virgil (first century BC) personifies the rumor through the features of the goddess Fama, a monster with innumerable eyes, wings, ears, and mouths, and a swift messenger of truth and falsehood. This fabulous description gave inspiration to Shakespeare for *Henry IV* (1598), in giving *Rumor* a character of its own, its costume covered with painted tongues. Judeo-Christian tradition reproves gossip as a sin, ranking it with slander. The Talmud puts *lachen hara* ('ill tongue') on equal terms with atheism, adultery, and murder. In Matthew's Gospel (12: 33–7), it is said that people will also be judged by what comes out of their mouths, and curses those who make a baseless accusation against someone.

The philosophers of the Enlightenment apply the rationalist analysis to 'fables' (myths, legends, rumors). For Fontenelle (*De l'origine des fables* 1684), they are the result of peoples' ignorance, the strength of the imagination, the verbal transmission of narratives, and the explanatory function of the myth. For Voltaire, doubt does not only relate to supernatural legends, but also to historical narratives. In *Le Siècle de Louis XIV* (1751), he shows how a rumor could transform a minor war operation—the French army's crossing of the Rhine River in 1672—into a grandiose epic.

Rumors and legends are deemed to be the result of people's ignorance, fancy and credulity: A philosophical reprobation can be added to the moral reprobation of rumors.

2. Variety of Psychosociological Approaches to Rumors

The first scientific studies of rumors started in the 1940s in the USA, during the growth of communication and public opinion researches in social sciences, and being in the state of war, which drew the ruling classes' attention to the prominent part that rumors play.

Allport and Postman ([1947] 1965) formulated concepts that remain relevant today. First, they established that a given subject would more likely be the subject of rumors if perceived as important and ambiguous by the members of a social group. For example, the Japanese attack of Pearl Harbor in 1941 gave way to rumors on account of the importance of this first military attack, which made the Americans fear other assaults, and the ambiguity about the extent of casualties.

Allport and Postman attribute an affective function to rumors, when easing emotional pressure (fear, hostility) of individuals, and a cognitive function, when answering the need for information and explanation.

Lastly, through an experimental study (linear transmission of information by word of mouth), Allport and Postman pointed out three basic processes that lead to the gradual distortion of the message. *Leveling* is the rapid reduction of the volume of details. Rumors are inclined to become a short statement with the form 'subject + predicate': The subject is any person, animal, thing, institution, social or ethnic group; the predicate is the state or action attributed to the subject. *Sharpening* consists of selecting, and often magnifying, details. For example, numerical accentuation increases quantity; temporal accentuation brings rumors up to date; size accentuation exaggerates pronounced features (like a caricaturist who turns a small man into a dwarf). Lastly, *assimilation* is the alteration of details to fit them into the prejudices, stereotypes, and interests of the rumor transmitters. A rumor is the result of a psychological and collective process reflecting the lowest common denominator of ideas, values, concerns and feelings of the people making up a social group.

It remains necessary to analyze the rumor's degree of actuality and to study the mechanisms of distortion of facts or factual information. However, it is most important to understand how and why false news is spread and believed.

Shibutani ([1966], 1977) distinguishes among three different kinds of communication channels, in a descending order of social control and institutionalization: *formal channels* (media, official statements), *auxiliary channels* (clubs, circles), and *informal channels* (the word of mouth). At the normal rate of the communication system, information supply and demand are balanced: the main group of information is conveyed by formal channels, and just a few rumors

Figure 1
The rumor syndrome adapted from Rouquette (1990)

are spread by informal channels. On the contrary, in a critical rate (war, social or economic crisis, natural disaster, etc.), information demand exceeds supply, formal channels fall into discredit and informal channels abound with rumors.

Today, the distinction between official and informal channels must be moderated to the extent that rumors are also circulating by flyer, fax, e-mail, Internet, and even the mass media.

The inquiry into the 'Rumor in Orléans' by Morin (1971) is a model case study. Rather than the experimental method, he prefers the clinical approach, investigating *in vivo* the spread, then the extinction, of a rumor. Rather than take an interest in critical periods, he studies everyday life rumors, in a French provincial town. In spring 1969, it was said in Orléans that young girls vanished in dress shops owned by Jews to supply a 'white slavery' trade (i.e., prostitution). Morin tried to understand why so many people had believed these false allegations. The rumor drew its scenario from the pseudo-information of popular culture about white young girls abducted and forced into prostitution in exotic countries. Two 'catalyses' converted this scenario into 'reality.' First was a popular magazine's publishing of an unverified anecdote about the failed abduction of a young girl, found unconscious and drugged in back of a dress shop in Grenoble in France. The other was the opening of a clothes department for teenagers, named '*Aux Oubliettes*' (i.e., secret dungeon) in a medieval decorated basement of a clothing shop in Orléans. The rumor did not affect the shopkeeper, who belonged to the traditional bourgeoisie, but fixed itself on several shops owned by Jews. For Morin, the reactivation of two old myths—white slavery and the Jew—allowed

the population to symbolically express the deep fears caused by social and cultural changes at the end of the 1960s. Feminine emancipation and clothing and sexual liberalization fascinate and worry mothers and daughters: the rumor explicates the idea that miniskirts lead girls to prostitution. Second, urban modernization and growing anonymity put people in fear of losing the control of their city. The rumor expresses, through metaphors, the 'bad' city hidden behind the 'good' one: the trick dressing room, the vault under the shop, the clothes tradesman who also deals in young women, and the Jew as a figure of the one who hides his difference. One of the fundamental contributions by Morin is to have shown that a rumor is carrying a hidden message, an implicit moral, and that the study of rumors must undertake a hermeneutical work to reveal their symbolic meanings.

Morin has also suggested that, in the fight against a rumor, antirumor (denial) was less effective than counter-rumor. Thus, the rumor of Orléans died out, not so much due to police and press denials, but to an emerging counterrumor claiming that the rumor-mongers were anti-Semites and fascists.

3. A Unified Pattern: The Rumor Syndrome by Rouquette

Rouquette (1975, 1990) has built up an unified pattern of rumor in four typical features (see Fig. 1). When information or a narrative presents these characteristics, it is more than likely a rumor or an urban legend.

Instability refers to the alterations of the message, mainly at the time of its formation but also when the rumor is adapted to a new cultural environment. The presence of variants for a rumor or legend is a basic characteristic of the phenomenon.

Involvement is the fact that the rumor transmitter is feeling concerned by the message. The more rumor-mongers are involved in a rumor, the more they will believe it and pass it on. A rumor is any information or story 'worth telling.' Involvement is at its maximum when a rumor leads to behavior (e.g., panic).

Negativity is a dominating feature of rumors. Searchers estimate that 90 percent of rumors are '*noir*,' reporting news of aggression, accident, failure, scarcity, scandal, etc.; and only 10 percent are '*rose*,' containing optimistic content and attaining imaginary shared hopes and desires.

Lastly, *attribution* is the alleged source of a rumor. The rumor transmitters mention a trustworthy source, who assures the narrative's truth.

Rouquette's pattern offers a strong consistency of its features through six links.

Instability and involvement. Contrary to accepted opinion, the transmission of a message is less accurate when the subjects who spread the rumors are involved—there is an unconscious interference by interest, in their remembrance of the subject—than when they are

not concerned by the rumor. In transforming the message, the rumor transmitters tend to keep their cognitive consonance, in other words, the mental consistency of information, opinions, and beliefs they have about a situation.

Instability and negativity. The distortions of the message are commonly negative.

Instability and attribution. The rumor changes and enriches its attributions as it circulates. For example, a relay becomes a source (when rumors are passed on by the press or by a company's internal memos), a denial becomes a confirmation (in a French variant of the flyer about 'LSD tattoos,' the heading 'The Narcotic Bureau Confirms' appeared just after the organization denied the allegations. Cf. Campion-Vincent and Renard 1992).

The next three links show the role that rumors play in social cohesion.

Involvement and negativity. The discrediting of 'others' is implicitly corollary to giving importance to 'ourselves.' This sets up a mental and moral convergence between the rumor transmitter and his or her audience, therefore strengthening the social cohesion.

Involvement and attribution. Calling upon a trustworthy source weaves social ties that give value to the rumor transmitter.

Negativity and attribution. The more the rumor is negative, the stronger the guarantee of veracity.

Rouquette (1989) has also expressed the idea that rumors are multiple 'answers' to a small number of 'problems': how to account for an unexplained fact, how to vindicate an attitude or a belief, how to instigate behavior (warning rumors), how to intensify the social differentiation, or how to favor social integration. These problems take shape through themes, whether they are universal or specific of a given culture at a given time. In the Western modern world, the recurring themes of rumors and urban legends relate to just a few preoccupations (Kapferer 1990, Renard 1999): health, sex, money, new techniques, strangers, urban violence, nature, the change of manners, and the supernatural.

4. Folklore's Contribution to the Study of Rumors

Since rumors and legends are subjects of research that usually depend on distinct sciences—sociology for the former and folklore for the latter—their profound identity has been hidden for a long time. It was not until the emergence of a new concept—'modern or urban legend' (Mullen 1972, Brunvand 1981)—that sociologists and folklorists collaborated profitably and renewed their perspective on their own research topic. Mullen has emphasized the great resemblance between rumor and legend: Both are the result of a collective interactive process, they are usually first spread by word of mouth, their message is passed on as the truth,

and their social functions are similar. Rumor and legend are two aspects of the same phenomenon but one aspect sometimes outweighs the other. Studying the legendary aspect of rumors reveals their mythical deep-rootedness. Studying the 'rumoral' aspect of legends brings enlightenment to the transformations of content and the production of variants.

This aspect appears in the following tendencies: briefness of content, instability, and actualization, active and brief circulation in a certain time and place and among a given social group. The legendary aspect expresses complementary tendencies: the patterning of the content into a narrative form; the exploitation of motifs and themes, sometimes of ancient origin, emerging from the collective imagination and having strong symbolic contents; insertion into long, sometimes secular, periods of time, spreading internationally (Brunvand 1981, 1993, etc.).

A rumor may expand—become 'authentic'—and embody itself in a legendary narrative; reciprocally, a legend may be reduced to a mere statement. For instance, 'There are alligators in the sewers of New York' is the brief rumor form of the story reporting that New Yorkers brought back baby alligators from Florida, and then disposed of them when they became burdensome by flushing them down the toilet, where they ended up in the sewer (Brunvand 1981).

A similar legend may arise in both a traditional version and a modern version. For instance, the narrative motif 'Animal lives in person's body' is treated in Africa as witchcraft, whereas in the West it is explained by pseudomedical reasons.

In his pertinently headed article 'From Trolls to Turks,' Tangherlini (1995) shows many correlations between rumors and urban legends, circulating in modern Denmark, and the traditional narratives of the Danish folklore. He proves that beliefs about immigrants are revived from old motifs concerning supernatural beings (elves, trolls, witches): loathsome food customs, abduction of women or children, physical violence.

