Central Business Districts and inner-ring suburbs have gone through ups and downs over the last 50 years as many companies and higher-income residents have moved to outer-ring suburbs and smaller towns at the urban fringe. The constant outward migration has created enormous expansion of rapidly growing cities such as Atlanta, Phoenix, Dallas, Denver, Los Angeles, San Francisco, and Seattle. The outward growth has put pressure on open space and natural resources and placed demand on the public sector to build highways and other infrastructure to serve the new development.

At the same time, central cities and inner suburbs have suffered under declining municipal tax revenues and increasing demands for services from a poorer population, often augmented by new immigrants. While many cities such as Manhattan and Los Angeles are seeing signs of a return to the CBD by investors and residents, outward migration is likely to continue. Urban containment boundaries are a popular though controversial, technique for containing outward expansion. Developers have historically tended to prefer green-field suburban sites because they are easier to build, easier to finance, and more attractive to tenants and homeowners. Whether central cities and inner suburbs will be able to attract new investment and redevelopment is one of their most important challenges.

4.3 Smart Growth/Urban Sprawl

The rapid expansion of suburban growth in the last half of the twentieth century has fueled a backlash against development and *NIMBYism* (not in my backyard). 'Smart growth' is the latest approach to solving the problems associated with urban sprawl—congestion, loss of farmland, lack of functional open space, monotonous and boring development, and inadequate infrastructure (see Gordon et al. 1989, Peiser 1989).

4.4 Public–Private Development

As the regulatory process for major development projects has become more time consuming and costly, more developers are joining forces with cities, redevelopment agencies, school districts, armed forces, and other government agencies to develop property. The public–private partnerships help developers to obtain lower cost financing and necessary public approvals

while giving public agencies a share in the profits and the ability to deliver more public benefits such as parks, plazas, roads, sewer plants, and other infrastructure (Kotin and Peiser 1997).

4.5 Technology

The internet and other new technologies are having dramatic impacts on all aspects of real estate, from office building construction to shopping center functionality resulting from Internet commerce. As old shopping centers and industrial buildings become obsolete faster, new industrial distribution centers and 'entertainment' shopping centers are replacing them. While home offices and telecommuting have caused alarm for future office space demand and spawned new work patterns such as 'hot desks' (where employees share office space, plugging their lap top into the company computer network as they move from office to office) workers still appear to want the 'social' aspects of coming to work. Suburban corporate campuses with high tech communications, on-site recreation and sporting facilities, and high security are being built to respond to new workplace needs and employee preferences.

5. Social Responsibility

Real estate development touches on every aspect of people's lives. It determines not only the quality of the built-form environment, but also affects the life-style and social wellbeing of residents and workers in every community. What developers build may last a lifetime or longer. Because of their far-reaching role, developers bear a special responsibility. Most developers care deeply about the quality of their projects. High quality development depends as much on public sector support and services as it does on the private activities and financial resources of the developer. Since real estate involves very long-term investment, the long-term stability of the community and continuing attractiveness to new residents and firms is essential to long-term profitability for the developer. While developers are often vilified for destroying the environment and hastening neighborhood change, good development is responsive to neighborhood concerns and is sensitive to maintaining and improving environmental conditions. As public funds have been reduced for open space infrastructure improvements, development is often the instrument through which open space is preserved and new infrastructure is built. As their role expands, developers need to be ever more knowledgeable about the urban context in which they build and about the multitude of forces with which they must deal. The Urban Land Institute's mission statement sums up the developer's charge: 'to provide responsible leadership in the use of land in order to enhance the total environment.'

Realism/Neorealism

Realism is a tenet that views the world as it is, and not in terms of an unrealized ideal. It emphasizes the constraints of the real world and the need for pragmatism and prudence. Applied to international politics, realism sees a conflict-ridden world of states concerned pre-eminently with their security and pursuing power as the means to assure their survival. Realists therefore see the distribution of power as the major determinant of state behavior and international stability. Within this broad rubric, realists have developed alternative formulations, emphases, and distinctions.

1. The Realist Vision

The realist vision of international politics holds that states interact in an anarchical international environment in which survival is uncertain. Because power is the key requisite for survival, states define their interests in terms of power and constantly assess their strength relative to that of others. What emerges from their interaction is a balance of power that is the sole basis for order, regularity, and stability in international politics.

Realism emphasizes the competitive and conflictual nature of international politics. States either constantly prepare for war or are at war with one another. Fearing adverse shifts in the balance of power, they respond with internal mobilization and, should that prove inadequate, with external alignment. Self-reliance is preferred in a system of self-help, but allying with others to confront a common threat may be temporarily necessary. Cooperation is thus short-lived, lasting only as long as the common threat, and is a function of common interests and not common values or ideology. Realism can therefore readily explain alliances, such as the Nazi–Soviet pact of 1939, between wholly antithetical political systems. The result, mobilization and alignment in response to adverse shifts in the balance of power, returns the system to equilibrium. Hence, balances of power recur and reemerge in international politics.

1.1 Realist Assumptions

Realism is a statist perspective, for it assumes states to be the key actors in the international system. It excludes multinational corporations, nongovernmental organizations, and a variety of transnational and subnational entities that matter only to the extent that they affect states.

The theory assumes that states face recurrent threats and challenges in the international system. Power, especially military power, is the basis of both threats to a state and to its ability to assure its survival.

Realism presumes survival and its requisites to be the highest priority of states, indeed, their very reason for being (*raison d'état*). States value security considerations above all and respond to the imperatives of the international system. The primacy of security also implies that other policies, including foreign economic ones, reflect considerations of international power politics.

1.2 Realism Deemphasizes

For realists, international law and international organizations are largely irrelevant to international politics. Both reflect the interests of powerful states, for in international politics might makes right, and international institutions do not constrain great powers but merely provide additional venues for the

exercise of power. At most, both play a role only in matters of low politics, in regulating transportation, communication, and economic exchange, for example, and not in matters of high politics, especially military security.

Realists also consider the requisites of survival to dominate any moral considerations. Indeed, realists transform necessity into a moral imperative.

Realism downplays the role of domestic politics. It treats states as unitary actors that are functionally equivalent to one another, and the constraints imposed by the international system generate similar behavior even by dissimilar states. The international system once consisted largely of monarchies and then of authoritarian and military governments, and is now increasingly composed of democratic states. For realists, however, it continues to function in the same way.

Self-reliance precludes states from allowing the development of any division of labor or any interdependence regarding the requisites of state survival. Small states may have no choice but to rely on others, but great powers do have such choices and thus do not allow the emergence of any meaningful interdependence.

1.3 Realism as Equilibrium Theory

The balance of power is an equilibrium theory. The security policies of nations result in a balance of power among states. The equilibrium can be disturbed, but only by exogenous shocks, ones outside the model. The disturbance then sets in motion forces that return the system to a new equilibrium. The implosion of the Soviet Union, for example, disturbed the balance of international power, but was an event outside the model and inexplicable by it. But realism does purport to explain the set of forces that then would come into play to return the system to equilibrium.

Put this way, balance of power theory functions like Adam Smith's invisible hand in creating an unintended outcome. For Smith, the self-interested behavior of producers in a competitive market generated the best price for consumers. In international politics, the pursuit of national interest and the struggle for power in an anarchical system create a peaceful stable order. It is not the search for peace but the search for security that creates this stability.

1.4 Realism—its Historical Roots

Realism traces its lineage to Thucydides, who argued that his *History of the Peloponnesian War* (1996) provided the one and true explanation of the war: the growth of Athenian power and the fear this struck in Sparta. Thucydides argued that preceding incidents and specific complaints notwithstanding, the true cause was a shift in the balance of power.

As important to current realist formulations is the work of Thomas Hobbes, who translated Thucydides into English and argued (in *Leviathan*) that the state of nature, which he characterized as a war of all against all, is one in which war and preparation for war are a constant. Conflict is limited within societies by the creation of the Leviathan, a coercive state. For modern realists, who distinguish international from domestic politics, international relations remains an anarchic realm; there is no Leviathan and the war of all against all endures.

Realism dominated the study of international relations in the middle of the twentieth century as the world came to grips with the very occurrence of the Second World War and the failure of both international law and international organizations to prevent it. Hans Morgenthau's (1948) influential formulation of realism drew upon psychology and rooted realism in a human nature presumed to be inherently aggressive and in a view of individuals as power seeking.

Beginning in the 1950s and increasingly in the 1970s, realists (led by Waltz 1959, 1979) linked their arguments to systems theory and structuralism. This variant rejected basing realism in any theory of human nature or any internalized commitment on a balance of power. This neorealist formulation did not posit any individual or collective propensity toward power maximization *per se*. Rather, it posited a minimalist concern with survival in an anarchic setting as the only necessary conditions. Even good people and good states caught in an anarchic structure have no choice but to arm themselves in preparation for the possibility of war and must assiduously guard their relative power. Neorealism or structural realism firmly rooted the problem of international politics in the international system and not in the nature of individuals or states.

2. Disagreements

Despite the consensus in emphasizing states as the central actors, security as their prime concern, and power as their key instrumentality, there is some confusion and disagreement in the core of realist thought. First, there is confusion whether the theory is positive or normative. Realists typically argue that theirs is a positive theory of how the system actually works (an iron law of international politics), yet many have also used realist precepts to criticize the foreign policies of specific countries. Realists have argued, for example, that states do only what is in their national interest but have criticized specific actions, such as US intervention in Vietnam, as not being in the national interest.

That politicians adopted the argument has also led to confusion. First, the term balance of power has come to be used loosely and applied to virtually every configuration of power. Second, there is a disagree-

ment between scholars as to whether realism operates through intention (states must aim for a balance of power) or irrespective of it (as an unintended consequence).

Despite agreement that the distribution of power determines stability, scholars disagree about the relative stability of different configurations of power. Within the balance of power tradition, some scholars find bipolarity more stable, others find multipolar systems more stable. Although most agree that the international system tends towards balance (though more predictably and more quickly in some settings than others) and that hegemony and unipolarity are not possible or sustainable, some hold that the system tends towards power preponderance rather than balance, and that hegemony is stable but that a balance of power is not.

3. Problems

Realism is criticized for leaving too much out. A pristine realism that only says that balances recur cannot explain most foreign policies of most states most of the time. Moreover, the theory is static and cannot explain change over time. Important transformations of recent centuries, such as the rise of nationalism, the industrial revolution, the rise of ideological politics, the spread of democracy, the revolutions in communication, transportation, and warfare, realists judge irrelevant to international politics, which they treat as unchanged as long as anarchy continues to characterize international politics. Realists deem these factors to matter only to the extent that they affect the relative power of states (whose alteration is the only source of change in international relations) and are viewed as exogenous shocks. The only transformation that some realists accept as affecting world politics is the nuclear revolution, which they consider to undercut fundamentally the importance of relative power in a classical military sense.

The theory is also vague and imprecise. It is not clear what factors enter into a calculation of the balance of power, nor how balance is ascertained. It is difficult to test assertions of the theory when there can be wide disagreement over whether a particular distribution of power is balanced or not. Scholars dispute whether stability during the Cold War derived from US military superiority, a balance of power between the US and USSR, or the existence of nuclear weapons.

More important, the theory is indeterminate. It cannot predict which particular distribution of power will emerge, only that balance will. Nor can it predict the process by which balance is restored. US containment of the Soviet Union during the Cold War can be explained as the working of the balance of power, but so can the US roll back of German and Japanese

power during World War II. A US decision simply to contain German and Japanese power in the 1940s would have been as consistent with realism as the actual US decision to wage war and undo the consequences of German and Japanese aggression.

The theory makes precise predictions only when the constraints of the international system are presumed to be tight. Although the theory holds that it is great powers that structure global politics, the international system is most constraining of small powers and least constraining of large ones. Hence, the theory is typically indeterminate regarding the behavior of the great powers, which are presumed to matter most for international politics.

Formal studies have shown that realist premises are consistent with international cooperation, the construction of international organizations, and even the emergence of international norms. These works challenge the deductive logic of realism, arguing that the premises are insufficient to lead to realist conclusions.

Realists have had some difficulty in recent years in explaining significant international developments. The disjuncture between military and economic power has been sustained for an extended period of time. During the later stages of the Cold War, the world remained militarily bipolar, dominated by the might of the United States and the Soviet Union. Yet economically the world was multipolar, with Germany (and the EU more broadly) and Japan as significant economic powers that did not translate their economic prowess into military strength. Such sustained disjuncture between the distribution of economic and military power is problematic for realism.

4. Modifications

Realist thought continues to develop, in part to deal with such anomalies. One variant now posits that it is the perception of power rather than the actual distribution of power that matters. Another decouples changes in the distribution of power from the perception of threat, and holds that states respond to threats and not just shifts in power. Some see realism as characterizing particular eras rather than international politics generally. Eras in which territorial acquisition brings greater rewards than does commercial exchange are ones to which the logic of realism is more applicable; eras in which the nature of warfare gives the offense an edge are ones in which a realist logic is more likely to prevail.

Realism has a core strength: its emphasis on power and interest and an unregulated international system. Yet its most pristine formulation is rejected by many, if not most, scholars who articulate their positions relative to a core realist argument.

Realisms and their Opponents: Philosophical Aspects

In everyday usage, ‘realism’ is often used as a name for a practically or epistemically low-ambition attitude, while ‘idealism’ is often taken to denote a high-ambition—if not utopian—attitude. In philosophical usage, mostly, it is the other way around: those who are called realists tend to claim more than their opponents—they are the philosophical optimists.

Within philosophy itself, ‘realism’ adopts a variety of interrelated and contested meanings. It is used as the name for doctrines about issues such as perceptual access to reality, the existence of universals, the goals and achievements of science, the nature of truth, the objectivity of morality, and many other things. Given this variety, no single shorthand definition of the term ‘realism’ can be provided.

One manifestation of this variety is that the opponents of realism about these issues are not called

uniformly by a single label (other than the rather uninformative ‘antirealism’): the labels used include idealism, phenomenism, instrumentalism, conventionalism, fictionalism, noncognitivism, constructivism, relativism, irrealism, and others. Sometimes such labels vary from one dispute or domain to another even when similar ideas are being expressed. Sometimes they are used to make claims that are specific to the domain at hand and distinct from other antirealist theses.

In what follows a brief tour will be taken along some of the representative philosophical highways and lanes, from ontology through semantics to epistemology. Along the way, realism will be confronted with some of its various opponents and internal conflicts. The philosophical landscape in the neighborhood of realism is nowadays much broader than it used to be: in a typical older encyclopedia, ‘realism’ was taken to name doctrines about universals or about perception, or both, to the exclusion of much of its present coverage, and many of the current opponents were missing from view altogether.

1. Ontology

As an ontological doctrine, realism is a claim about the existence of something. Versions of ontological realism differ from one another in regard to what this something is—the domain of existents (things that exist)—and what kind of claim is being made about items in this domain. If we take ontological realism to have the form of the statement ‘*X* exists,’ then in order to identify different versions of realism and its denial we need to examine the various ways in which its two components are interpreted. We need to consider the two questions: ‘what exists?’ and ‘what is existence?’

If we just claim that the world exists, without providing further specifications of the constituents and structure of the world, our realism will remain rather uninteresting. Philosophers of the nominalist persuasion add that particulars, and nothing but particulars in time and space, exist. The world consists of objects such as you and me and the particular copy of this encyclopedia that you are reading now. A radical nominalist will claim that only ‘bare’ or propertyless particulars exist, while properties do not. Whereas nominalists can be realists of sorts, they are opposed by those who have been called the realists in the debate over the existence of universals. In this debate, realists claim that universals—kinds, properties, relations—exist, that they are, or are among, the constituents of the world. Not only does this particular encyclopedia exist, but among the furniture of the world are books as a cultural kind, properties such as weight and colour, and the relation of being owned by someone. Such universals can be multiply instantiated in particular objects in space and time. Platonic realism takes universals to constitute reality: redness, ‘book-

ness' and ownership inhabit a separate realm of ideas, independent of the particulars that exemplify them. Aristotelean realism takes both universals and particulars to be real, and claims that universals only exist when exemplified in particulars. In the philosophy of mathematics, the view that numbers, real-valued functions, and sets exist as 'abstract entities' is called Platonism, while the opponents denying their existence are known as intuitionists, formalists, and logicians.

Common sense takes the world to be furnished with medium-sized material objects that are the possible objects of sense perception. Considering these objects to exist leads to realist doctrines about the ontology of perception. The opponents of realism in the theory of perception include the idealists (to whom it is 'ideas' that constitute the world) and phenomenologists (who try to construe the world out of 'sense data'). *Direct realism* says that perception is a direct awareness of material objects that exist in reality and that nothing else exists between perception and perceptible objects. Naïve realism, entertained by philosophers as a target of criticism, is a version of direct realism that takes sensible qualities to be the intrinsic properties of material objects and these objects to have all the properties they are perceived as having. *Indirect realism* states that perception is directly about mental representations (such as bodily sensations and after-images) and only indirectly about the external world and that both the direct and indirect objects of perception exist.

An encompassing commonsense realism takes objects in the commonsense domain, whether material or mental, to exist. Its list of existents includes my bathroom and my belief that it is vacant, as well as ducks and the desire to eat one. Anyone ontologically committed to folk psychology, holding the commonsense view that beliefs, desires, hopes, and fears exist, is a realist about the mental. Common sense also seems to suggest that there are moral facts about the world. To say that something is morally good or morally bad is to describe aspects of objective reality. Moral realists deny a sharp distinction between facts and values, holding that moral values are among the facts of commonsense experience. In contrast to these views, an eliminative materialist denies that mental and moral facts exist and takes only matter or physical objects to exist, thus counting as a realist about the material but not about the mental or the moral.

Scientific theories characteristically discuss unobservable entities such as quarks and electromagnetic fields. If we take these to exist, we hold the ontological position of *scientific realism*. The opponents of realism about the ontology of scientific theories are the phenomenologists and fictionalists. For them, unobservables do not exist—only observables do. Rather than being among the fully authorized inhabitants of the real world, the unobservables of science are nothing but fictions of imagination in the scientists' minds.

One may combine scientific realism with a commonsense realism that takes both scientific objects and the objects of folk physics, folk psychology, morality, and folk sociology to exist: the full set of existents includes plans and plaitiveness, plantations and plebeians, plants and planets, platelets and plastids. This is disputed by a radical scientific realism that holds that only scientific objects exist; thus, trees do not exist, but the atomic and cellular structures that constitute them do. A radical commonsense realist will deny existence to scientific objects while granting existence to commonsense objects: plants exist while plastids do not. One can also be more discriminate among the various classes of commonsense objects, granting or denying existence to material, mental, and moral facts in different permutations, for example, holding that only the material exists; or that the material and the mental exist; or that all three exist.

One's notion of scientific realism has to be qualified in relation to specific scientific disciplines. The standard formulations are in terms of unobservable entities that lie far beyond the commonsense domain, with physics serving as the paradigm science. But suppose one wants to be a scientific realist about the explanatory posits of a sociological theory that discusses community and custom, role and authority, motive and reciprocity? If one takes these commonsense items to exist, the scientific realism that ensues will not be strictly modeled after the realism about photons and neutrinos and other noncommonsense posits of physical theories.

One can also choose to be a realist about modality. Modal realists argue that science and common sense deal with possibilities and necessities as aspects of the world. In decision theory, the decision-maker is viewed as considering possible choices and possible outcomes with probability values. In experimental science, the experimentalist considers various possible designs and possible outcomes with estimated probabilities. A modal realist takes such possibilities as real. An actualist denies the existence of possibilities and only regards actual things in a realist fashion. Yet, among the actual existents (in contrast to merely possible), one may include dispositions, propensities, capacities, and causal powers: they are potentialities that, under certain conditions, manifest themselves.

Having thus listed some possible domains of existents, and having made a selection from among them, the realist might leave it there. Of some *X*, the realist about *X* just says that *X* exists. Yet, pressed by antirealist arguments, the realist may feel forced to take a few more steps. This is because antirealists can go along with the realist to accept that *X* exists, but just interpret the meaning of '*X* exists' differently. Thus the realist has to raise the further question of what is claimed about the existence of the existents, or what is meant by '*X* exists'.

This question has a number of variants. One is about whether one reads existence claims literally or

reductively. A phenomenalist may say that electrons and elm trees exist, and add that what she means to say is that certain constellations of sense data exist; claims about electrons and elm trees and other such entities can be reduced to claims about sensory experiences. A realist would say that electrons and elm trees exist, period—signaling that the claim is to be understood literally. An eliminative materialist may say that a given mental property exists, and then add that this is just another way of saying that a certain neurophysiological configuration exists. A mental realist would resist such a reduction. In general, when considering the existence of *X*, the issue is whether the statement '*X* exists' is to be taken literally or to be reduced to another claim: '*Y* exists.'

Once we have fixed a literal answer to the question of what is claimed about the existence of the existents, another version of the question can be raised. This concerns the possibility and actuality of existence. The weakest realist claim is that it is *possible* for *X* to exist: the claim that *X* exists is intelligible and coherent. One is a realist about *X* not by claiming that *X* actually exists, but by claiming that *X* is the sort of thing that might exist. This is consistent with having doubts about its actual existence or a later discovery that it does not exist after all.

Many realists make stronger claims than just possible existence. They include statements about *actual* existence in their definition of realism. There are different versions of this, depending on the quantifier that is used in relation to the sets of items that are claimed to exist. No realist would like to claim that *all* alleged universals, particulars, commonsense objects, and/or scientific objects exist (this would imply that unicorns and ether are as real as magnolia trees and DNA molecules). Many realists would say that *some* of them, or *most* of them, exist.

Another version of the question (of what is claimed about the existence of existents) arises as we recognize that such claims are customarily formulated in terms of independence. Such claims take on the form, '*X* exists independently of *Z*'. Two further questions arise from such a claim: 'what is *Z*?' and 'what is independence?'

The ordinary formulation is that something exists mind-independently or independently of the mental, with 'mind' and 'mental' designating facts about the human mind. The paradigm meaning of 'exists' is based on an image of physical reality that existed before there were any humans around. Physical particles and their systems, such as molecules and galaxies as well as natural laws, existed independently of human perception and thought, and now that humans are around, these things continue to so exist—and were human life to disappear, they would still exist. One issue is whether 'exists' in this paradigm meaning applies to anything at all. Another issue is whether it is appropriately general to be extended to cover all important cases of existence claims, including

those about things that have emerged along with or since the arrival of humankind into the world. But what is independence?

If we take it to mean logical independence, we may want to say that physical objects are logically mind-independent since statements about them do not imply the existence of any human minds. This will require reading '*X*' literally as denoting physical objects: otherwise it would be open to a nonrealist to argue that *X*'s existence is logically mind-dependent for the simple reason that '*X*' is just another name for a bundle of sense data or some such. But if '*X*' denotes a human mind or a mental property itself, we cannot say that its existence is logically independent of the mental, because it entails the existence of the mental.

We may also say that something exists in the sense that it is causally independent of the mental: the human mind does not causally produce or reproduce it. Were this to apply to physical objects, 'causal production' itself would have to be literally understood as denoting a real connection in the world rather than a function of our minds. Whether it applies to human minds themselves depends on whether we take the reproduction of the species of sentient creatures like us to be causally mind-dependent activity. But it certainly does not apply to the many things in the world that are causally mind-dependent, such as material artifacts and social institutions.

Other notions of independence may be more successful in taking care of logically or causally mind-dependent things. We may choose to say that *X* exists independently of its recognition or any evidence we may have for its existence, or that it exists independently of any particular inquiry addressing it, or that it exists independently of any particular linguistic or other representation of it. Such formulations may enable realism about mental matters as well as about artifacts and many social entities that are causally dependent on the mental. The question of whether a given mental property or social entity exists is an objective question in the sense that it is separate from the question of whether anybody has thoughts, beliefs, or representations about it, has inquired into it, or has evidence for it.

Many realists hold the view that the world has a definite structure independently of our conceptual accounts of it. One may think that the world consists of propertied and related objects, such as natural kinds that are linked with one another by causal relations, and that these causal relations have a specific character, such as involving causal powers, causal transmission, and natural necessity. A nominalist would object to this by arguing that the world itself has no intrinsic structure, even though it may exist as an unstructured collection of propertyless particulars. Whatever structure the world is taken to have, it is rather our conceptualizations that impose it upon the world. The world is conceptually constructed so as to grant it a structure, and the origins of that structure

are in our ideas and conversations. This gives us an idealist and constructivist view on this matter. Thinkers are capable of 'worldmaking' as Nelson Goodman's 'irrealism' puts it, or of the 'social construction of reality' as the radical wing of social constructivism alleges. Insofar as our ideas are permitted to legitimately vary, this results in a form of ontological relativism as well: to each different communally-held or justified conceptualization corresponds a different structure of the world. Thomas Kuhn's suggestion that after a scientific revolution from one paradigm to another, scientists 'live in a different world,' can be—contestably—read as implying this idea.

The social world poses a special challenge to the realist: the social world *is* constructed and *is* dependent on people's ideas. There can be no communities and conventions, authorities and audiences without people acting on their ideas. Yet the realist wants to say they exist. These things may be taken to exist independently of, say, scientific theories about them, in the sense that the construction of a theory about a social entity is not a matter of constructing the entity.

2. *Semantics*

Ontological realism is about the existence of *X*. One may also raise questions about linguistic expressions '*X*' and '*X* is such-and-such' in relation to *X*. Indeed, 'realism' has become increasingly defined, especially by many antirealists, as a name for certain semantic views concerning such things as reference, meaning, and truth. It is characteristic of many antirealists to take semantic issues pertaining to language as primary, whereas realists often give priority to ontology and view semantic theses as derivative of, or motivated by, ontological positions.

The claim that scientific theories and the terms they include refer to real existents is part of the semantic thesis of scientific realism. Another part is the view that at least some of the major sentences contained in scientific theories can be used to make genuine statements about the real world, and as such, they may be true or may be false. More generally, semantic realism about some subject matter or domain maintains that statements about that domain are capable of being true or false—that they are capable of describing facts about the domain truly or falsely.

Some philosophers, such as Michael Dummett, have taken bivalence as a defining notion of realism: one is a realist about a statement or theory if one takes it to be either true or false. The ontological ramification of this is as follows: if there were gaps between these truth-values, this would indicate that the world itself is somehow indeterminate. If 'N is bald' is not clearly true or false but somewhere in between, then it would seem there is no determinate fact of the matter about N's baldness. This may be taken to motivate anti-realism. The realist should not reason along these

lines. If bivalence has a difficulty with statements like 'N is bald,' this may be nothing but an indication of the vagueness of the language of baldness, not a matter of some indeterminacy about N's head. For a realist, the properties of language have no implications for the properties of reality in such cases.

Realist theses about possible reference and possible truth in scientific theories are often complemented with claims about actual properties of actual science. One such claim—made by Richard Boyd, Michael Devitt and others—is that the theoretical terms of most current (or the best of 'mature') scientific theories typically refer and that their lawlike statements are at least approximately true. Another related claim is the convergence thesis: as science develops, its theories get progressively closer to the truth. Both of these are empirical claims about actual science and should not be made part of the concept of scientific realism. Their truth is dependent on contingent matters such as the institutional structure and other resources of scientific research as these happen to be in any given society and time period. This is not to deny that a realist may need a concept of approximate truth, truth-likeness, or closeness to the truth in order to defend the possibility of truth acquisition in science. Nor is it to deny the obvious idea that the notion of convergence towards the truth may be used to give content to the notion of scientific progress.

As for the concept of truth itself, a realist will hold the view that truth transcends any conceivable evidence. In this sense, truth is characterized negatively as nonepistemic, as being independent of whether, and how, we may have epistemic access to it. This runs counter to neopragmatist suggestions to define truth as provability (as does Dummett) or ideal acceptability (as does Hilary Putnam). For a realist, truth is one thing, and it is quite another to prove it, discover it, confirm our belief in it, or find evidential warrants for our beliefs. Since there is no necessary connection between truth and these things, the realist thinks that evidence-transcendent truth is not necessarily attainable. This implies that even if the epistemic warrants for a statement or theory were as good as possible, or in some sense ideal, our theory might be mistaken.

'Realism' is also used in connection with—but is not defined by—a specific view of what truth is: the correspondence account of truth. This view allows for many alternative formulations. A generic formulation is to say that a sentence (or proposition, or utterance, or whatever the appropriate truth-bearer is taken to be) is true in virtue of its correspondence with certain facts about the world, the truth-makers. This can be linked with ontological matters. On the one hand, truth presupposes an ontology within which truth-makers find a place. On the other hand, there is the route from an account of truth to ontology, from claims of truth to claims of existence. If it is up to the truth-makers to make the truth-bearers true, and if the truth-makers are objective facts about the world, then

the truth-makers of a true truth-bearer must exist. Thus, if mathematical statements can be true, then there must be mathematical objects of which they are true. If moral statements can be true, then there must be objective moral facts that make them so. Some realists have severed the connection between realism and the correspondence account of truth: they want to endorse the former without endorsing the latter. Most of these realists hold a deflationary or minimalist account of truth.

Nonrealists can also choose from different options. An instrumentalist about scientific theories can insist that no truth-values can be ascribed to theories as they make no claims about the world. Theories are no more than instruments for organizing the data, predicting future events, or helping to manipulate the world. They are tools of management or tickets of inference, and it is in the nature of tools that one should not ascribe truth or falsehood to them. Tools are characterized as useful or useless, convenient or inconvenient, relevant or irrelevant, powerful or powerless, and so on—all these attributions being relative to the purpose to which a given theory is put. This is the traditional version of instrumentalism that has been inspired by the familiar feature of physical theories that they appear to postulate unobservable entities. In case one has empiricist suspicions about such unobservables, it is tempting to construe theories as neither referring to them nor making any claims about them, whether true or false.

Likewise, in case one is ontologically suspicious about intentional properties, there is still an option to use the intentional vocabulary of folk psychology instrumentally: even though there really are no intentional properties on top of the physical ones, folk psychology can be usefully employed for predictive purposes provided it is construed nonreferentially. Daniel Dennett's 'intentional stance' serves as an example. One may adopt this stance as a perspective from which to treat systems *as* intentional without asserting that they really *are* intentional. No truth claims are being made about a system *really* possessing beliefs and intentions, but the predictive benefits created or lost by treating any given system as intentional is an objective matter.

Another instrumentalist possibility is to view a theory as a false tool, rather than as a truth-valueless tool. This is in line with Hans Vaihinger's fictionalism: falsehood is a characteristic of scientific theories regarded as fictions. Even though Vaihinger did not discriminate between natural and social sciences in applying his fictionalism—Isaac Newton's gravity and Adam Smith's economic man served as his examples—this view may be able to accommodate a feature of many social scientific theories: they do not seem to postulate unobservables in the same sense in which one finds them in physical sciences. Many social theories, and especially economic theories, involve idealizations and simplifications about familiar com-

monsense objects: immensely informed consumers with transitive preferences over all options of choice, and international economies with two countries with identical production functions, two goods, two fully-employed and internationally-immobile factors of production. Since many such idealizations are wide of the mark, one may be tempted to construe theories involving them as false, but nevertheless useful, instruments.