It is not accidental that interest in urban legends first arose among the folklorists, at least in English- and German-speaking countries. Rumors and contemporary popular narratives are actually modern equivalents of ancient legends, all of them expressing social or symbolic thought.

J.-B. Renard

Rural Geography

While it is widely accepted today that those working in the rural context can make a significant contribution to the theory and practice of human geography more broadly, this has not always been the view. At times rural geography has been regarded as a poor relation of modern geography, (see Cloke 1980) trailing behind the 'real' intellectual advances in the discipline and generally presenting a largely traditional and often atheoretical perspective on key debates. Moreover, the very existence of a sub-discipline of geography defined according to a set of shifting, obscured, and contested spatial boundaries has been questioned at times, particularly in the context of geographers' interests in national, international, and global systems and processes. This review of rural geography will focus on how the sub-discipline has developed and, in particular, how its various phases have been influenced by broader theoretical and conceptual ideas within geography as a whole.

1. From Regionalism to Political Economy

The regional approaches that dominated geography before 1960 favored rural spaces and places. Descriptive studies of land use frequently focused on the

countryside, while work on population change and settlement also tended to be approached from a rural perspective. Such dominance was put down to the importance of agriculture as a land use and to the emphasis that regional approaches placed on describing identifiable physical characteristics. The demise of regional geography in the 1960s, however, shifted attention away from the countryside; new directions in human geography saw the introduction of more 'relevant' approaches in which the sheer size and visibility of urban problems ensured that they received most attention. During the next 15 years interest in rural geography declined while the work that did continue became:

entrenched in its agricultural roots and seemingly oblivious to the theoretical strides being achieved within urban studies (Cloke 1989 p. 65).

Following this rather fallow period, rural geography experienced something of a resurgence during the 1970s (particularly in Britain, Canada, and Europe). Textbooks specifically devoted to rural areas emerged (for example, Clout 1972) claiming that the urban emphasis of recent geographical research had resulted in an imbalance in terms of wider geographical inquiry and a profound absence of knowledge about rural places and people. This renewed focus on rural geography yielded a large amount of data on the countryside in developed countries, but rural studies at this time continued to follow a highly traditional pattern. Much of the research was descriptive, establishing rural areas as interesting places to study but lacking explanation and avoiding theoretical debate. Emphasis was placed on identifying the rural as different or unique (leading to rather sterile debates on the definition of 'rurality,' see Cloke 1977) rather than on showing how an understanding of patterns and processes operating in rural areas could inform human geography more broadly.

The willingness of rural geographers to engage with theory marks perhaps a key watershed in the development of the sub-discipline. During the mid 1980s those working within the rural context began to argue that rural research needed to be informed by theoretical approaches being developed outside the field and that a failure to locate studies within a broader theoretical and conceptual framework was seriously undermining their value. Although some reference was made through the 1960s and 1970s to debates taking place in radical rural sociology—especially the use of Marxist approaches in the study of agriculture—the theoretical concepts used were not generally taken up by rural geographers. It was thus only with the development of political economic approaches that the need to engage with theory outside rural geography started to influence its scope and direction to any significant degree. An awareness of the importance of processes of restructuring and capital accumulation to rural economies and societies

had begun to demonstrate to rural researchers the relevance of macroeconomic and political transformations to the detail of change within the countryside. So, considerably later than their urban counterparts, rural researchers turned to political economy approaches to inform their analyses and explanations. Space is insufficient here for a detailed review of the nature and contribution of political economic approaches to the study of rural geography (but see Cloke and Little 1990, Marsden et al. 1986, Phillips and Williams 1984, Urry 1984). It is possible, however, to identify a number of key themes that emerged (and were sometimes transformed) through the use of such approaches.

2. *Economic and Social Restructuring*

During the 1980s changes in the patterns and processes of capital accumulation were visible in the transformation of agricultural production and shifts in the location of industry. Understanding changes in rural areas required grounding such changes conceptually within more global patterns of restructuring and capital accumulation, essentially within a political economy framework. Particularly important in this context were arguments surrounding the unevenness of restructuring and the ways in which global processes of transformation impacted differently on different places at different times.

The adoption of political economy approaches provided research on agricultural geography in particular with a rich and highly fruitful arena for debate (see, in particular, Buttel and Newby 1980, Goodman and Redclift 1985, Marsden et al. 1986) as studies sought to detail and explain the major shifts taking place in the agricultural and associated industries. Research concentrated initially on the capitalization of agriculture and on the implications of new technologies on the methods of farming and on the ownership of the means of agricultural production. Later, however, the debate expanded to consider the broader transformation of food production including issues such as the role of 'downstream' and 'upstream' industries together with the social relations of agricultural production (especially changes to the family farm) (Goodman et al. 1987, Whatmore et al. 1987). Although not all work on agriculture adopted an explicitly political economic frameworks (indeed some consciously rejected political economy perspectives), the influence on this aspect of rural geography was profound, providing a much more informed understanding of the changes taking place in rural areas and of their links with global patterns of economic change.

The application of political economy approaches to another major research direction in rural geography, the restructuring and relocation of industrial development, was also reflected in increased output (see, for example, Bradley and Lowe 1984). More importantly, perhaps, it encouraged research into the distributional

impacts of shifts in the location of industrial capital, including a consideration of the effects on different sections of the labor market and the implications for the changing social structure of rural areas. Such issues were also incorporated in the second key theme to be highlighted in the discussion of political economy and rural geography, that of class and social inequality.

3. *Inequality in Rural Society*

The renewed focus on rural geography that took place in the 1970s and early 1980s, produced a number of studies from Britain and the USA on rural deprivation and 'welfare' issues, but it was only with the application of political economic approaches that such studies began to address issues of social inequality and to develop class-based analyses of the causes and effects of rural deprivation. For the first time research included not only an examination of the nature and extent of deprivation in rural areas but also the relationship between individuals and groups according to access to resources. A 'service' based model of rural deprivation in which the welfare of rural people was seen to be a function of the availability of certain essential public and private services, was gradually replaced (or in some cases augmented) by one that related deprivation to people's personal access to resources in terms of income, property, status, and power (Moseley 1982, Newby 1979). Detailed studies of access to housing, employment, transport, health care, etc., emerged through which the inequalities existing in contemporary rural societies were highlighted (for summaries see Champion and Watkins 1991, Troughton 1995). Such studies were then used in the broader examination of access to the countryside and of the transformation of rural societies and the gentrification of rural communities (see Little 1987a, Marsden et al. 1993).

4. *State-Society Relations*

Political economy approaches highlighted the centrality of power relations to the composition and well-being of the rural population. While the class-based analysis of access to rural resources contributed to an understanding of rural residents' personal power (especially financial but also in terms of status), the wider discussion of the structures and operation of power prompted researchers to explore the relationship between the state and the rural community (see Cloke and Little 1990). Importantly, this work drew on urban-based debates on the nature of the local state and on the changing mechanisms and practices of central government. At a time when the developed economies, particular the USA and Britain, were seeing attempts by the center to curtail the responsibilities of the local state, rural research began to

investigate the implications for rural areas and to document the localized power struggles and resistance that accompanied the changing balance of power.

Political economy approaches to central–local relations provided a framework for the investigation of power in a variety of ways. Studies focused on inter agency relations, the changing role of the private sector, and the role of key actors, elites, and institutions within the policymaking process. An area of particular attention, (especially within British rural geography), was that of town and country planning, and a number of studies on the negotiation and distributional consequence of planning decisions contributed to the wider understanding of power relations and political control within the regulatory process in the countryside. One particular strand of such research sought to highlight the role and status of environmental pressure groups in an examination of the priorities of the dominant interests in the countryside. Much of this work revolved around a discussion of the changing status and power of agriculture and raised questions concerning the position of farmers and landowners in relation to other interests within both urban and rural communities.

Forms of explanation that originated beyond the rural led to questions concerning the validity of ‘the rural’ as a legitimate category of analysis or even subject of research activity (see Hoggart 1990). The spatial unevenness of patterns and processes of capital accumulation and the specificity of local level responses to economic and social restructuring were used in defence of a focus on the rural, but research moved away from attributing causal properties to rural areas in the explanation of issues such as population migration, inequality, and access to resources. As well as contributing in its own right to the development of rural geography, the adoption of political economy perspectives, it may be argued, helped to open up the subject to other theoretical approaches. Particularly important here was the emergence of feminist perspectives in rural geography in the late 1980s (see Darque and Gasson 1991, Little 1986, 1987b, Whatmore 1991).

5. Feminist Rural Geography

The experience of women in the countryside were referred to fleetingly in the early development of rural geography, in, for example, the discussion of labour relations within family farm businesses (Sachs 1983, Symes and Marsden 1983) and the sociology of the rural community (see Davidoff et al. 1976). Only in the late 1980s, however, did a sustained attempt to incorporate explicitly feminist perspectives into the subject emerge. As with the adoption of political economy approaches, the introduction of feminist perspectives was a response to theoretical ideas being applied within other areas of geography and drew on

a wide range of literature from urban/social geography as well as from other academic disciplines such as sociology and women’s studies. It also reflected a need to go beyond the description of the constraints and opportunities experienced by women living in the countryside in explaining their position. Useful data on the detail of women’s lives had been collected in research on issues such as employment, access, and service provision (for a summary see Little 1991). Rural women in developed countries, for example, had lower activity rates than their urban counterparts and that their paid work was generally characterized by poor conditions and low wages. Women’s lives were also disproportionately constrained by limited transport and other public and private services. It was argued, however, that such work failed to go beyond the examination of women’s roles and that it provided little explanation for the basis of women’s inequality. Lacking alternative forms of explanation, such work was in danger of attributing ‘rurality’ with causal powers and identifying characteristics of rural economies and societies as wholly responsible for the experiences of rural women.

In keeping with work in other parts of the discipline, feminist rural geographers argued that studies of women needed to be located within a broader consideration of gender relations and their operation in the countryside. An understanding of women’s experiences in all areas from their contribution to the family farm to their access to child care, had to recognize, it was asserted, the underlying power relations that exist between men and women and needed to acknowledge the role of patriarchy as a fundamental element of social control in the countryside (see Little 1987b, Whatmore 1991). Having argued that the experiences of rural women needed to be conceptualized in terms of more universal patriarchal systems and gender relations, the research also sought to demonstrate the specificity of the experiences of rural women, showing how rural communities exhibited a particularly traditional form of gender relations and were dominated, as a result, by more conventional gender roles and attitudes towards gender equality. Women’s position was seen as a function of a particular view of rural communities, one in which the family, and women’s reproductive role within it, were central. Research also argued, in the discussion of the daily detail of women’s lives and experiences, that women’s ability to take part in paid work as well as their position within the rural community were very much shaped by this dominant understanding of the ‘appropriate’ role of women in the countryside.

Research on rural women and gender relations has continued to develop this theme and in so doing has drawn on and contributed to the ‘cultural turn’ within rural geography. More recent research has explored notions of gender identity in the context of the (re)construction of rural cultures, suggesting that certain aspects of women’s (and men’s) gender ident-

ities are prioritized within certain dominant cultural constructions of rurality within developed economies (see Hughes 1997, Agg and Phillips 1998, Little 1997). Again, such work has explored the implications of more traditional views of gender identity within rural culture for the reality of women's lives. Furthermore, some researchers have shown how dominant constructions of the relationship between gender and rurality will be experienced differently by groups of women and men; such as gay men and lesbians (see Bell and Valentine 1995, Kramer 1995) or young women (Dahlström 1996). Increasingly, work on gender identity and on sexuality has led to a discussion of the construction of femininity and masculinity within a rural context (Brandth 1995, Woodward 1998).

6. *Rural Geography and the Cultural Turn*

Recent evidence of another 'resurgence' in rural geography (documented by Cloke 1997) has accompanied the adoption of cultural approaches in geography and the social sciences generally. Cloke maintains that three important foci of cultural studies have provided a particular impetus for the study of rural spaces and societies: landscape, the rural other, and the spatiality of nature. In addition, a willingness by rural researchers to engage with important theoretical dualisms such as society/space, nature/culture, self/other has brought rural studies back into the mainstream of geographical inquiry.

A widely quoted springboard for new cultural approaches in rural geography came in the form of Chris Philo's 1992 article on 'neglected rural geographies.' In this short piece Philo challenged the implicit and explicit preoccupation of rural geographers with the experiences of 'Mr Average,' arguing that both the content and the practice of rural geography were dominated by middle-aged, middle-class, white, males. He suggested that this emphasis be redressed in the study of 'other' elements of the rural population and that in so doing researchers take on board the variety that exists in the composition and experience of the rural population. The fact that such variety has been 'hidden' from both academic and lay discourses of rural spaces reflects the dominance of particular constructions of rurality.

Following Philo's article there has indeed been a concerted attempt by rural geographers to focus on the experiences of previously neglected, and frequently marginalized groups. Studies of, for example, young people (Jones 1999, Valentine 1997), black and ethnic minority people (Snipp 1996), New Age Travellers, (Halfacree 1996) have helped to increase our understanding of the diversity of rural lifestyles. Moreover, many studies of 'other' groups within rural society have attempted to locate their findings within a theorization of difference and in so doing to draw on

critical debates in social and cultural theory. These attempts to theorize the experience of difference and diversity have demonstrated the existence of multiple ways of seeing rural spaces and drawn attention to the important power relations involved in the privileging of certain views over others. Thus, it has been argued that the experiences of groups such as the young or black people in the countryside are profoundly shaped by their (in)ability to be accommodated within dominant construction of the rural. This sense of being 'out of place' will influence their own perceptions or constructions of rural spaces and reinforce their marginalization.

An interest in the dominant, multiple, and contested constructions of rurality has led to (and drawn from) an interest in the different representations of the countryside. Studies have sought to demonstrate the various ways in which rural spaces and people have been represented in different arena, identifying the key signs and symbols that are selected to reflect rurality and exploring their cultural significance. Research has also attempted to show how these images have been used in particular situations and how they have contributed to the projection of idealized and sanitized rural spaces, masking the existence of poverty and marginalization and creating a sense of staged authenticity that differs drastically from 'reality.' Their ability to influence lived behavior at the local level in addition to some sort of wider notion of rurality has been a central concern of some studies as they investigate the circulation of symbolic meanings.

Debates surrounding the construction of rurality and the power relations bound up in the representation of rural spaces and people have raised questions about the role of human agency and the relationship between humans and non-humans in the control of the countryside. Nowhere is this more relevant than in the study of 'nature' and the direction of environmental change (see Murdoch 1997, Whatmore and Thorne 1998). While not confined to rural/environmental studies, issues concerning the nature/society dualism and the changing relationship between 'humans' and 'animals' have opened up major areas of research within rural geography from the development of food networks and the 'quality' of agricultural produce (Arce and Marsden 1995) to the role and purpose of different forms of landscape/environmental protection (Winter and Gaskell 1998).

Exploring the different conceptualizations, structures, and mechanisms of power has once again highlighted the theme of policy and governance within rural geography. As noted above, political economy approaches encouraged the examination of both formal and informal structures of power and their operation within the policy process. Recently there has been a re-examination and development of such work in relation to a broader conceptualization of governance and to the changing social, economic, and cultural context of rural policymaking (see Goodwin

1998). Research has considered, for example, the changing practices and mechanisms of governance in rural areas in the analysis of partnerships and the growth of community participation. Such work has also been informed by cultural perspectives in the examination of the values and attitudes underlying shifts in the regulatory framework.

Clearly, the cultural turn in rural geography has had a major impact on the direction and content of research within the subdiscipline. It has also had a far-reaching influence on the methods employed by rural researchers; on the way data is collected, analyzed, and used. In common with other areas of geography, there has been a significant growth in the adoption of ethnographic methods in rural research and in the use of 'grounded theory' and while such approaches may have characterized some of the early rural 'community studies,' it is only recently that they have been more widely applied to a range of economic, environmental, and policy-based issues in rural studies. Those working on rural lifestyles and marginalization have argued, in particular, that a real understanding of the lives of those living in the countryside needs to emerge from the detailed analysis of their behavior, attitudes, and beliefs and that this can only be obtained through ethnographic methods. In addition, rural researchers have started to make use of a variety of other sources of data, drawing on art, literature, diaries, and other cultural artefacts, both historical and contemporary, in their work. With a shift in the methods used by (some) rural researchers has come something of a change in attitudes towards research. The sensitivity of work on marginalization and deprivation has opened rural geographers' eyes to the potential dangers of research tourism and encouraged them to think more carefully about the way their work may be used to the advantage or disadvantage of particular groups at particular times.

7. Conclusion

This short article has highlighted some of the main 'stages' in the evolution of rural geography since the 1950s. The goal has been to identify key shifts in thought within rural geography and show how they have influenced the nature and direction of rural studies. An impression that the subject has moved smoothly from one dominant theoretical influence to another is inevitable but misleading.

Rural geography is in a buoyant period, having been theoretically invigorated by the application of perspectives from cultural and feminist studies. Rural researchers appear more open to the influence of perspectives from outside the narrow confines of the subject and the willingness to engage with and contribute to debates in other parts of academia as well as other areas of geography, has raised the profile of rural geography generally and ensured that the wider applicability of their arguments is acknowledged.

Rural Industrialization in Developing Nations and Gender

1. Expansion of Rural Industrialization

During the 1970s, transformative industries spread throughout the rural zones of many developing nations. These enterprises shared five features: they all involved industries engaged in the manufacture of basic consumer goods; the goods were produced in small- to medium-sized firms; working conditions and wages were marginal relative to those in the formal economy of state-regulated employer-worker relations; many, though not all, of the workers were women laboring in their own homes; and the women recruited for such labor tended to be young and single (Arias 1988, Wilson 1991).

Women have always participated in the domestic chores and contributed to the income of rural households, but heretofore their work was unpaid and involved activities that were labeled as 'female.' Rural industrialization changed all that and unleashed paid labor and contractual employment outside of the household yet within the rural setting (Bachrach Ehlers 1993, Boris and Daniels 1989). Until then, female contact with paid work and manufacturing employment only occurred through migration to the city.

The most common transformative industries now present in developing rural areas are, in decreasing order: the canning of fruits, vegetables, meats, and marine products; making clothing and fabrics; the manufacture of goods, candies, and electronics; and the transformation of popular crafts into marketable 'folk art.' Until recently, this manufacturing generally occurred in 'traditional' industries, which relied on the intensive use of poorly-paid labor as the preferred strategy for adapting to markets that are substantial, but fragmented and ever-changing, and to consumer demands that may be intense but ephemeral. Under these circumstances, access to a ready niche of low-cost labor has been crucial to sustaining the economic viability of these firms (Bradley 1989).

The expansion of industry into rural areas has been particularly intense in Asia (notably in China, Bangladesh, India, Indonesia, Malaysia, and Taiwan) and Latin America (especially Mexico, Paraguay, Puerto Rico, and the Dominican Republic), as well as in the

less-developed countries of southern Europe (Greece, Portugal, Turkey, and to a lesser extent Spain and Italy). Rural industrialization is more common in countries with high fertility and a large share of the population living outside of cities.

The association between rural industrialization and female employment across such a wide variety of countries suggests that, under the present global economic regime, certain industries have come upon a powerful political-economic strategy that takes advantage of and reinforces gender relations within rural environments. As a result, rural women have increasingly become one of the best options for securing a steady supply of labor that is cheap, docile, flexible, and unorganized, that is widely available in many developing settings (Dwyer and Bruce 1988, Mencher 1988).

The rapid expansion of rural industrialization and its effective rooting in many peasant societies has been interpreted from two principal perspectives: that of the labor market and that of the household. The notion of the *social construction of difference* is essential to understanding the issue that both perspectives seek to theorize: how to construct and maintain a workforce that will accept the low salaries, unstable working conditions, and discriminatory treatment of women that prevail in rural manufacturing?

The endless search for and creation of niches of cheap manual labor is made possible by what Maruani (1991) calls the 'social construction of difference,' which can be understood as a dynamic mechanism permitting the selective definition of jobs and wages along the lines of gender, race, legal status, and other demographic criteria in such a way as to invent, recreate, and conserve hierarchies that legitimate segregation, inequality, and discrimination. Through the social construction of difference, rural industrialists have been able to keep labor costs down by creating social categories of people who can be offered lower wages for work under precarious conditions (Maruani 1991).

2. The Labor Market Perspective

The creation of niches of low-cost manual labor might be explained simply as a consequence of macro-economic changes and recent policies of structural adjustment, not only in poor sectors, but in the traditional sectors that have assured the survival of rural society despite its long state of crisis. Indeed, the dyad of rural industrialization/female work appears to be strongly associated with the deterioration and stagnation of tasks characteristic of rural life: agriculture, cattle raising, and sheep herding. This association implies an irremediable crisis of the proverbially male occupations of rural society that affirmed the role of men as principal providers for their households.

In the context of local poverty and family crisis, women have been compelled to accept whatever offers of work have come along, however undesirable. This acceptance was facilitated by rural women's low level of education and information about the norms and rules of paid labor in formal urban settings. But education and information are not the only factors. Conserving female labor as a low-cost resource results from a social process of 'deskilling' of those tasks carried out by women.