A popular view among the opponents of moral realism is to claim that apparent statements about some domain are not really genuine statements at all, but that they are rather used to express emotions or commitments or to persuade audiences. Thus, one may argue that moral claims of the form, '*X* is morally good' are not statements of some objective moral facts capable of being true or false, but express the utterer's emotions or persuasive intentions. This nonrealist position is called a noncognitivist position in contrast to its realist opponent, the cognitivist view, which takes moral claims to be truth-valued. This is an example of a reductive, nonliteral account: a descriptive claim that '*X* is good' is not supposed to be taken literally, but rather to be reduced to recommendations or approvals.

Yet another nonrealist possibility is to retain the vocabulary of truth and refute the correspondence account. Truth can be viewed as essentially involving pragmatic features, such as instrumental efficiency, ideal consensus, or warranted assertability. Whatever works for this or that purpose and meets certain constraints is true. These views make truth dependent on things such as our interests and goals, our thoughts and recognitional capabilities, our linguistic and other social conventions. Realists tend to think of truth as independent of such things.

Radical relativism regards all truths as indexical: '*P* is true in culture or community *C* but not in *D*,' '*P* is true for me but not for her,' and so on. Some formulations of constructivist sociology of scientific knowledge result in relativism of this sort by equating truth with acceptability within a scientific community. Equating truth with *ideal* acceptability is supposed to avoid the pitfalls of such relativism: the ideal conditions are supposed to fix truth uniquely. Realists claim to avoid them by not equating truth with anything epistemic.

3. Epistemology

Many of the issues above can be turned into issues of belief, justification, and knowledge. Some formulations of scientific realism refer to epistemic attitudes: scientists accepting a theory believe it to be true; and it is the goal of science to pursue true theories. Both formulations are problematic. A scientist with ontologically and semantically realist convictions may, with no inconsistency, accept for some purposes a

theory not believed to be true or not yet so believed. And whether or not truth is actually pursued as a goal is not implied by the notion that scientific theories include sentences that are capable of being true or false—or that their posits are capable of existence. It is also questionable whether science is the sort of entity to which goals can be attributed. Whether truth is among the goals of a particular body of scientists, and whether science as a collective endeavor will actually deliver truths as an outcome, depends on the actual prevailing institutional organization of science. Claims about scientists' actual beliefs, goals, and achievements are empirical claims whose truth depends on various contingencies; they should not be included in one's core definition of 'realism'. Of course, to accommodate such ideas, one may stipulate complex labels such as 'axiological veristic scientific realism,' which says that scientists had better pursue true accounts of the world.

Forms of epistemological realism are best formulated in terms of 'knowability'—of believability and justifiability. Supposing the world, and these or those of its constituents exist, can we acquire knowledge about them? Realist theories of perception share the view that there is no veil of perception, that perception is able to provide us with (perhaps very complex and indirect) access to at least some parts of reality. More generally, an epistemological realist holds that the world is knowable; for example, the theoretical claims of science may be justifiably believed to be (approximately) true.

With respect to scientific theories and the entities and relations they postulate, one may hold the view that the ontological question of their existence is irrelevant. They may exist, and theories may be true or false about them, but what is crucial is that we *cannot know* that they exist, nor that claims about them are true or are false. Therefore all that matters for science—insofar as its goals and criteria of success are concerned—is empirical adequacy, that is, the truth of the claims science makes about observable phenomena. This empiricist combination of ontological realism and epistemological antirealism has a long tradition, including Auguste Comte's positivism and, presently, Bas van Fraassen's constructive empiricism. People like Ernst Mach have been closer to taking the more radical step from epistemological to ontological antirealism, from denying epistemic access to the unobservable posits of science to denying their existence.

Many contemporary versions of antirealism, including Putnam's 'internal realism,' hold that insofar as truth is concerned, the semantic and epistemological issues cannot be kept distinct: truth is epistemic. Truth consists in warranted assertability, or in ideal acceptability. This means that a theory that is epistemically ideal cannot be false. An epistemically ideal theory is a fully justified theory: it is a product of our very best efforts in the most favorable circumstances, one that is

perfectly supported by all available evidence and meets all relevant theoretical constraints. While the realist will distinguish between the notions of being true and passing for truth in any circumstances, the antirealist will not acknowledge a difference between truth and passing for truth in ideal circumstances. The antirealist view makes truth conditions identical to the conditions of the recognition of truth, thus there is no recognition-independent or evidence-transcendent truth to be sought. Truth becomes epistemic; semantics and epistemology become fused. This may be taken to have ontological import. If an ideal theory suggests that quarks exist, then the statement 'quarks exist' is true, and therefore quarks exist. In this picture, ontic matters are derivative from epistemic matters.

This antirealist view is often presented as providing protection against skepticism about truth acquisition: making truth attainable by definition is supposed to help avoid the misery of truth possibly escaping us in all circumstances. Semantic realism decouples truth and justification by viewing truth as evidence-transcendent and otherwise nonepistemic. This may be taken to create room for skepticism: since even epistemically ideal theories may be false, we may be doomed to be mistaken forever, even though most realists would say that, as a matter of fact, we are not. Indeed, epistemological realists believe that we are able to acquire justified true beliefs about the world, thus they deny skepticism. Whether one formulates scientific realism as suggesting that most (or some) current scientific theories are recognizably and justifiably (approximately) true, or as the implied weaker view that it is in the character of scientific theories that they can be recognized as being true or false, one thereby subscribes to epistemological realism. Yet, given that truth and justification have been conceptually decoupled, the realist has to face the difficult problem of showing how these two things are related empirically so as to ensure that our cognitive efforts are somehow conducive to truth-acquisition.

The antirealist who holds truth to be epistemic is not necessarily much better equipped against skepticism. While actual justification will not guarantee truth, ideal justification does, or so some antirealists suggest. The challenge is to give a detailed account of what ideal justification consists of, and to do this in purely epistemic terms without invoking a prior grasp of the notion of truth itself. This may be difficult or impossible. If we say that ideal justification takes place in circumstances where all sources of error have been removed, and take this to mean circumstances where there are no obstacles to the attainment of truth, we will have failed to meet the challenge.

Reasoning with Mental Models

Reasoning is the mental process of drawing a conclusion from a set of premises. The premises may be statements, perceptions, beliefs, or items of general knowledge. The conclusion may be a statement or a thought that guides action. Reasoning is a central component of human intelligence, and without it, there would be no laws, civilization, or science (see *Scientific Reasoning and Discovery, Cognitive Psychology of*). Laws would have no application because individuals would be unable to make the following sort of inference:

Pat has a license or else Pat is disqualified from driving;

Pat does not have a license;

∴ Pat is disqualified from driving.

This inference is a valid deduction, that is, its conclusion must be true given that its premises are true. Logic is the science of valid deductions, but not a theory of how people reason. Such theories are the province of psychology, and psychologists have proposed a variety of theories (see *Logic and Cognition, Psychology of*). Human beings can reason about topics for which they have no general knowledge, and theories of this ability fall into two main categories.

Some theorists postulate that reasoners rely unconsciously on formal rules of inference akin to those of a logical calculus (see *Natural Concepts, Psychology of*). The preceding inference depends on a rule of the form: A or else B, not A, therefore B. Other theorists propose that reasoners rely instead on their grasp of meaning and of principles akin to those for the semantics of a logical calculus. These theories rely on mental models, which are internal representations mirroring the structure of the external world. This article describes their role in reasoning and evidence corroborating it.

1. Mental Models

The idea that humans construct models of the external world goes back to the Scottish psychologist, Craik (see also *Mental Models, Psychology of*). He wrote:

If the organism carries a 'small-scale model' of external reality and of its own possible actions within its head, it is able to try out various alternatives, conclude which is the best of them, react to future situations before they arise, utilize the knowledge of past events in dealing with the present and the future, and in every way to react in a much fuller, safer, and more competent manner to the emergencies which face it (Craik 1943, Chap. 5).

Another antecedent is Wittgenstein's (1922) thesis that propositions represent reality in a similar way to pictures. What the modern theory of mental models adds to these programmatic proposals are three main assumptions:

(a) Each model represents a possibility. Thus, the assertion: either Pat has a license or else Pat is disqualified from driving calls for two models to represent the two possibilities (shown here in simplified form on separate horizontal lines):

License

Disqualified

where 'License' denotes a model of the possibility in which Pat has a license, and 'Disqualified' denotes a model of the possibility in which Pat is disqualified from driving.

(b) Models have a rich internal structure (not shown in the preceding diagram). Like an architect's plan, the parts of a model correspond to the parts of what it represents, and so the structure of a model corresponds to the structure of the world (Wittgenstein 1922, Propositions 2.13–2.17). Visual images are based on models, though many models are not visualizable (see *Imagery versus Propositional Reasoning*).

(c) The principle of truth: models normally represent what is true according to the premises, but not what is false. Hence, the preceding models of the disjunction represent only the possibilities that are true. Likewise, for true possibilities, models represent clauses in premises only when they are true in the possibility. For instance, the first model in the set above represents the possibility that Pat has a license,

but it does not represent explicitly that in this case it is false that Pat is disqualified from driving; likewise, the second model does not represent explicitly that in this case it is false that Pat has a license. Individuals make 'mental footnotes' about these matters, but normally they soon forget them. The principle of truth makes for parsimonious representations: reasoners do not have to bother with what is false.

Models are constructed as a result of perception, the comprehension of discourse, and imagination (see *Vision, Psychology of; Situation Model: Psychological*). They can represent real, hypothetical, or imaginary situations. They may also reside in long-term memory as a representation of knowledge (see *Mental Models, Psychology of*). They are accordingly a form of mental representation advocated by many psychologists as the way in which the mind represents reality, conceives alternative possibilities, and simulates the workings of the world. In principle, they could also underlie reasoning.

2. Deduction with Mental Models

The model theory of reasoning is due originally to the present author and his colleagues, notably the Irish psychologist Ruth Byrne (see Johnson-Laird and Byrne 1991, and for a recent alternative, Polk and Newell 1995). The theory postulates that models are based on the meaning of each premise, and that reasoners formulate a conclusion by describing something in the models that was not explicit in the premises. A conclusion that holds in all the models is necessary given the premises. A conclusion that holds in at least one model is possible given the premises. If models represent equiprobable possibilities—as reasoners often assume—the probability of a conclusion depends on the proportion of models in which it holds, as shown by the Italian psychologists Paolo Legrenzi, Maria Legrenzi, and Vittorio Girotto, and the French psychologist Jean-Paul Caverni (see Johnson-Laird et al. 1999). The model theory accordingly unifies logical reasoning, reasoning about possibilities, and probabilistic reasoning.

To illustrate the theory, consider again the inference:

Pat has a license or else Pat is disqualified from driving.

Pat does not have a license.

Therefore Pat is disqualified from driving.

The disjunctive premise calls for the models above. The second premise eliminates the model representing the possibility that Pat has a license. The remaining model is:

Disqualified

It yields the conclusion that Pat is disqualified from driving. This conclusion is a valid deduction because it holds in all the models—in this case, the single model—of the premises.

If individuals reason with models, then the more models that they have to construct—the more possibilities they have to envisage—the harder the task should be. Many experiments have corroborated this prediction (for a review including the studies described in this section, see Johnson-Laird 1999). For example, consider the following problem in spatial reasoning:

The cup is on the right of the knife.

The plate is on the left of knife.

The fork is in front of the plate.

The saucer is in front of the knife.

What is the relation between the fork and the saucer?

The theory predicts that reasoners should construct a two-dimensional model of the spatial layout of the items of the sort shown in the following plan:

plate	knife	cup
fork	saucer	

This model yields the conclusion: the fork is on the left of the saucer. In contrast, consider a problem in which the first premise is instead:

The knife is on the right of the cup

and the remaining premises are the same as above. This problem calls for two distinct models because the premises do not fix the relation between the plate and the cup:

plate	cup	knife	cup	plate	knife
fork		saucer		fork	saucer

The two models yield the same conclusion as before, but the problem should be harder because reasoners have to envisage two models. They do indeed draw a smaller percentage of correct conclusions to such multiple-model problems than to the one-model problems (Johnson-Laird and Byrne 1991).

Schaeken et al. have demonstrated similar differences between one-model and multiple-model problems about the temporal relations between events, using such premises as: John takes a shower before he drinks his coffee. Another group of Belgian psychologists (Vandierendonck et al.) have confirmed the difference in both temporal and spatial problems, and also shown that a task which preoccupies working memory for visual and spatial relations interferes with these inferences. Madruga et al. in Madrid have shown that inferences based on a conjunction, which calls for a single model, become harder when that premise is replaced by a disjunction, which calls for multiple models. Likewise, the Italian psychologists, Girotto et al. have shown that an inference based on a conditional premise of the form, If A then B, which calls for at least two models, becomes easier when a premise that eliminates one of these models is presented first rather than after the conditional premise. Two other Italian psychologists at Turin University, Bara and Bucciarelli, have shown that the difficulty of inferences known as syllogisms can also be predicted from the number of models that they require. Thus, the following syllogism is easy:

Some of the artists are beekeepers.

All of the beekeepers are chemists.

What follows?

Seven year-old children can draw the valid conclusion: some of the artists are chemists. In contrast, the next syllogism is hard even for adults:

None of the athletes is a banker.

All the bankers are chefs.

What follows?

Most reasoners construct a model in which the athletes are distinct from the chefs, and conclude that none of the athletes is a chef. To reach the correct conclusion, they need to realize that there could be chefs who are not bankers, and that each of the athletes could be such a chef. The only valid conclusion about chefs and athletes is accordingly that at least some of the chefs (i.e., those who are bankers) are not athletes. Few people reach this conclusion.

Another corroboration of the model theory comes from the study of children's understanding of assertions. Various experimenters, notably the French psychologists Barrouillet and Lecas, have demonstrated a trend in how children develop an understanding of conditional assertions of the form, If *A* then *B*. Young children treat them as though they were compatible with just a single model (in which both *A* and *B* occur), slightly older children treat them as compatible with two models (*A* and *B*, and not-*A* and not-*B*), and adolescents correctly treat them as compatible with three models (*A* and *B*, not-*A* and *B*, and not-*A* and not-*B*). Similarly, Sloutsky et al. at Ohio State University have observed that children tend to ignore the second clause of a disjunctive premise in order to ensure that the premise calls for just one model. This tendency to minimize the number of models has been corroborated by Ormerod et al. in their studies of how people paraphrase conditionals and other assertions.

A computer program implementing the model theory made a striking prediction. It showed that if reasoners abide by the principle of truth, then they should make systematic fallacies. These errors should arise because reasoners fail to represent what is false. Several recent studies have corroborated the occurrence of these 'illusory' inferences. Here is an example from an experiment carried out by Goldvarg and Johnson-Laird. Suppose that only one of the following assertions is true about a particular hand of cards:

There is a king in the hand or there is an ace in the hand, or both.

There is a queen in the hand or there is an ace in the hand, or both.

There is a jack in the hand or there is a ten in the hand, or both.

Is it possible that there is an ace in the hand?

In the experiment, 99 percent of the participants responded 'yes,' and the answer seems obvious. Yet, it is an illusion. It is impossible for an ace to be in the hand, because both of the first two assertions would then be true, contrary to the rubric that only one

assertion is true. Other experiments have corroborated the occurrence of illusions in causal and conditional reasoning, and Yang, a Chinese psychologist, has shown that they occur with syllogistic premises.

The model theory and theories based on formal rules, which were mentioned earlier, run in parallel for many inferences, but illusory inferences are a case where the two accounts diverge. The model theory predicts the illusions, but the formal rule theories rely solely on valid principles of inference and so they are unable to explain them.

3. *Models, Induction, and Reasoning in Daily Life*

Many of the inferences that you make in daily life are not deductive, that is, even granted the truth of your premises, there is no guarantee that your conclusion is true. You leap to a conclusion that goes beyond the information in your premises. The conclusion rules out some additional possibilities over and above those that the premises rule out, and so it may be false. By definition, such inferences are known as inductions.

The model theory extends naturally to inductive inferences including the informal inductions of daily life (see *Informal Reasoning, Psychology of*). Induction consists in the addition of information to models, sometimes with the consequence of eliminating a model (of a possibility). Often the process is hardly distinct from the normal business of making sense of the world. For instance, you use a voltmeter to examine an electrical circuit and you discover that the following proposition is true:

The battery is dead or the voltmeter is faulty (or both).

You then find out that:

The voltmeter is faulty.

And so you infer: the battery is not dead. Your inference is an induction, because your conclusion could be false even though your premises are true. Your disjunctive premise has three models:

dead

faulty

dead faulty

where 'dead' is a model of the battery as dead and 'faulty' is a model of the voltmeter as faulty. Your discovery that the voltmeter is faulty is consistent with two of these models, and in one of them, the battery is dead (contrary to your conclusion). Hence, your conclusion goes beyond your premises. Yet, it is highly plausible. You may have based it on an unstated belief that the chances are remote of both a dead battery and a faulty voltmeter. This belief leads to you to discount a model so that only the single model yielding your conclusion survives.

Reasoning in real life almost always depends on background knowledge—a knowledge of the meaning of words, of the world, and of the situation at hand.

This knowledge enables you to leap to plausible conclusions. In logic, when a conclusion follows validly from premises, no subsequent information can invalidate it. Logic is monotonic in that additional premises lead merely to additional conclusions, and never to the withdrawal of an earlier conclusion. Logic means never having to be sorry about a valid conclusion. In daily life, however, you do withdraw a conclusion when it conflicts with subsequent evidence. Sometimes, you do so because the conclusion was based on an assumption that you made by default—an assumption warranted only if no evidence exists to the contrary, for example, Quakers are pacifists. If a President is a Quaker, then you may infer that he is a pacifist, but when you learn that he is war-mongering, you withdraw this conclusion. The model theory allows for the withdrawal of the consequences of default assumptions (Johnson-Laird and Byrne 1991).

Many other sorts of inference in daily life lead to conflicts with reality. Suppose you know, for example:

If I turn on the ignition then the engine will start.

You turn on the ignition, and so it follows validly:

The engine will start.

Unfortunately, nothing happens. There is a conflict between a valid consequence of your beliefs and the facts of the matter. Something has to give. At the very least, you have to withdraw your conclusion. Researchers in artificial intelligence have developed various systems of nonmonotonic reasoning to try to deal with such cases (see Brewka et al. 1997), but no one knows what mental processes underlie human nonmonotonic reasoning. At its heart, however, there appears to be the generation of diagnostic possibilities. You try to imagine a scenario—a mental model—that explains why the engine did not start.

4. Conclusions

The theory of mental models postulates that human beings reason by imagining the circumstances described in the premises. They envisage mental models of these possibilities, focusing on what is true at the expense of what is false. Unlike other theories of reasoning, this principle correctly predicts the occurrence of certain systematic fallacies. The evidence accordingly confirms that human reasoners do rely on mental models. They construct them from perception, memory, and imagination, manipulate them to make inferences, and base their actions on the results.

Rechtsstaat (Rule of Law: German Perspective)

‘*Rechtsstaat*’ is a term of the German language and is not easily translated. ‘*Recht*’ stands for ‘law’ and ‘*Staat*’ for ‘state’; in English and most other languages grammar or semantics stand in the way of combining both elements into a compound. The theme evoked by the term ‘*Rechtsstaat*’ is often referred to as ‘rule of law,’ although the latter expression possesses a tradition of its own and carries connotations different from the German ‘*Rechtsstaat*.’

1. ‘Rechtsstaat’: an Introduction

Rechtsstaat concerns the age-old question of how to achieve order and freedom within a state. It connotes a balance between creating government authority powerful enough to keep peace both internally and

externally, to protect the state from violence or intervention on the one hand, and to secure a maximum of individual freedom on the other.

Rechtsstaat is a modern coinage which gained currency in German-speaking Europe in the early nineteenth century, when political thought from the French Revolution and the struggle for independence in British North America found wide support among the middle classes in Germany. English concepts for reining in the exercise of governmental power through law thus also count among the sources which influenced the evolution of '*Rechtsstaat*.' From this point of view, a '*Rechtsstaat*' is more than mere statehood characterized by an exercise of government power based on, and limited by, law. *Rechtsstaat* is closely connected to democracy, as democracy is a mode of legitimizing the exercise of power. If a democratic system is intended to be a *Rechtsstaat*, it needs to be governed by legal rules on the sources of such legitimacy.

The German-language term *Rechtsstaat* does not represent a phenomenon unique to Germany, but is the semantic and conceptual reaction to a fundamental issue of modern statehood. In the course of efforts to establish the rule of law in Germany, *Rechtsstaat* had been a political slogan to which various contents and political demands attached. It was only later that the term became textually included in written constitutions. With its many facets and unclear limits, it was misused during the Nazi period. After the end of Nazism, *Rechtsstaat* substantially informed constitutional thinking and is now considered to be a key element characterizing the German constitution of 1949, the Basic Law (*Grundgesetz*); its significance in that text will be further explored in Sect. 2.2. For the moment, we wish to concentrate on how and with what kind of implications *Rechtsstaat* describes a type or a model of state organization (see Sect. 2.1).

Counterbalancing authority and freedom, *Rechtsstaat* is a task not only for today's states, but also for organizations transcending the state level. This is true in particular of integrative processes that have progressed quite far, as in the case of the European Community or similar processes that have been launched in South America and other regions. In a wider perspective, it applies likewise to the task of consolidating the United Nations. Evidence for this may be seen in references to a European Constitution and in increasing references to a 'constitutional order' in international law, which has been considerably shaped by the United Nations (see Sect. 3).

2. The Modern Meaning of '*Rechtsstaat*': The State Level

The present-day meaning of *Rechtsstaat*—in general theory of the state—on the one hand stands for a category or type of state and, on the other hand, a legal

principle. We may speak of '*Rechtsstaat*' as a type, if the law of a state exhibits certain characteristics; these will be presented in Sect. 2.1. They derive above all from the constitution of the state in question and may be identified therein. It is immaterial in this regard whether the constitution is embodied textually in a document, as will most often be the case, or whether it is founded wholly or partly on unwritten law. The question of whether a given state may be considered a *Rechtsstaat* is a theoretical as well as a practical matter. It is a matter of theory insofar as political and legal doctrine seeks to comprehend and to differentiate hypothetical as well as existing states through systematic concepts. It is a matter of practice in the sense that the tradition of the term *Rechtsstaat* as a slogan continues to exert its influence: states whose laws wholly or partly fail to satisfy the requirements of *Rechtsstaat* will be forced to justify these failures in domestic political controversy and even in international relations. The more consensus exists on which core elements are necessary to a reasonable organization of a state which optimally balances the contrasting factors of effective government authority and individual freedom, the more will states be inclined, in their mutual relations, to demand that the concept of *Rechtsstaat* be made reality.

Traditional international law treated such demands as an illegal interference in internal affairs, contradicting the rule of the sovereign equality of states. The principle of non-interference in internal affairs has, however, been much eroded during the latter half of the last century. This concerned initially the area of fundamental human rights. International law today no longer categorically rules out demands from one state that another respect fundamental human rights. Moreover, there is a tendency to widen the ambit of human rights that are thus internationalized and to include aspects of domestic state organization: this pertains in particular to human rights which are directly related to democracy, such as freedom of expression. For example, states may make the establishment of economic or general political relations conditional on beneficiary states satisfying, in their municipal laws, the requirements of *Rechtsstaat*. While formal international recognition of another state used to be a merely declaratory act, this might change in future: recognition of another state is increasingly being predicated on substantive criteria. In the wake of the transformation in Europe during the last decade of the twentieth century, the Member States of the European Union, for example, demanded that the newly emerged states establish governmental structures of a *Rechtsstaat* type before the EU would put relations with these states on a formal footing.

While *Rechtsstaat* as a type covers all states, '*Rechtsstaat*' as a principle of constitutional law is confined to a particular state within whose constitutional law this principle may operate. *Rechtsstaat* as a principle is a legal norm. It governs state authority

and may serve as a yardstick in the jurisprudence of a constitutional court. This case is briefly described under Sect. 2.2 with reference to German constitutional law.

2.1 '*Rechtsstaat*' as a Type

Consensus may be assumed today that certain elements have to be present for a state to be considered a *Rechtsstaat*. Regarding aspects of state organization (so called formal *Rechtsstaat*) it is first and foremost the separation of powers, the independence of the judiciary, the need for administrative behavior to be law-based, and recourse to the courts against acts of government. These elements, however, are closely interrelated with substantive matters. A substantive *Rechtsstaat* refers to a state aiming at safeguarding justice through law-conforming actions of its legislative bodies, i.e., legislative enactments must respect higher-ranking constitutional law. More recently the notion of substantive *Rechtsstaat* has come to include the constitutional guarantee of individual rights, including fundamental and human rights. Central to all this is the need for government authority to be bound by law. Thus the distinction between formal and substantive *Rechtsstaat* is merely a rough one, and the following three aspects may better illustrate the commonly accepted constituent components of *Rechtsstaat*. *Rechtsstaat* formulates requirements for the make-up of a constitution; *Rechtsstaat* is a state whose objective is the realization of human dignity; and *Rechtsstaat* formulates requirements for the make-up of law in general (not merely constitutional law).

The idea of *Rechtsstaat* implies precedence of the constitution over other law. The legislative power is likewise bound by law, in the tradition of most states through a constitutional instrument, i.e., a written constitution, although this is not a necessary feature. Binding the legislative power through higher-ranking law does not mean that legislation to amend the constitution may not be passed. A *Rechtsstaat*, however, will be characterized by formalizing any changes to its constitution and by erecting barriers to its modification, usually by requiring especially enhanced majorities. A *Rechtsstaat*-type constitution will also be guarded against constitutional change through stipulating—in the case of written constitutions—that any amendments shall be expressly made in the text, i.e., by modification of the wording itself or appendix to the constitutional document. This avoids transgressing the bounds of the constitution and prevents confusion which may be caused by the coexistence of texts of equal legal standing. A *Rechtsstaat* does not require that a constitution purport to declare some particularly important component parts or substantive elements as immutable, thus fixing them 'in perpetuity,' although this has indeed been done in some constitutions.

The distinction between higher-ranking constitutional and other law in the concept of *Rechtsstaat* entails the precedence of the higher-ranking law in cases of conflict. Law incompatible with the higher-ranking law is void or, if possible, has to be interpreted in conformity with constitutional law. *Rechtsstaat*-type constitutions often spell out which judicial body is qualified to rule with binding effect on the constitutionality or unconstitutionality of ordinary law, in order to protect the authority of the law from those applying it (executive or judicial branches of government) who might otherwise be tempted to avoid applying the law by alleging its unconstitutionality. It is part of the logic of a *Rechtsstaat* that, for this reason among others, special courts are created for constitutional matters; however, this is not an essential element of a *Rechtsstaat* as long as other courts remain competent to safeguard the constitution and maintain its precedence over ordinary law.

The classical doctrine of separation of powers, which distinguishes between legislative, executive and judicial branches of government, forms the core of the modern concept of *Rechtsstaat*. It should be noted, however, that this distinction is only a basic one, with creation of legal norms by the executive branch or administrative bodies not being alien to the concept of *Rechtsstaat*. Such creation of legal norms does, however, need legal boundaries: laws not enacted by parliament will be acceptable in a *Rechtsstaat* only if the body creating such laws is by itself sufficiently legitimized. If such laws generate rights and duties of individuals, their creation needs to be backed up by an act of the parliamentary legislature. This in turn requires a sufficiently defined scope of the law-making power so delegated—parliament may not transfer its primary legislative responsibility summarily and without limitation to other governmental bodies, or even private norm-creating institutions. *Rechtsstaat* also demands that political parties—as associations designed to gain political power and which are legitimately also oriented towards particular group interests—are placed outside the ambit of government authority.

A *Rechtsstaat*-type constitution purports to make fundamental decisions on values regarding the organization of the state—but only of the state: it does not pretend to achieve comprehensive regulation of society as a whole. On the contrary, such a constitution will leave room for choice. Similarly, it will leave room for choice as regards ordinary domestic law, which must confirm to the constitution without, however, being predetermined by it. Legislating and applying laws does not amount to mere implementation of a constitution. The constitution of a state will not permit us to predict how political processes may unfold in terms of substance. This limits constitutional courts or other bodies entrusted with safeguarding the constitution—for them, interpreting the constitution means bearing in mind its openness. Safeguarding the constitution

thus means identifying where it draws strict limits and where it leaves room for choice and development. Modern constitutions characteristically use general terms, which may imply the prerogative of legislative choices yet to be made. Constitutional jurisprudence in a *Rechtsstaat* does bear political traits but remains confined to retracing the decisions already made in the constitution; it may not disregard the decisions of the constituent power.

Rechtsstaat includes also the guarantee of individual rights. The core of individual rights is the protection of human dignity. Rights to freedom and to equality alike are intended to afford such protection; they are defensive rights vis-à-vis the state which has a duty to prevent, or at least to make an effort to prevent, infringement of these rights in societal relations, i.e., between private persons dealing on an equal footing. Individual rights, whether manifested in international, domestic, constitutional, or ordinary law, have developed in great variety. While not all of these rights will count among the minimum of what a *Rechtsstaat* requires, a *Rechtsstaat* must include individual rights guaranteeing life and health, property and the freedom to choose one's occupation, freedom of expression, assembly, and association, of individual access to the courts, and of protection from discrimination. Access to the courts must not be understood in a formalistic sense: there needs also to be effective protection through granting a fair hearing and independence of the courts. Since *Rechtsstaat*, as has been explained, denotes a type, the concept of *Rechtsstaat* does not intend to impose a uniform level of fundamental rights. It does not prescribe, for instance, the scope of the protection to be afforded to property or the manner of safeguarding judicial independence.

Given the coexistence on an equal footing of numerous persons enjoying fundamental rights—i.e., all citizens—and given also the need to limit the latitude of individual behavior in the interests of the state as a whole, a *Rechtsstaat* needs to formulate rules on the limitability of individual rights and also to define the boundaries of such limitability. In this context, the principle of proportionality in a *Rechtsstaat* merits emphasis. Proportionality requires a balance between different rights and interests. The test of proportionality in a *Rechtsstaat* will be met only by such governmental action as is suitable to further a legitimate objective, which is necessary in the sense that it provides the least restrictive, yet equally suitable alternative available, and which, on consideration of all relevant circumstances, can be regarded as reasonable.