3. Deskilling as a Social Construction

In rural society, it is commonly accepted that female employment occurs thanks to abilities acquired in the home, such as housekeeping, a knowledge of the kitchen, and dexterity at sewing, which together open the door to canneries and workshops that make shoes, clothes, toys, and other consumer goods. As these abilities are taken to be 'natural,' or at least learned at home, employers treat them as 'unskilled' jobs to which a low value may be assigned relative to the manufacturing tasks learned by men.

This 'cheapening' of female labor also arises from seeing the work of women in terms of 'feminine' attributes: that they are careful, attentive, fine, delicate, and sensitive. These qualities are seen as part of the innate character of woman, rather than as part of the skill set associated with paid labor and priced in the market.

Another factor in women's low wages and hours of work is their responsibility for reproductive tasks and to domestic responsibilities (England 1993). Indeed, Dwyer and Bruce (1988) have calculated that most of the part-time labor done in the world today is carried out by women. This limits the possibilities for women to approach work as a career developed over the long term. Because of domestic responsibilities, in-home paid labor, which is easier to combine with domestic tasks, has been embraced among rural women. They know that it is poorly paid, but for some it is the only combination possible for making money while not neglecting household obligations (Fernández-Kelly and García 1989).

In this way, there has been an effective adaptation of the rural market for manufacturing labor to the situation of rural women. The instability of the rhythms of production, a key entrepreneurial element in cheapening the cost of manual labor, is manipulated as a mechanism to achieve labor 'flexibility,' which in turn emanates from and is adapted to the needs of female workers. The irregularity and instability of production, the continual opening and closing of factory doors, and payment by piece rate (according to the number of units produced) all form part of the prevailing economic model, which comes to exemplify and derogate the women themselves: it is *they* who are unskilled, *they* who require labor flexibility, and *they*

who earn what they want, when they want it. In this way, rural manufacturing has been able to maintain and recreate the precarious conditions of the labor market such that they are viewed as a concession on the part of employers to women's domestic responsibilities. This social disqualification of female labor might diminish over time, but that process is slowed by another deeply rooted social fact: gender differences within the family.

4. The Household Perspective

It is only recently that investigators began to underscore the importance of *household survival strategies* as crucial mechanisms that permit poor households to organize production and consumption, not simply to adapt to changes associated with the life cycle, but to surmount the repeated economic crises that have buffeted Third World economies in recent years. We know that family survival strategies include not only cooperation, but also conflict, domination, and inequality, such that men are often able to impose their preferences and decisions on women (Dwyer and Bruce 1988, Ward 1993). The household is an arena in which the tasks and obligations of members, whose interests and powers may clash, are subject to continuous contestation.

Gender inequalities are manifested in the labor force behavior of family members. The broader political economy extends into intradomestic struggles. Rural men and women conceive of, are conceived of, and for that matter offer themselves very differently to the labor market, at least in certain core matters that not only signal differences, but reflect broader inequalities and hierarchies with respect to gender: the family-individual relation and conceptualization of male and female work.

4.1 Family-Individual Relations

During the 1970s, the availability of paid labor in canneries, workshops, factories, and *maquiladoras* was, in many cases, something entirely new in the life of rural communities (Ward 1993). Given economic crisis, rural families could not afford to pass up opportunities for work within their own communities. They began to redefine priorities and reorganize to harness emergent opportunities; and they did this in accord with traditional gender hierarchies. It was clearly a complex undertaking trying to incorporate these new labor opportunities while conforming to the idea that the female condition is permanent and immutable. With the aim of mitigating the social effects that women's wages and the power they potentially bring, the family positioned itself as the crucial intermediary in recruiting and organizing the new systems of work that arrived in the countryside (Hareven 1982, Rosado 1988).

In general, families looked to assure the permanence of two basic principles: to assure new income for the family, and to safeguard 'morality' in the face of the compromises entailed in taking paid labor. One form of mitigating the potentially disruptive effects of female work and extra-familial income was to send only young, single women into the workforce, i.e., those who lived in their paternal home and therefore had much less power to negotiate within the family. The selection of young unmarried women assured that the new earnings would be incorporated directly into the family circle. Under the authority of the father, the income generated by daughters was socially defined as an obligatory family *contribution*, much the same as the fulfilling of any other domestic obligation of a daughter or sister.

The contrasting family responsibilities of men and women are also evident in what happens to the earnings. As has been shown in a variety of societies, men experience much greater latitude than women in deciding what to do with their money, even when they are unmarried (Dwyer and Bruce 1988). In the end, the conservation of family norms and values was more important to male family members than the struggle to better working conditions or wages for their wives and daughters.

4.2 Male Work as 'Obligation'

The conceptualization of work and what one expects to achieve through it also distinguishes men from women. For men, work is viewed as an obligation through which the man must (but also can) fulfill the role of fundamental family provider. Through work, he hopes to generate income, sufficient to cover the basic necessities of those who depend on him, although this, as we know, is an ideological construction of relative recency in history, with little relation to economic reality (Rothstein 1995).

This social construction has assigned men both the obligations and the rights of a family provider. This means that men have the freedom to seek out the best pay and working conditions, rejecting jobs that cannot support their family. This makes it socially acceptable for men to reject poorly paid jobs and to migrate far from home in search of better jobs. Through mobility, men may avoid the low salaries offered in agriculture, agribusiness, manufacturing, and the *maquiladoras* that were built throughout the rural world in the 1970s (Arias and Wilson 1997). This helps explain the association in the countryside between an abundant demand for labor and at the same time the ongoing departure of men for other regions or countries in search of work.

This paradox illustrates another characteristic of male migration: that they can move away for work while still meeting their family obligations and not disturbing (indeed, reinforcing) the social framework in which they form a part, for they know that mothers,

wives, and sisters will be charged with maintaining their filial and familial obligations (Massey et al. 1987). In most societies, as Dwyer and Bruce (1988) indicate, the time that men actually devote to their children has always been meager and is easily reduced without repercussion.

The situation of the rural woman is entirely different. For her, liberty and the freedom to disengage from domestic obligations do not exist, so that her justification in leaving to look for work, or to find better working conditions, is truly limited and is supposed to be arranged through a long and costly negotiation with other women to take charge of the domestic responsibilities that she will no longer be able to meet.

4.3 Feminine Work as Complementary 'Help'

The paid work of women is governed by very different notions; it is seen as complementary help. Women's work is, and has always been seen as a form of altruistic collaboration, that is voluntary, generous, and absolute in comparison with male labor (Folbre 1988). That a woman is hardworking and that her efforts indeed 'help' and 'complement' the family income speaks well of her in moral and marital terms, but may limit her cash contribution to the family. In this gendered process, women's paid work, as 'complementary help,' is devalued. The efforts of women are socially recognized, but they are not seen as important work and are assigned an inferior status relative to men's work (Dwyer and Bruce 1988, Safilios-Rothschild 1988).

To speak of work as 'complementary' because it is female is a way of downgrading and devaluing, *a priori*, the contribution of women to household resources. Moreover, as Dwyer and Bruce (1988) and Ward (1993) have pointed out, in many societies it is socially accepted that men can retain a part of their earnings for themselves (and often the family never knows exactly *what* proportion of male earnings are retained). In contrast, wives and daughters are expected to hand over to the family *all* resources obtained outside the household (Mencher 1988). Thus, women's earnings may be a resource families count on more than men's. Thus, seeing women's work as secondary 'complementary help' is a social construction rather than an accurate portrayal of the situation.

Seeing female labor as 'help' makes it socially manageable by the family. But, the notion of women's work as 'help' limits it several ways. First, it reaffirms that the female priority remains reproduction and domestic responsibilities; if the work of the woman is only 'help,' it is by definition insufficiently important to require renegotiation of the distribution of roles and tasks within the household. Second, the notion of female paid labor as 'help' assures that it remains of lower value, and in this way, that the woman is always available to leave it to resume her function in the

family if needed. Third, viewing female labor as 'help' guarantees that in the face of family economic crises, the woman can (and *must*) enter the market to work and to accept conditions and wages that men are not expected to take, but that once the immediate crisis passes, she will return to her fundamental priority of the family (Hareven 1982). Finally, the notion of female work as 'help' is a key mechanism to avoid discrediting socially or maritally the work and earnings of men. Facing transitional labor markets that have shifted the balance of work opportunities between the sexes, the notion of 'help' contributes to the maintenance of traditional obligations and rights within the family, in obvious detriment to the position of the women themselves.

Thus, the conceptualization of female work as 'help' of a 'complementary' nature can be seen, in the end, as a porous category in which the social devaluation occurring in the labor market intersects with the social hierarchies of gender within the household. This intersection is what permits employers continued access to sources of low-cost labor, on the one hand, and the perpetuation of female work as subordinate to family obligations, on the other.

5. Recent Changes

As expected, the experience of female labor outside the household has affected gender relations within communities and families. Notwithstanding social resistance from employers as well as their families, women have begun to modify their relationships within the family and with employers. In rural societies in which the paid work of women forms an integral or intermittent part of local economic life, and where it is possible to encounter two or more generations of female workers, they have been renegotiating relations with their families that are less unequal, particularly with respect to education, mobility, and control over earnings, against the backdrop of a labor market ever more oriented to labor rights (Rosado 1988).

National and international struggles have been undertaken by nongovernmental organizations (NGOs) and women themselves during the 1990s, especially in Southeast Asia. The globalization of the economy has helped women to understand their conditions better and has extended the struggle of female workers to a geographic scale never before seen. Increasingly women have contested not only wages and work conditions that function outside the law, but those that violate basic human rights, such as the right of association, the limitation of child labor, and exposure to hazardous conditions, as well as combating different types of labor market discrimination. The struggle by female workers and NGOs has now succeeded to the point where some large international companies operating at the global level have developed norms assuring human and labor rights for workers connected to them under various subcontracting arrangements. Al-

though this is only a beginning, it indicates that rural industrialization may have entered a new phase of development.

Rural Planning: General

The heading 'rural planning' as a sector of government involvement is often absent from plan documents in many countries. But policy and legislation related to agricultural, transportation and communications, education, health and human services, and social welfare, sectors generally addressed in plans, have had far reaching and profound impacts on the physical conditions of, and infrastructure availability in, rural areas. They have also determined the range and quality of services accessible to rural populations. When headings such as rural planning, rural development, integrated rural development are present in plan documents, as discrete sectors requiring attention and having related funding lines in national and state budgets, these sectors are often defined in terms of engagement with social welfare agendas. The goals of such sectoral policies have often included statements about the need to redress inequalities in access to public services and redistributive justice. A broader definition of rural planning as encompassing policy that has both explicit and implicit intention to impact rural conditions, economic, social, and physical is adopted here.

During the formative period of the United States in the nineteenth century, agriculture production was a central element in its' robust growth and development. Similarly, an agriculture-based economy and a predominantly agrarian population was the legacy of heavily populated, newly independent, countries like China and India, which faced the task of nation building in the second half of the twentieth century.

But over the years these countries have differed significantly in their approach to rural planning. The interventions of their governments in the rural sector define a spectrum of strategies and approaches, from total centralized control to indirect, market-driven change. Furthermore, their strategies, which took divergent paths at the start of nation formation, have over time sharply changed direction.

The United States (US), India, and China provide examples of countries that have developed rural planning-related policies based on quite differing ideologies about planning and the role of rural areas in national development. Their positions have ranged from the free market, laissez faire orientation typical of 'First World' countries like the US to policies of 'Second World' countries like China that adopted a centralized, cooperatives based model of rural planning of the Soviet Union. Seeking a more intermediate path between these two extremes were countries like India, a founding member of the block of so-called 'Third World' countries that sought to chart a distinct path to development. Examining the development of the rural planning concept in countries like the US and India provides a glimpse of the differing interpretations of rural planning that have been evolving around the world in countries where the government's ability to control, plan, and implement has been limited by, and has been cognizant of, the significant role of the private sector in the farming endeavor. Study of the China model provides insight on the strengths and limitations of sustained, centralized efforts to control developments in rural economy and society.

1. The United States Model of Rural Planning

The US is acknowledged to be one of the most open and laissez faire economies in the world. Within the US, the idea that attention needs to be turned specifically to rural planning is not a widely embraced concept. But models of economic growth that guide policy are accepted and in these the agricultural sector is factored as an integral component of the national economy. Historically, US agricultural policy has defined and shaped rural conditions and had far-reaching consequences on the development of rural areas, but it has not been recognized as an instrument for rural planning.

This American ambivalence towards acknowledging the existence of rural planning is understandable given historical antecedents. After American independence, the feudalistic land law that prevailed under British rule was replaced with a freehold land tenure system under which public lands were sold to raise cash for the new government. To facilitate sales the US Congress ordered a land survey in 1785 that established a grid system of land division as the dominant pattern for the area west of Pittsburgh. Its

indelible stamp ordered the transportation and communication systems and helped give shape to rural administrative areas. Subsequent land laws and purchase allowed 'a mass distribution of land to those who tilled the soil [that] was unique in the history of the world up to that time' Cocharane (1979, p. 57). The philosophy of land ownership as vesting freehold in an individual, and the establishment of a unique American tradition of independent and self reliant farm families scattered in a regular pattern, each in isolation, on their own individual pieces of land, has perhaps contributed to a national antipathy to identifying government interventions as responsible for rural development. Nonetheless these early interventions shaped the rural context, with plans that were not always openly agreed to or publicly articulated, and embedded it with desired outcomes that might have been contested if formally acknowledged in planning documents.

The movement of the US agricultural enterprise from the subsistence cultivation of the pioneer to the high tech, mechanized, computerized, agro industry of today's corporate farm is not the product of free-market forces but of significant government actions. The role of the government in shaping US farming is noted and generally accepted in the literature pertaining to American agriculture (Rasmussen 1960, Cocharane 1979, McConnell 1953). Cocharane (1979, p. 277) delineates a broad and inclusive set of categories in which government has been active, asserting that it has been involved in almost every aspect of agricultural development. With the passage of the Agricultural Adjustment Acts of 1933 and 1938 the Department of Agriculture has supported and managed agricultural production pursuing policies affecting both the supply and distribution systems of agricultural production (Cocharane 1979, pp. 141-2).

1.1 Modern Farming in the US

Government activities in the transport, research, and education sectors have transformed American agriculture from subsistence to cash cropping for regional and national markets and later to capital-intensive agribusiness. Significant government support of educational and research institutions assisting in agricultural development through scientific and technological innovations has been sustained for more than a century. The Morrill Act of 1862 enabled government to fund land grant colleges in each state and the Hatch Act of 1887 allowed annual allocations for state agricultural experimentation stations devoted to basic agriculture research (Rasmussen 1960). The impact of this activity on shaping the scientific base of modern American farming and increasing productivity and efficiency was significant and to date has had resonance and wielded influence around the world.

In response to the worldwide Depression of 1929 New Deal agricultural economists created the Agricultural Adjustment Acts of 1933 and 1938, to set the price and allowable level of farm production. The central theme in these legislative efforts was to stabilize agricultural prices and income by offering subsidy payments to farmers to reduce production, price support measures, and commodity storage. In the postwar period from 1945 to 1975 the modern farm evolved in the context of rapid advances in national/international transport the emergence of the United States as a major world power, and the corresponding change in its domestic and foreign policy, and tremendous advances in scientific/technological farming in the United States including development of high-yield hybrids, fertilizers, pest controls, and extensive mechanization. The modern farm featured large-scale production for national and international markets. Cultivation for sale rather than family subsistence became the central production objective of the farm enterprise. However the ideological underpinnings of the earlier time of minimum government control in the farm enterprise persisted. There was support for government to be an agent responsible for presenting new options and alternatives which might voluntarily be subscribed to, or not, by the American farmer.

1.2 Corporate Farming in the US

A shift from modern to corporate farming after 1975 was triggered by changes in the role the United States played in world affairs and the tack it took with respect to its foreign policy following World War II. The United States emerged as a leading proponent of global free trade. This posture meant that the highly efficient farms in the US began to function as the 'world's breadbasket.' Farmers produced and exported crops to India, Russia, and other countries when these countries faced domestic shortfalls in food production. Advances in national and international transport aided this expansion of the market. 'Green revolution' technology packages of high-yielding hybrids, super fertilizers, and pest controls were developed leading to unexpectedly large crop yields. Specialization and mono-crop farms become common. Although energy intensive in their use of new products and machinery, they were viable as energy costs were kept relatively low by the government. A process of consolidation of family and modern farms into larger and larger vertically and horizontally integrated corporate entities occurred. The resulting corporate super farms have changed the rural landscape tremendously as fewer and fewer farms account for more and more of the of total farm sales and total farm profits in the United States. This concentration is apparent in the fact that in 1997 two percent of all farms in the US produced 50 percent of total farm sales.

1.3 Services-oriented Rural Planning

In the 1980s and 1990s it has been increasingly obvious in the United States that although the link between agriculture policy and rural planning has traditionally been very strong it may be less important in the emerging 'global' economy of the twenty-first century. Today the link that needs to be forged for rural planning is with economic sectors such as manufacturing and services. The emerging 'new economy' is based on the growth of the service sector and geared to the information industry that has centralized population in metropolitan areas. The impact of this centralization on populations that remain rural and dispersed is significant. For example in rural areas public services in education, health, and social welfare provision are of lower quality than in metropolitan areas. Currently US rural planning efforts have focused on providing quality services despite the delivery difficulties posed by lower population densities that mean that greater distances must be covered to reach targeted rural populations. A second strand of rural planning pertains to national settlement patterns and the belief that it is important to maintain numbers of people in rural areas. Planning efforts creating rural enterprise and empowerment zones have involved job-training programs as an economic development policy to attract entrepreneurs. The second element of this strategy aims to reduce costs for entrepreneurship in rural areas by programs that make capital available for business development. The scale of such efforts is however quite modest. Finally, the current paradigm of rural planning focuses on equalizing rural communication and infrastructure with urban. Supporting the expansion of Internet and high-speed communications links, wireless, and satellite connections all aimed at linking dispersed populations are an integral part of this agenda.

2. The 'Third World' Approach to Rural Planning

Numerous countries attained independence from European colonial rule at the end of World War II. Some, like the Peoples' Republic of China, became 'Second World' countries that adopted planning models emulating Soviet style control by a strong central government. Another block of countries attempted to forge a separate third path to development differing from United States style capitalism and Soviet style socialism. This 'Third World' forged constitutions endorsing centralized planning by government to attain modernization by facilitating rapid industrialization of both the private and public sectors. In these models rural planning tended to be a key element in national economic development. Rural planning measures aimed to increase production but also to redistribute wealth on the grounds of social justice and human welfare. The latter provided legitimacy for governmental planning which was essential

in countries recently released from colonization. Furthermore the majority of these nations' populations were rural. In approaching the development of rural areas many of these countries emulated the US model. They aimed to increase and improve agricultural production through the application of scientific research that was to be developed, disseminated, and implemented in farming practice through agricultural extension services. This was seen as the modern way for rural planning to support national economic development.

Third World countries aimed to use agricultural production to raise capital for industrialization and the development of related infrastructure, as well as for the provision of urban as well as rural based populations. However they tempered their desire to increase agriculture production with the broader objective of bringing about an increased living standard and quality of life for economically disadvantaged populations in the countryside. Their emphasis on rural planning for human development reflected their recognition that the majority of their populations were rural, asset poor, involved in subsistence production, and members of lower status social groups of social structures that were feudal in character. Over time, these countries evolved a planning model for 'integrated rural development' that recognized gender and class differences and attempted to address social inequalities in access to rural resources; a process differentiated from earlier production oriented agricultural development models. This more recent approach to rural planning attempted to combine and balance between agricultural and economic development and social welfare and redistributive justice.

3. The Indian Model

At the point of independence from British rule India embraced rural planning directly. Initial Indian national-planning efforts to achieve rapid socioeconomic change concentrated on industrialization at chosen metropolitan centers, on the assumption that the benefits would 'trickle down' through the economy. Planners believed that although initially benefits would be concentrated in the core cities they would spread to rural areas. However, they also recognized the need to promote complementary rural planning to reduce existing and anticipated urban-rural disparities in wealth.

Rural planning measures in India conspicuously emulated the US model of agricultural development. They included: irrigation projects; the promotion of scientifically developed cash crops through the provision of improved seeds, equipment and fertilizer (the so-called Green Revolution approach to making agriculture productive); providing credit for agricultural investments to stimulate agricultural production; and, the establishment of a system of extension services

to introduce scientific farming techniques at the village level. They also regulated markets to stimulate trade in agricultural commodities; invested in roads and communications; and founded cooperatives to buy and sell agricultural products and facilitate the marketing of goods in rural areas.

3.1 Redistribution and Equity

The national policy of investing in industry and commercial agriculture increased the gap between those involved in the corporate formal sectors of the economy, urban and rural, and those in the informal, traditional, subsistence sectors. Rural landless and land poor, squeezed out of traditional positions in village society, migrated to the city in unprecedented numbers. Cities were unable to accommodate the massive influx of displaced, often unskilled, rural laborers and their families and urban environments deteriorated as slum settlements of the poor proliferated. Responding to this phenomenon inspired a new set of rural planning policies. Stemming migration to the city by improving rural life and diversifying the rural economy emerged as prime planning objectives. Making rural living more attractive included provision of postal service, healthcare facilities, clean drinking water, and electricity in the countryside. As this policy evolved, its objectives also expanded to include increasing equity and distributing the benefits of development to the poor more explicitly. This change inspired such planning measures as putting a ceiling on individual land holdings, reforming tenancy to enhance the rights to the land of those who cultivated it, initiating programs to support traditional artisans with better tools, establishing credit and marketing networks to allow them to compete with industry or at least sustain them until alternative jobs were created. Finally, the Indian government emphasized free, mandatory elementary school education throughout rural areas to improve skills the poor needed to compete for development benefits.