A third characteristic of *Rechtsstaat* is the quality of its law, encompassing the entire legal order and not merely those norms primarily concerned with state-individual relationships; the quality of civil and criminal law are also included. The whole legal system must possess certain qualities. For example, it must meet requirements as to normative clarity to provide legal

certainty, because indeterminate standards are incapable of lending themselves to judicial scrutiny. Moreover, law has to satisfy certain immanent criteria in order to serve as an instrument of guidance: it has to be free of contradictions and designed to retain continuity without unduly impeding social change. It has to be capable of acceptance by those bound by it, not perhaps in every detail but in its entirety. Law whose only prospect of implementation would lie in coercive measures or the threat of such would be doomed to fail. Law in a *Rechtsstaat* needs to be founded on a basic consensus of what is just.

2.2 '*Rechtsstaat*' as a Constitutional Principle

As explained above, one needs to differentiate between using the term *Rechtsstaat* for denoting a type and, on the other hand, for denoting a legally operative norm of constitutional law. To qualify a state as a *Rechtsstaat* does not require such a constitutional principle; its existence is not required if the sum total of constitutional norms already suffices to safeguard the objectives of *Rechtsstaat*, as described in Sect. 2.1. Some constitutions spell out expressly a principle of *Rechtsstaat*; in others the principle is derived from interpreting the constitution. In the Basic Law of the Federal Republic of Germany, for example, *Rechtsstaat* appears as a legal norm in its own right and is frequently referred to by the Constitutional Court. While there is disagreement as to which provision of the Basic Law should serve as the basis for the principle of *Rechtsstaat*, it is by most considered to be Article 20 para. 3 of the *Basic Law*, which reads that legislation shall be subject to the constitutional order and that the executive and the judiciary shall be bound by law and justice. This covers only a segment of the objectives of *Rechtsstaat*. Beyond this, the provision is taken to be a directly operative precept to ensure legal certainty, such as by avoiding indeterminacy in ordinary law or retroactivity of enactments; the principle of proportionality is likewise derived from this precept. State acts not in conformity with this precept are unconstitutional, being incompatible with the principle of *Rechtsstaat*. Laws may be null and void for this reason.

A general principle of *Rechtsstaat* as a constitutional norm in its own right is not without risks, due to its own indeterminacy. *Rechtsstaat* shares this risk with all blanket clauses. Workable civil law could not be imagined if it were limited to stating that behavior in legal relations should be governed by the principle of good faith alone, and constitutional law may similarly not retreat to merely stating a principle of *Rechtsstaat*, as this would leave decisions on what has to be considered in conformity with *Rechtsstaat* entirely to the judicial branch. Law dominated by blanket clauses concedes considerable decision-making powers to the courts and could thus not be safe

from arbitrariness. This is why a blanket-clause style of the *Rechtsstaat* principle can only have secondary relevance. Translating a *Rechtsstaat* into reality is better achieved by detailed norms that specify relevant objectives and that furnish a safer foundation for applying the law.

3. 'Rechtsstaat' and International Organizations

The notion of *Rechtsstaat* could be a useful concept also in the sphere of structures transcending individual states, as international organizations need to strike a balance between overarching interests affecting the whole organization and those regarding individual members. In the case of traditional international organizations, the issue has hardly ever been put forward. These organizations group together equal subjects of international law, i.e., states, in order to pursue jointly certain aims which as a rule remain individual objectives; the sovereignty of participating states remains unaffected. The European integrative community had its starting point in such a structure, but from the beginning it was designed to include transfer of sovereignty, and this community has increasingly acquired legal powers that justify looking at it as a new type of organization. Here, as in other organizations which initially aimed at economic integration but which have the potential to expand beyond this particular sphere, the question of arrangements addressing requirements of *Rechtsstaat* needs to be raised. The basic distinction between higher-ranking constitutional law and other law would apply in such a case. Matters of the quality of the law, such as the absence of systemic logical inconsistency or its indeterminacy, would also need to be addressed, as would issues of safeguarding compliance with the law and judicial control. Derived from the municipal laws of its member states, the objective of building a *Rechtsstaat* legal environment has already been realized in the European Union to a considerable degree, especially in the judicial branch. The European Court, while not a constitutional court, may be considered as a guardian of the fundamentals of Community law. Preserving the municipal *Rechtsstaat* heritage in supranational structures is an important task for the future that will grow more urgent as creation, enforcement, and control in the area of law is transferred to the integrated, supranational level.

Experiences gained in connection with *Rechtsstaat* are of interest also to international organizations to which member states have not transferred sovereign rights, insofar as such organizations are competent to issue legally binding decisions, to define legal norms, or to impose sanctions. Special organizations such as the World Trade Organization (WTO) or the United Nations (UN) (the global international organization designed to secure peace, to renounce the use of force, and, beyond that, to secure basic human needs), come to mind in this regard as their charters comprise

normative potentiality. The UN Security Council has powers that would enable it to fashion international relations in a legally binding manner far more than it has to date. The UN Security Council may be viewed as an organ of law enforcement. Apart from the right of self-defence of individual states, the Council enjoys a kind of monopoly of the use of force. Measuring this position against the yardstick of *Rechtsstaat* will reveal numerous shortcomings. The Council acts on the strength of norms whose determinacy may be open to question. It enjoys a monopoly on the use of force without legal safeguards, which would ensure that it acts to protect subjects of law who are threatened with violence by individual states. Being dominated by a privileged group of states, its legitimacy is in doubt. Judicial control is not ensured either, as the International Court of Justice does not exercise the role of a constitutional court in respect of the UN Charter as an international constitutional order. Any step in the direction of transforming the United Nations into a global state-like structure therefore imperiously calls for expansion of *Rechtsstaat* elements. This naturally cannot be achieved by simply imposing regulatory patterns tried and tested in *Rechtsstaat*-type national jurisdictions, but the tradition of *Rechtsstaat* offers a rich lode of lessons that will have to be heeded in the efforts to find an adequate legal framework for the modern world system and its segments.

Recognition Memory (in Primates), Neural Basis of

The term *recognition* refers to the knowledge or feeling that an object has been encountered previously. Two different mental processes may contribute to recognition judgments: a general feeling of 'familiarity' and a specific 'recollection.' These two aspects of recognition may depend on different brain systems, but are treated together here.

1. Neural Systems Mediating Visual Recognition

For most sensory modalities (e.g., vision and touch), receptors convert sensory information into neural signals, and modality-specific cortical fields, such as the primary visual cortex ('V1' in Figure 1), process that information further. These early sensory processing stages are a prerequisite for recognition memory. However, the core recognition system must function more generally. If a blind person fails to recognize a visually presented object, we say that he or she has a visual impairment, not a failure of recognition memory. Therefore, this article will focus on general aspects of recognition and its neural basis, neglecting modality-specific ones.

1.1 Methods for Assessing Recognition Memory in Nonhuman Primates

Because both human and nonhuman primates rely heavily on visual information in their daily activities, recognition is best understood for visible objects. Visual recognition memory in monkeys has been studied by making selective brain lesions and by disconnecting one brain region from another. These studies identify whether a given brain structure is critical for recognition. Monkeys, of course, cannot tell us whether they remember seeing an object. For this reason, methods have been developed that allow them to reveal that information. One commonly used method is the *delayed nonmatching-to-sample task* (DNMS). In DNMS, each trial has two parts: a

sample presentation followed by a choice test. During the sample presentation, the monkey sees a single object, which covers the central well of a three-well test tray. The monkey then displaces the object to obtain a small piece of food hidden in the well underneath. A few seconds later the monkey sees the same, now-familiar object plus a novel one, with one object over the left well of the test tray and the other over the right well. The monkey can obtain more food by displacing the novel object but not by pushing aside the familiar one. Thus, on the choice test, the monkey solves the problem by applying a 'nonmatching' rule, i.e., by choosing the object that does not match the sample. If the monkey consistently chooses the novel object on the choice test, one can infer that the monkey *recognizes* the sample. In the laboratory, there are many variations of this basic method. For example, monkeys can be trained using a 'matching' rule (the *delayed matching-to-sample task*, or DMS) rather than the nonmatching one. It is also common to use a computerized apparatus that presents two-dimensional pictures on a touch-sensitive video screen rather than using actual objects on a test tray.

1.2 Role of the Medial Temporal Lobe in Monkeys

It has been known for many years that a limited set of brain structures, including components of the medial temporal lobe (MTL), are necessary for storing information about facts, objects, and events from all sensory modalities (Squire 1987). Early investigations into the neural basis of recognition memory pointed to two structures buried deep in the MTL: the amygdala and hippocampus (Mishkin 1982, see Figure 1). However, those experiments involved the mechanical removal of brain tissue, a technique that produced unintended damage to other parts of the MTL. More recent studies have used stereotaxic injection of neurotoxins to make more selective tests. These experiments show that, within the MTL, the perirhinal cortex and the entorhinal cortex, rather than the amygdala and hippocampus, are essential for visual recognition (Murray 2000). Monkeys with an intact amygdala and hippocampus, but without the perirhinal and entorhinal cortex, cannot recognize objects if they have to remember them for more than a few seconds.

Experts accept a central role for perirhinal and entorhinal cortex in object recognition and also agree that the amygdala is not important for this type of memory. Controversy remains, however, about the potential contribution of the hippocampus. Damage to the hippocampus leads to impairments in recognition memory in some studies but not in others. For example, one test of recognition relies on the tendency of monkeys to spend more time looking at novel objects than at familiar ones. This innate tendency is called 'preferential viewing.' Although hippocampal damage fails to produce consistent and systematic deficits on DNMS, it does disrupt pref-

Figure 1

Diagram of the lateral view of a monkey brain showing some of the brain structures mediating visual recognition memory. The perirhinal and entorhinal cortex (PRER) are located on the ventromedial surface of the temporal lobe, and so are only visible by looking through a 'transparent' temporal lobe. The amygdala (AMYG) and hippocampus (HIPPO) are buried deep in the medial temporal lobe, and the hippocampus is shown slightly higher than its real location, for ease in viewing the lateral temporal cortex. Arrows indicate two-way information flow from early (V1–V4) to late (TEO and TE) cortical visual processing areas. These regions then transfer information into the amygdala and into the perirhinal and entorhinal cortex, which provide the main route by which information reaches the hippocampus. Abbreviations: ai, inferior arcuate sulcus; amt, anterior middle temporal sulcus; as, superior arcuate sulcus; ce, central sulcus; ec, external calcarine sulcus; io, inferior occipital sulcus; ip, intraparietal sulcus; lu, lunate sulcus; la, lateral fissure; p, principal sulcus; pmt, posterior middle temporal sulcus; st, superior temporal sulcus

erential viewing. This could be because the preferential viewing test, unlike DNMS, does not rely on learned rules, or because the stimuli have no association with food. Interestingly, on DNMS, larger perirhinal and entorhinal cortex lesions cause greater memory deficits than smaller ones, which is what one would predict if a structure were playing a direct role in a particular function. The reverse relationship holds for the hippocampus. That is, larger hippocampal lesions are associated with better recognition memory than smaller lesions, suggesting an indirect relationship of the damage to recognition memory deficits. The fact that only the perirhinal and entorhinal cortex have the predicted relationship to recognition memory supports the view that they are the parts of the MTL mediating that function.

The same parts of the MTL that are essential for visual recognition memory subserve tactual recog-

nition memory as well. They are also critical for many types of stimulus–stimulus association memory. Accordingly, their function may best be characterized as one of object identification. Through this process, the visual, tactual, gustatory, olfactory, and auditory properties of objects are somehow linked or 'bound.' Thus, the perirhinal and entorhinal cortex are essential not only for visual recognition, but also for storage of information about objects generally (Murray 2000).

1.3 Role of the Thalamus and Frontal Lobe in Monkeys

The perirhinal and entorhinal cortex do not operate alone, but instead work in concert with other anatomically connected brain structures that, together, form a neural network mediating visual recognition

memory. At least two other brain regions participate: the medial thalamus and the ventromedial part of the prefrontal cortex (Mishkin and Murray 1994). Damage to either of these structures produces essentially the same effect on visual recognition memory as does damage to the perirhinal and entorhinal cortex. In addition, the thalamic and frontal regions noted above are connected with each other, and each is connected to the perirhinal and entorhinal cortex. These structures need to interact to mediate visual recognition; surgical manipulations that prevent information from one structure from reaching a second produce a deficit in recognition memory much like that seen after lesions to each individual site (Parker and Gaffan 1998). Precisely how these structures interact to produce recognition memory remains uncertain; it is possible that each structure underlies some unique aspect of recognition memory.

1.4 The Recognition Network in the Human Brain

The same neural structures that are critical for recognition memory in monkeys appear to be essential in humans as well. For example, memory impairments are found in humans following damage to the MTL as a result of either brain infections (e.g., Herpes encephalitis) or temporary interruption of the blood supply. Damage to the medial thalamus, as a result of Korsakoff's disease, and to portions of the ventromedial prefrontal cortex, as a result of aneurysms of the anterior communicating artery, yield similar effects. It must be kept in mind, however, that in clinical cases brain damage rarely respects the boundaries of individual structures, so that the kind of precision outlined above for monkeys is not often possible for the human brain. Nevertheless, there is evidence that in humans, as in monkeys, the perirhinal and entorhinal cortex are important for recognizing objects. And, as in monkeys, there is controversy about the role of the hippocampus. People with damage to the hippocampus and adjacent perirhinal and entorhinal cortex are much more impaired in stimulus recognition than those with damage restricted to the hippocampus. Whereas some studies have shown that humans with damage limited to the hippocampus and closely related structures have relatively intact recognition abilities (Aggleton and Brown 1999), others have reported that such subjects are, on average, impaired in recognition memory (Squire and Knowlton 2000). In humans, the hippocampal contribution to recognition memory appears to reflect 'recollection' as opposed to 'familiarity' judgments.

2. Neurophysiology of Visual Recognition

Although the neuronal mechanisms mediating visual recognition memory are not known, there is some

information about the way in which neurons signal that a visual stimulus has been seen previously (Brown 1996). As shown in Figure 1, the temporal lobe consists of several parts. The MTL has already been discussed. On the outer, lateral surface of the temporal lobe are located visual areas TE and TEO. These regions are called the *inferior temporal cortex* (IT). The perirhinal and entorhinal cortex may be considered part of either IT or MTL. Many neurons in IT, including the perirhinal and entorhinal cortex, show changes in sensory responses with stimulus repetition. Two main kinds of recognition-related responses predominate.

Some neurons respond less to a visual stimulus on a monkey's second or subsequent viewing of an object than they do on the first. Other neurons respond more. Similar phenomena occur in the medial thalamus and the prefrontal cortex, but not in the hippocampus. Thus, these types of activity signaling stimulus repetition occur in precisely those areas thought to be essential for performance on DNMS. In addition, there is a third type of neuronal activity related to recognition. In monkeys performing DMS (see Sect. 1.1), some neurons in both IT and the prefrontal cortex reflect information about the sample object during the interval between sample presentation and choice test, as though the cell were maintaining a memory of the sample (Desimone et al. 1995).

Furthermore, for prefrontal neurons, this type of activity persists even when other objects appear during a memory period. This kind of activity could be very useful for the short-term storage of information about an object and for directing attention to items of interest.

3. Cognition and Recognition

Recognition is only one among many kinds of memory and cognition. It means, literally, to 'know again.' In people, recognition can be normal, or nearly so, in the face of devastating memory impairments of other types—for example, an inability to remember personal daily activities. Conversely, recognition can be extremely impaired in people who are capable of learning and applying complex rules and strategies. Accordingly, recognition memory can be viewed as an aid to more complex cognitive operations, but is, itself, a modular function with adaptive advantages of its own. The nature of these advantages is uncertain, but probably involves the ability to direct attention to novelties in the environment (perhaps by reducing the sensory responses to recognized objects) or to familiar objects that are of importance to the behavior of the moment. It remains to be seen whether the mechanisms that underlie the recognition of objects, as discussed in this article, also subserve the recognition of thoughts and ideas, logical truth and falsity, esthetic beauty and ugliness, or other abstract aspects of human recognition that distinguish us from our fellow primates.

Recognition Memory, Psychology of

Recognition memory is usually used to refer to both a memory measurement and a memory process that occurs in this measure of memory. When discussing recognition memory as a memory measurement, the difference between a recognition memory test and other memory tests such as recall tests can be easily distinguished. Recognition tests also produce certain effects that are particular to the processes underlying recognition memory. Even though the nature of these processes is very complicated, some models of recognition memory have nonetheless been proposed (see, for example, Raaijmakers and Shiffrin 1992). In this article, these two characteristics of recognition memory are examined in more detail.

1. Recognition Memory as a Memory Test

1.1 The Nature of a Recognition Memory Test

In a recognition memory experiment, to-be-remembered items (also called target items) are presented to

subjects. An item may refer to a nonsense syllable, a word, a number, a picture, and so on. In such tasks, subjects are given a recognition memory test after exposure to such items.

There are basically two types of recognition memory tests. In a yes/no recognition memory test, a subject is presented a series of items one at a time. The subject is then asked to say 'yes' or 'old' if the subject thinks the current item is a target item, and 'no' or 'new' if the subject thinks it does not qualify as a target one (nontarget items are called distractor items).

This type of a recognition memory test is similar to the sort of true/false test often encountered in school examinations. Another type of recognition memory test is a forced-choice test. In a forced-choice test, the subject is shown two or more items at a time. One of the items is usually a target item and the others are distractor items. In this type of recognition memory test, the subject is asked to pick out the target item from a set of items. If the subject is shown three items at a time, for example, it is called a three-alternative forced-choice test.

As such, the forced-choice test is similar to multiple-choice tests often encountered in school examinations. Of course, many additional variations on recognition memory tests may be considered. For instance, in addition to judging whether an item given on a recognition memory test is a target item or a distractor item, a subject may be asked to give a numerical confidence rating consisting of the range of, for example, 1 (least certain) to 5 (most certain), to indicate how certain the subject is that the judgment is correct.

In order to develop a better understanding of recognition memory tests, it is worthwhile contrasting them with other popular forms of memory test, such as the aforementioned recall tests. In recall tests of memory, a subject is asked to reproduce or generate all the items that had been presented during an earlier study phase. Thus, the basic difference between recognition and recall test procedures is that in a recognition memory test, subjects are given the target and distractor items during the test, whereas in a recall test, the subjects are given instructions to reproduce or generate the items without displaying them.

One of the important differences is that, in general, the subjects can recognize items in a study list much better than they can recall them. In fact, if the subjects are first given a recall test and then given a recognition memory test, it will be usually found that they can recognize many items that they were unable to recall.

1.2 Signal Detection Theory and Performance on a Recognition Memory Test

In a recognition memory test, instead of being assumed that subjects either memorize target items or don't memorize them, it is assumed that the subjects judge as

the target items on something like level of familiarity which varies in memory strength. When an item can be retrieved more readily than the other items, it will be said that the item is at full strength.

The memory strength of a test item is thought of as the degree of its familiarity in long-term memory (LTM). The stronger the test item is in LTM, the more familiar it will be.

To illustrate the assumption, one recognition memory experiment will be considered. Assume that a list of items is given to two groups of subjects, followed by a yes/no recognition memory test. The subjects are tested with a mixed sequence of target and distractor items one at a time. Prior to the recognition memory test, one group of subjects (called a guessing group) is instructed to say 'yes' if they think an item was on the list, and 'no' if they think it is a distractor item. Guessing is permitted in this group when the subjects receive a recognition memory test. The other group of subjects (called a strict group) receives the same instruction as the guessing group except the guessing instruction. The subjects in this group are instructed not to make a guess when they judge whether an item given on a recognition memory test is a target item or a distractor item. The subjects in the guessing group will of course use guessing strategies. So the results may show that the subjects in the guessing group will pick up more target and distractor items than those in the strict group. The results mean that the subjects in the guessing group judge the target and distractor items on a higher level of familiarity than those in the strict group. However, as can be seen, performance on a recognition memory test in the guessing group may be very similar to that in the strict group.

The signal detection theory which originates with the study of auditory detection tasks (see Green and Swets 1966) and has been applied to recognition memory explains the results of this experiment clearly. The signal detection theory enables researchers to estimate the amount of information stored in LTM on which subjects' judgments on a recognition memory test are based.

The signal detection theory assumes that the subjects estimate the probabilities that a test item came from the distributions for target and distractor items, respectively, on the basis of its memory strength (or familiarity).

In a typical yes/no recognition memory test, there are four cells that can occur in combination with a subject's 'yes' or 'no' responses and target-distractor items. First, the item is a target item and the subject says 'yes'; this is the correct response and is called a *hit*. Second, the item is a target item but the subject says 'no' to it; this is not the correct response and is called a *miss*. Third, the item is a distractor item and the subject says 'no'; this is the correct response and is called a *correct rejection*. Fourth, the item is a distractor item but the subject says 'yes' to it; this is not the correct response and is called a *false alarm*.

These four cells are not independent. As shown above, the hit rate and the miss rate mean the response rates to the target items and the false alarm rate and the correct rejection rate mean the response rates to the distractor items. When the hit rate is known, the miss rate can be understood automatically. Similarly, when the correct rejection rate is known, the false alarm rate can be understood. Generally, the hit rate and the false alarm rate are referred to on recognition memory.

Figure 1 shows both a relationship between the distributions of memory strength for target and distractor items and four cells in a yes/no recognition memory test. Figure 1 shows that the distributions for target and distractor items on the basis of their memory strength represent normal curves and that the mean strength of the target items is usually higher than that of the distractor items.

The distance between the means of the distributions for target and distractor items is called d' (called *d-prime*). More precisely, the d' value is obtained by dividing the difference between the two means by the common standard deviation of the distributions. We can easily get the d' value from some publications (e.g., Elliot 1964, Hochhaus 1972). When the d' value increases, the subject will discriminate between target and distractor items easily. When the d' value is small, the subject will find it difficult to discriminate between two sets of items.

In addition to the d' value, there is another value called β (beta). The β value means the level of the criterion strength on which the subject bases the decision. When the d' value remains constant and the β value goes up (e.g., the β value moves to the target distribution), both hit rate and false alarm rate go down. When the d' value remains constant and the β value goes down (e.g., the β value moves to the distractor distribution), both hit rate and false alarm rate go up. When the d' values are assumed to be the same, the β value in the guessing group stated earlier may be very low and the β value in the strict group may be very high. Figure 1 shows one example of d' and β values on recognition memory. As can be seen, the d' value is referred to recognition accuracy which means the strength difference between target and distractor items in LTM and the β value is referred to as decision criterion. The subject evaluates the memory strength difference between target and distractor items on the basis of decision criterion.

1.3 Some Effects in Recognition Memory

Some effects have been demonstrated in recognition memory, which are referred to as the mirror effect and the context effect. These effects in recognition memory are explained in brief.

First, there is a strong regularity of recognition memory called the mirror effect (see Glanzer and

Figure 1

Four types of response results (hit, miss, false alarm (FA), and correct rejection (CR)), d' , and β in recognition memory

Adams 1985). The mirror effect refers to the regularity of recognition memory in which the type of items that is relatively easy to recognize as old when old is also relatively easy to recognize as new when new. Glanzer and Adams (1985) analyzed a total of 80 experimental findings with several different classes of items and found that performance on new items from each class is correlated with performance on the corresponding classes of old items.

Second, subjects can usually recognize target items better than they can recall them. However, in such test circumstances as recognition memory is measured under the changes in the context between study and test, it will be found that the subjects fail to recognize target items. It is known as the context effect in recognition memory. The context effect in recognition memory shows that even recognition memory depends on the relation between the context at the time of the study and at the time of its test. For detailed treatment of the context effect see *Encoding Specificity in Memory*.

2. Retrieval Processes in Recognition Memory

As stated earlier, recognition and recall are usually used to refer to not only memory measurements, but also memory (or retrieval) processes which occur in these memory measurements. There have been hot controversies about how retrieval processes in recognition and recall are similar and different. That question is very difficult to answer and is still controversial (Brown 1976, Tulving 1983).

Generally speaking, recognition memory seems to be easier than recall. Subjects who receive a recognition memory test only discriminate between target and distractor items, even though they do not know

the target items clearly. There are some reasons why recognition memory seems to be easier than recall. According to a classical threshold model of recognition memory, the level of the discriminative threshold in recognition is thought to be higher than that in recall. According to the two-process model of recall (Kintsch 1970), recognition memory and recall involve different retrieval processes. Recall involves an extra search (or generate) process in addition to a recognition (or decision) process. For more detailed treatment of retrieval processes in recall see *Memory: Organization and Recall; Memory Retrieval; Encoding Specificity in Memory*.

2.1 One-process Models or Two-process Models in Recognition Memory

How about retrieval processes in recognition memory? Recognition memory can usually be referred to by two types of models, one known as one-process models and the other known as two-process models.

One-process models include the Search of Associative Memory (SAM) model proposed by Gillund and Shiffrin (1984) and the Hintzman (1988) model. They assume that recognition judgments are based on the target item's familiarity involving a single retrieval (search-like) step. Two-process models include the Atkinson and Juola (1974) model and the Mandler (1980) model.

They assume that the retrieval processes in recognition memory are the result of two processes: familiarity and search. For example, Atkinson and Juola (1974) carried out response time experiments from well-learned lists. They obtained the results that items with high or low familiarity values are associated with a fast response of a target item or a fast response

of a distractor item, respectively, whereas items with intermediate familiarity values are associated with a slower search process to judge whether an item is a target item or a distractor item. This search process is generally supposed to be slower than the familiarity-based process in the two-process models of recognition memory. The controversies about whether there is a search process in recognition memory are still continuing.

2.2 Recognition Memory With and Without Recollective Experiences

In recent years, there has been considerable interest in comparing performance on a task that does not require conscious or intentional recollection of previous experiences with performance on a task that requires it (see *Implicit Memory, Cognitive Psychology of*). A recognition memory test is known as one of the tests that requires conscious recollection of previous experiences. However, Gardiner (1988) assumes that recognition memory may entail two processes concerning recollective experiences: one is a process with recollective experiences and the other is a process without recollective experiences. These two processes are related to differences in subjective experiences.

In a recognition memory test, when recognizing each item, subjects are instructed to indicate whether they are able consciously to recollect its prior occurrence in the study list (called 'remember') or whether they recognize it on some other basis (called 'know'). The results show that a few independent variables, such as levels of processing (deep vs. shallow processing), generating vs. reading target items, and divided vs. undivided attention, have been found to influence 'remember' recognition and to have little effect on 'know' recognition. For example, performance on semantic processing was better than that on shallow processing in 'remember' recognition. However, performance on semantic processing was the same as that on shallow processing in 'know' recognition.

The measures of a 'remember' judgment and of a 'know' judgment are introduced by Tulving (1985), according to which conscious recollection or 'remembering' is a by-product of retrieval from the episodic memory system. Feelings of familiarity or 'knowing' are characteristic of retrieval from the semantic memory system. Using 'remember'-'know' judgments in recognition memory, it may be possible to examine retrieval processes in recognition memory and memory systems.

Reconstruction/Disaster Planning: Germany

In 1945, with World War II over and the National Socialist dictatorship under siege by Allied troops, great parts of German cities lay in rubble, their populations often reduced to only a few tens of thousands. Despite great hardship, life reemerged unexpectedly fast and soon discussions began on rebuilding the cities. Reconstruction plans had been in preparation since 1943. There was therefore no 'zero hour' for urban planning. The following article will underline the continual development in planning

theory and practice, the inspirations for the concepts, and the debate about urban design before and after 1945.

1. Preliminaries

After World War I, town and country planning in Germany in general changed its focus from the policy of improvement—slowly introduced since the late-nineteenth century—to a strategic approach. This phase was hampered by the economic crisis in 1929. When the National Socialists came to power in 1933, they had in fact no specific policies for urban planning but were able to select from existing scholarship those strategies which were useful to the new dictatorship: 1933/34: Improvement of both traffic and housing conditions in the historic urban cores of German cities had been widely neglected since World War I in favor of building new housing schemes at the urban fringe. The first concepts for the renewal of historically valuable and attractive housing stock from pre-industrial periods date from around 1930. This new approach then was to maintain the pretty street layout by clearing the blocks' interiors (as occurred in Brunswick, Frankfurt, and Kassel). Lack of money due to armaments production led to such schemes being deferred. However, it was useful to early National Socialist policy to support them as work providing measures which brought beneficial improvements to local economies, as well as for ideological reasons (see von Petz 1990).

1937: Albert Speer's plan to redesign Berlin as a future 'Germania' became the model for the redesign of German provincial capitals. Showing conventional architecture of monumental style with axes appropriate to the parading party and public buildings within central urban areas, these plans were nevertheless designed according to existing planning knowledge which had already been developed widely in the preceding decade.

1940: The policy of armament and the war of conquest led to a stronger functional approach to planning. Growing individual mobility and the change from the detached settlements of the early 'blood and soil' period to compact housing concepts provoked a change to planning paradigms even in wartime. The advance to the East led to initiatives for redesigning the settlement structure of the conquered territories. Walter Christaller's 'central places' theory of 1933 was easily adaptable to the required hierarchical structural system. Political goals combined with military ambitions also led to marked improvements in planning methods and techniques, such as statistics, cartography, and aerial photography.

1943: The disastrous bombing of cities forced a return to the debate dating back to the CIAM discussion of 1933 on rebuilding towns. A decree by the Führer regarding the reconstruction of German

cities after the anticipated victory empowered Albert Speer to establish a team of reconstruction planners, with each member given responsibility for one or more cities. The plans were quite heavily influenced by comparisons with advanced design methods to international standard and some, indeed, served as first concepts for reconstruction after 1945 (Durth 1986).

2. Political Reconstruction

From 1871, national state pride and the desire for international reputation dominated the politics of the Imperial Reich. The Morgenthau doctrine aimed to prevent Germany from returning to such a powerful state. In 1945, therefore, the Allies promoted the decentralization of Germany, basing their strategy on a tradition dating from the Middle Ages to the nineteenth century of strong feudal states with attractive provincial capitals. The city of Bonn, a modest city among those former feudal seats, became the capital of the Federal Republic of Germany. However, many of the new West German states retained their former seats as capitals. Berlin was divided and the German Democratic Republic kept East Berlin as its capital. In the East, the former state capitals were promoted less. Thus two systems existed simultaneously between 1961 and 1990: East Berlin as the capital and center of power in the socialist state, with other cities as only regional centers, and in the western federal state a more modest capital with 11 quite strong state capitals and, under them, a tier of regional towns.