In 1976 A. T. Mosher an international agricultural development expert summarized the various phases of Indian rural development planning in *Thinking about Rural Development*. He described some common characteristics. They were:

(a) Recognition that although economic development is important it is not an essential precondition to the social transformation that is considered the central objective of a rural development strategy;

(b) Attention to increasing efficiency with the technical revolution of fertilizers and high yield varieties of cereals. The attempt was to boost both food grain production and commercial crops and monoculture production of commodities for which there was an international market;

(c) Development of programs that addressed equity and asset redistribution; and

(d) Enhancing rural citizen's participation in the evolution of locally appropriate planning programs. Elements of these phases of rural planning policy and objectives in India—moral and social transformation, economic efficiency, redistribution and social justice, and popular participation in decision making—are to be found in the rural planning approaches of many countries around the world although there is a great deal of variation both in emphasis in policy and in the capacity to implement.

4. *Current Priorities and Approaches in Rural Planning*

Rural planning oriented to improving physical infrastructure and the quality of life for rural populations was an important policy agenda in developing countries in the earlier periods of their post-independence histories. More recently, as rates of urbanization have remained high in these countries and cities have experienced hyper growth, despite efforts to stem rural migration and population increases, rural planning in many countries has become a lower priority endeavor. The worldwide liberalization of economies attention is focused on World cities of over 10 million people, and, as a result, notions of intervention in rural areas to improve rural conditions have been given far less significance.

Concerns about the long-term negative impacts of the 'Green Revolution' have emerged in many parts of the World. They are related to degradation of soil quality; depletion of groundwater tables; the long-term sustainability of modern agricultural cultivation on prime land; and, as supply of such land is exhausted, about the viability of applications of this technology package on poorer quality, more fragile lands; and rising concern about genetically modified crops entering the food system of human populations. These concerns have led to calls for a modified, mixed approach to rural development that recognizes traditional, sustainable practices. In contexts of risk prone environments, development planners are describing a need for a rural planning strategy in which 'top down' science driven Green Revolution strategies of intensifying agricultural cultivation are tempered with the understanding that can be attained by tapping the knowledge of rural cultivators who are following traditional, self sustaining forms of agricultural production (Pichón et al. 1999). This position, labeled 'sustainable agriculture', has stimulated rural planning efforts based on more traditional modes of agriculture (National Research Council 1989). The task of helping rural places has been defined as a set of two complementary concerns related to how people will earn a living (Lapping et al. 1989) and how they will do it so that natural, environmental resources will be conserved (Sargent et al. 1991).

In the 'First World' rural planning is coming full circle. From a 'universalistic' modern-science driven notion of development and progress there is a renewed orientation to the specificities of the local, rural, asset base of both physical and human capital. In much of the developing world, facing the waves of change engulfing countries in the throes of economic liberalization, rural planning has been placed much lower in priority to programs that address issues of rapid urbanization and globalization. Thus programs related to social justice, participatory decision making, sustainability, and the environment have taken second place to economic transformation of rural production.

Rural Sociology

Rural sociology has traditionally been defined as the study of social organization and social processes that are characteristic of geographical zones where population sizes and densities are relatively low. Rural societies, however, do not exist in isolation or a social vacuum, and thus the subject matters of rural sociology increasingly reflect the larger processes of the regional differentiation and allocation of populations and economic activities, and of social relations within

a society as a whole (and, increasingly, within global economy and society).

Perhaps the single most crucial fact about this field is that, as a formal sociological specialty, rural sociology is largely US in its origins, and that rural sociology emerged within the land-grant agricultural college system and in close association with major US historical trends in agrarian politics. In this article I will begin with the history of US rural sociology, particularly in relation to major contemporary emphases within the field. In the second section I will focus on the major branches of contemporary rural sociology, and especially on the significance of the 'new rural sociology' during the last two decades of the twentieth century.

1. *The Origins of Rural Sociology*

In a sense rural sociology, much like the discipline at large, has had very strong roots in nineteenth century social thought. Many of the major issues of concern to the classical theorists were in some sense germane to rural sociology, and have remained important to the subdiscipline a century later. Among the most important of the preoccupations of nineteenth century social theory was whether village and farm life was more socially cohesive than, or morally or socially superior to, metropolitan life, and whether rural social relations would be resilient in the face of capitalist industrialization. Emile Durkheim (1858–1917) and Karl Marx (1818–83) both argued that urban-industrial capitalism, the advancing division of labor, and modern technologies and organizational practices were inexorable—and, on balance, progressive—social forces that would eventually supersede or supplant rural social forms. Ferdinand Tönnies (1855–1936) concurred that urbanization and industrial capitalism were tending to lead to the decline of intimate village communal bonds, though Tönnies was more optimistic than Durkheim and Marx that rural social relations could be sustained. For most of its history, rural sociology has reflected these nineteenth century debates over the desirability and resilience of traditional rural social organization.

It is now generally agreed that the pioneering rural sociological studies in the USA were those by W. E. B. DuBois in the late 1890s on the social consequences of the postbellum crop-lien system in Southern plantation agriculture. But while DuBois was the pioneering American rural sociologist and there were several prominent nonland grant rural sociologists (e.g., F. H. Giddings of Columbia University) in the field's early years, the character of rural sociology in the twentieth century was largely shaped by its articulation with the land grant college system. Rural sociology as a recognized subdiscipline largely had its origins in the preoccupation of land grant college leaders with the challenge of Populism. Founded and funded by

industrial and other elites after the turn of the century, the Country Life movement promoted the view that the problems of rural society were not due to the shortcomings of industrial capitalism as the Populists had held. These problems were rather seen to be due to a lack of organization, poor infrastructure, and technological backwardness in rural areas, which in turn led rural society to lag behind urban USA.

In 1908 President Theodore Roosevelt recognized this reform movement by appointing a Presidential Commission on Country Life. The next six decades of US rural sociology were largely prefigured by the County Life Commission Report, which was published in 1909. The Report did acknowledge many of the social problems of rural USA (e.g., the inequities of the crop-lien system, widespread tenancy, land speculation). But the dominant thrust of the Commission Report was the case it made that an expanded effort to modernize rural USA technologically and structurally was integral to improving the condition of rural USA. The Commission recommended the harnessing of the social sciences, particularly agricultural economics and rural sociology, to support the technological modernizationist vision for rural America. The land grant colleges responded to the Country Life Commission Report by hiring rural sociologists and establishing rural sociology units or departments. Rural sociological studies in land grant colleges of agriculture were seen to be important in order to help remove social barriers to technological modernization and to stabilize rural communities.

Sorokin and Zimmerman's (1929) influential treatise *Principles of Rural-Urban Sociology* exemplified the first three decades of US rural sociology. *Principles* synthesized the European classical tradition (particularly that of Tönnies) and land grant technological progressivism with the emerging empirical tradition of research on rural people and communities. The Sorokin-Zimmerman perspective was essentially a theory of rural-urban continuum, in which the character of social relations was posited to be shaped by the size, density, and related parameters of settlement patterns.

Very soon after *Principles* was published, rural sociology would be confronted with the Great Depression and rural squalor, and most rural sociologists embraced New Deal reformism. The Great Depression and the fashioning of the Depression-era New Deal opened up vast opportunities for rural sociological scholarship on rural communities and peoples which was closely linked with the New Deal reform agenda (e.g., land tenure reform, encouragement of co-operatives, commodity programs) (see the summaries in Buttel et al. 1990, Chap. 1, Larson et al. 1992).

Reform-minded rural sociology, however, was short lived as a result of the ideological shift to the right that had largely swept away most New Deal rural programs by the mid-1940s (Larson et al. 2000). The jettisoning of the New Deal rural programs induced the land

grant colleges to refocus their efforts on the technological upgrading of the countryside. In the late 1940s and early 1950s a handful of prescient rural sociologists developed the diffusion of innovations perspective on agricultural innovation and change which provided sociological support to the land grant technological project. The diffusion of innovations perspective was a social-psychological perspective on farmer technology adoption behavior that posited that innovative and progressive technologies and value orientations tend to diffuse from metropolitan institutions to rural people and localities, and that persons with more modern orientations are most likely to adopt improved metropolitan-developed technologies and practices (see Rogers 1995 for a contemporary summary, and Fliegel 1993 for a historical perspective and sympathetic critique). Shortly thereafter the social psychology of farm practice adoption, and of related rural behaviors such as educational aspirations, provided a comfortable niche for rural sociology within the land grant college system.

Rural sociology now exists in dozens of world nations. Much of the impetus for the global spread of rural sociology was due to the missionary zeal of US rural sociologists who from the 1940s through the 1960s sowed the seeds of US-style rural sociology across an impressive range of countries across the globe. Since the 1970s, however, rural sociology has become increasingly diverse and less influential globally. US rural sociology increasingly borrows from the ideas of European and Third World scholars (e.g., Goodman and Redclift 1991, Llambi 1990, van der Ploeg 1992), and is sometimes criticized for its parochialism and quantitative emphasis.

2. *The Major Focuses of Contemporary Rural Sociology*

Rural sociology has increasingly become a less coherent subdiscipline, and more of an 'umbrella' for an assemblage of research, much of which no longer pertains primarily to rural people or rural social relations. Rural sociology now has six major branches: rural population, rural community, natural resources and environment, agriculture, sociology of international rural development, and sociology of agricultural science and technology.

From the very inception of rural sociology, sociological analysis of rural population and rural community dynamics through census and social survey data has been central to the field. In the early days of rural sociology, rural population and rural community studies were very closely articulated. In large part this was because census of population data for counties and rural places were the most accessible data sources for characterizing rural communities and farm structures. Even by the end of the twentieth century there remains a significant relationship between rural

population and community studies (see, e.g., Fuguitt et al. 1989, Garkovich 1989).

While there has been a continuing basis for articulation between rural population and community studies, these areas of work have become increasingly differentiated so that they are now seen as quite distinct specialties. The use of census and survey data to document rural-urban differences, as in Sorokin and Zimmerman's (1929) *Principles*, fell into disrepute, and the rural-urban continuum perspective was slowly but surely undermined empirically (Newby 1980). Rural population research has followed the larger subdiscipline of demography in becoming more quantitative, while the rural sociological analysis of communities, though it has a strong quantitative wing, has continued to have a significant cadre of researchers who use qualitative or field methodologies (Wilkinson 1991). Studies of regional and labor market inequalities (Lyson and Falk 1993, Lobao 1990), rural poverty dynamics and racial inequalities (Duncan 1999), and rural gender inequalities (Sachs 1996) have complemented the traditional rural sociological emphasis on community studies.