3. Rebuilding the Cities: The Western Approach

Before the war the modernization process in German cities was badly impeded by their historic heritage. West German postwar planners therefore used the opportunity of rebuilding the bombed cities according to modern international planning standards that, before 1933, had been developed continuously and which Germany, with its dreams of a thousand-year Reich, had for a while gambled away. Nevertheless a very few international links were maintained (Fischer 1990). The founding of the Federal Republic in 1948, the monetary reform urged by the Marshall Plan, and the Korean War, produced economic growth which helped to speed reconstruction. This focused on two goals: first, to bring sun, air, and light into the urban cores which, to most minds, had suffered so much from urban concentration and industrialization and, second, to provide motor car access to the cities.

But West Germany adopted different approaches for rebuilding the demolished core areas in the post-war period (for statistics on rubble, see Diefendorf 1993, pp. 3–17). The schemes ranged from radical modernization to a moderate reconstruction or tra-

ditional adaptation (also Beyme 1987, pp. 175–7). Munster in Westfalia or the Bavarian capital of Munich, for example, employed quite traditional lines, based on the historic layout and scale and, in cases of new constructions, a moderate adaptation of modern design for the facades. Monuments were rebuilt or restored. Cities such as Kassel, Dortmund, Cologne or Hanover, on the other hand, were proud of their rather radical approach to the modern town plan.

Recently some cities have given greater emphasis to re-evaluating historic structures and inner city areas. In Frankfurt, rebuilding from scratch the eastern row of buildings along Römerberg in medieval style in 1984 provoked an intense controversy in West Germany about reconstruction and the 'truth' of history. This is one of several examples of postmodern city design in Germany.

4. Urban Development Policy

The Athens Charter was published in Germany only in 1957 but its ideas were already 25 years old and, during these years, had more or less been the basis for urban development policies. Organizing the city according to four main functions (work, housing, leisure, transport) was from this point the planner's core strategy. The treatment of the neighborhood as the basic planning unit was introduced into German planning from 1940. News of Abercrombie's Greater London Plan of 1943/44 with its green belt strategy spread quickly, as did the reconstruction plan for Rotterdam. Thus, after 1948, a flourishing economy

Figure 1
Marcel Lods, Werbung für die Forderungen der 'Charta von Athen.' Section du Plan (Mainz) 1947: Lichtfülle—Finsternis (Marcel Lods, promotion for the demands of the Athens Charter, (Mainz) 1947: richness of light—darkness)

Figure 2
Marcel Lods, Werbung für die Forderungen der 'Charta von Athen.' Section du Plan (Mainz) 1947: modernes—traditionelles Wohnen (Marcel Lods, promotion for the demands of the Athens Charter, (Mainz) 1947: modern—traditional housing)

Figure 3
Marcel Lods, Werbung für die Forderungen der 'Charta von Athen.' Section du Plan (Mainz) 1947: Die Naturgegebenheiten—Sonne, Weiträumigkeit, Grünflächen (Marcel Lods, promotion for the demands of the Athens Charter, (Mainz) 1947: natural conditions—sun, space, green)

helped urban growth to develop to modern standards, based until the mid-sixties on the main concept of the 'organic art of town planning' (Reichow 1948), the 'composite and disaggregated city' (Göderitz, Rainer, Hoffmann 1957) or 'the car city' (Reichow 1959). The tenement house (*Mietskaserne*) and the noisy, crowded and dusty nineteenth-century industrial city were seen in a negative light (Figs. 1–3). The vision was of a green

city spread across the landscape, designed on a basic human scale as neighborhoods each with its own facilities, located in zones, suburbs or quarters. Motor car access was universal, but separated from walkways and rail systems, with a rich variety of open green spaces for leisure pursuits. The city center and central business district (CBD) were the dominant feature, incorporating reconstructed historic monuments and some high-rise buildings as the crown of the city.

The comprehensive urban renewal of nineteenth-century housing stock meanwhile aggravated the need for new housing, necessitating a change to a new policy of high-density housing in the periphery. Density outside the city also needed to be increased substantially to make public transport schemes efficient, and dreary suburban neighborhoods should, based on the perceptions of Jane Jacobs, or Hans Paul Bahrdt in Germany, be amended by 'urbanity,' by the transfer of urban design and dimensions to the periphery, without its lamentable deficiencies and defects.

Around 1975, severe economic changes stemming from the oil crisis and new technologies demanded an urgent review of planning aims and procedures. Several new arguments had already influenced planning—participation, ecology, the rediscovery of the nineteenth-century city and the attractiveness of its tenement house, and the ineffectiveness and inflexibility of large-scale planning. Planning was put under the microscope, necessitating reflection on, and alteration to, its theories, strategies, methods, and procedures. The new planning culture had to work with new technologies and economies, greater social mobility and the breakup of society and as a result new urban models developed. This discussion is still in progress.

5. *Rebuilding the Cities: The Eastern Approach*

Without a doubt, East Germany did things differently. Apart from Berlin, Dresden, Magdeburg, Leipzig and Chemnitz and a few others, many cities in the East were not touched by air raids. The building stock and inner areas of these cities therefore still date more or less from Hanseatic or court tradition as well as from the nineteenth and early twentieth centuries.

The German Democratic Republic (GDR) after its founding in 1948 abolished the private market, nationalized land and built structures, while the government took responsibility for their regulation. But the priority of the new socialist state was the improvement of its own economy to provide the population with basic goods and to make the productive sector independent from the Western market. Money for housing was scarce. Projects of the mid-1950s, like the *Stalinallee* in East Berlin (riposted in West Berlin with the International Building Exhibition, the 'Interbau'

at Hansaviertel, Tiergarten with buildings by internationally renowned architects such as Aalto or le Corbusier), or the construction of the new industrial town of Stalinstadt (later Eisenhüttenstadt) (May in press), were outstanding and proved to be excellent propaganda. As early as 1950, however, East Berlin developed a list of 16 principles of town planning as a socialist riposte to the Athens Charter, at the insistence of Moscow. According to these principles, a city had to be compact and of a traditional national, or regional style.

Only after Stalin's death was the GDR able to adopt a functional town plan and a modern language in architecture. This led to industrialization in the building sector. Lack of building materials and a dramatic shortage of housing forced the government to rationalize the building process radically. Nationally organized housing production units with regional competence, were from the early 1960s responsible for planning and construction. The planning competencies of local authorities were limited. Urban reconstruction under these circumstances meant erecting new prefabricated housing schemes in rows of multi-storey blocks on the urban fringe and moving people to them. The existing building stock was not renewed as no building material or a sufficiently skilled labor force were available. Private initiative was therefore more or less impossible. It was intended to replace the existing but decaying late-nineteenth century urban housing stock at a later date with new prefabricated blocks. Inspired by West Germany, a few test projects started around 1980 and some modified concrete slabs were produced to integrate better into the urban fabric. This proved too expensive. The policy to replace old housing stock as quickly as possible with blocks of prefabricated concrete units also met with limited success. The reprehensible treatment of the urban environment and the appalling decay of the cities was at the root of the people's movement in 1989.

Reconstruction/Disaster Planning: Japan

Japan has been prone to natural disasters, especially as it lies in the Pacific volcano zone, but among the most destructive have been frequent earthquakes. Moreover, its traditional urban dwellings, typically wooden buildings made with thatched roofs, are easily inflammable, making cities liable to major conflagrations. But it was not until the Meiji Restoration in 1868 and the subsequent era of rapid industrialization and urban growth that serious thought was given to constructing urban structures to survive such disasters. Since then, the development of reconstruction and disaster planning has been interrelated closely with that of modern urban planning, which in turn has been influenced by changes in the political, economic, and social environment.

1. Reconstruction/Disaster Planning in the Meiji Period

One of the earliest examples of reconstruction and disaster planning after the Meiji Restoration was the *Ginza district project* following the large 1872 fire in Tokyo that burnt out some 3,000 dwellings. A radical proposal was put forward to rebuild the entire district with Western-style buildings made of bricks. It was an

attempt to set a precedent in transforming the traditional urban structure of the capital into a modern one, reflecting the Meiji government's strenuous efforts to swiftly Westernize the country in order to facilitate the revision of the unequal treaties with the Western powers. Individual buildings were designed by expert foreign advisers employed by the government, and the project was completed in 1877. Although the financial difficulties allowed just half the planned area to be rebuilt with bricks, the newly reborn Ginza district quickly became popular as the most fashionable shopping center in the country.

However, there was a gradual realization that a more comprehensive and yet realistic approach than this kind of extravagant but essentially superficial Westernization of the capital was necessary. While this recognition led to the urban improvement projects for Tokyo, mainly consisting of road, water supply, and drainage works, that started in 1888 and lasted for 30 years, there were important prior developments in the form of reconstruction and disaster planning. In the wake of four big fires within a few months during the winter of 1880–81, the governor of Tokyo proclaimed regulations mandating fire-prevention measures in the central wards of Tokyo. Twenty-two streets and canals were designated as areas along which buildings had to be constructed of either bricks or stone, or as godowns made of clay, with roofs of incombustible materials. Extensive slum clearance was also carried out in the Kandahashimotocho district following one of the four big fires in 1880–81, though it meant the merciless uprooting of inhabitants from their old community, admittedly one of the major slums in Tokyo at that time. Meanwhile, the demand for national planning legislation intensified, and the *Urban Planning Act* was enacted in 1919. In practical terms, its prime concern was to check indiscriminate urban expansion by controlling future development through such measures as land readjustment projects, a principal feature of Japanese urban planning based on street widening and realignments. But an opportunity for its application to built-up areas soon came about in a tragic way.

2. Reconstruction after the Great Kanto Earthquake

On September 1, 1923, a severe earthquake of magnitude 7.9 hit the southern Kanto region including Tokyo and Yokohama. As it occurred just before noon, when people were cooking meals, the Great Kanto Earthquake caused massive fires that claimed more than 100,000 lives and destroyed 460,000 dwellings. The total damage amounted to approximately six billion yen, four times the amount of the national budget. The government set to reconstruction planning immediately, with Shinpei Goto, the Home

Minister, as the man in charge. He tackled the task enthusiastically, not least because he saw an opportunity to restore his reputation. The renovation plan for Tokyo made public five months earlier when he was the mayor of Tokyo had been criticized heavily as too extravagant, and he had been derided as a braggart. Within a week, he established basic principles for reconstruction, which included proposals for a powerful Ministry for Reconstruction and public purchase by the state of all land affected at an estimated cost of 3 billion yen, reflecting his determination to rebuild in a bold and comprehensive way. However, neither of these proposals was put into practice: opposition from other ministers and ministries to a mighty reconstruction ministry led to the abandonment of the idea. Public purchase of land was out of the question not only on financial grounds but also on political ones, for the landed interests had a strong say within the government as well as in the Diet. Moreover, the budget was reduced to 468 million yen at the 47th extraordinary Diet session in December, three months after the disaster.

Nonetheless, reconstruction projects with actual working expenses of 847 million yen over seven years between 1924 and 1930 meant grand engineering on an unprecedented scale. This becomes clear when they are compared with the earlier urban improvement projects for Tokyo which took 30 years but cost only 42 million yen. Approximately 80 percent of the afflicted area in Tokyo, 3,600 hectares, were covered by reconstruction land readjustment projects under the *Ad Hoc Special Urban Planning Act*, which made possible large-scale land readjustment in built-up areas. As a result, Tokyo's urban structure, of which the core had been Edo-era construction modified by the Meiji-era urban improvement projects, was transformed. This change laid the foundation for the infrastructure of the capital's central area until the 1960s. The reconstruction land readjustment projects gave rise to 52 principal roads (114 kilometers in total length), 122 subsidiary principal roads (139 kilometers), 55 parks (42 hectares), and a number of structures built of reinforced concrete to render them earthquake- and fire-proof. The latter included 121 schools and 424 bridges. Of particular interest were the activities of *Dojunkai*, an extra-departmental body to the Home Ministry set up in 1924. It provided, among other things, 2,501 apartments of reinforced concrete with the most up-to-date communal facilities, built on 15 estates between 1926 and 1933. These became the forerunner of the public apartments built to alleviate major urban housing shortages in the postwar years.

It should be also noted that reconstruction planning after the Kanto earthquake brought important advances in planning techniques and the training of technocrats and other planning personnel. This contributed to the substantial progress made in the development of Japanese urban planning in the 1930s and 1940s. However, the main cause of this progress,

the intensification of military preparations, was soon to lead to a war that would bring massive destruction to the country.

3. Air Defense Planning and Postwar Urban Reconstruction

During the 1930s, air defense became the prime concern of Japanese urban planning, as was duly shown in the *revised Urban Planning Act* of 1940, which made air defense an integral part of urban planning. Emphasis was placed upon the provision of open spaces and wider streets for fire-preventive purposes. Admittedly, urban planning benefited from this. For instance, the state purchase of an area of 13,730 hectares was decided in 1939 to provide a number of parks as air defense measures. Out of these, six large parks in Tokyo with a total of 640 hectares were established as part of the ceremony commemorating the 2,600th anniversary of the founding of the Japanese Empire. Evacuation of buildings to make room for air defense roads also led to the building of wide thoroughfares in cities such as Nagoya, Hiroshima, and Kyoto.

However, the sheer intensity of air raids during the closing months of WWII was far more devastating than these measures could handle, and Japan found its urban areas in ruins when it surrendered in August 1945. One hundred and fifteen cities and towns throughout the four main islands in Japan were officially designated in November 1945 by the government as war-damaged cities. Approximately 2,300,000 houses or 20 percent of the stock in those cities had been destroyed or seriously damaged, and 63,000 hectares of land burnt out. The damage was particularly extensive in the two largest cities, Tokyo and Osaka, and these accounted for nearly 40 percent of the total of land (26.8 percent for Tokyo and 12.1 percent for Osaka) and more than 45 percent of houses (32.9 percent for Tokyo and 13.8 percent for Osaka) affected. The area affected in Tokyo was more than four times as great as that afflicted in the Great Earthquake in 1923.

Despite the extent of damage and the fact that Japan was under American occupation, official policies and plans for postwar reconstruction were formulated speedily and implemented with determination. Evidently, such destruction was regarded as having provided an opportunity for drastic urban renovation. In November 1945, the War damage Rehabilitation Board (WRB; *Sensaifukkoin*) was set up as a responsible central body. Ichizo Kobayashi, a well-known businessman, was appointed as its first president and given ministerial status. The intention underlying his appointment was to introduce the spirit of private enterprise and thus to get rid of the bureaucracy that had dominated Japanese urban planning before the war. This reflected the wave of

democratization of Japan's political, economic, and social systems. The following month, the cabinet adopted the Basic Policy Principles for the Planned Reconstruction of War damaged Areas (*Sensaichi-fukkokeikaku Kihonhoshin*). It featured nine principles in planning, according to which the local authorities drew up plans very quickly. It was recommended that the damaged areas should be covered by land readjustment projects, and that principal roads should be quite wide, even as much as 100 meters for large cities.

However, the planning process continued to be dominated by civil servants. For one thing, the WRB officials simply ignored Kobayashi, their superior, when he argued for compact rather than grandiose reconstruction. The officials insisted that plans had to be bold and comprehensive. This was perhaps in line with what cities like Tokyo wished, but many other cities thought quite differently, only to be forced to accept the officials' arguments. Osaka, for instance, had no choice but to add a couple of 100-meter-wide thoroughfares to its original plan when it was told by the WRB officials that any approval of their plan would otherwise be out of the question. Osaka officials believed that such proposals were too extravagant given the country's economic situation. In fact, the plans were subject to constant cutbacks due to the economic difficulties, culminating in the Revision (*Saikento*) in 1949 of the basic principles for reconstruction drafted in 1945. The revision was made following the *Dodge Line*, a draconian anti-inflation program implemented by the occupation authorities in 1949. The *Dodge Line* forced the government to cut spending drastically. As a result, the area covered by land readjustment projects was reduced by approximately 30,000 hectares, or 50 percent over the country as a whole, and many ambitious road and park projects were eliminated. The cuts were especially severe for big cities. In the Tokyo plan, all seven of the proposed 100-meter-wide roads were simply abandoned, and the area for land readjustment projects was reduced by three-fourths. In the Osaka plan, proposals for 100-meter-wide roads were also dropped and the extent of land readjustment projects reduced by nearly 45 percent. Moreover, there was widespread public disapproval of reconstruction planning: in large cities, the open space proposals were often simply ignored by those who erected illegal houses on the designated sites, which thus became prejudicial to planned development in the future. In many provincial cities, there emerged organized opposition by citizens to the official plans, usually reflecting discontent that their opinions were not heard in the planning process.

4. Conclusions

Nevertheless, planning for disaster-proof urban structures made some progress from the 1950s onwards, thanks to a series of legislative measures aimed at enhancing public safety, such as the *Fireproof*

Building Promotion Act of 1952 (covering the total area of 64 hectares in some 80 cities), and the *Disaster-proof Building Blocks Construction Act* of 1961 (covering 253 hectares in 101 cities). Further, the *Urban Renewal Act* of 1969 led to the redevelopment of six disaster-prevention districts covering 526 hectares in Koto Ward, a heavily populated downtown area in Tokyo. But the country is still vulnerable to disasters, as shown in the Hanshin/Awaji Earthquake in 1995. Regrettably, there was considerable anger among local residents in Kobe, the worst-hit city, about the lack of consultation in the reconstruction planning and the manner in which plans were imposed from above. As Japan cannot be immune from earthquakes, there is still an enormous need to plan for disaster-proof urban structures throughout the country, and to promote greater public participation in the process.

Reconstruction/Disaster Planning: United States

Reconstruction/disaster planning includes plans prepared specifically to guide reconstruction following disasters, plans prepared to mitigate losses from hazards through actions taken prior to the onset of disasters, and hazard-mitigation elements of more general urban and regional comprehensive plans. Although the content of each type of plan differs, the critical components and key features of the planning process are similar. In this article, the basic elements of reconstruction/disaster plans and the processes involved in preparing them are described.

1. The Problem

World-wide, the risks from natural and related technological hazards has been increasing at an accelerating pace. Population growth and migration toward at-risk areas, increased development and urbanization of hazard zones, long-term climactic trends, and other factors have combined to expose populations to losses of life and property. Although improved forecasting and warning systems have generally reduced the number of fatalities associated with disasters, particularly in developed countries, annual monetary losses everywhere are staggering.

This problem is particularly severe in the United States, where losses of property and income attributed to natural hazards are estimated at \$500 million per week (Mileti 1999). Large disasters, such as Hurricane Andrew in 1992, the Midwest floods of 1993, and the Northridge earthquake of 1994 have resulted in damages ranging from \$15 to \$44 billion (Board on Natural Disasters 1999). Worst case scenarios suggest that much larger disasters are probable. A \$200 billion earthquake in California and a \$50 billion hurricane in Florida are distinct possibilities. In the face of this large and growing exposure to economic loss, policy makers are slowly coming to realize that urban planning may be an effective way to foster greater resilience to natural disasters.

2. Evolution of Planning for Resilience

Throughout history, communities have been located so as to limit the potential for disaster and after disasters, governments have sought to rebuild in ways to reduce the likelihood of future catastrophes. Italian hill towns, for example, were located on high ground to avoid flooding and diseases such as malaria that were prevalent on the valley floors. After the Great Fire of London in 1666, Charles II issued a proclamation that called for rebuilding in ways that would reduce the potential for future disasters. In more recent times, however, the lessons of the past were forgotten. After the San Francisco earthquake and fire of 1906, for example, the city was quickly rebuilt with little attention to hazard mitigation. In fact, some of the largest losses in the Loma Prieta earthquake of 1989 occurred in the Marina District, which is located on debris pushed into the bay after the 1906 disaster.

Modern thinking about planning for resilience to hazards can be traced to the geographer Gilbert White, who first proposed the concept in 1936 in an article in the *Planners Journal* (1936). White's ideas were not acted upon until twenty years later, when the Tennessee Valley Authority prepared a flood-plain management plan for Bristol, Tennessee-Virginia in 1956. However, because few communities followed the TVA lead, state governments, beginning with California in 1972, began to require that local governments incorporate hazard mitigation provisions in their com-

prehensive planning. At last count, half of the states mention natural hazards in their planning enabling statutes, and eleven states, like California, actually mandate local government planning for the mitigation of natural hazards (Schwab et al. 1998).

Plans that address natural hazards take two forms. Post-disaster reconstruction and recovery plans focus on policies and actions to bring about rapid recovery from a disaster and to guide reconstruction of damaged structures and infrastructure to increase resilience to future disasters. Hazard mitigation plans focus on policies and actions that can prevent damage and loss of life before disasters occur. Each type of plan may be formulated as a stand-alone plan or as an element of a broader comprehensive plan, but the latter approach is probably best, since it embeds hazard mitigation in regular planning processes that have legal standing.

3. Post-disaster Reconstruction and Recovery Plans

The post-disaster period creates a window of opportunity to make changes that can improve resilience to future disasters and accomplish a number of other community goals. But, these opportunities are often lost due to the need to make decisions quickly in an atmosphere of confusion and strong political pressures to return quickly to normalcy. Post-disaster reconstruction and recovery plans provide a means to ensure that reconstruction occurs in ways that contribute to long-term sustainability. These plans focus on decisions, made in the short-term recovery period after a disaster, that have long-term repercussions. Schwab and his associates (1998) call attention to four groups of decisions that are particularly important to address in plans: (1) sites for temporary housing, relocation of damaged businesses, and dumping of debris; (2) closure of roads and bridges; (3) restoration or relocation of critical infrastructure; and (4) reconstruction or relocation of dwelling units and nonconforming uses that have suffered substantial damage. In addition, the plan should clarify roles and responsibilities in recovery, identify potential sources of financing, and minimize wasteful and conflicting efforts (Mileti 1999).

Experts such as Mileti (1999) and Schwab (1998) argue that postdisaster recovery and reconstruction plans will be most effective if they are prepared in accordance with the following principles. *Consensus building* through community involvement should be sought to avoid community conflict over reconstruction strategies. *Information* should be provided about the hazard, exposed populations, buildings, and infrastructure, resources available for recovery after the disaster, and governmental powers and programs to aid recovery. *Organization* should be addressed through identification of topic-specific groups that can

be put in place immediately after a disaster (in particular, designation of an official rebuilding/restoration group is critical). *Procedures* should vary as little as possible from those followed during pre-disaster periods, although permitting and code-review procedures should be streamlined in order to expedite rebuilding. *Damage evaluation* protocols should be in place, such as protocols for damage assessment by building inspectors and standards for post-disaster repair and construction. *Finances* for reconstruction should be identified including funding from both governmental and private sources. Finally, provision should be made to adjust the local government's *planning style* so that more flexible and cooperative procedures replace the formal, deliberative rule-oriented procedures that characterize pre-disaster decision-making.

4. Hazard Mitigation Plans

The American Planning Association recommends in its *Growing Smart Legislative Guidebook* (1998) that local government comprehensive plans include an element on hazard mitigation. A number of states (e.g., California, Florida, North Carolina for coastal areas) not only recommend this, they require it of every community (see Burby et al. 1997). Through a comprehensive plan's safety element, hazard mitigation is addressed directly and hazard considerations are also included in portions of the plan dealing with housing, transportation, protection of environmentally sensitive areas, natural resource protection, and capital improvements. Hazard mitigation plans, as stand-alone documents, also have been prepared to address a variety of hazards. In either case, the preparation of a plan involves similar steps.

The first step is to secure a resolution by the local governing body to put someone in charge of the planning effort and to establish a planning committee or task force. Official sanction for the planning process is essential to obtain the participation of other agencies and to tap into their resources and expertise. Participating agencies should include planning/community development, engineering/public works, finance, public safety (police, fire, emergency management), code enforcement, parks and recreation, public information, and a representative of the governing board.

One of the planning group's first jobs is to build a constituency for hazard mitigation and consensus about the need to take action. The lack of such a constituency, coupled with local officials' own lack of concern about hazards, has resulted in minimal attention to hazards in past planning (e.g., Burby 1998, Mileti 1999, Platt 1999). This is best accomplished by involving key stakeholders in the planning process from the beginning. The public involvement effort should target people and organizations exposed to hazards, neighborhood and civic organizations, the

business community, managers of critical facilities, land developers and others whose decisions affect urban development. In addition to gaining support for the planning effort, citizen involvement helps secure local knowledge about hazards, insures that information gathered in the planning process is relevant to issues citizens view as important, and helps to prevent misunderstandings and gain consensus for the plan's recommendations.

The next step in the planning process is to develop information about the problems hazards pose and the capacity of the community to build resilience to hazards. Hazard assessment includes identifying hazards (magnitude, severity, frequency, and causative factors) and mapping the areas of a community that are exposed to them. Losses experienced in past disasters are identified, and vulnerability to loss in future disasters is estimated by examining potential property damages in hazard events of various magnitudes.

Analysis of capacity helps in identifying hazard reduction measures that are feasible for a community and actions that are needed to increase capacity, such as adding staff with hazards expertise or developing dedicated revenue sources to fund mitigation. Other topics for capacity analysis include funding sources, legal authority for hazard mitigation actions, and evaluation of hazard mitigation measures that are already in use. The hazard assessment and capacity analysis lead to a statement of the problem facing the community and formulation of goals and objectives. It can be combined with a visioning process to develop, in collaboration with citizens and policy makers, an image of what a hazard resilient community would look like in the future. Visioning can help develop consensus about the goals of hazard mitigation and can be useful in tying hazard mitigation to other community concerns such as economic development and environmental protection.

Once the problem is understood and a vision of a hazard resilient community is agreed upon, preparation of the hazard mitigation plan involves making choices among possible strategies to build resilience. Six sets of possible measures should be reviewed.

(a) *Preventive* policies and actions are designed to limit the exposure of new development to losses from hazards (e.g., building code standards, zoning, and land acquisition).

(b) *Property protection* policies and actions limit the exposure of existing development to hazards on a parcel-by-parcel basis (e.g., retrofitting, relocation, acquisition and clearance, and insurance).

(c) *Structural protection* policies and actions limit the exposure of existing development to hazards (principally flooding) on an area-wide basis (e.g., flood control dams, levees, sea walls, and channel modifications).

(d) *Emergency services* policies and actions lessen the impact of a hazard after its onset (e.g., warning,

evacuation, flood fighting, fire fighting, and emergency sheltering).

(e) *Natural resource protection* policies and actions preserve and restore natural areas that also help lessen the magnitude of hazards (e.g., wetland protection, erosion and sedimentation control, and sand dune protection).

(f) *Public information* policies and actions build awareness of hazards and knowledge of individual actions to mitigate them (e.g., hazard maps, library resources, and technical assistance).

The strategies that have been identified as useful in creating a sustainable community that is resilient to hazards are evaluated in terms of their effectiveness, efficiency, equity, and feasibility (administrative, technical, financial, legal, and political). The goal is to formulate a program that draws wide support, addresses existing problems from hazards, and also prevents new ones from developing. The final plan includes, at a minimum, five components. These include

(a) a description of how the plan was prepared and who participated in its preparation,

(b) an assessment of hazards facing the community,

(c) the vision of a hazard-resilient community,

(d) recommendations of policies and actions, and

(e) identification when they will be undertaken, who is to undertake them, how they will be financed, and who will monitor performance (see Wetmore and Jamieson 1999).

5. Conclusion

The preparation of a post-disaster-reconstruction/hazard-mitigation plan provides the technical analysis, coordination among governmental agencies, and community involvement and consensus building necessary to increase resilience to natural and related technological hazards. Communities with coherent plans are able to build human settlements that are resistant to disasters and able to recover from disasters quickly. The plan-making processes and principles discussed in this article are proven to be effective. But state and local governments have been slow to prepare and adopt the needed plans. The challenge for governments at every level is to act on the knowledge that is available to reduce or even reverse the steady rise in destruction and human suffering from disasters.

Reconstructive Memory, Psychology of

Reconstructive memory refers to the idea that retrieval of memories does not occur in some completely accurate form, as a video-recorder might replay a scene, but rather that recollection of memories is a process of trying to reconstruct (rather than replay) past events. Although the reconstruction can be quite accurate, the processes responsible can also introduce errors during retrieval. In fact, systematic errors in memory are the primary evidence for its reconstructive nature. This article provides an overview of the evidence that remembering is reconstructive (see also *Eyewitness Memory: Psychological Aspects*; *False Memories, Psychology of*; *Memory for Meaning and Surface Memory*).

1. Background

The hypothesis that remembering should be viewed as reconstructive dates to an important book by Sir Frederic Bartlett (1932). Bartlett contrasted reproductive memory (veridical, rote forms of memory, such as reproducing a telephone number) with recon-

structive memory and argued that the latter was more typical of our uses of memory outside laboratory and educational circumstances. That is, we are rarely faced with the task of remembering something exactly the way it happened, but more typically need only to get the essence of the event right. If a friend asks you, 'What did Kathleen tell you last night?' the request is not for a literal rendering of last night's conversation, but rather for the gist of what was said.

Bartlett argued that perceiving and comprehending events do not simply happen automatically, but that every event of comprehension involves the mental construction of one's understanding of the event in the world. We all struggle with the 'effort after meaning' in comprehending the events in the world around us. If encoding or perceiving is a construction, then when one wants to recall the events later, the attempt is to reconstruct the event.

Bartlett argued that recollection is guided by schemas, or general organizing structures, which aid encoding and retrieval. If you see a scene at the beach and are asked to recall it later, you might recall seeing a beach umbrella even if none was present in the actual scene itself, because it is consistent with the general schema of items that belong in a beach scene. Therefore, although schema can aid encoding and retrieval of information, they can also lead to errors.

A large amount of research is consistent with the idea that remembering is reconstructive. The standard textbook account holds that certain forms of remembering are reconstructive whereas others are reproductive. However, a strong case can be made that all remembering is reconstructive. What appears to be reproductive memory occurs in situations in which the reconstruction is quite accurate (Roediger and McDermott 1995). This article considers various forms of memory as they are experimentally studied and discusses evidence for reconstructive processes at work.

2. Sensory and Short-term Memory

The greatest challenge to the claim in the previous paragraph perhaps comes from studies of sensory memory, the borderline between perceiving and remembering. However, many theorists have argued that perceiving is itself a constructive activity, with fascinating phenomena of visual and auditory illusions used as evidence for this claim (see Gregory 1998, among many others). Sensory memory refers to the temporary persistence of information that has struck the senses, which lingers briefly as it is being comprehended. Visual persistence is called iconic memory and auditory persistence is labeled echoic memory. It would seem that iconic memory—essentially a fleeting after-image of the scene from the outside world—would surely be a form of reproductive memory. Yet even in these situations errors arise, showing that

at least the retrieval processes from this type of memory involve reconstruction. For example, in Sperling's studies of iconic storage, in which people had to report letters that they had briefly seen on a screen, a common error when people missed a letter was to report another letter than either looked like or sounded like the original letter (Sperling 1967). This type of error indicates that people may code even such simple items as single letters into visual patterns and associated sounds. When people miss a *b* in these experiments, they may substitute a *v* (which sounds like *b*) or a *p* or *d*, which share both similar appearance (a long line and a curve) and similar sound (the letters rhyme with *b*). Even reports from iconic memory may show reconstructive tendencies.