While there has been a long and significant tradition of rural sociological scholarship on the relations among people, communities, and natural resources (Field and Burch 1988), the sociology of natural resources and environment in the contemporary sense did not emerge until the early 1970s. Rural sociology pioneered in development of the larger subdiscipline of environmental sociology and natural resource sociology. Rural sociologists have figured prominently in both environmental sociology (Redclift and Woodgate 1997) and the more management-oriented field of the sociology of natural resources (Field and Burch 1988).

As noted earlier, many of the most prominent US rural sociologists of the post-World War II period devoted major segments of their careers to encouraging the diffusion of rural sociology across the globe, particularly in the developing world. Part of the early impulse for elaborating an international rural sociology was the intellectual one of wanting to promote a comparative approach to understanding rural social organization. But equally important was the fact that the postwar period was an emerging era of 'developmentalism' (i.e., an era of faith in the efficacy of planned social change and development in the decolonizing world, see McMichael 2000). Rural sociologists trained in the adoption-diffusion tradition were particularly well represented among the first cohort of international rural sociologists (see Fliegel 1993, Rogers 1995). Scholars adhering to the diffusion of innovations perspective found their work very compatible with modernization theory, the dominant theory at the time in the sociology of development. This modernizationist/developmentalist tradition of rural sociology predominated for nearly three decades, but ultimately it would be undermined as a result of

critical assessments of the Green Revolution experience and of the role of rural sociology in international assistance (e.g., Koppel 1995).

Of all the major rural sociological specializations, the sociology of agricultural science and technology is, in one sense, one of its oldest, and in another sense, rural sociology's newest major speciality area. There were significant studies of technological change and labor displacement in Southern plantation agriculture during the 1930s through the 1950s. And, as noted earlier, the diffusion of agricultural innovations predominated in US rural sociology from the late 1940s through the late 1960s (see the summaries in Buttel et al. 1990 and Fliegel 1993).

Diffusionism, however, declined for three main reasons, each of which corresponded with an important new dimension in sociological research on agricultural science and technology. The first reason, as suggested earlier, was the growing criticism of the ability of the technological modernization project to generate equitable social benefits. This criticism was originally focused on the shortcomings of the Green Revolution, but was soon extended to the publicly funded agricultural-technological project in the advanced countries as well (see Newby 1980). Second, beginning in the late 1970s the Busch-Lacy group drew on world systems theory and the sociology of science to develop an influential critical perspective on the social causes and consequences of technological change in agriculture (Busch and Lacy 1983). Busch and Lacy's approach to the sociology of agricultural science demonstrated that social factors shape the content of new technologies, that new technologies tend to have social costs as well as benefits, and that rural sociologists need to take a more agnostic position toward new technologies than was generally the case among diffusionists. Third, in the 1970s and 1980s US rural sociology was increasingly influenced by the rise of Marxism in sociology at large. Neo-Marxism played a particularly prominent role in the sociology of agricultural science and technology (Kloppenburger 1988, Goodman and Redclift 1991). The neo-Marxist literature on agricultural science focused sociological attention on the class character of agricultural research institutions and agricultural technologies, and in so doing was often critical of diffusionism for having obscured how agricultural research is implicated in class and power relations.

It was noted at the outset of this article that rural sociology's history has been one of alternating between opposing views about the distinctiveness and resilience of traditional rural social structures. Rural sociology came into its own during the post-World War II era when it rejected rural romanticism and transcended New Deal reformism by embracing the technological-modernizationist assumptions. In the 1970s and early 1980s, however, the balance between these two views would be equalized to a degree. As noted, emerging controversies over agricultural technologies and their

social and environmental impacts removed some of the luster from the technological-modernizationist perspective in rural sociology. In addition, the 1970s were a period of 'rural renaissance' in the USA, as the population of nonmetropolitan counties grew faster than that of metropolitan counties due to net metro-to-nonmetro migration (Fuguitt et al. 1989).

These new realities of rural USA during the 1970s, along with the growing popularity within sociology of various 'critical' theories, led to what is often referred to as the 'new rural sociology.' These new theories were actually quite diverse, drawing heavily from neo-Marxism but also from neo-Weberianism, the peasant studies literature, and critical theories drawn from hermeneutics and related traditions (e.g., Mann 1990, Friedmann 1978, Friedland et al. 1981). To the degree there was a coherence within the new rural sociology, it was its critique of modernizationism and diffusionism within rural sociology, and its insistence on spotlighting the role of class and power relations. The 'new rural sociology' was originally most prominent in the sociological literature on agricultural change (see the summary in Buttel et al. 1990), but most recently it exhibited a major shift toward research on cross-border agricultural commodity chains and on the globalization of agrifood systems more generally (Bonanno et al. 1994, McMichael 2000).

Perhaps the clearest indication of the importance of this new scholarly tradition was that even scholars who have been ambivalent about the new rural sociology have been obliged to address its premises and hypotheses (van der Ploeg 1992). The new rural sociology has also directly or indirectly influenced most other areas of rural sociology (see, e.g., Lyson and Falk 1993, Lobao 1990). But despite the fact that the new rural sociology is the most pervasive new trend during the last quarter century of rural sociology, rural sociology remains highly diversified. The new rural sociology, even in its heyday of the 1980s through the mid-1990s, did not come close to dominating the field in the way the diffusion paradigm did in the 1950s.

F. H. Buttel

Russian Revolution, The

The term is used in different ways. It refers to varying events and time frames. Normally it means the major upheaval of 1917 that replaced the tsarist empire with Bolshevik rule. In this case the term can refer to

either the demise of the monarchy in the so-called *February Revolution* (February 23/March 8 N. S. to March 2/15) or to the *overthrow of October* 25–26 (November 7–8) when the Bolsheviks seized power in the Petrograd Soviet of Workers' and Soldiers' Deputies. But 'Russian Revolution' is often extended to denote longer processes and obviously related sequences of events of the same type. In this case, the term encompasses the 1918–20 Civil War immediately following the October Revolution as well as the subsequent early Soviet period up to the *Stalin Revolution* of 1929–30 or—the widest definition—the entire transformation of Russia from the turn of the century and so-called *First Revolution* of 1905–6 all the way down to the Stalin Era. Looking at it this way, the 'Russian Revolution' covers Russia's peculiar political and socioeconomic modernization crisis which ended in the establishment of the Soviet Communist developmental dictatorship (1900–1930).

Substantive reasons and the question of research feasibility suggest narrowing this range of definitions somewhat. 'Russian Revolution' should be restricted to the convulsive transition from the Russian *ancien régime* to the Bolshevik form of government. The term properly denotes the two core events of the transfer of power: the overthrows of February and October and their consequences. However, there are valid reasons for including the Civil War because it was by nature the inevitable, belatedly-waged war of revolution. Both time frames (1917 and 1917–21) lend themselves to differentiation of processes into *politics and power struggle*, *socioeconomic change*, and *cultural and nationalist developments*.

1. The Political Constitution and System of Government

Political change in 1917 consisted of the succession from the monarchy to the 'emergency democracy' (Geyer), the Provisional Government (March 2–15 to October 26–November 8), to the soviet-based rule of the Bolsheviks with the 'Left Socialist Revolutionary Party' as a junior partner. Neither the direction of change nor the options in the year of revolution can be understood without a look at preceding developments. By the same token, the consolidation and transformation of the outcome cannot be explained without reference to the Civil War. The impetus for criticism of the autocracy definitely came from circles just outside the seat of power. 'Liberal' forces in the aristocracy, the industrial-commercial upper class, which had developed a bourgeois self-image, and the recently established academic intelligentsia rallied to the cause of the constitutional restraint of the absolute monarch. But already during the grave State crisis of 1905–6 widely differing views were held on the extent of the say that parliament (the Duma) should get in govern-

ment. Following the restabilization of tsarist rule only moderate demands were still voiced by the groups that were allowed to operate legally. Nonetheless the 'revolution,' a term which cannot withstand any close scrutiny, clearly engendered a new political system and apparently a new distribution of power, although opinion is divided on the latter claim. Its legacy included a parliament, a party spectrum (albeit an incomplete one) and a politically outspoken press. Moreover, regional self-government (*zemstva*) appeared alongside the central government. Provincial authorities gained more and more powers. World War I accelerated this shift. Ultimately the *zemstva* guaranteed the last remnants of public administration.

Only this background explains why a protest by workers' wives against hunger and cold swelled to a mass uprising, which toppled the monarchy. The last week of the 300-year Romanov rule began with an International Women's Day demonstration, which differed from numerous past rallies only in the number of participants. A repeat performance represented a new quality. In the next few days the movement escalated into a general strike of workers in the capital, and local military units joined the protest. The revolution, in the strict legal sense as a new edition of sovereignty, took place on February 28 when a Duma committee without authorization of the tsar appointed itself as the Provisional Committee for the Restoration of Public Order, thereby seizing power. At the same time the Workers' Soviet, which had convened the day before on the lines of the autumn 1905 council, elected an analogous body. This established the *two principal political institutions* which constituted the so-called *February Regime* ('dual power') of the following year. They represented two different social classes, requiring mediation of their interests by the Provisional Government, first formed by the Liberals (embodied by the *Constitutional Democratic Party*), after May 5–8 together with the moderate wings of the *Socialist Revolutionary* and *Menshevik Social Democratic* parties. The remarkable correspondence between social status and party orientation including institutional representation is indicative first of the marked polarization in the society and second of the absolutely crucial requisite for survival of the February order: building a bridge between the two fronts.

This became harder and harder to do from early summer on. Several factors contributed. With the government and the ruling parties it was a growing hardening of personal animosities and of positions on issues. But a more serious aggravation was the result of omissions and a bad decision. The *Kerensky* Offensive of June/July, named after the premier, was a fatal error. It ended in a fiasco, which not only caused foreign policy damage. It also discredited the Provisional Government at home. Economic depression worsened simultaneously. Unemployment spread as more and more companies failed. Strikes and demonstrations proliferated, bringing the State to the brink

of anarchy. The formation of new coalitions and two 'Reconciliation Congresses' (with different compositions) were unable to check the rapid erosion of authority of the February Regime.

This benefited the *Bolshevik* Social Democratic Party, which declared an irreconcilable struggle with the 'capitalist government' when their undisputed leader, V. I. Lenin, returned to Petrograd from Swiss exile on April 3/16. They only had to channel the workers' and soldiers' misery and disenchantment over the failure of the new system. With all this grist for their mills, the Bolsheviks easily won great popularity. The spring splinter party was the strongest political force by the time the capital city councils were re-elected in September. What had happened and was about to happen was clearly evidenced by the dramatic change of leadership in the Petrograd Workers Soviet. The Bolshevik Trotsky replaced the Menshevik Chkheidze as chairman.