Short-term memory or working memory (see related entries on these topics) hold information for longer than sensory memories, but people are still ordinarily accurate in retrieving information from short-term stores, if no interference occurs. Does this accuracy reflect a rote, reproductive process? The answer seems to be no, because when the short-term memory system is challenged by having people operate under, for example, fast rates of presentation, errors occur. Errors are often (but not always) phonological in nature. That is, if someone tries to recall letter strings and misses a letter, similar sounding letters are confused (Conrad 1964). In the case of words, those that share visual and phonemic (sound-based) features are confused (Crowder 1976, Chap. 4). Therefore, even though short-term memory processes are often considered quite accurate (and they can be), recall in these situations typically occurs under conditions (short unfilled delays between study and test) that make for accurate reconstructions. Stress the system by presenting material fast, or by creating interference, and the characteristic error pattern indicative of a reconstructive process appears.

3. Long-term Memory

By far the greatest amount of research on reconstructive memory has occurred in the domain of long-term, episodic memory. Many different kinds of experiments have been conducted and we will consider some of the main types here, which have used a wide variety of materials: word lists, pictures and scenes, sentences, prose passages, and videotape. Research with all these materials reveals remembrance to be quite prone to error and to filling in the gaps.

3.1 Word Lists

Roediger and McDermott (1995) developed a paradigm in which people heard lists of 15 words that were generated as associates to another word, which was not itself presented. So, for example, subjects heard

Figure 1

False recognition and false remembering. Mean probability of recognizing (total bar) and remembering (cross-hatched bar) studied words and lures. Unrelated lures were rarely recognized, but critical lures were recognized and remembered at about the same levels as studied words. People remember the occurrence of the critical items at the same level as words that were actually studied. Data are from Roediger and McDermott (1995, Experiment 2)

the list 'hot, snow, warm, winter, ice, wet, frigid, chilly, heat, weather, freeze, air, shiver, Arctic, frost.' All these words are associated to the word 'cold,' which was the generator of the list, but 'cold' was not presented. Immediately after hearing the list, subjects were asked to recall the items and were urged to be sure that the words they recalled had actually been presented in the list. Despite this warning not to guess, Roediger and McDermott (1995) found that their subjects recalled missing words like 'cold' at very high levels; in fact, probability of recalling the critical item often equals probability of recall of list items in this paradigm. After recall of many lists, subjects received a recognition test in which they were instructed to pick out only items that had actually appeared in the list. The test included words from the list ('winter,' 'chilly'), completely unrelated words ('automobile'), and the critical words such as 'cold.' Subjects examined each word and, if they judged it to be old (or studied), they were asked to make a further remember/know judgment. This judgment (Tulving 1985) asks people to report if they can remember the moment of the item's occurrence in the study list (a remember judgment) or if they just know it was on the list but cannot remember its moment of occurrence (a know judgment).

The recognition results are shown in Fig. 1, where it can be seen that subjects were good at distinguishing studied words from unrelated lures or distracters. However, the critical lures such as 'cold' were recognized at the same level as were the words in the list, about 80 percent. People recognize the related but nonstudied word at the same level as they do items in the list. In addition, subjects claimed to remember the moment of occurrence of the critical words (that, of course, were not actually presented) at the same level as for the words that were actually studied). In short,

in this paradigm subjects recall, recognize, and claim to remember the occurrence of words that were never presented at the same level as of the words that really were presented, which provides a compelling demonstration of illusory memory. The implication is that subjects reconstruct the list using their general knowledge and yet insert a quite specific memory—they remember 'cold' as having occurred—because it fits with the general theme or schema of the list.

3.2 Pictures and Scenes

Miller and Gazzaniga (1998) developed a similar procedure with common pictorial scenes, ones that had been covers of the *Saturday Evening Post* magazine. They showed people the scenes with a critical object from the scene removed. To use our earlier example, people might view a beach scene with a beach umbrella either present in the scene or absent from it. Miller and Gazzaniga (1998) found that when people were given recognition tests on objects in the scene, they were very likely to recognize the object as having been present when in fact it was not. Again, in reconstructing the scene, the object is inserted and seems part of the memory.

3.3 The Misinformation Paradigm

One of the most popular paradigms for studying reconstructive processes in memory was developed by Elizabeth Loftus and her colleagues (e.g., Loftus et al. 1978) and is called the misinformation paradigm. It is modeled after the events that an eyewitness to a crime might experience. In the lab, subjects view a set of slides or a videotape, then later they receive questions or a narrative. In Loftus et al. (1978), subjects witnessed an automobile accident that occurred at an intersection where a car failed to stop at a stop sign. In the later series of questions, subjects would be asked either one of three types of question: 'Did the car stop at the traffic sign?' (control condition), 'Did the car stop at the stop sign?' (consistent information condition) or 'Did the car stop at the yield sign?' (inconsistent or misleading information condition). This question served as the experimental manipulation for a question asked at a later point in time: 'What kind of sign was at the intersection, stop or yield?'

Results of this experiment are shown in Fig. 2, where it can be seen that, relative to the control condition in which the question was posed in a neutral manner, wording of the question that was consistent with the original information improved recognition whereas the conflicting information reduced recognition. This last finding is the misinformation effect—wrong information received after an event is often incorporated into one's memory for the event. This misinformation effect has been demonstrated in

Figure 2

Probability correct (on a two-alternative forced choice recognition test) as a function of whether subjects had received information consistent with what they had previously seen, information inconsistent with what had been seen, or no specific postevent information. Misleading information after the event can reshape memory for the event. Data from Loftus et al. (1978, Experiment 2)

hundreds of experiments, although the magnitude of the effect depends on the exact nature of the test.

The general principle to arise from experiments on the misinformation effect is that memory for an event is not encapsulated in time the way the event itself is. Rather, information provided after the event can modify our memories for the event itself. Consistent information improves our later reconstruction, whereas conflicting or misleading information is harmful. When we are trying to reconstruct events from our past, we draw on all the information and resources at our disposal and the reported memory may include 'facts' that were not really part of the event, but incorporated into it later. Practically, if police or other people ask suggestive questions or embed wrong information into questions asked of witnesses after the event, then the witnesses' later recollections and testimony might be tainted (see *Eyewitness Memory: Psychological Aspects*).

3.4 Prose Recall

Perhaps the greatest body of research demonstrating reconstructive processes in retrieval has been carried out in prose recall. Brewer (1977) examined pragmatic implications in retention of sentences. A pragmatic implication is made when the person reading or hearing a sentence infers something that is neither explicitly stated nor logically implied by the sentence (see *Inferences in Discourse, Psychology of*). For example, 'The karate champion hit the cinder block' implies that the block was broken. However, this is a pragmatic implication; it is perfectly possible that the

block was struck but not broken. After people studied sentences of this type mixed with other sentences, they were given the first parts of the sentences as cues to recall the entire sentence. Brewer showed that in recall of sentences with pragmatic inferences, people were more likely to recall the implied verb than the verb actually used in the sentence. When reconstructing the action, they remember the champion as breaking the cinder block, not just hitting it. This result reflects a kind of inferential momentum, with people going beyond the literal truth of a statement to infer the events that probably occurred next. Often such inferences may be correct, but they are not necessarily so. When the inference is strongly made, but false, it can generate a false memory.

Sulin and Dooling (1974) also studied people's remembrance of implications as facts. In one case, they presented subjects with short paragraphs about a troubled girl and later tested for recognition both of ideas from the paragraph and of nonpresented ideas that were either consistent or inconsistent with the theme of the passage. The paragraphs studied by two groups of subjects were identical, with the exception of the name above the story. In one case it was Helen Keller and in the other case it was Carol Harris. One item on the recognition test asked subjects if the following sentence had appeared in the narrative: 'She was deaf, dumb, and blind.' Students who had read the story about Helen Keller frequently made the error of saying that this sentence had appeared in the passage, whereas those reading about Carol Harris almost never made this error. In trying to reconstruct whether the sentence may have been in the story, the knowledge about Helen Keller caused subjects to fill in what 'must have been' in the story and led subjects erroneously to conclude that the sentence was there.

Sometimes people remember the sentences that were in a prose passage no better than sentences they have never read before, so long as the new sentences are consistent with the material that was actually presented. Bransford and Franks (1971) gave subjects short sentences such as 'The rock rolled down the hill' or 'The rock crushed the hut.' There were four simple ideas like this that, when put together, would make up the complex sentence: 'The rock rolled down the hill and crushed the tiny hut.' The experimenters gave their subjects various sentences to build up the complex idea unit. They later tested subjects by asking them to pick out sentences they had actually studied from among other sentences. Two types of distractor sentences were used: some were consistent with the idea unit but had not been studied, whereas other sentences were unrelated to the idea unit. The test sentences themselves could vary in the number of idea units present, from one to four. Subjects rated their belief that the sentences had been previously studied on a 10-point scale, from -5 (sure the sentence was new or nonstudied) to +5 (sure the sentence was old or studied). The sentences that were not consistent

Figure 3

Mean recognition ratings for studied and nonstudied sentences as a function of number of propositions per sentence. Subjects could not distinguish sentences actually presented from those that had not been presented but that were consistent with the ideas. Data from Bransford and Franks (1971)

with the idea units were accurately rejected as not having been studied.

The results for the other two types of items are shown in Fig. 3 and reveal that the more idea units embedded in the test sentence, the higher the confidence rating that the sentence had been studied. Interestingly, this relation held both for sentences that had been studied and for new, nonstudied, sentences that were consistent with the overarching idea unit. Remarkably, except for sentences expressing only one idea, subjects were equally confident in the sentences that had not been presented in the study phase as for those that had been presented! Therefore, consistent with Bartlett's ideas, people seemed to retain the meaning of the sentences, but did not retain the literal wording of the sentences (see *Memory for Meaning and Surface Memory*).

Bartlett (1932), who began this tradition of work, was interested in repeated recollection of material. He presented subjects with a native American folktale, *'The War of the Ghosts,'* which he had them read twice. The story is a bit disjointed, has supernatural elements, and is rather difficult to understand. He found that subjects frequently made errors in recalling the story and that these errors increased over repeated retellings of the story. The stories got shorter, reflecting forgetting, but more importantly for present purposes, the story changed in systematic ways by subjects introducing errors that served to rationalize its bizarre elements. For example, people might 'remember' elements that had not been present to explain some of the unusual features in the story. Interestingly, this tendency to rationalization—to reconstruct the story more in line with the rememberers' own schema—seemed to grow over time and repeated retellings. Although Bartlett's original studies were rather informal, the work has been replicated under more systematic conditions (Bergman and Roediger 1999).

4. Conclusion

This article has reviewed selectively some key evidence that permits us to draw the conclusion that remembering the past should be viewed as reconstructing it. To draw on a metaphor from Hebb (1949), we can think of the process of remembering the past as we can conceive of paleontologists' reconstruction of a dinosaur from bone fragments and chips. The archeologist recovers a partial skeleton, but the finished product in a museum is shown as complete, with new bones added, old ones refinished or enhanced, and the entire skeleton constructed based on knowledge of what the animal must have looked like. Similarly, Hebb (1949) argued, remembering the past involves recollection of specific facts and details (the bones) that are woven together into a complete story of the event (like the skeleton). However, the story about the event might involve considerable constructive activity on the rememberer's part and the rememberer's present knowledge and goals may shape and determine how he or she remembers the past. A quote from Bartlett captures the essence of this reconstructive approach:

... the one overwhelming impression produced by this more "realistic" type of memory experiment is that human remembering is normally exceedingly subject to error. It looks as if what is said to be reproduced is, far more generally than is commonly admitted, really a construction, serving to justify whatever impression may have been left by the original. It is this "impression," rarely defined as with much exactitude, which most readily persists. So long as the details which can be built up around it are such that they would give it a "reasonable" setting, most of us are fairly content, and we are apt to think that what we have built we have literally retained (Bartlett 1932, pp. 175–6).

Recovery of Function: Dependency on Age

When the brain is injured in adulthood there is a loss of function followed by a prolonged period during which there is partial recovery of some types of cognitive and motor functions. The extent of functional recovery varies with age and although injury to the infant brain can have less severe consequences than similar injury in adulthood, there are times when injury is especially devastating. These differences are related to the details of anatomical changes at different stages of brain development. The difference in functional outcome after injury at different ages is related to the injury-induced changes in neuronal structure, changes that are referred to as plastic changes. These plastic changes are similar to the neural and glial changes that are associated with learning in the normal brain. Various factors, such as experience, hormones, and drugs, modulate these plastic changes. Even these factors cannot completely restore lost functions because there are limits to brain plasticity.

1. The Nature of 'Recovery' after Brain Injury

There are many ways to damage the brain (e.g., stroke, disease, trauma) and it is rare indeed for a family not to contain a member who is affected by one of them. For example, it is estimated that about 400,000 people with new head injuries are admitted to hospitals each

year in the United States. Similarly, it is estimated that there are about 400,000 new cases of stroke every year in the United States and most surviving stroke victims experience significant cognitive loss. These figures do not include neurological disorders such as Parkinson's and Alzheimer's diseases, which together affect more than 1 percent of the population. The estimate in the United States is that about 48 million people have some sort of neurological disorder, excluding mental diseases such as schizophrenia, which are clearly a result of neural dysfunction.

The high incidence of brain injury and disease thus poses perhaps the most perplexing clinical neurological problem, which is the issue of how to repair the damaged brain. It is tempting to assume that if behavior improves after injury, then there is recovery of the original behavior. However, just because a behavior appears to recover does not mean that the lost behavior itself has returned. The problem is to determine when recovery has actually occurred. In fact, true recovery is a rare occurrence after brain injury.

We can identify at least three outcomes that could occur after brain injury. First, there may be compensation resulting from an adaptation to the lost function. Compensation could reflect a change in strategy or it may represent a substitution of a new behavior for the lost one. For example, a person who has a deficit in moving the eyes can be expected to have difficulty in reading. This difficulty can be solved, however, by moving the head, which allows restitution of function (reading) by substitution of one behavior for another. Similarly, if, following a stroke, a person can walk only with the aid of a cane, the ability to walk has returned but the original walking ability has not returned, just an adaptation to the behavioral difficulty.

A second outcome might be partial restitution of the original behavior. This could reflect recovery from some sort of nonspecific effect of the injury, such as swelling, or it may reflect a genuine return of function. Behaviors that return over a period of months are likely to reflect a partial restitution of function. This is most clearly seen in people with significant language disturbances (i.e., aphasia) in which the severe deficits in making the movements of the tongue and mouth necessary to speak may diminish leaving the person with more subtle language disturbances, such as in finding words (anomia).

Third, there is the possibility that there could be a complete restitution of the original behavior. Although it is at least theoretically possible for lost functions to return completely in a plastic brain, careful behavioral analysis shows that this is rarely, if ever, the case in either adult laboratory animals or human patients. In principle, however, it ought to be possible to reorganize the brain to allow at least some functions to completely recover. This process is most likely in the developing brain and it has been docu-

mented for over 100 years that children with damage to language areas can show an almost complete recovery of lost language functions.

2. Age-dependent Recovery

Broca first noticed in the late 1800s that damage to the speech zones of the left hemisphere during infancy did not interfere with the later development of language (for a review, see Finger and Almli 1988). Rasmussen and Milner (1977) later showed that the sparing of language functions was due to the shifting of the speech zones either to the opposite hemisphere or, in some circumstances, within the left hemisphere. In these later studies the critical factor was age: lesions of the left hemisphere language zones prior to 5 years of age changed the speech representation so that the affected language zone moved to the right hemisphere.

Similar lesions from the ages of about 6 to 12 still allowed recovery of language functions but this was accomplished by intrahemispheric reorganization (see also Krashen 1973). The studies of the recovery of language functions after infant brain injury led to the idea that damage to the infant brain led to better functional outcomes than damage after similar injury in adulthood. This conclusion was supported by the studies of Margaret Kennard in the late 1930s in which she showed that unilateral motor cortex impairments are less severe after motor cortex injury if the lesion occurs in infancy rather than adulthood (e.g., Kennard 1940). One difficulty with the studies of both Kennard and the language reorganization in children is that there are also many examples in which early brain damage results in rather severe functional loss, such as in cerebral palsy or hemiplegia resulting from unilateral cerebral injury at birth. In fact, Hebb (1949) noted that children with frontal lobe injuries in infancy showed little functional recovery in adulthood and for some behavior, such as social behavior, these children might actually have more severe deficits than adults with similar injuries.

The apparent contradiction between the recovery of language and some motor functions on the one hand, and the poor recovery of some executive, social, and other motor functions on the other hand, has been resolved by laboratory studies in which precise age at injury and the nature of the behavioral deficits have been systematically examined. A key element of these studies is that the age of the brain is measured not in relation to the birth day, but rather it is measured by its stage of anatomical development. For example, compared to humans, newborn rats are approximately equivalent to about 6-month old fetuses when they are born. Thus, if the newborn rat brain is damaged, we would anticipate functional symptoms similar to those of human infants whose brain is injured at the beginning of the third trimester. In order to compare across species we can separate the periods of brain development into five broad stages: neurogenesis, cell

migration, cell differentiation, synaptogenesis, and gliogenesis (see *Prenatal and Infant Development: Overview*).

Studies on both laboratory rats and cats have shown that if the cortex is injured bilaterally during neurogenesis, when neurons are formed, there is substantial recovery and, if the injury is not too extensive, there can be virtually complete functional recovery. In contrast, however, if the cortex is injured in the first few days after birth in the rat, which is a time of neural migration and cell differentiation, the effect is functionally devastating as animals show far more severe effects of injury than would be expected even in aging animals. This poor outcome is not a function of extent of injury, nor is it localized to particular cortical areas (see Kolb 1995).

Rather, there is something about the rat cortex shortly after birth that makes it especially vulnerable. For example, damage during this time may disturb the subsequent process of synapse formation or may even alter stem cell activity in some way. Once this phase of development is over, however, and brain development moves to the production of connections and glia, the brain shows a remarkable ability to compensate for injury. Rats or cats with cortical injuries during this phase show far better behavioral capacities in adulthood than animals with similar lesions at any other time. In fact, on some behavioral tests these animals show recovery that is virtually complete.

Importantly, this recovery is far more extensive in cognitive tasks, such as the learning of various spatial navigation problems, than it is on tests of species-typical or motor behavior (e.g., Bachevalier and Malkova 2000, Kolb and Whishaw 1989). In humans, spatial behavior appears to show less recovery than verbal behavior (Stiles 2000). This behavior-specific recovery likely reflects the relative ease of reorganizing cortical circuitry in supporting different types of behavior. The neural substrates for less plastic behavior are presumably more highly specified and constrained during development than the neural substrates for more plastic behavior. It also reflects a difference in the way the brain produces cognitive processes versus basic sensory and motor processing. Thus, the most extensive recovery is associated with lesions of the frontal areas and the least extensive recovery is associated with damage to the primary sensory areas.

3. Mechanisms Underlying Recovery of Function

The fundamental assumption here is that recovery of function can occur only if there is some type of modification of the structure of the remaining brain. This structural change is necessary if the remaining brain cells are to be recruited in some manner to control behaviors that preinjury were controlled by the lost neurons. In principle, there are three ways that the brain could make changes that might support

recovery. First, there could be changes in the organization of the remaining, intact, circuits in the brain. The general idea is that the brain could reorganize in some way to do 'more with less.' It is unlikely that a complexly integrated structure like the cerebral cortex could undergo a wholesale reorganization of cortical connectivity, but rather, recovery from cortical injury would be most likely to result from a change in the intrinsic organization of local cortical circuits in regions directly or indirectly disrupted by the cortical injury. Although it might be possible to produce significant reorganization of cortical connections in the young brain, the overwhelming evidence in experimental animals is that this is rare and it is just as likely to be associated with abnormal functioning as with recovery.

Second, there could be a generation of new circuitry. Cerebral reorganization can be stimulated either by some sort of behavioral therapy or the application of some sort of pharmacological treatment. In either event, the stimulus could influence reparative processes in the remaining brain or could enhance the production of new circuitry. Once again, it seems most likely that the induced neuronal changes would be in the intrinsic organization of the cortex. One might predict that induced neuronal changes might be more extensive than in the case of endogenous change, in part because the treatment can act upon the whole brain rather than just on affected regions.

Third, there could be a generation of new neurons and glia to replace at least some lost cells. Stem cells that give rise to the neurons and glia of the brain remain active in the brain throughout life (see *Cognitive Development in Infancy: Neural Mechanisms; Cortical Development: Transplantation and Rewiring Studies; Hypnosis, Neural Basis of*). It is thus possible that neurogenesis could be stimulated after injury, especially during development, and that these new neurons could replace those lost to injury or disease (e.g., Weiss et al. 1996). All three of these possibilities for cerebral plasticity do occur, but the likelihood of each type of change varies with age at injury.

4. Structural Correlates of Functional Recovery

When the brain is damaged, there is a loss of neurons in the injured area but, in addition, many neurons that are not directly injured lose their normal synaptic inputs. The immediate effect of this synaptic loss is (a) neuronal death, (b) atrophy of the dendritic and/or axonal fields that have lost their connections, and/or subsequent reorganization of the connections. This reorganization can be inferred by using a Golgi stain to visualize the dendritic fields of the remaining neurons. Because the dendritic branches of a neuron provide the substrate for most of a cell's synapses, a decrease (or increase) in the amount of dendritic space available is correlated with a decrease (or increase) in the number of synapses.

The hippocampal formation of adult rats has provided a good model to study synaptic replacement. When input to the hippocampus is reduced by damage to the major input pathway via the entorhinal cortex, there is a massive denervation of the hippocampal formation, which can be seen in the atrophy of the dendritic fields of the hippocampal cells in the week after injury. Beginning at about 7–10 days after the injury, there is then a slow regrowth of the dendritic fields, although the pattern of regrowth is different from the original pattern. This regrowth reflects a reorganization of the circuitry and it is correlated with a partial recovery of function. The restructuring of the synaptic organization of the hippocampus occurs primarily because the remaining inputs to the hippocampus expand to occupy the regions of lost inputs.

A similar process appears to occur after restricted neocortical injury in adulthood as well, although the changes are less dramatic than in the hippocampus and there is much less functional recovery (for a review, see Kolb 1995). In contrast, however, there is extensive reorganization after cortical injury during development, and this reorganization is correlated with functional outcome. Golgi analyses of cortical neurons of rats with perinatal lesions consistently show a general atrophy of dendritic fields and a drop in spine density across the cortical mantle. In contrast, rats with cortical lesions around 10 days of age show an increase in dendritic fields and an increase in spine density relative to normal control littermates. Thus, animals with the best functional outcome show the greatest synaptic increase whereas animals with the worst functional outcome have a decrease in synapses relative to control animals.

But infant animals not only show changes in local cortical circuits but also in more distant cortical connectivity. Perhaps the most extensive studies of changes in cortical connectivity are those showing that after unilateral motor cortex lesions in infant rats or cats there is a major expansion of the ipsilateral corticospinal pathway from the undamaged hemisphere, which is correlated with partial recovery of skilled forelimb use (e.g., Castro 1990). These expanded connections do not reflect the growth of new pathways, however, but rather reflect the failure of superfluous pathways to die off during development. That is, in development there is normally a period during which many pathways are eliminated but after some types of brain injury these pathways are maintained (for a review, see O'Leary 1992). The presence of these abnormal pathways may support some types of functional recovery but it may also interfere with the normal functioning of remaining cortical functions. This possibility has been termed 'crowding' to reflect the idea that the normal functions of a cortical region can be crowded out by the development of abnormal connections (e.g., Teuber 1975). Thus, there may be recovery of some types of behavior, such as

motor functions, at the expense of other functions (e.g., Kolb et al. 2000). This appears to be especially likely if the injury occurs during the period of neuronal migration and unlikely if it occurs during the period of maximal synaptogenesis.

As noted earlier, synaptic change may also occur after injury because the brain generates new neurons. Although this is likely to be rare in the adult, it does occur during development, but the generation of these neurons varies with precise embryonic age and location of injury. If it is damaged during the time of neuronal generation, the brain can compensate by generating rather large numbers of new cells that appear to support at least partial restitution of function (e.g., Hicks et al. 1984). It is not known if this regenerative process occurs after injury to specific regions of the brain but it is likely a general phenomenon. Thus, if the brain is injured while it is still producing neurons, it appears capable of generating replacements (e.g., Kolb et al. 1998a). In contrast, if the brain is injured during neuronal migration there appears to be little generation of new neurons. If the same injury occurs during maximal glial formation, there is neuronal generation. This generation is selective, however, and occurs only if the midline telencephalon is damaged, namely the olfactory bulb or midline cortex (e.g., Kolb et al. 1998b). The newly generated tissue is functional and animals regain at least partial function.

Recovery of Function, Neural Basis of

Everyone has had the experience of having had an injury in one's life, from burning a finger to scraping an elbow to stubbing a toe, perhaps cutting oneself or

breaking a bone. The universal feature of this experience is that, with care and treatment and time, the injury heals and usually nothing more than a scar and a faded memory remain.

Such recovery is not common with an injury to the nervous system. One of the most important goals in the field of neuroscience is the issue of recovery of function following nerve, spinal cord, and brain injury. It is an unfortunate fact that injuries of the nervous system can produce profound deficits in the quality of life. Sometimes these deficits are obvious, as when an injured nerve affects motor or sensory functioning. Sometimes there are profound deficits without obvious signs of injury, as when someone suffers from memory loss from injury or developmental/aging effects, for example, autism or Alzheimer's disease. In either case we would like to be able to restore functioning.

Sometimes, however, there are instances of considerable recovery of function following brain injury. Stroke patients who initially have profound language disorders, for example, may in the long term have considerable restoration of function. Until recently, in the animal experimental literature, there has been difficulty in localizing neural correlates of functioning because the effects of damage were only temporarily observed with significant amounts of recovery of function over time. Ideally, if we had enough understanding of the nervous system then we might be able to promote recovery of function. The study of brain-behavior relationships, of localization of function, and of recovery of function, are intimately associated themes.

1. Theories

The four major theories that account for instances of recovery of function following brain injury are examined in this article. No one theory fully accounts for the spectrum of observed recovery, nor are the theories mutually exclusive—more than one factor may be involved in recovery. To a certain extent, these theories provide a heuristic outline of the factors that affect recovery. It is the hope that a better understanding of these factors will lead to more effective treatment of the injured.

1.1 Vicariation

Vicariation means second-handed. Recovery by vicariation occurs when an injury damages the part of the nervous system that is actually responsible for a function, and a second neural structure that had never been involved in that function now takes over for the injured structure and performs that previously lost function. A key feature of vicariation is that the structure that takes over the function was never involved in the original behavior. This distinction is lost in some treatments.

The best example of vicariation is the observation that injuries in young individuals are said to be less deleterious than similar damage when it occurs in adults. For example, damage to the left hemisphere in a stroke can cause profound loss of language functions in the adult. Children with left hemisphere damage, however, often do not show severe language deficits. This observation fits our concept of the plasticity of the developing organism.

This concept—that youngsters are less affected by brain injury—has been applied to laboratory experiments where it has generally been found that damage is less intrusive in young individuals. For example, damage to the frontal lobes does not produce delayed response deficits in monkeys, and damage to the septal region does not produce social cohesiveness in rats. However, it is not always true that an early lesion is beneficial. In these two examples, when the individual becomes an adult then delayed response deficits and increased social cohesiveness appear. Thus, the effects of the damage may not be obvious until the individual matures.

Of all the theories of recovery of function, the theory of vicariation is the least likely one to be true. This is because much of the recovery that has been attributed to vicariation is actually due to a region that already has some functioning. As a result, the following theories are more likely explanations, and thus more likely to cause recovery.

1.2 Diaschesis

Diaschesis refers to the effects of shock. Recovery by diaschesis occurs when a nervous system injury does not actually damage the tissue that is responsible for the lost function, but rather that the injury causes a shock effect which indirectly and deleteriously affects normal functioning, and function returns when the shock subsides. Shock can occur when there is temporary loss of the blood supply (loss of nutrients including glucose and oxygen, or loss of functions to remove waste metabolic products) or temporary loss of necessary modulating neural activity. The key feature is that when functioning returns it is mediated by the very same tissue that was responsible for the function in the first place, so that the recovered behavior is exactly the same as the original one. Thus, the idea of sparing is essential in the context of diaschesis.

Time appears to be the major manipulation to effect diaschesis. However, time itself is not a very profound or necessarily a helpful explanation. The real question is what happens that takes time to dissipate the effects of shock, or more to the point, what can be done to diminish the effects of shock. Steroid drugs have been given to prevent the effects of swelling, for example, and have some effect in mitigating loss of function from some spinal cord injuries. To be effective the treatment must occur soon after the injury. Since the

brain and spinal cord are enclosed within the cranium and spinal column, respectively, any swelling of the nervous system in these confined spaces can cause substantial damage that is secondary to the original injury. Thus, besides indirect effects of shock any injury can cause additional damage.

One example of diaschesis from the laboratory is known as the Sprague effect. Damage to one superior colliculus in cats causes a visual neglect in the opposite visual field; that is, objects are ignored if they are presented in that visual field. Subsequent damage to the visual cortex on the same side as the visual neglect immediately restores reactions in the affected visual field. This example represents diaschesis by loss of normal neural modulatory influences. Here subcortical visual regions in the tectal area receive three visual inputs, one from the eye through the optic nerve to the superior colliculus, one from the opposite superior colliculus, and the other through the visual cortex. By damaging the superior colliculus there is an imbalance in the surviving tectal region. By subsequently damaging the visual cortex on the same side as the visual neglect, the balance in the surviving tectal region is restored. This illustrates one of the major ways of thinking about diaschesis, which is to think of it as a balance of modulation of neural sources.

Another example from the laboratory is the loss of a simple visual discrimination for brightness. Rats trained on a black-white discrimination will appear to have lost that memory when their visual cortices are removed. With subsequent training the rats reacquire the ability to discriminate black from white. Since it takes about as many trials to relearn as it did to originally learn, this appears to be a case of vicariation where another part of the brain (presumably the remaining cortex) takes over functioning. If that is the case, however, that subsequent training is creating a new memory, then it should not matter whether training after the brain injury is made with the black or white stimulus as the correct choice. But reversing the correct choice profoundly interferes with subsequent training. This shows that although it appears that the brain injury has removed the original memory that in fact the memory remains to interfere with reversal training.

A number of manipulations have been found to affect recovery through diaschesis, each associated with diminishing the effects of shock and enhancing the expression of the spared tissue: extensive preoperative training, interoperative retraining (serial lesions), extensive postoperative retraining, cross-modal training on similar problems (i.e., training using other sensory modalities), drugs that diminish shock (e.g., steroids), drugs that enhance access to the spared tissue. As with strategies to improve performance on exams, a practical strategy to lessen the effects of future brain injury or the inevitable effects of aging would be to overlearn with multiple cues and learning methods.

Parkinson's disease provides an example from the clinical literature where the diminishing effects of diaschesis prevents the initial appearance of symptoms. Parkinson's disease is a movement and thought disorder caused by progressive degeneration of cells in the substantia nigra that project dopamine to the basal ganglia. Its symptoms only appear when so many nigra cells die that only about 20 percent of the normal amount of dopamine remains in the basal ganglia. Until that point, it appears that the basal ganglia can compensate for the loss of dopamine (see below). It is only when the dopamine projection to the basal ganglia falls below a critical point that the symptoms of Parkinson's show themselves. Presumably, slow progressive disorder does not produce the effects of shock that would be seen with one larger lesion.

Of the factors that account for recovery of function from brain injury, diaschesis is one of the most important.

1.3 Neural Reorganization

Neural reorganization generally refers to the body's own mechanisms for recognizing loss and for healing itself. However, man-made interventions can also be classified as reorganization. By far, neural reorganization receives the most attention of the four theories, although its practical usefulness has yet to be realized. Several means of effecting neural reorganization have been described. Importantly, these mechanisms are adaptations of means that the nervous system has for normal development and growth rather than specialized adaptations that might have evolved solely for the purpose of a complex brain being able to repair itself. That is, one questionable idea about brain organization in general is the idea that more complex brains, being more susceptible to injury of its delicate mechanisms, somehow developed a new method of dealing with brain injury. That seems not to be the case. Here the known mechanisms of reorganization are reviewed.

1.3.1 Reactive synaptogenesis. Synaptogenesis refers to new synapse formation. This mechanism is essential developmentally for correctly hooking up the nervous system (along with overproduction and selective cell death, as in programmed cell death or apoptosis). Reactive refers to an action in response to injury. New connections can be made by a number of activities, including new axonal growth (sprouting), new pre- and post-synaptic growth and terminal and dendrite formation, new receptor formation and/or distribution, for example. Furthermore, injury to the visual cortex causes degeneration of its projections to subcortical visual areas which leaves vacated synaptic space that is filled by sprouting of the optic nerve. In the example above (see Sect.

1.2) where rats were trained on a black–white discrimination, sprouting in subcortical visual areas could account for the recovery of function. It is generally thought that sprouting should be beneficial and attempts have been made to promote sprouting. However, in the case of brightness discrimination this idea is questionable since subsequent damage to the areas of sprouting has no permanent effect in preventing learning differences in brightness. In general, since rats with visual cortical damage do not recover perceptions of form and pattern, neural reorganization is not a significant factor for those functions.

Two examples illustrate where sprouting is actually less than helpful. First, spinal cord injuries cause sprouting that is accompanied by tremors. The tremors are alleviated when the sprouted connections are destroyed. Second, injury of one superior colliculus in hamsters causes sprouting to the opposite superior colliculus. The result is that the animals visually orient to the side away from the visual stimulus. Cutting the sprouted optic nerve to the remaining superior colliculus resolves the problem. Thus, in these two examples, blindly enhancing sprouting by generally giving nerve growth factors, for example, may not be such a good idea. The problem with sprouting is to have control over where and what type of new growth takes place.

1.3.2 Neurogenesis. We learn that we are born with the total number of neurons that we are ever going to have, and that we continually lose neurons as we grow older. The one celebrated exception to this rule is that certain birds which learn a new song each mating season show cell division and new neuron development as adults. Adult rats and recently adult humans have been shown to create new neurons in the hippocampus, a limbic system structure associated with certain kinds of memories. It remains to be determined whether there are sufficient numbers of new neurons and whether there are functional connections of these newly available neurons. Similarly, it is unknown whether these neurons have a role in repairing brain injury. However, on the face of it, this is an exciting development.

1.3.3 Transplants. Related to the idea of natural neural replacement (neurogenesis) is the idea that we can purposely implant neurons to replace the damaged ones. Transplants have been tried most often in the case of patients with Parkinson's disease, where the transplant donor is either the patient (dopamine producing cells from the patient's own adrenal glands) or an aborted fetus (dopamine producing cells from the substantia nigra; this source is controversial). Initial results of such operations were mixed at best,

with more recent limited successes. The ameliorating effects may not be due to the effects of dopamine or to neural connections formed by the implant, however. Nerve growth factors that are secreted by the implant are more likely candidates. Transplants themselves have been recently overshadowed by a return to surgical intervention, a procedure known as a pallidotomy which is a lesion of the globus pallidus.

1.3.4 Supersensitivity. Synapses that are deprived of their normal expected amount of input activity can become supersensitive whereby the synaptic transmission becomes unusually sensitive to small amounts of neurotransmitter. In Parkinson's disease the deleterious symptoms are delayed presumably because of the compensating supersensitivity of cells in the basal ganglia that are deprived of their usual amount of dopamine from degenerating neurons in the substantia nigra. It is only when there is too much loss of dopamine that the basal ganglia neurons cannot compensate and symptoms of Parkinson's appear. The actual mechanism of supersensitivity can involve increased sensitivity of the postsynaptic receptors, increased reactivity of postsynaptic receptors, increased number of postsynaptic receptors, changes in dendritic spines that reduce impedance (i.e., enhance transmission), increased transmitter release, and changes in intracellular events that enhance the signal.

1.3.5 Prostheses. Man–machine implants may be used to overcome deficits. For sensory loss, these involve a transduction device to convert an external stimulus into a neural-like signal with a neural stimulator. Currently, auditory implants into the cochlear nerve or nuclei are being tried to restore hearing. Visual implants using a primitive camera and stimulation of visual cortex have a history of limited success in effecting primitive sensations. Not all prostheses are surgically placed into the brain. One alternative for visual problems is to place the pattern of visual stimuli onto a skin surface where the visual stimulus is now interpreted as a tactile stimulus. Other approaches have not involved sensory transduction but rather replace the damaged element responsible for higher level processing. In this regard a recent attempt has been made to implement functioning in a silicon chip that is used to replace a damaged hippocampus. For motor loss, electrodes have been implanted to stimulate muscles, coordinated by a computer, to effect walking. This requires sensors for proprioception and balance.

1.3.6 Unmasking. It is now well appreciated that the nervous system has multiple representations for each

of the senses and motor functions. Moreover, it is becoming clear that representations may overlap each other, and that under normal circumstances some of the underlying representations may be suppressed. When a part of the main representation is damaged the underlying map may now express itself, either preventing any deficit or causing an apparent recovery. Unmasking is generally found in instances where the recovery occurs too quickly for sprouting or other types of reorganization to have been made.

1.3.7 Regeneration. Certain amphibians and lizards will grow a new limb to replace one that has been lost to a predator. Amphibians and lizards also have the ability to re-establish connections when a nerve is severed. This regeneration is also seen to varying degrees in the peripheral nervous system of mammals, aided by the supporting Schwann cells which guide the reconnection. Although the capacity for regeneration persists in the central nervous system of mammals, regeneration is not a significant factor in recovery of function because central glial cells create scar tissue which becomes a significant barrier to reconnection.

1.4 Substitution

Substitution refers to using an alternative means to achieve the same goal. If damage has actually removed that part of the brain that is responsible for a function (as opposed to Diaschisis, above, for example) then substitution is the most likely means of recovery. Within the animal literature one needs to be cognizant of factors like substitution because otherwise false conclusions can be made about the nature of the recovery. Yet substitution is often ignored because it does not involve surgical or chemical intervention. There are three significant means of substitution. Recovery by substitution occurs when another sense, motor act or strategy can be used.

1.4.1 Sensory. A sensory stimulus or property of a stimulus can be used as a substitute for the original sensation. Damage to visual cortex in rats makes them blind to form and pattern perception yet they are still capable of detecting primitive visual experiences such as brightness and contour. As a result, such rats appear to be able to solve discriminations for orientation (e. g., horizontal vs. vertical black and white stripes) because they can make use of local brightness and contour cues to solve the problem. In extreme conditions where the rats are prevented from using these local cues, they can no longer 'solve' the orientation problem, and thus they are blind. The goal for a therapist would be to design conditions

where a problem can be solved in multiple ways. For example, persons who are red-green color blind can learn to drive by noting the position of the active light on a traffic signal.

1.4.2 Motor. One motor act can substitute for the original motor act. Cats with dorsal rhizotomies (denervation of the sensory roots of the spinal cord) for the hind limb initially have difficulty walking a thin railing. After a period of time, however, the cats negotiate the task very well and appear to be completely normal. However, upon close examination with high-speed photography, it has been shown that these cats adopt a motor strategy of shifting their weight to properly place the hind foot. Clearly, functional recovery does not imply neural recovery.

Another example from the older literature would be the instance where a rat has been trained to run a maze. The same rat that has been trained to run can solve the very same maze when it is flooded and it has to swim. The same idea applies to conditions where brain damage prevents the original behavior.

1.4.3 Strategy. After ruling out that the senses and motor functions are not affected, it might be found that there may be a problem with the implementation of a sequence of perceptions and actions. This higher order activity can be referred to as a strategy. For example, a woman with global (diffuse) brain damage got easily distracted, so much so that a telephone ring would be enough of an interruption that she would forget she was cooking. Or she would spend her whole day watching TV. Her strategy to overcome this deficit was to write a list of things to do, checking them off as she did them, and to have a timer set to go off every 15 mins. At every alarm she would check her list to see what it was she was supposed to be doing.

From the animal literature comes another example. Rats with hippocampal brain damage have difficulty in alternately pressing one of two bars for a food reward. This task requires that the animals remember which bar was pressed last so that they can press the other bar the next time. Some clever rats figure out that if they hold onto the bar that they just pressed then they immediately know to press the other bar the next time.

2. Factors

The discussion above identifies the major theories that can account for instances of recovery of function. Within this discussion we have identified a number of factors that can be used clinically and within the laboratory to promote recovery of function. It is

reasonable at this time to simply list those factors, because although they were discussed in terms of theories above in truth many of these factors apply to more than one theory. Here is a listing of some factors that might enhance recovery of function: age at time of the injury, reduction in secondary effects of the injury (shock), the proficiency of preinjury training, training on alternative stimuli or strategies or acts, training between injuries (serial lesion effect), time after injury, amount of postinjury training on the same or similar tasks, substitutions. It would be misleading to suggest that any or all of these factors will lead to recovery in all instances. It is a sad fact that injuries to the nervous system produce profound and lasting deficits. The hope for further research is to find new applications of these factors and to develop new methods of treatment.

3. Implications

Clinically the importance of finding methods that enhance recovery of function is obvious. What is not so obvious is that the clinical and experimental literature about brain injury also give insight into the fundamental organization and operation of the brain and our mental life. The mind-body problem—the relationship of our physical being with our mental experience—continues to be a fundamental interest in psychology. Both the clinical and experimental literature make fundamental contributions to each other. Newer methods for imaging the brain during cognitive activity (fMRI, PET, neuromagnetic methods, along with the old standby EEG) have confirmed much of our understanding of the organization of the brain and what happens during injury, on the one hand, and given insights and further directions, on the other. The optimism of our times holds out great promise for sophisticated advances that may someday allow us to repair the damaged mind.

Importantly, we learn from the field of recovery of function the following lessons. First, localization of function is the norm in the nervous system. Second, there is a hierarchical organization to the nervous system, with basic functions organized at low levels. Third, even low levels of the nervous system are capable of seemingly sophisticated functions like learning and memory. Fourth, any one function is probably represented in only one place in the nervous system. However, fifth, similar functions can often accomplish the same goals.

Reduction, Varieties of

Fundamental issues in the ontology of the sciences can depend on whether the elements of one domain turn out to be 'nothing over and above' a congeries of elements of some other, perhaps less mysterious or more basic, domain. It has been argued that natural numbers, for example, are nothing over and above certain sets, and their properties just the familiar properties of those sets; that temperature is nothing over and above the mean kinetic energy of molecules; that genes are nothing over and above strings of DNA molecules; that the mental is nothing over and above the physical; and that the social is nothing over and above an aggregate of individuals, their antics, and attitudes. Each such claim, whether correct or not, postulates a dependency of one domain on another, a dependency strong enough to justify regarding the dependent domain as ontologically derivative, the other as ontologically more basic. Given the more basic domain, the dependent domain can plausibly be regarded as an ontological 'free lunch.' The elements of the dependent domain are not denied existence or reality, but neither are they granted an independent reality.

Such dependency claims have been thought to have far-reaching ramifications not just for ontology but also for methodology. For example, the social sciences investigate social phenomena, involving distinctively

social entities, properties, facts, and laws. The individualism–holism debate concerns, in the first instance, the status of these items—whether they are anything over and above the totality of individual entities, properties, laws, and facts—but also the methodological autonomy of the associated sciences. (For an even finer-grained analysis which disentangles other conflated but independent components of this debate, see Pettit 1993.) According to Watkins (writing in the 1950s), individualism holds that social institutions ‘do not possess a quasi-divine autonomy’ (in O’Neill 1973, p. 149), and that ‘every complex social situation or event is the result of a particular configuration of individuals, their dispositions, situations, beliefs, and physical resources and environments’ (in O’Neill 1973, p. 168). He argued that, as a consequence, explanations of social phenomena should be couched in terms of the ‘situations, dispositions, and beliefs of individuals’ (in O’Neill 1973, p. 179). His adversary, Mandelbaum, states *holism* thus: ‘Societal facts are as ultimate as are psychological facts ... those concepts which are used to refer to the form or organization of a society cannot be reduced without remainder to concepts which only refer to the thoughts and actions of specific individuals’ (in O’Neill 1973, p. 223).

As Mandelbaum’s claim here illustrates, definability was once the Holy Grail of the reductionist enterprise. Bertrand Russell famously maintained that postulating entities, in contrast to defining (or ‘constructing’) them, ‘has many advantages; they are the same as the advantages of theft over honest toil’ (Russell 1919, p. 71). But just as when the quest for the Holy Grail looked misguided, some more realistic venture might engage a knight’s energies, so when definability failed to capture the interesting dependency claims, philosophers looked elsewhere. And they have discovered a plethora of dependency relations, some of which hold out the promise of prizing apart the methodological and ontological issues, enabling, for example, both the metaphysical strictures of the individualist and the methodological dispositions of the holist to be accommodated.

1. Explicit Definability

Explicit definition is the clearest way of demonstrating that *As* are nothing over and above *Bs*, guaranteeing that all truths about *As* are expressible by talking overtly only about *Bs*. A full specification of the *Bs* yields *ipso facto* a full specification of the *As*. An explicit definition of *A* in terms of $B_1, \dots, B_n$ has the following general form:

$$A =_{\text{defn.}} F(B_1, \dots, B_n)$$

The right-hand side, $F(B_1, \dots, B_n)$, may involve, in addition to $B_1, \dots, B_n$, only certain *permissible* operations. In the strictest case these are the purely logical connectives (*and*, *not*, *all*, and *identity*). More liberally

one might include the concept of *set* and *set membership*, or perhaps the whole apparatus of mathematics. At least as traditionally understood, the definition should be knowable *a priori*, through pure analysis of the concepts involved, and it should hold by logical *necessity*.

A striking illustration of the power of definition is *logicism*, the program to reduce mathematics to logic (Russell 1919). In the nineteenth century, the basic concepts of analysis had been successively defined in terms of the concepts of natural numbers and sets. It began with the elimination of infinitesimals via the definition of a limit. Irrationals were defined as sequences of rationals, and rationals as sets of pairs of natural numbers, leaving the natural numbers alone as primitive, undefined entities. The Russell–Frege definition of natural numbers is remarkable in that it reaches right outside the category of number. Numbers are defined using only the apparatus of logic—including the logic of sets. For example:

zero = the set of all empty sets

one = the set of all singleton sets

For this to be adequate, truths about numbers must follow from the definitions, together with definitions of the mathematical operations, and the logic of sets. This hope was almost vindicated—but for the discovery of troublesome paradoxes in the foundations of set theory. Despite the paradoxes, the program remained a paradigm of ontological reduction, inspiring much subsequent philosophical activity (Carnap 1928) and providing the framework for most debates about ontological commitments.

2. Reducibility

Definability proved too strong a requirement for typical claims of ontological dependence for reasons involving the constraints that definitions be known *a priori* and that they hold true by logical necessity.

As is well known, our understanding of the phenomena of heat, codified in thermodynamics, was transformed by the reduction of thermodynamics to statistical mechanics (Nagel 1961, Chap. 11). The reduction involves deducing the laws of thermodynamics from laws of statistical mechanics together with bridge assumptions connecting the concepts of the two domains (*temperature* and *heat* with *molecule*, *mass*, and *motion*). For example, the Boyle–Charles law for ideal gases (pressure times volume is proportional to temperature) can be shown to follow from the assumptions of statistical mechanics and the following assumption:

(1) *Temperature is mean kinetic energy of component molecules.*

Assumption (1) may look like a definition, and is sometimes touted as such, but it is not the result of a

priori analysis of its concepts, and it is not logically necessary. (Suppose everything were continuous stuff all the way down and temperature were, say, proportional to density of calorific fluid.) If true, (1) is not logically necessary, and if known, not known *a priori*.

Some maintain that (1), even if not true by definition or by logical necessity, is nevertheless a matter of identity, vindicating the reductive claim that temperature is nothing but motion of molecules. However, unlike definitional identities, it is a *contingent* identity, analogous to the contingent identity of *the morning star* and *the evening star* (Smart 1959). Analysis of concepts would not yield the fact that the brightest celestial body in the morning sky is identical with the brightest celestial body in the evening sky, and we can easily imagine a world in which they are not. But the morning and evening stars are nevertheless one and the same—Venus. So perhaps (1) states a contingent identity known *a posteriori*.

The idea that *identity* (the relation which each entity bears to itself necessarily and to no other thing) could be a contingent matter is still baffling. One way to reduce the baffle is to distinguish between intension (concept) and extension (item singled out). The intension is a certain way of singling out the extension. The extension of both *the morning star* and *the evening star* is a chunk of matter, but the intensions are different ways of determining that chunk. The intensions are *coextensive* in fact but not of necessity.

Property terms also come with an extensional and an intensional component. The extension of *black* is the class of things that are black. If all black things happened to be chunks of coal, and all chunks of coal happened to be black, then *black* and *coal* would be coextensive. They would single out the same class of objects. But is coextensiveness enough for reduction? The two terms are associated with different intensions, they pick out distinct features of the objects, and even if coextensive they would not be coextensive of necessity. Further, we would not be inclined to say that *black* reduces to *coal* (or vice versa) just because they were coextensive. So there must be more to reduction of properties than coextensiveness.

Temperature and *mean kinetic energy* are not properties but *magnitudes*. Unlike a property, the extension of temperature is not a class of objects. Rather, the *temperature* of an item can be any one of a number of different possible numerical values—relative to a unit of measure and an origin. The extension of *temperature*, like *mean kinetic energy*, thus associates an item with a number. We could construe (1) as the simple claim that the magnitudes *temperature* and *mean kinetic energy* are coextensive. However, as the argument concerning *black* and *coal* illustrates, a reduction requires a tighter connection. The extensional equivalence reported by (1) has to hold by *some kind of necessity* (not logical necessity).

A possible world is a complete way the totality of things might be. A state is logically necessary if it holds

in all possible worlds. Laws of nature rule out some but not all possibilities (some laws might have been different from what they are in fact) so they are not logically necessary. But what the laws of nature entail involves a kind of necessity—*nomological* necessity. A state is nomologically necessary if it holds in all worlds in which the actual laws of nature hold. For example, if the theory of relativity is true then in some sense it is impossible for an object to accelerate through the light barrier. This is not just an accidental fact, like the decay of some radium atom, but it is not *logically* necessary either. It is nomologically necessary.

For (1) to constitute a reduction it must be understood as the claim that *temperature* is coextensive with *mean kinetic energy* by nomological necessity. We can now exhibit the difference between definability and reducibility:

A is *definable* in terms of the *Bs*, just in case *A* is coextensive with $F(B_1, \dots, B_n)$ by *logical* necessity.

(Or: *A* is logically equivalent to $F(B_1, \dots, B_n)$.)

A is *reducible* to the *Bs*, just in case *A* is coextensive with $F(B_1, \dots, B_n)$ by *nomological* necessity (in the domain of the *Bs*).

(Or: *A* is nomologically equivalent to $F(B_1, \dots, B_n)$.)

It follows that *A* is reducible to the *Bs* if *A* is nomologically equivalent to something definable in terms of the *Bs*. Definability entails reducibility (since logical necessity entails nomological necessity) but not vice versa.

Just as (1) transformed our understanding of temperature, our understanding of a mental state like *pain* may be transformed by the following claim:

(2) *Pain is the stimulation of C-fibers in the brain.*

For this to be a reductive claim on the model of (1), *pain* must be nomologically equivalent to *C-fiber stimulation*. What play the roles here of reducing and reduced theory? The reducing theory would be neurophysiology, and the reduced theory could be our ordinary everyday conception of pain—collections of platitudes like:

Pain is typically brought about by bodily damage, and results in wincing, groaning, and avoidance behavior.

Such platitudes were central to the *behaviorist* hope that pain might be characterized, or *defined*, in purely behavioral terms (Ryle 1949). When this hope of definability was abandoned the platitudes were central to the *functionalist* hope that pain could be suitably *reduced* to physical states of the brain (Lewis 1993, essay 7, Armstrong 1968). Assumption (2), together with a suitably rich scientific theory, might well yield such platitudes. There is a puzzle here to do with the status of the bridging principles like (1) and (2). If we want to reduce the mental to the physical, for example, by exhibiting purely physical (nomological) equivalents of mental features, we would not want to have to acknowledge irreducible laws governing the psychological realm, or irreducible connections between the two realisms. So for reductionism to follow, the laws underpinning nomological equivalents stated in the

bridging principles would have to be laws of the lower-level domain—in this case purely physical laws. The puzzle is how purely physical laws could entail principles straddling the two domains—an answer will be presented in Sect. 5.

If analogous reductions were to hold for all mental features then *physicalism*—the thesis that the mental is nothing over and above the physical—would be vindicated. Undergirding the reduction would be a multitude of nomologically necessary extensional equivalences between mental terms on the one hand and logical products of purely physical terms on the other. A successful reduction would not, of course, entail the elimination of mental entities or of the laws within the mental realm. (The reducibility of thermodynamic laws to statistical mechanics is rather a *vindication* of the former.) And far from being the denial of systematic and lawlike mental–physical connections it is the very affirmation of them—in the form of bridge principles.

3. The Problem of Networking

For a successful reduction we must have appropriate logical or nomological equivalents. There is, however, an important objection to the existence of such equivalents in two central cases—the relation between the mental and the physical, and the relation between the social and the individual—namely, the heavily networked character of the concepts characteristic of different domains. Mental concepts are heavily networked not just with behavioral and physical concepts but also with other mental concepts. Social concepts are heavily networked not only with each other but also with psychological concepts via those very same social concepts.

Consider *pain* again. Pain is tied not only to physical inputs and behavioral outputs, but also to other psychological states. Those in pain tend to believe they are in pain, and desire to get out of it. These are platitudes about pain which any reductive account of pain should accommodate. So it looks as though there may be no simple way of giving logical or nomological equivalents of pain in purely physical terms.

The case of social concepts is even more acute. Consider the statement, ‘Jones cashes a check at the bank.’ The predicate involves a social property—making essential use of the social concept of a *bank*—and the claim itself entails the existence of a bank. According to Mandelbaum, we cannot eliminate the concept *bank* in explicating the content of this claim. An analysis in terms of psychological states (of Jones, the teller, the bank manager, etc.) would have to include beliefs and desires the contents of which will essentially involve the concept of bank.

... concepts involving the notion of status and role cannot themselves be reduced to a conjunction of statements in

which these or other societal concepts do not appear (O’Neill 1973, p. 225).

So here is an obstacle to finding a purely individualistic equivalent of the social property. While Mandelbaum is thinking in terms of definability, a similar argument might be mounted against reducibility.

4. Implicit Definability

The networking problem was solved by an elegant theory of implicit definition, initially discovered by Carnap in the course of his search for a reduction of the theoretical to the observable (Carnap 1966) and fully developed by Lewis into a general reductionist framework (Lewis 1993, essay 6).

Quine famously argued, against positivism, that theoretical terms gain their meaning from being heavily networked with each other and with observable terms only in the context of a rich and testable theory (Quine 1961). Carnap proposed an essentially reductionist account of such terms which nevertheless accommodated this holistic thesis. The essential ingredient was provided by a then little known result of Ramsey (1931). Ramsey showed how a theory about, for example, electrons and protons, $T(\text{electron}, \text{proton}, \dots)$ could be stripped of explicit mention of unobservable entities and replaced by a lean purely observational surrogate, its so-called *ramsification*. Theoretical terms—*electron*, *proton*—are first replaced with variables, E , P , (or ‘gaps’) to yield a ‘gappy’ sentence $T(E, P, \dots)$ which may or may not be true depending on what the gaps are filled with. Now consider the definite claim that the gaps can be indeed truly filled by something or other:

$$\begin{aligned} &\text{Ramsification of } T(\text{electron}, \text{proton}) \\ &= \text{there are items } E, P \text{ satisfying } T(E, P) \end{aligned}$$

This stripped-down version of the theory entails nothing nontrivial about electrons or protons (because it does not mention them at all), but does entail all the purely observational consequences of the full-blown theory. Since the point of the theory (according to the positivists) is to generate observational consequences, and the ramsification does this without reference to theoretical entities, Ramsey concluded that the theoretical ontology is redundant (Ramsey 1931).

Carnap drew a different lesson. He agreed with Ramsey that the factual component of the theory is delivered by its ramsification, but he noted that for the factual claim to be true there must be some items satisfying the gappy statement $T(E, P, \dots)$ —for that is exactly what the ramsification says. In that case, we may as well regard those items as the intended

extensions of the concepts *electron* and *proton*. The whole theory thus serves as a partial constraint on the meanings of its own theoretical terms. It is partial, both because it places no constraints in the case in which the theory is not observationally adequate, and because even when it is there may be a range of legitimate satisfiers of the gappy claim. However, in certain cases we may be lucky and the theory might be strong enough to single out a unique set of satisfiers. In that case we can use the theory to give an explicit definition (Lewis 1993, essay 6).

Something analogous can be sketched for mental properties. We begin with our ordinary everyday collection of platitudes about the mental ('folk psychology') in which, as noted, the mental concepts such as pain and desire are heavily networked with each other and with behavioral and physical concepts. Now ramsify this theory, eliminating the mental concepts and replacing them with variables (*P* for pain and *D* for desire). The ramsified theory will look something like this: there is a property *P* typically caused by bodily damage and which causes wincing, and if a something has *P* it typically bears *D* to getting rid of *P*.

This ramsification is stated purely in physicalistic and behavioral terms and might be true of a system which consisted only of physical constituents with purely physical properties. Neurophysiologists might discover that C-fiber stimulation is a feature typically caused by bodily damage and causes wincing; that C-fiber stimulation initiates D-fiber stimulation, which in turn causes C-fiber stimulation-ridding behavior, and so on. Enough of these would support the claim that pain is nomologically equivalent to C-fiber stimulation; the desire to get rid of pain nomologically equivalent to D-fiber stimulation, and so on.

If this is right, then the holistic and networked character of the mental is not itself an insurmountable obstacle to reduction in the case of the mental. Hopefully something similar might be achieved for the social domain. The reduction in the latter case would be to purely individual properties and relations—psychological, behavioral, and physical—which may in turn be reduced to the purely physical.

5. Multiple Realizability

Not long after functionalism had provided this systematic framework for reduction, philosophers began to worry that there may be no appropriate, lawlike extensional equivalences in the case of the mind (Putnam 1967, Davidson 1970). Suppose in a typical human being pain is 'realized' by C-fiber stimulation, whereas in some untypical humans it is D-fiber stimulation, and in Fido the dog it is E-fiber stimulation. Suppose, further, that there is no end to the number of different states which realize pain in different beings. Suppose in some distant galaxy silicon-based aliens have evolved, or could evolve,

with a very different physical structure. Would not they be capable of experiencing pain too? There may be no limit to the ways in which pain can be thus realized in physical beings. So there may be no single, purely physical, nomological equivalent of pain. Pain would not be reducible to the physical.

Or think of the economic institution of cash. Lots of different kinds of stuff in fact play the role of cash, and almost any suitably portable object could play the role of cash given an appropriate combination of beliefs, desires, and conventions. Now reducibility is a transitive relation: if *A* is reducible to the *B*s and the *B*s are reducible to the *C*s, then *A* is thereby reducible to the *C*s. So if the social is reducible to the physical and the psychological, and the psychological in turn to the physical, then the social is reducible to the physical. But, given that almost any physical item at all could be cash, is it plausible that there be a single, purely physicalistic, nomological equivalent of *cash*? Hardly.

Does multiple realizability render physicalism and individualism false? Alternatively, is reducibility as characterized necessary for ontological dependence? Suppose every property which realizes pain (or cash) in all nomologically possible circumstances is itself a purely physical property. Would that not be compatible with physicalism? This suggests the possibility of a relation between the mental and the physical weaker than full reducibility but strong enough to vindicate the idea that the mental is nothing over and above the physical.

6. Supervenience

The favored term for the desired relation, one which guarantees determination without entailing reducibility, is supervenience—a term first used to characterize the relation between the moral and the natural.

It is widely held that moral differences are undergirded by natural or nonmoral differences. Suppose Francis of Assisi is good in virtue of kissing a leper with putrefying flesh (Francis of Assisi 1903). Then if Clare kisses an exactly similar leper and she is not good then there must be some nonmoral difference between the two—perhaps, unlike Francis, Clare is suppressing revulsion. Sameness of nonmoral features guarantees sameness of moral features. A difference at the moral level requires a difference at the nonmoral level. The moral supervenes on the nonmoral.

In the social realm, the individualist's battle cry might be: no difference at the social level without some difference at the individual level. Sameness at the individual level guarantees sameness of social features. That kind of supervenience claim seems eminently reasonable, one which even a holist might be embarrassed to deny. If Jones cashes a check in situation A but not in situation B, then there must be *some* difference at the individual level between the two situations—either between Jones in A and B, or

between some other individuals in A and B. Kim generalizes the supervenience condition thus:

One family of properties is 'supervenient' upon another family of properties in the sense that two things alike with respect to the second must be alike with respect to the first (Kim 1978, p. 149).