The 'Red October' (Daniels 1967) has produced much controversy. Soviet historiography, adhering to ideology, saw it as the investing of the first socialist state in the history of the world by the power of the masses. Others insisted on interpreting it as a military coup. There is no question that the seizure of power in the city garrisons from October 22–November 4 was executed before everyone's eyes by the Bolshevik-dominated Military Revolution Committee in defence of the Soviet. It is also undisputed that the Bolsheviks were able to obtain the support of a majority of delegates to the Second All-Russian Congress of Soviets, which convened on October 25. With this backing they managed to elect a presidium, more than half of whose members were their loyal supporters, while another third consisted of their Left Socialist Revolutionary sympathizers. To top it all off, the 'Right' Social Revolutionaries and the Mensheviks did them the favor of resigning their seats. Finally, the unchallenged occupation of strategic buildings and points in the city suggests that, (unlike in Moscow a little later) there was no resistance worth mentioning. However, it is equally obvious that armed force was used against a legitimate government that had become unpopular but had been elected by parliament. The storming of the Winter Palace and the arrest of ministers pointedly attests to the nature of the overthrow. The maneuver, accomplished by the Bolsheviks with the help of their Red Guard, was technically a military rebellion, and politically a *coup d'état*. But it was possible only because it was undergirded by the majority of the Soviet deputies and the tolerance, if not the sympathy, of the urban lower classes, and locally stationed soldiers in particular. Thus, the 'art of insurrection' preached and wholeheartedly practised by Lenin more or less boiled down to picking up the power that was lying in the street (N. Sukhanov).

The only question remaining was whether the Bolsheviks could maintain control. The wishes of the rebellious and potentially rebellious masses were

quickly satisfied. Early on October 26, the Soviet Congress passed a Peace Decree and a Land Decree. The intention of obtaining an immediate ceasefire secured the support of the soldiers for the overthrow. Distribution of large estates among village communes sanctioned transfers that had taken place much earlier and neutralized the peasantry. Overcoming the other parties and adherents of the *ancien régime* entailed a real struggle. It was inextricably tied to the independence movements of non-Russian nations and lasted until March 1921. Beginning in spring 1918 it escalated into the bloodiest war fought on Russian soil since the early seventeenth century. It actually started, still without recourse to weapons, right after the October coup. In the end the Bolsheviks maintained the upper hand so that they could begin the peaceful construction of 'their' State. However, at this juncture the fundamental decisions on its structure had already been made, and they were only superficially and temporarily amended, if at all, by the proclamation of the New Economic Policy.

The most important trend reflected Lenin's practical 'interpretation' of the slogan, 'All Power to the Soviets,' as 'All Power to the Bolsheviks,' which is what he had in mind in the first place. This usurpation was gradual. The cooperation between the Bolsheviks and the Left Socialist Revolutionaries in the October night session became a formal coalition in mid-November. Even this collaboration was based on the exclusion of not only the Liberals, but also the Mensheviks and 'Right' Socialist Revolutionaries. This confrontation manifested itself in the *alternative* between the *soviets* and the *Constituent Assembly*. When the latter was forcibly dispersed on January 6–19, 1918, it was not only the final curtain on the attempt to erect a democracy in post-tsarist Russia. It also dissolved most of the common ground between the coalition partners. The fate of the bipartisan government was sealed. All that was needed to precipitate its collapse was the separate peace treaty of Brest–Litovsk in March. Now one-party rule and the fusion of party and State began in earnest. The system which lasted until 1991 was established.

Moreover, at least three other features of the new government and political system had their roots in the post-October clashes. First, the life-and-death struggle fostered the emergence of extraordinary organs and extreme centralization of decision making. Both measures were only partially rescinded. The most important institutional legacy was the Cheka, which was soon an army of its own, operating in the hinterland and authorized to administer martial law. As a secret police, the Cheka later became a synonym for totalitarian rule because it was empowered to execute arbitrary force beyond and above the law and was only subordinated to the top Party leaders. A second fundamental decision was subjecting the economy to the control of the Party and the government. Starting in December 1917, the regime nationalized

first the banks and big industry; then, during the Civil War, commerce and small business as well. Officially control was assumed by a pyramid of economic councils; *de facto*, however, since the unions had been forced to march in step, by members of the only legal party. In addition, an increasing intolerance of intra-party criticism reinforced the concentration of power and authority. The relative laxness which the Civil War encouraged in 1919 yielded at the conclusion of hostilities to a 'prohibition of factions' (March 1921), which Stalin used as a decisive weapon in the power struggle for Lenin's succession. Finally, the Red Army was created in the fight for the spoils of the October Revolution. Even though its structure and personnel underwent several reshuffles, one birthmark was never effaced—its orientation on the regime and the Party.

2. Social Upheaval

The revolutionary movement united political and social objectives from the start. It laid its claims in the name of the lower classes, which it always viewed as exploited. The Socialist Revolutionaries acted on behalf of all the 'enslaved,' but primarily the peasants, while the Social Democrats marched in the name of the urban 'proletariat.' The Liberals, on the other hand, considered themselves to be 'class neutral.' But actually this camp had a social stratum of its own, ranging from the reform-oriented aristocracy and the intelligentsia to the commercial-industrial bourgeoisie. In the first revolution these various tendencies underwent symbiosis. The nearly identical timing of the general strike in the capital and the peasants' storming of the agricultural estates in the autumn of 1905 shocked the State to such an extent that it agreed to concessions to the democratic demands of the Liberals.

In February 1917 a similar convergence took place, with one fundamental difference. Instead of the pincer attack of workers and peasants, an alliance of workers and garrisoned (not frontline) soldiers led the assault. This time the *peasants* remained aloof. The agrarian revolution took place later, but more violently than ever before, *after* the collapse of the tsarist state and its rule by force in summer 1917. Later the rural population divorced itself from the urban revolutionary movement and went its own separate way until the autumn of 1918. The core significance of the upheaval can be summed up with *one* result: the wildcat (i.e., spontaneous) redistribution of the property of the landed aristocracy. The peasants seized that which they had always believed to be their rightful possession. The predominant form of the operations was characteristic of the peasants' ties to tradition. Most villages acted collectively and allotted the land to commune members according to the dictates of custom to be used for a certain length of time. Ownership remained in the hands of the *obshchina*, and private

property came into *de facto* existence only because hardly any redistribution occurred thereafter. Following this, their revolution, the peasants were sated. Events and problems beyond their village left them cold. Since the New Economic Policy legalized the reform, they could perceive themselves as the winners of the revolution despite the horrors of the Civil War. However, this redistribution wreaked havoc on the economy. It abolished the large cultivated holdings which yielded the bulk of the farm produce sold elsewhere and reduced the average acreage to a level which hardly sufficed for efficient and stable production for the market. The outcome was a crisis-proneness that provided a convincing argument for a centrally planned economy.

The consequences of the February 1917 general strike of the Petrograd *workers* were more complicated. From the standpoint of the protagonists, the medium-term ramifications were negative. The rebels managed to obtain their demands only in the short run. Wages increased substantially, and working hours were reduced, even though the principal demand, a law stipulating an eight-hour workday, was not achieved. Personal and social security were markedly improved. But the galloping inflation and unemployment following the economic collapse offset these benefits from early summer on. This setback made it possible for the syndical factory committee movement to extend the say in management it had gained in Petrograd in March to full control. Its victory was hollow because the victors inherited the administration of the bankruptcy. To add insult to injury, the expectations it cherished after the October overthrow were completely dashed. If the Bolsheviks had a typical way of dealing with 'their' constituency, it was revealed in their relations with the factory committees. Before the overthrow they adopted the demands of the committees; after the Bolsheviks seized power, they also succeeded in gaining control of these organs. At the beginning of the year the 'anarchistic-decentralized' factory committees were muzzled by the unions, which were themselves on the way to becoming a 'transmission belt' (Lenin) of the Party. All that remained was the disappointment over unkept promises, which triggered spreading strikes, the rebellion of Kronstadt sailors and intraparty criticism ('Workers' Opposition'). All this dissidence was suppressed by spring 1921, in many cases with extreme brutality.

3. *Disintegration of the Empire and National Independence Movements*

Liberal political and sociological views of the Russian Revolution have overlooked too much evidence that it was also a *national* movement. Incipient emancipation campaigns were exhibited in the first 'crisis of authority' in 1905–06. Social unrest in the Baltic provinces

and in Poland were particularly violent. Both there and in the Caucasus it expressed a desire for autonomy. The first authentically freely-elected State Duma had several national factions and a total of about 45 percent non-Russian deputies. Following the 'prewar' and war period, which gave these movements an enormous boost, and the collapse of the tsarist empire, the national outbursts flared up as attempts to secede by force. Favored by the 'anarchy' in the literal sense created by the power vacuum, the 'old' nations like Poland and Finland and non-Slavic Baltic and Caucasian regions declared independence from the Petrograd central government. Nuclei of the old empire such as Ukraine joined the breakaway trend. It was not without cause that the June 1917 resolution of the Ukrainian *Rada* (Council) declaring it would act as a formally independent body plunged the Provisional Government into an extremely severe crisis. The Bolsheviks supported this national emancipation only verbally and for tactical reasons. Prior to their power seizure and during the Civil War in the peripheral areas of the empire, they espoused the doctrine that nation states had to reclaim their historical rights in the 'bourgeois phase' of the revolution. However, the stronger the *socialist* self-awareness of the new regime became, the more it again embraced the necessity for a unitary state. In fact, the Red Army acted from the beginning as an arm and an instrument of Great Russian centralism which regained control of the old empire—with the exception of Finland, Poland, and the new Baltic republics—by the end of the Civil War. If one looks very closely, this resulted inevitably from the political foundations of the new State. Since only one political force was legal, it had to be centralist. Therefore the Soviet Union established in 1922 was only formally a federal system. In truth it was an anachronistic multinational empire in a postwar world organized into nation states and dominated by nationalisms.

4. *'Iconoclasm'*

Last but not least, scholars have recently remembered to highlight the extremely radical cultural upheaval the Russian Revolution entailed. In the first place, it had a salient 'ideocratic' dimension. The Leninist version of radical Marxism was an ideology with the political power to stake a claim to shaping all sectors of public life, and ultimately also of all private life of the people under its sway, from work to education, according to fundamentally new, theoretically preconceived principles. The October overthrow ushered in the first regime in modern history to make a specified interpretation of world history and destiny, including a programmatic, militant atheism, obligatory. The radical Bolshevik Revolution unleashed an unprecedented outburst of all kinds of 'anti-establishment' movements, almost entirely borrowed from Western

European modernism. They were of a sociopolitical (women's liberation), intellectual-aesthetic (abstract art, 'Proletkult') and pedagogical nature (polytechnic education, public health). Even though this experimental exuberance was a source of aggravation to the Party and government leadership and its wings were gradually clipped after the conclusion of the Civil War, it survived in isolated pockets until definitively forced into submission by Stalin. In the aesthetic sector, the 'revolutionary culture' is universally credited with significant achievements.