So stated the principle is open to interpretation. The necessity involved ('must be alike') may be logical or nomological. Some supervenience claims—like the supervenience of the moral on the non-moral—are a matter of logical necessity (although see Oddie 1991). Other supervenience claims are a contingent affair. Most physicalists think that the supervenience of the mental on the physical is a contingent matter—for we can imagine worlds consisting of unembodied minds differing in their mental attributes but (lacking bodies) being physically indistinguishable. The supervenience of the social on the individual is disputed—some hold it to be a logical affair (Currie 1984) others a contingent affair (Pettit 1993).

Kim's statement of the supervenience principle requires individual by individual comparison: any two *B*-indiscernible individuals must be *A*-indiscernible. It has therefore been dubbed a kind of local supervenience. This may be too stringent for characterizing the supervenience of the social on the individual (Currie 1984) and even for the supervenience of the mental on the physical (Burge 1979). In both cases, it is claimed, the supervening properties involve not only the local properties of the individual, but the relations of the individual to its environment as well as to other individuals. (Whether Clinton is the President depends not just on Clinton's psychological and physical state but on psychological and physical states nationwide. Whether Clinton thinks that *that* woman is sexy requires a real woman, not just an hallucinated woman, to be there.) Furthermore, in the social case, some of the supervening entities (First Bank of Boulder, the Stock Market, France) are in any case of a different logical type from the individuals on which they are claimed to supervene, so we need to compare more than just the social properties of individuals. Finally, a number of arguments have shown that, given reasonable assumptions, local supervenience of the logical variety entails definability, and local supervenience of the nomological variety entails reducibility (Kim 1978, 1989, Bacon 1986, Oddie 1991), thereby failing the nonreductionist desideratum.

In order to avoid these problems global supervenience has been put forward as the salient relation. Call two worlds *B*-indiscernible if the *B*s have the same extensions in both (that is, the *B*s are identically distributed in the two worlds). Then *A* globally supervenes on the *B*s if any two (nomologically) possible worlds which are *B*-indiscernible (the *B*s have the same extensions in both) are also *A*-indiscernible (*A* has the same extension in both). This principle is a

desideratum of any concept of determination, and so it is the weakest relation that might serve the supervenience theorist's purposes.

Definability entails global supervenience of both logical and nomological varieties, and reducibility entails global supervenience of the nomological variety. Since global supervenience is the weakest principle guaranteeing determination, the crucial remaining question is whether it avoids reducibility. To illustrate this possibility let us define a very simple, albeit artificial, property, *G*:

(3) *G* = *being both poor and identical either to Clare or to Francis*.

Only Clare and Francis can have *G*, and they have it just in case they are poor. So any two worlds which are identical in the distribution of poverty will be identical in the distribution of *G*. That is to say, *G* globally supervenes on poverty.

Is *G* reducible to poverty? Let us suppose all four logically possible distributions of *G* are also nomologically possible. Is *G* nomologically equivalent to something definable solely in terms of poverty? (3) is not such a definition. On the right-hand side, in addition to *poor*, the logical connectives (*and* and *or*) and the identity relation, we have reference to two individuals. Identity, like the logical connectives, is typically counted part of the logical apparatus and so a permissible component of a definition. But the individuals Francis and Clare are not. If we disallow direct reference to Francis and Clare, or to any entity like the property of *being identical to either Francis or Clare* which could perform the same logical role, then *G* cannot be defined in terms of *poverty* alone. Given this, there is no nomological equivalent of *G* in terms of *poverty*. *G* is neither definable in terms of, nor reducible to, *poverty*.

Like nearly every philosophical argument, this one involves some disputed assumptions, but if it is right then it illustrates the possibility of global supervenience without reducibility (a substantial simplification of the point first made by Hellman and Thompson (1975)).

7. Conclusion

If global supervenience yields determination without reducibility then this is good news indeed for non-reductive physicalists and non-reductive individualists. The determination component articulates a clear sense in which the social and the mental are nothing over and above the physical. In creating the actual world God would not first have to create physical stuff and the laws governing it, then add a whole layer of extra mental entities, properties, and laws, and finish it up with social entities and laws. The physical by itself would suffice, guaranteeing its mental and social superstructure. The nonreductive component, how-

ever, would guarantee that mental and social concepts would still be essential for discourse and theorizing. The social sciences could enjoy methodological autonomy without having to apologize for a bloated ontology.

Reference and Representation: Philosophical Aspects

Paintings, barometers, sentences, and minds are examples of things that represent—they represent things as being one way or another. In this sense, they can be thought of as being about, or as referring to, certain things: the putative subject of the painting, air pressure, or approaching weather, etc. This article addresses the connections between representation and reference; the notion of representational content; representation in language and mental representation; discusses some theories of reference for names; and discusses some issues about the representational content of mental states.

1. Representation: the Most General Notion

What is common to all cases of representation is a correspondence between various states of what does the representing and various states of what is represented. Thus, the number of tree rings represents the age of a tree by virtue of the fact of the possibility of matching different tree ring states with the different ages. In this case, the correspondence is a very simple one: n tree rings corresponds to an age of n years. Likewise, there is a simple correspondence between various states of petrol gages and various levels of gas in the tank to which the gage is connected. But there are highly complex cases as well. Inscriptions in secure codes of credit card numbers represent those numbers, but via extraordinarily complex correspondences. When there are pairwise correspondences between differing states, there is the possibility of carrying information. This is how the number of tree rings can give information about the age of a tree. But, of course, the nature of the correspondence needs to be known for this possibility to be realized.

In many cases, the relevant correspondence relation has a causal underpinning that runs from the various states being represented to the various states doing the representing. For example, the level of gas in the tank causes the reading on the gage, and the appearance of the subject causes the array of paint on the canvas (via the actions of the painter). But structures can represent how things *will* be; a drawing may represent where a playground will be located but is, obviously, not

caused by where it will be. There is representation in the wide sense when there are nonaccidental correspondences between states of affairs. There will be a causal explanation of these nonaccidental correspondences but its precise nature varies from case to case. (See Dretske 1995, Chap. 1 for more on the variety, but note that he ties representation to *purpose*.)

1.1 Representational Content and Reference in General

Things that represent are said to have representational content, that content being how things are being represented as being. The usual way of capturing representational content is set theoretically: content is given by a division of all the complete ways things might be—the event space in the language of statistics—into those that accord with how things are being represented as being and those that do not. Complete ways things might be are ways things might be in which *everything* is settled one way or the other. They are often called possible worlds. The content is then the set of possible worlds that accords with how things are being represented as being. For example, if a petrol gage represents a gas tank as half-full, its being half-full is the content, and that is identified with the set of possible worlds where the tank is half-full. There are, though, considerable differences of opinion about the nature of the possible worlds appealed to in this style of account. This article touches briefly on these in the discussion of representation in mind and language. (For an accessible discussion of the main views, see Bigelow and Pargetter 1990, Chap. 4.)

One advantage of the set-theoretic approach to content is that it allows a simple account of when things are as they are being represented as being. Things are as they are being represented as being—the representation is true or correct or accurate—if and only if the way things actually are is a member of the content. Or, to say it in terms of possible worlds, the representation is accurate if and only if the actual world is a member of the set of worlds which is the content of the representation. In still other words, states that represent say that things are a certain way in the sense of delimiting the possibilities for how they might be, and count as accurate when how things actually are is inside the relevant region of ‘logical space.’

A second advantage is that it allows a simple account of the widest sense in which states that represent are about, or refer to, this, that, or the next thing. Suppose that a barometer’s reading such and such represents that the surrounding air pressure is so and so. Intuitively, the reading is about the air pressure being so and so. This can be spelt out as follows. In every possible world where the reading is correct, in every world where things are as the barometer represents them, the air pressure is so and so. States which

represent are about or refer to what is the case in all the worlds where things are as they are being represented as being. (For more on ‘aboutness’ and the difference between being about an object and a property, see Dretske 1995, Chap. 1, Sect. 5.)

1.2 Mental Representation

A footprint can be thought of as representing the shape of the foot that made it an hour ago. But equally it can be thought of as representing the weight of the person who made it, the shape of the footprint itself half an hour ago, the shape of the foot that made it one day before the foot print was made, and so on. Almost any state that represents will have many representational contents, and it is a nonsense question to ask which is its real content, to ask what the state really represents.

Among the representational structures of especial interest to humans are their brains, and, especially, those parts of our brains that constitute our powers of mental representation. In particular, humans *believe* that things are thus and so, and do so by virtue of the processes in their brains which constitute their belief representing that things are thus and so. These processes *qua* states of brains will themselves have many contents including, for example, that the temperature of the surrounding brain fluid is thus and so, but only one will be the content of what is believed. To suppose otherwise would make what is believed absurdly indeterminate. Therefore, a major question in the philosophy of mind is what determines, out of all the contents of the brain structures that are beliefs, the one which is the content of those beliefs.

One popular answer is: the functional role the structure plays, where this is understood as the role the structure plays in mediating between: inputs to subjects, typically via their sense organs, outputs understood in terms of behavioral responses, and other internal states. However, there are many different ways of fleshing out this answer. (For a recent survey, see Braddon-Mitchell and Jackson 1996, Chaps. 3, 5.)

2. Linguistic Representation and Reference

2.1 Introduction

Language is an especially powerful representational device. With it, highly detailed claims are possible concerning how things are that far outrun, in terms of detail and precision, what can be done with barometers, petrol gages, etc. There is a syntactical distinction between sentences and parts of sentences that roughly corresponds to an important semantic or representational distinction.

A sentence makes a claim about how things are. This is how it gets to be true or false: true when the way the sentence represents things is the way they are, false otherwise. This explains the self-evident status of the biconditional 'Snow is white' is true if and only if snow is white. The left-hand side is true if and only if things are as 'Snow is white' represents them as being. Moreover, as a good way of stating how 'Snow is white' represents things as being is to use the sentence itself, the biconditional comes out true.

By contrast, parts of sentences like 'Snow' and 'is white' contribute in a systematic way to how whole sentences in which they appear represent things as being, but do not themselves represent how things are. This is why they are not themselves either true or false. They can, however, be thought of as referring to, respectively, snow and white things. This is because the contribution that the presence of the word 'snow' makes to the conditions under which 'Snow is white' is true, that is, to how the sentence represents things as being, is such that the sentence cannot be true unless there is some snow. Similarly, the contribution that the presence of 'is white' makes is such that the sentence cannot be true unless there are some white things.

Many recent discussions have focused on the referential properties of names, and many authors restrict the use of the term 'refer' to names. They prefer to talk of the relation between predicates (and, sometimes, common nouns) and things in terms of whether the predicates are *true of* the things or whether the things *satisfy* the predicates.

The next section considers the three main theories of reference for names.

2.2 Theories of Reference for Names

A word like 'London' is used for something taken to have certain properties. This is why it is not used for water or Paris—it is known that they do not have the right properties. On the other hand, the large city that is the capital of England does have the right properties. In short, certain properties or descriptions are associated with the word 'London' and this guides its use. This suggests a simple theory of reference for names in general: 'N' refers to that which satisfies the descriptions associated with 'N.' If we use 'D' for those descriptions, another way of stating this theory is by saying that 'N' is short for the definite description 'the D.'

A famous advantage of the *description theory of reference* is that it can explain why certain identity sentences are informative. Everything is, trivially, self-identical. How then can it be informative to be told that Hesperus is identical to Phosphorus? The answer is that the first name is associated with being the star first seen in the evening and the second name is associated with being the last star to disappear from the night sky as morning approaches, and it is

informative to be told that one thing has these two properties. (The classic source for claims of this kind is Frege 1952.)

Recent discussions in the philosophy of language have raised a number of objections to the description theory of reference. (A good account of the major objections can be found in Devitt and Sterelny 1987. A classic source is Kripke 1980.)

First, if 'N' is an abbreviation of 'the D,' it should make no sense to suppose that N might have failed to be D. But, in fact, it typically makes perfect sense. For example, the descriptions associated with 'Shakespeare' include as a major part that he was the author of certain plays. (Surprisingly little is known about Shakespeare's life.) But it makes perfect sense to suppose that Shakespeare did not write the plays associated with his name. This, indeed, is what those who think that Bacon wrote them do suppose. A similar point can be made for names of natural kinds. The description associated with 'water' is something like potable, clear liquid that fills lakes and falls as rain from the sky—this is roughly what is in a dictionary. However, if on some remote planet—traditionally called 'Twin Earth' by philosophers—there is found clear potable stuff in its lakes which falls from its sky, etc. that is not H₂O, it seems that the right thing to say would be that this stuff—XYZ, as it is often dubbed—is not water. As it would naturally be said, 'It has been discovered that water is not the only clear potable liquid that fills lakes, falls from skies etc. in the universe.' Conversely, if H₂O on Twin Earth were black and rather tar-like, it would still be water. As it would naturally be said, 'It has been discovered that water comes in a quite different form on Twin Earth from its form at room temperature on Earth.' (The classic source for Twin Earth is Putnam 1975.)

Second, if names are abbreviated definite descriptions, then their reference should in general be variable. By changing what is supposed to be the case, it should be possible to shift what they refer to. This is because the reference of definite descriptions is in general shiftable. 'The President of the USA in 1998' refers to Bill Clinton, but had he lost to George Bush, it would refer to Bush and not Clinton. But it seems that the reference of names cannot be shifted; they are, as it is said, rigid designators. 'Clinton' always refers to the very same person.

Description theorists have proposed a number of replies to these (and other) objections. For example, they have urged that it is wrong to conflate the description that settles the reference of a name with the description (s) most famously associated with a name. Although Shakespeare is most famous for the plays, the key description that settles the reference of the name is something like 'the person who is a certain kind of causal origin of the use of the term "Shakespeare."' The debate over whether or not Shakespeare wrote the plays is the debate over whether the person who is a certain kind of causal origin of the occurrences

of the name on the covers of plays etc. did indeed write the plays. (For a recent catalogue of replies that the description theorists might make to various objections, see Jackson 1998.)

The causal theory of reference is the best known alternative to the description theory. The fundamental idea is that 'Aristotle' in our mouths refers to the person it does because of an initial act of baptism that tags that person with a name which then got passed on from speaker to speaker as the name to use for that tagged person until it ended up in our mouths. Of course, the name itself underwent various changes as it passed from the ancient Greek to Modern English. A similar account is suggested to explain why 'water' refers to H_2O . H_2O was baptized with the word 'water' (in ignorance of the fact that it was H_2O that was being baptized) and then the word was passed on as the word to use for that which had been baptized. This account explains why the clear potable stuff that fills the lakes etc. on Twin Earth is not water, is not what is referred to when the word 'water' is used, by appealing to the fact that it was not the natural kind baptized.

There are a number of questions to ask about the causal theory. Is it superior to a description theory that gives a prominent role to a description like 'was baptized ... and subsequently used for what had been so baptized'? Is it supposed to apply to the naming of as yet unborn children? Remembering that causal interactions are invariably with a very large number of factors, should a descriptive element be added to ensure the 'right' reference? (Some of these questions are addressed in Devitt and Sterelny 1987.)

Finally, there is the direct reference theory of reference. On this view, names like 'Aristotle' refer directly to Aristotle. The only semantic property of a name is its bearer. It is hard to discuss this view because it steadfastly refuses to address what seems a perfectly legitimate question, namely, what makes it true that 'Aristotle' refers to Aristotle and not to Plato or my dog? It is also hard to see what it can say about empty names. It has sometimes been speculated that Socrates never existed. 'He' was merely an expository device of Plato's. Although this is almost certainly false, it makes sense to suppose that it is true. But is this possible if 'Socrates' has no meaning apart from its bearer? (For references and more discussion and dissent, see Devitt 1996, Chap. 4.)

3. Mental Representation and Linguistic Representation

3.1 How are they Connected?

As noted above, our minds represent; in particular, to believe is to represent that things are thus and so. Usually, the easiest way for humans to express how they believe things are is to use a sentence. For example, the sentence 'Clinton will not be impeached'

was used in February 1999 by many commentators on American politics to express what they believed. It is obvious that there is an intimate connection between mental and linguistic representation. What is controversial is the extent to which mental representation requires linguistic representation.

One view is that the phenomenon of mental representation in general, and belief in particular, is independent of language; dogs, for example, really do have thoughts and beliefs. Language is simply a device for telling about how things are taken to be. This view can though allow that there are some beliefs one could not have without having a language. It is, for instance, hard to make sense of a creature believing that there are a prime number of apples in the bowl in front of it in the absence of that creature having mastery of a complex coding system, i.e., a language.

However, some hold that belief in general requires language, where language means something substantially more sophisticated than the kind of signaling systems that, e.g., dogs have. On this view, although contentful utterance requires *mental* representation—telephone answering machines do not *mean* anything by the sentences they produce—in order to be a believer, you must have a language. Sometimes, this seems to be, at bottom, a verbal stipulation about the use of the term 'belief': dogs have quasibelief which is very like belief except that it is not expressed in a public language. But sometimes it is clear that the view is that dogs do not have anything like belief at all. A major question for this view is the very close connection between perception and belief. Perceptual experience seems to be shot through with belief-like representational content: the experience of it's raining seems to be a state that by its very nature points to believing that it is raining, though it may be overridden by collateral information, for example, about the operation of a nearby sprinkler system. It is, accordingly, hard for advocates of the more radical view to avoid the implausible view that animals like dogs do not see or hear. (For a defense of the view that belief requires language, see Davidson 1984, Chap. 11, see also McDowell 1994.)

3.2 Capturing the Content of Mental and Linguistic Representation

It was noted earlier that the standard way of capturing representational content is in terms of divisions among complete ways things might be, possible worlds. The problem of the content of logically equivalent sentences and beliefs raises an important question for how to think of these possible worlds. Intuitively, the sentences 'X is an equilateral triangle' and 'X is an equiangular triangle' differ in meaning. Likewise, intuitively, the belief that X is an equilateral triangle and the belief that X is an equiangular triangle are different beliefs. In both cases, the intuition rests on

the fact that it was a *discovery* that, necessarily, every equilateral triangle was equiangular, and conversely. But, on standard conceptions of possible worlds, 'X is an equilateral triangle' and 'X is an equiangular triangle' are true in exactly the same possible worlds precisely because they are logically equivalent.

There have been, broadly speaking, two reactions to this problem. One has been to bite the bullet and insist that the contents are the same. (The most worked out version of this response can be found in Stalnaker 1984.) The other has been to argue that, for the purposes of capturing content, a more fine-grained conception of the entities among which the division is being made is needed. For example, possible worlds might be thought of as constructions out of certain concepts so that, for example, the constructions at which 'X is an equilateral triangle' is true differ from those at which 'X is an equiangular triangle' is true by virtue of the former having the concept *side*, where the latter have the concept *angle*. (See Peacocke 1983, for an overview of the issues see Braddon-Mitchell and Jackson 1996.)

3.3 Mental Representation and the Language of Thought

The functionalist answer to how a belief gets to have the belief content that it does—and, more generally, how a mental state gets to be the mental state that it is—was described earlier, and it was noted that there are many views about how to spell out the key functional roles. However, a popular answer holds that an important part of any functionalist account is the way belief and desire work together to produce behavior: roughly, subjects behave in a way such that what they desire is satisfied if what they believe is true (Stalnaker 1984, Braddon-Mitchell and Jackson 1996).

An alternative approach—the language of thought hypothesis—appeals to the idea that creatures capable of representational thought, creatures capable of having intentional mental states, have a language of thought. When subjects believe that snow is white, they have in their heads a sentence in 'mentalese' that says that snow is white. (This approach allows that dogs may have beliefs, because it is possible to have an internal language of thought, while lacking a public language in which to express thoughts.) This approach gives functional role a place in determining the difference, for example, between belief and desire, but content is treated via a 'semantics for mentalese.' Consider, for example, subjects who believe that snow is white. They have in their heads a token that stands for snow (the mentalese word for snow), a token that stands for whiteness (the mentalese predicate for whiteness), put together in a structure that makes up the mentalese sentence *snow is white*. What makes it true that they believe rather than desire that snow is white is the functional role this structure plays: it

serves more of a 'responding to the world' role and less of a 'changing the world' role. (A classic source is Fodor 1988.)

This approach raises many important issues. One is how we should spell out the crucial relation between the words of mentalese and what they stand for? What makes it true that a structure in the brain is the mentalese for snow and not water, for example? One proffered answer is some kind of causal cum informational link between brain token and what is tokened, but the details are controversial. A second issue is whether neurological investigations might refute the language of thought hypothesis. Some cognitive scientists have argued that the way the brain represents the environment is more like the way maps represent than the way sentences represents (see Braddon-Mitchell and Jackson 1996).

4. Representation and Context

Representational content is often thought of as context dependent. For example, what a petrol gage represents about the level of gas in the tank depends on the nature of the connection between gage and tank. Connected in one of the more usual ways, the gage having its pointer in the far left position indicates that the tank is empty, but connected differently that pointer position might represent that the tank is full. That is to say, identical gage configurations can have very different representational contents depending on the gage's 'context.' Or, as it is often put, representational content with respect to the amount of gas in the tank does not *supervene* on a petrol gage's configuration. As it is said, the content is broad or wide or context dependent.

It is equally possible, however, to think of any given reading as saying: either the gage is connected to the tank in way W_1 and the gas level is L_1 , or the gage is connected in way W_2 and the level is L_2 , or In this way of thinking, a way naturally adopted when the manner of connection between gage and tank is unknown, the content is not dependent on the manner of connection.

In other words, and speaking more generally, there are two essentially equivalent ways of thinking of the interplay of representational content and context. In the first, it looks like this:

In C_1 , S represents that P_1
 ...
 In C_i , S represents that P_i
 In the second, it looks like this:
 S represents that if C_1 then P_1
 ...
 S represents that if C_i then P_i

In the first way of thinking, content comes out as context dependent or broad; in the second, it comes out context independent or, as it is said, narrow.

A pressing, currently much debated question about both mental and linguistic content is whether we should think of it in the context dependent or in the context independent way. Or, equivalently, is what a person believes and what a person claims about how things are when they speak and write a broad or narrow property of them?

The traditional view is that mental and linguistic content is narrow. A principal source for this view is a powerful intuition often exploited by science fiction writers. The idea is that if the stimuli actually impinging on subjects via their environments is duplicated *exactly*, say, by a computer, the subjects will not be able to tell the difference. This is the core idea behind flight simulators and virtual reality machines, of course. Although these devices fall short of perfectly duplicating the impacts of their target environments on their subjects, their makers take it for granted that were perfect duplication achieved, subjects would be unable to tell whether, for example, they were really flying or were in a simulator. This suggests that subjects' mental lives, including how their mental states represent things as being, supervene on their nature from the skin in (or, perhaps, from their central processors in). How their mental states represent things as being is, therefore, a narrow property of subjects: two subjects which are identical from the skin in are identical in how they take, desire etc. their worlds to be. Moreover, if the content of sentences is given by the content of the mental states they serve to express, it will follow that linguistic content is narrow.

However, many philosophers, often influenced by the Twin Earth example discussed earlier, repudiate this intuition. Consider, runs their argument, Mary and Mary's duplicate from the skin in, Twin Mary, on Twin Earth. They both use the word 'water' for the clear, potable etc. stuff around them, but the conditions under which what is said is true, and equally those under which what is thought is true, differ. What Mary says and thinks when she uses the sentence 'There is water nearby' is true if and only if there is H₂O nearby, but what Twin Mary says and believes will be true if and only if there is XYZ nearby. Hence, runs the argument, the contents of the words and thoughts of Mary and Twin Mary differ; ergo, content is context dependent.

The issue is complicated, however, by the fact that it is plausible that there is an indexical element to the use of a great many words including 'water.' It is plausible that the word 'water' is used in part to mean the stuff that the users of the word have come across which is clear, potable etc. If this is right, a plausible explanation of why Mary and Twin Mary refer to different stuff in thought and talk when they use the word 'water' is that they and their language communities interact with different stuff when the word 'water' is used. That is, Mary refers to the clear, potable stuff that *she* and *her* community interact with, whereas Twin Mary refers to the stuff *she* and *her*

(different) community interact with, and the reason they refer differently is that the stuff they interact with is different. This means that there is *a* sense in which what they say and think is the same when they say and think 'There is water nearby.' They both say and think that some of the clear potable etc. stuff that *she* herself interacts with is nearby. This does not affect the point that the truth conditions of what they say and think differ, but they differ in the same way that the truth conditions of 'I am bald' differ depending on who is speaking. There is a good sense in which each person who says or thinks 'I am bald' says or thinks the same thing, namely, that I myself am bald. (There is a large literature on this important question; see Pessin and Goldberg 1996 and Braddon-Mitchell and Jackson 1996.)

Referendums

The referendum allows citizens to vote on a public issue in an election at the local, subnational, or national level. The vote may be advisory or mandatory, statutory or constitutional. Most democracies have voted on a referendum, and the incidence of referendums increased in the last quarter of the twentieth century. The referendum agenda does not have a distinctive ideological slant (Butler and Ranney 1994). National and subnational referendums on matters like entry into international agreements, new constitutional arrangements, and changes in monetary systems have been frequent topics put to voters. Recently in the USA conservative issues have driven the process, but liberal concerns dominated in other decades (Magleby 1994).

Several notable referendums from the last quarter of the twentieth century include the vote in the UK on entry into the European Economic community, the separatist votes in Quebec, the devolution votes in Scotland and Wales, the votes in several European countries on a common currency, and a growing interest in the process in the new democracies of Africa, South America, or Eastern Europe. The USA is one of the few democracies that never experimented with a national referendum, although the process has occasionally been proposed. One notable proposal for a national referendum in the USA was the failed Ludlow Amendment to the US Constitution, which would have required a national referendum before war could be declared (Magleby 1984). More recently, forms of national referendums have been proposed by former Representative Jack Kemp, among others (Kemp 1979).

Referendums can be proposed by the elected representatives and put before the voters in a special or regular election. When such referendums are optional they are called facultative (Bogdanor 1994). The popular referendum permits citizens to petition to place a law or constitutional change before the voters that has previously been enacted by the legislature.

Referendums are sometimes called plebiscites, a reflection of the early use of the process in the Greek city-states. More recently, critics of the process point to plebiscites called by Hitler and other totalitarian leaders as examples of how the process can be used for undemocratic ends. Referendums were found to be consistent with representative democracy in the USA

by the Supreme Court (*Pacific States Telephone and Telegraph Company vs. Oregon* 1912).

In their expansive review of referendums around the world, David Butler and Austin Ranney (1994) find that the subject matter of referendums falls into four main categories: constitutional issues especially after a revolution, territorial breakup, or when changes in the rules are needed; territorial issues; moral issues on matters that reflect deep divisions and which may best be resolved by a popular vote (e.g., alcoholic beverage regulation, divorce, or abortion); and finally a range of miscellaneous issues.

A more common form of citizen petitioning is the initiative process. Under the initiative, citizens may petition to place before the voters statutes (statutory initiative) or constitutional changes (constitutional initiative). As with the popular referendum, access to the ballot is based on the proponents obtaining a specified number of petition signatures. Some governments permit the direct initiative whereby petitioners go directly to the ballot, while some require the proposal to be considered by the legislature before it may go to the voters (the indirect initiative).

At the national level, the initiative process is more identified with Switzerland. Swiss cantons also use the initiative with as many as four elections per year where voters decide initiatives or referendums (Kobach 1994).

Imitating the Swiss, several American states adopted the initiative and popular referendum process—sometimes called direct legislation—shortly after the turn of the last century. As with other Progressive reforms like the direct election of US Senators and the direct primary, reformers hoped to expand the role of voters and limit the role of elected officials and intermediary institutions like political parties, legislatures, or elected executives. The United States experienced a second wave of reform during the 1970s and since; these reforms again expanded suffrage, pressed for more expansive use of direct primaries especially in presidential elections, and renewed interest in and use of initiatives and popular referendums.

In the United States, the initiative and popular referendum occur most frequently in western states (see Fig. 1). These states were in their formative political years during the peak of the movement, and this region was a stronghold for the Progressives (Price 1975). Only five states have adopted the process since the 1920s: Alaska (1956), Wyoming (1968), Illinois (1970), and Florida (1972). Since the mid-1970s, several states have considered adopting the process but only Mississippi has done so. Direct legislation is even more common at the local level in the United States, although precise counts of the numbers of jurisdictions with the process nor the extent of use do not exist.

As in Switzerland, the most common form of initiative and popular referendum in the USA requires

Figure 1
Provisions for initiative and popular referendum in the USA

voters to vote for or against specific statutes or constitutional amendments. As a result, ballot measures are lengthy and written in technical and legal language. Official summaries provided by state election officials are also written at a sophisticated level, making it difficult for voters to often obtain a simple neutral summary of the proposition (Magleby 1984). The length and complexity of the process in the USA makes the process less accessible to less educated voters, having a policy bias against the poor and racial minorities. Initiatives are preferred over popular referendums because petitions may be in circulation longer, and initiatives permit their sponsors to write the language of the measure rather than the legislature. An example of an initiative that was in effect a referendum is the 1964 vote on open housing in California (Wolfinger and Greenstein 1969).

Referendums put on the ballot by state legislatures or changes to the state constitution occur frequently. Every state except Delaware requires that changes in the state constitution be approved by voters. Voters are much more likely to vote affirmatively on these legislative referendums than they are on initiatives. More than 60 percent of legislative referendums pass while the same percent of initiatives fail (Magleby 1994).

Since the mid-1970s, the initiative has experienced

renewed usage (see Fig. 2). The growth in initiative usage includes an even more dramatic increase in the number of proposed initiatives in the petition circulation process that fail to reach the ballot. Why the increase? Initiative activists have learned that the process is a powerful agenda-setting device. A vote in a single state can push an issue onto the national agenda, as votes on tax reduction, elimination of affirmative action, a nuclear weapons freeze, and legislative term limitation has demonstrated. The news media give substantial attention to contentious initiatives, calling attention to the sponsors of the measures and, in some instances, advancing political careers. California gubernatorial candidates make frequent use of the process for self-promotion and governors in noninitiative states advocate the process to establish populist credentials. The large sums of money spent on initiatives have also called attention to the renewed use of the process. Not surprisingly, an initiative industry has developed that helps with petition circulation, legal appeals, campaign management, and media advertising. The process has become an integral part of the governance of several states, most notably California (Schrag 1998).

Absent from the initiative process are the normal checks and balances of the US political system. There is no bicameral check except for Nevada's requirement

Figure 2

History of initiatives and referendums USA 1900-97. Source: Initiatives and Referendums Institute

that constitutional initiatives must pass in identical form in two consecutive elections. There is no gubernatorial veto, no hearing process, and no ability to amend or modify. The only institutional check on the initiative is the courts. Judicial review of initiatives occurs often before the election on matters having to do with signature collection, ballot title, and summary, and whether the initiative contains more than one subject. Postelection judicial review is more concerned with constitutionality, and federal courts have not been timid about overturning the people's votes. State courts, like the California Supreme Court, faced a voter backlash in the 1980s because of the frequency with which that court had declared initiatives unconstitutional.

With the growth in democracy around the world, there has followed renewed interest in referendum devices as a mode of popular consultation. Indeed, some analysts point to a coming clash between direct and representative democracy in the USA, in part precipitated by technology (Broder 2000). States like Oregon have experimented with statewide referendums entirely with mail balloting and some see the Internet as a way to facilitate frequent referendum voting (Becker and Slaton 2000).

As the process has grown in importance, so has research on it. Much of the research focuses on voter decision making in the absence of party cues. Ideology and elite cues are important to voting in this context

(Magleby 1984, Lupia 1994). Other research has focused on the role of consultants in the process, finding that these campaign professionals find the process more lucrative than candidate elections, and prefer it because it gives them greater creative license and means they can avoid the problems associated with candidate scandals and intrusive spouses (Magleby and Patterson 2000).

Another expanding research emphasis is the policy consequences of initiatives. Scores of books have been written on the impact of California's Proposition 13 property tax reduction and similar measures in other states (Sears and Citrin 1985, O'Sullivan et al. 1995). Other books examine the policy and institutional implication of the process (Gerber et al. 2001).

One major methodological challenge to researchers is the lack of a centralized database on local initiatives. Administration of local elections is left to counties and rarely are records kept for more than a few years. Given the large number of counties and the frequency of referendums at the local level, the task of assembling this database has proven difficult.

Given the likely ease of electronic referendum voting, research on how voters behave in this environment will be important. Do electronic voting schemes limit some voters' ability to participate? Would voting electronically further disenfranchise poor and less educated voters from a process that they already find difficult to navigate?

Reflective Equilibrium

A 'reflective equilibrium' is the end point of a deliberative process in which we reflect on and revise

our beliefs about an area of inquiry. The inquiry might be as specific as the question, 'What is the right thing to do in this case?' or 'Is this the correct inference to make?' Alternatively, the inquiry might be much more general, asking which theory or account of justice or right action we should accept, or which principles of inductive reasoning are justifiable. We can also refer to the process or method itself as the 'method of reflective equilibrium.' After briefly describing the method, we shall describe its history, the controversy surrounding it, and some implications it has for work in ethics.

1. The Method of Reflective Equilibrium

The method of reflective equilibrium consists in working back and forth among our considered judgments (some say our 'intuitions') about particular instances or cases, the principles or rules that we believe govern them, and the theoretical considerations that we believe bear on accepting these considered judgments, principles, or rules, revising any of these elements wherever necessary in order to achieve an acceptable coherence among them. The method succeeds and we achieve reflective equilibrium when we arrive at an acceptable coherence among these beliefs. An acceptable coherence requires that our beliefs not only be consistent with each other (a weak requirement), but that some of these beliefs provide support or provide a best explanation for others. We arrive at an optimal equilibrium when the component judgments, principles, and theories are ones we are uninclined to revise any further.

The method of reflective equilibrium has been advocated as a coherence account of justification in several areas of inquiry, including inductive and deductive logic as well as ethics and political philosophy. The key idea underlying this view of justification is that we 'test' various parts of our system of beliefs against the other beliefs we hold, looking for ways in which some of these beliefs support others, seeking coherence among the widest set of beliefs, and revising and refining them at all levels when challenges to some arise from others. For example, a moral principle or moral judgment about a particular case (or, alternatively, a rule of inductive or deductive inference or a particular inference) would be justified if it cohered with the rest of our beliefs about right action (or correct inferences) on due reflection and after appropriate revisions throughout our system of beliefs. By extension of this account, a person who holds a principle or judgment in reflective equilibrium with other relevant beliefs can be said to be justified in believing that principle or judgment.

Because there is revisability of our beliefs at all levels, this coherence view contrasts sharply with foundationalist approaches to justification. A foundationalist approach would take some of these beliefs—some theoretical claim, or moral principles or judgments—as fixed. As we shall see, however, the point of

controversy, especially in ethics, is not that reflective equilibrium allows for the revision of moral judgments, but rather that it involves giving some justificatory weight to them.

2. Recent History

This approach to the justification of rules of inductive logic was proposed by Nelson Goodman in his classic *Fact, Fiction, and Forecast* (1955). Goodman's idea was that we justify rules of inference in inductive or deductive logic by bringing them into reflective equilibrium with what we judge to be acceptable inferences in a broad range of particular cases. No rule of inference would be acceptable as a logical principle if it was not compatible with what we take to be acceptable instances of inferential reasoning. In this sense, our beliefs about acceptable rules of inference are constrained by the 'evidence' provided by what we believe to be good or correct examples or instances of inferential reasoning. At the same time, we should correct or revise our views about particular inferences we initially might think are acceptable if we come to see them as incompatible with rules that we generally accept and refuse to reject because they, in turn, best account for a broad range of other acceptable inferences.

Despite the fact that the origins of reflective equilibrium lie in mid-twentieth century discussions about the justification of inductive logic, its principal development through the rest of the century lies primarily in ethics and political philosophy. Specifically, the method was given prominence by John Rawls's description and use of it in *A Theory of Justice* (1971). Most of our discussion will concentrate on its use in ethics and political philosophy. (Although accounts of the justification of empirical knowledge were developed that share with reflective equilibrium its coherentist approach, they generally do not make explicit use of the terminology of reflective equilibrium.)

Rawls argues that the goal of a theory of justice is to establish the terms of fair cooperation that should govern free and equal moral agents. On this view, the appropriate perspective from which to choose among competing conceptions or principles of justice is a hypothetical social contract or choice situation in which contractors are constrained in their knowledge, motivations, and tasks in specific ways. Because this choice situation is fair to all participants, Rawls calls the conception of justice that emerges from this choice 'justice as fairness.' Under these constraints, he argues, rational contractors would choose principles guaranteeing equal basic liberties and equality of opportunity, and a principle that permitted inequalities only if they made the worst-off groups in society as well off as possible.

Instead of simply accepting whatever principles contractors would choose under these constraints on choice, however, Rawls imposed a further condition of

adequacy on them. The chosen principles must also match our considered judgments about justice in reflective equilibrium. If they do not, then we are to revise the constraints on choice in the contract situation until we arrive at a contract that yields principles that are in reflective equilibrium with our considered judgments about justice. In effect, the device of the contract must itself be in reflective equilibrium with the rest of our beliefs about justice. The contract helps us determine what principles we should choose from among competing views, but the justification for using it and designing it so that it serves that purpose must itself derive from the reflective equilibrium that it helps us achieve.

The method of reflective equilibrium thus plays a role in both the construction and justification of Rawls's theory of justice. Critics of Rawls's theory and his method of reflective equilibrium, especially utilitarians, challenge the prominence the method gives to moral judgments or intuitions. Indeed, some argue that there is no justificatory force to the contract itself if we 'rig' the contract so that it yields principles that match our intuitions (Hare 1973). Despite various criticisms, defenders of the method have elaborated it and extended its use in broad areas of ethics. Later in this entry we shall consider some of the criticisms of this method and some of its extensions in more detail. Before doing so, however, it is necessary to describe it more fully.

3. Narrow and Wide Reflective Equilibrium

3.1 Narrow Reflective Equilibrium

A reflective equilibrium may be *narrow* or *wide* (Rawls 1974). All of us are familiar with a process in moral deliberation in which we work back and forth between a judgment we are inclined to make about right action in a particular case, and the reasons or principles we offer for that judgment. Often we consider variations on the particular case, 'testing' the principle against them, and then refining and specifying it to accommodate our judgments about these variations. We might also revise what we say about certain cases if our initial views do not fit with the principles we grow inclined to accept.

Such a revision may constitute a moral surprise or discovery (Daniels 1996). Suppose, for example, that we are considering whether we should ignore age in the distribution of medical treatments. Many initially believe that age is a 'morally irrelevant trait,' just like race, and they would insist that rationing medical services by age is just as unacceptable as rationing by race. On considering a variety of cases, however, it might become apparent that we all age, but that we do not change race, and that this means that the different treatment of people at different ages, if systematically applied over the life span, does not create inequalities

between persons, as it would in the case of race. We might be led by this realization to think that age rationing might be acceptable under some conditions, when race rationing would never be, and this would be a moral surprise for many who changed their view.

To the extent that we focus solely on particular cases and a group of principles that apply to them, we are seeking only *narrow* reflective equilibrium. Presumably, the principles we arrive at best 'account for' the cases examined. Others, however, may arrive at different narrow reflective equilibria, containing different principles and judgments about justice. As a result, we still face an important question about justification unanswered by the method of narrow reflective equilibrium: which set of beliefs about justice should we accept?

Because narrow reflective equilibrium does not answer this question, it may seem to be a *descriptive* method appropriate to moral anthropology, not a *normative* account of justification in ethics. In fact, Rawls (1971) at one point suggested that arriving at the principles that match our moral judgments in reflective equilibrium might reveal our 'moral grammar' in a way that is analogous to uncovering the grammar that underlies our syntactic ability as native speakers of a language to make judgments about grammatical form. In support of the analogy, some contemporary theorists who systematically examine our moral intuitions, often through hypothetical as opposed to real cases, believe they are uncovering a moral structure of principles that is *a priori*.

Uncovering a syntax, however, is a descriptive and not a justificatory task. Once we can identify the grammar or rules that best account for a person's syntactic competency, we do not ask the question, 'Should that person have this grammar?' We are satisfied to have captured the grammar underlying a person's idiolect. In ethics and political philosophy, in contrast, we must answer that justificatory question, especially since there is often disagreement among people about what is right, disagreement that is not resolved simply by pursuing narrow reflective equilibrium.

3.2 Wide Reflective Equilibrium

Rawls's proposal is that we can achieve real justification in the choice of principles of justice by broadening the circle of beliefs that must cohere. In a *wide* reflective equilibrium, for example, we broaden the field of relevant moral and nonmoral beliefs to include an account of the conditions under which it would be fair for reasonable people to choose among competing principles, as well as evidence that the resulting principles constitute a feasible or stable conception of justice, that is that people could sustain their commitment to such principles.

For example, the constraints on choice in Rawls's contract situation, such as the veil of ignorance that

keeps us from knowing facts about ourselves and our specific preferences, require justification. Rawls needs to show that these constraints are 'fair' to all contractors (thus 'justice as fairness' is his label for this procedural account of how we find out what is just). To provide such justification, Rawls appeals to beliefs about the fundamental 'moral powers' of 'free and equal' agents (they can form and revise their conceptions of what is good and they have a sense of justice). He also appeals to the ideal of a well-ordered society in which principles of justice play a particular role as public principles for reconciling disputes. Rawls must even provide us with an account of 'primary social goods,' necessary if agents who do not know their own actual preferences are to decide what principles would be better for them to choose. The device of the contract is thus in reflective equilibrium with certain background theories that themselves contain moral beliefs. The contract is not simply based on uncontroversial assumptions about human rationality (although it describes a rational choice problem within the constraints it imposes). Without acceptance of this wider circle of moral beliefs, Rawls's construction lacks support.

Our beliefs about justice are justified (and, by extension, we are justified in holding them) if they cohere in such a wide reflective equilibrium. Obviously, the method of wide reflective equilibrium is here only illustrated by appeal to the detail of Rawls's use of it. If we abstract from that detail, we see that there is a complex structure and interaction of beliefs, at many levels of generality, that bear on the construction of an account of justice. We shall later return to this point when we talk about implications of this method for work in ethics.

In *A Theory of Justice*, Rawls seemed to think that all people might converge on a common or *shared* wide reflective equilibrium that included 'justice as fairness,' the conception of justice for which he argues. Wide reflective equilibrium thus played a role in the construction of the theory, helping 'us' to articulate its key features in ways that led to principles that matched 'our' considered judgments. At the same time, wide reflective equilibrium constituted an account of justification. Shared agreement on that wide equilibrium would produce a well-ordered society governed by principles guaranteeing equal basic liberties, fair equality of opportunity, and the requirement that inequalities be arranged to make the worst-off groups as well off as possible.

In his later work, *Political Liberalism* (1993), Rawls abandons the suggestion that all people might converge in the same, shared wide reflective equilibrium that contains his conception of justice. This change comes about because Rawls believes that justification must accommodate the unavoidable 'fact' that human reason, exercised under conditions of liberty, will yield a pluralism of reasonable comprehensive moral views. Because of 'reasonable pluralism,' Rawls recasts jus-

tice as fairness as a 'free standing' political conception of justice on which people with different comprehensive views may agree in an 'overlapping consensus.' The *public* justification of such a political conception involves no appeal to the philosophical or religious views that appear in the comprehensive doctrines that form this overlapping consensus. Instead, we might think of this process of working back and forth among the key shared ideas in the public, democratic culture and the articulated features of the political conception of justice as a *political* reflective equilibrium (Daniels 1996).

Although there is no convergence on a shared wide reflective equilibrium that contains the political conception of justice, wide reflective equilibrium still plays a critical role in justification. For individuals to be *fully justified* in adopting the political conception of justice, the conception articulated in the political reflective equilibrium, they must incorporate it within a wide reflective equilibrium that includes their own comprehensive moral or religious doctrine. It will count as a reasonable view for them only if it coheres with their other (religious and philosophical) beliefs in reflective equilibrium. Over time, people modify their comprehensive views so that they may accommodate the overlapping consensus, a process that involves both philosophical reflection and the moderating influence of living under institutions that are governed by the shared conception of justice.

4. Criticisms of Reflective Equilibrium

4.1 Challenges to Moral Intuitions

Central to the method of reflective equilibrium in ethics and political philosophy is the claim that our considered moral judgments about particular cases carry weight, if only initial weight, in seeking justification. This claim is controversial. Some of the most vigorous criticism of it has come from utilitarians, and it is instructive to see why.

A traditional criticism of utilitarianism is that it leads us to moral judgments about what is right which conflict with our 'ordinary' moral judgments. In response, some utilitarians accept the relevance of some of these judgments and argue that utilitarianism is compatible with them. Thus Mill argued for a utilitarian foundation for our beliefs about the importance of individual liberty. Some utilitarians have even argued that key features of our 'common sense morality' approximate utilitarian requirements, and that we have acquired these beliefs just because they do, unconsciously, reflect what promotes utility—they reflect the wisdom of a heritage.

An alternative utilitarian response to the claim that utilitarianism conflicts with certain ordinary moral judgments is to dismiss these judgments as pretheoretical 'intuitions.' As such, they are likely to result from cultural indoctrination and thus reflect superstition,

bias, and mere historical accident. On this view, moral intuitions or judgments should have no evidentiary credentials and should play no role in moral theory construction or justification. Indeed, as the prominent utilitarians Richard Brandt and Richard Hare argued against Rawls, simply making 'coherent' a set of beliefs that have no 'initial credibility' cannot produce justification, since coherent fictions are still only fictions. Indeed, when Rawls describes the conditions under which we might solicit considered moral judgments, namely that people be calm and have adequate information about the cases, they do not by themselves do anything to assuage the utilitarian worries.

This criticism has some force, since two standard ways of supplying credentials for initial judgments are not available. One traditional way to support the reliability of these judgments or intuitions is to claim, as eighteenth-century theorists did, that they are the result of a special moral faculty that allows us to grasp particular moral facts or universal principles. Modern proponents of reflective equilibrium reject such mysterious faculties. Indeed, they claim moral judgments are revisable, not foundational.

A second way to support the initial credibility of considered judgments is to draw an analogy between them and observations in science or everyday life. For example, what counts as observational evidence in science depends on theory, and theory may give us reasons to reject some observations as not constituting counterevidence to a scientific law or theory. In this way we might see an analogy between the revisability of moral judgments and observations.

Developing this analogy, however, seems to require that we also tell some story about why moral judgments are reliable 'observations' about what is right. Perhaps we might need something like the causal story that some theorists of knowledge offer to explain the reliability of observations. Since no such story is forthcoming, opponents argue, proponents of reflective equilibrium must reject the requirement or give up the analogy. Proponents of reflective equilibrium might reject the requirement by suggesting it is premature to ask for such a story in ethics or by claiming that we can provide no analogous causal story for credible judgments we make in other areas, including mathematics or logic.

It might seem that the burden of argument has shifted to advocates of reflective equilibrium to show why 'initial credibility' should be ascribed to moral judgments or intuitions. Defenders of reflective equilibrium may nevertheless reject this burden, arguing that critics, especially utilitarian critics, actually face the same problem. For example, Richard Brandt argues that 'facts and logic' alone, and not moral intuitions, should play a role in moral theory construction and justification. On Brandt's view, we should choose moral principles when they are based on desires that have been subjected to maximal criticism by facts and logic alone (he calls it 'cognitive

psychotherapy'). We should avoid any appeal to moral intuitions that might infect this critique.

The desires that Brandt appeals to, however, are themselves shaped and influenced by the very same social structures that utilitarians complain have biased and corrupted our moral judgments. Nothing in the process of critique by facts and logic alone can eliminate this source of bias. If this claim is right, it undercuts the suggestion that we can step outside our beliefs to arrive at some more objective form of justification. Instead, we may be better off recognizing that our process of critique—in the method of wide reflective equilibrium—is explicit about exposing the sources of bias and historical accident to criticism and revision, rather than fooling ourselves into thinking that desires are some sort of morally uninfluenced layer of 'facts.'

4.2 Other Criticisms of Reflective Equilibrium

Other criticisms of reflective equilibrium in ethics have focused on points familiar from discussions in epistemology more generally. One important complaint concerns the vagueness of the concept of coherence. If we simply take logical consistency as the criterion for coherence, we have much too weak a constraint. What account can we give of a stronger notion?

More has to be said about how some parts of the system of beliefs 'support or explain' others than is provided in the account above. Critics of Rawls's requirement that the contract situation be adjusted, if necessary, to yield principles that are in reflective equilibrium with our judgments about justice complained that this was a 'rigged' contract and that it did no justificatory work beyond reflective equilibrium. If, however, the moral judgments that play a role in discussions of fair process, the well-ordered society, and the moral powers of agents are somewhat independent of the considered judgments about justice, then we get the kind of independent support for the principles that add justificatory force. Little work has actually been done, however, to flesh out a stronger account of coherence in ethics as opposed to epistemology more generally, where coherentism has been defended and elaborated.

A second line of objection derives from antioherentist accounts of justification rooted in the theory of knowledge. Some insist, for example, that coherence accounts of justification cannot be divorced from coherence accounts of truth. On the other hand, Rawls's view fits with the claim by some contemporary theorists of knowledge that a coherence account of justification is distinguishable from a coherence account of truth, and defensible when so separated.

This separability is important to Rawls, even more so in his later work than in *A Theory of Justice*. Rawls never took a stand on the question of whether there are 'truths' about justice that correspond to a conception of justice that we justify through reflective

equilibrium. In his early work, the method of reflective equilibrium suggested ways in which convergence might be achieved among those who began with disagreements about justice. By drawing attention to the many features of a comprehensive theory on which argument and evidence could be brought to bear, the method of wide reflective equilibrium held out promise that more convergence might result than if people had only considered judgments and principles to agree and disagree about. Convergence did not imply that truth was reached, but under some conditions, it could be taken as evidence for truth, just as it might be in non-normative areas of inquiry.

Once Rawls took the 'burdens of judgment' and reasonable pluralism seriously, that is once he 'politicized' justice in his later work, it became much less plausible to talk about convergence on a shared wide equilibrium that might contain moral truth. Instead, even if we converged in an 'overlapping consensus' on a conception of justice, it would have to be justified from the perspective of distinct wide reflective equilibria. It became more important for Rawls to suggest how claims about justice could be 'objective' without presupposing moral truth. These developments in Rawls's account thus appear to move him farther away from those who would seek to give a realist account of moral truth.

One further group of criticisms of reflective equilibrium derives largely from claims about human rationality. A starting point for this line of argument is the complaint that people who have different starting points as their initial set of beliefs, say with different degrees of credence given to their beliefs, may arrive at different reflective points of equilibrium. This possibility undercuts the suggestion that critical pressures alone can produce convergence. A more general form of this worry is that the model of reflection involved in reflective equilibrium, in which we are to produce coherence among all our beliefs, overemphasizes and idealizes human rationality. The suggestion is that we would be better off presupposing a more minimal form of rationality. A specific version of this complaint is that the method involves an information burden that cannot be met. Yet another version of this criticism is that we should allow for much less 'rationalist' forms of modification of our views, recognizing that 'conversion' experiences such as those involved in 'paradigm shifts' may affect any account of coherence.

A full defense of reflective equilibrium as a method would require a more developed response to many of these lines of criticism than exists in the literature.

5. Applications and Implications of Reflective Equilibrium

Despite these criticisms, some philosophers have argued for a broader understanding of the relevance of the method of reflective equilibrium to practical ethics.

In thinking about the course of right action in a particular case, we often appeal to reasons and principles that are notoriously general and lack the kind of specificity that make them suitable to govern the case at hand without committing us to implications we cannot accept in other contexts. This requires that we refine or specify the reasons and principles if we are to provide appropriate justifications for what we do and appropriate guidance for related cases. Philosophers who have focused attention on the importance of specification have drawn on the method of reflective equilibrium for their insights into the problem.

In practical ethics, especially bioethics, there has been a vigorous debate about methodology. Some argue that we must root all claims about specific cases in specific ethical theories, and that the hard work is showing how these theories apply to specific cases. Others argue that we may disagree about many aspects of general theory but still agree on principles, and that the hard work of practical ethics consists in fitting sometimes conflicting principles to particular cases. Still others argue that we must begin our philosophical work with detailed understanding of the texture and specificity of a case, avoiding the temptation to intrude general principles or theories into the analysis.

A grasp of the method of wide reflective equilibrium suggests a way around the exclusionary nature of this debate. Wide reflective equilibrium shows us the complex structure of justification in ethics and political philosophy, revealing many connections among our component beliefs. At the same time, there are many different types of ethical analysis and normative inquiry.

This suggests a more eclectic view of the debate about method. Work in ethics requires all levels of inquiry proposed by the disputants, not always all at once or in each case, but at some time or other. Sometimes it is true that we cannot resolve disputes about how to weigh conflicts among principles unless we bring more theoretical considerations to bear (these considerations need not involve comprehensive ethical theories). Sometimes we can agree on relevant principles and agree to disagree on other theoretical issues, still arriving at agreement about the rightness of particular policies or actions and their justification in light of relevant reasons and principles. Sometimes we must see what is distinctive about particular cases and revise or refine our reasons and principles before we can arrive at understanding of what to do. Finally, and of the greatest significance, the method of wide reflective equilibrium should make it clear that work in ethical theory cannot be divorced from work in practical ethics. We must test and revise theory in light of our considered judgments about moral practice. The condescending attitude of many who work in ethical theory toward work in practical ethics thus is incompatible with what wide reflective equilibrium establishes about the relationship between these areas of ethical inquiry.

The method of wide reflective equilibrium makes it plausible that all such 'methods' should be seen as appropriate to some tasks in ethics and are but parts of a more encompassing method.

Reflexivity in Anthropology

Critiques of the social sciences as practiced in the United States emerged in the 1980s in which reflexivity became a keyword, standing for both the means of the critiques as well as the form that alternative practices might take. The consequences for disciplinary practices of reflexivity as means of critique and alternative form of inquiry were nowhere as great among the social sciences as in social and cultural anthropology.

According to one of the early statements in this critical trend, reflexivity is '... the capacity of any system of signification to turn back upon itself, to make itself its own object by referring to itself: subject and object fuse' (Myerhoff and Ruby 1982). Myerhoff and Ruby go on to stress that 'significant distinctions exist between reflexivity and related attitudes such as self-regard, self-absorption, solipsism, self-reference, self-consciousness, and autobiography. Reflexivity does not leave the subject lost in its own concerns; it pulls one toward the other and away from isolated attentiveness toward oneself.'

Reflexivity as a practice in the social sciences is, thus, both a distinctive mode of thinking and a strategy

of writing that concerns itself with the process of inquiry as an integral part of the claims to knowledge that the inquiry might produce. As a concept, it is related to the idea of feedback in cybernetic models, of metacommunication, and of such functions as deixis and indexicality inherent in the faculty of language use. However, it is the more ideological uses of reflexivity in debates about the revision of anthropology's distinctive methods of fieldwork and ethnography that are of concern here. Debates about the role and purpose of reflexivity in the process of research as well as in the changing form of the ethnographic text became the major specifiable way of assessing the impact upon anthropology of the broader intellectual movement of the 1970s and 1980s known loosely as postmodernism.

In the broad sweep of European philosophy, reflexivity as a category of interest in social theory begins with Kant's distinction between analysis and an analytic in which an analytic is the kind of inquiry where the subject of inquiry is also the object of inquiry. One genealogical stream from this originary idea of reflexive inquiry leads through Hegel to phenomenology and eventually to Heidegger and existentialism in France. The other, and for us, more relevant genealogical stream leads to hermeneutics in the work of Hans-Georg Gadamer and Paul Ricoeur by way of the neo-Kantian writings of Dilthey and the work of Max Weber, in which reflexivity, while implicit, is a strong element of his methodological considerations. In the work of Gadamer and Ricoeur, reflexivity becomes an explicit and crucial intellectual operation in the activity of interpretation whereby the individual ethical consciousness expands reflectively through encounters with the foreign or the different. Thus, while long a potential existing in a sort of minor key to the predominant positivist tendency of social theory which oversaw the post-World War II expansion of sociology and anthropology in the United States, philosophical works of hermeneutics, in which the operation of reflexivity was highlighted, only developed explicitly a strong appeal among sociologists and anthropologists from the early 1980s onward.

Of all of the social sciences, the importance of reflexivity as a style of inquiry has been most natural to precisely those methods of anthropology which have distinguished it as a discipline. Pioneered by Bronislaw Malinowski and Franz Boas, the pursuit of fieldwork investigation through long-term participant observation, working directly in native languages, and the constant interpretation and translation of behaviors and speech encountered on a daily basis, inherently involves on the part of the investigator a keen consciousness of oneself and one's relations with specific others as the medium of all claims to knowledge from this research practice.

For a long time, anthropologists only came to terms with the complexities and problems of this distinctive form of knowledge production informally as a pastime

of professional culture and folklore, as something to be communicated between mentors and students. It was only at the end of the 1960s, and then again, and more definitively in the 1980s, that anthropologists examined and developed explicitly the varieties of meanings and implications of reflexivity as a major style of knowledge production for the future practice of their discipline.

Since the 1980s, reflexivity has become a 'keyword' indicating both a self-conscious, mainstream style of work in anthropology and part of its own enduring disciplinary politics of knowledge. Here, it is important to note that reflexivity has only served as such a central category, standing in turn for the most concrete aspect of the controversial impact of postmodernism on anthropological practice, in the recent evolution of the discipline in the United States. It has been discussed and debated from the 1980s on in other anthropological establishments around the world, but mainly through the stimulus of the prestige and diffusion of trends in United States anthropology.

1. Reflexivity in Two Moments in the Critique of Anthropology

During the late 1960s, US anthropologists became preoccupied openly with a long simmering critique of their discipline. This critique had theoretical and methodological dimensions, but it was primarily political in nature, stimulated by the ferment of domestic resistance to the Vietnam War, renewed discussions of anthropology's historic development within the expansion of European colonialisms, and the interest in new work in Marxist theory. At that time as well, Geertz was developing a broad and deep theoretical foundation for cultural anthropology in hermeneutic philosophy, work that was eventually to serve as both the primary foil and influence for later discussions of reflexivity in anthropological method. (See Geertz 1968 for his early position on reflexivity in fieldwork.) But in the *de facto* reflexive attempt to undertake a critical anthropology of anthropology in the politicized atmosphere of the 1960s, the issue of reflexivity itself as the major dynamic of what it was to practice critical analysis was little addressed. An important exception is the paper by Scholte (1969) which summarized this period of critique. Important as a figure who introduced currents of European social theory into US anthropology, Scholte foreshadowed what sort of theoretical work and changes in practice would be necessary to transform anthropology into a discipline with a sustained critical purpose beyond that moment of heightened political critique.

In the interval between the two periods of internal disciplinary critique, perhaps the most important work that served as the raw material on which the eventual surfacing of explicit considerations of reflexivity in

anthropology depended was the burgeoning of a literature on fieldwork experience, written alongside the production of more formal ethnographies from which such reflections about the process of inquiry were largely absent. This literature, fueled by the publication of Malinowski's diaries in 1967, incorporated the spirit of self-critique of the late 1960s and was produced by anthropologists who were then students and young professors. There emerged a more theoretical strain of this literature in which the reflexive character of fieldwork became the major preoccupation (e.g., Rabinow 1979) and that led eventually to experiments with the form of the ethnography itself (e.g., Crapanzano 1980). These works, combined with an interdisciplinary movement, variously characterized as postmodernism and poststructuralism and led by scholars of literature who were experiencing their own disciplinary crisis, stimulated the theoretically deeper, more wideranging, and sustained internal critique of anthropology of the 1980s.

Incorporating all of the dimensions of the earlier critique, the 1980s critique primarily examined the central practices of the discipline, especially in its character as a hermeneutic enterprise, a view for which Geertz had laid the foundation. In particular, it did so by a focus on the rhetoric and forms of the signature textual product of anthropology, the ethnography. (See Clifford and Marcus 1986, the volume that has stood for this critique in the way that the Hymes volume did for the earlier one.) This critique was, thus, the efflorescence of a comprehensive discussion of all of the issues relating to reflexivity that had long been so essential to the practice of anthropology. Influenced by the circulation of much more diverse and sophisticated theoretical resources, anthropologists looked with an unprecedented intensity and thoroughness at the relationships in their work between reflexive modes of knowing, critical and ethical awareness, the political contexts of inquiry, and alternative possibilities for practice.

The basic act of reflexivity which initiated this critique were the probing discussions of the relationships of anthropologists to informants—of the self to other—and the dependence of the production of anthropological knowledge on these relationships which had so often been effaced in the ways that ethnographies had in fact been written. Evoking alternative modes of representing others, questioning the act of representation itself, suggesting the ways ethnographic knowledge emerges from collaboration and dialogue, and probing the political conditions which have inhibited such possibilities, this moment of critique served both to stimulate degrees of experiment with the ethnographic form and to encourage ramifying discussions about the critical purpose of anthropological analysis (e.g., Marcus and Fischer 1999). This undertaking was itself an umbrella act of reflexivity, and reflexive practice became the common frame for thinking about past ethnographies, future

possibilities, and the form and purpose of anthropological knowledge itself. This field of discussion was highly contested: some felt that the critique by its nature was too hermetic, too literary, and not sufficiently committed to anthropology's study of social struggles in the contemporary world; some thought the attention to reflexive issues was an aesthetic distraction and a major blow to the production of objective knowledge that could be shared by a scholarly community and on which disciplinary progress depended; and contrastingly, for some, the kinds and levels of reflexivity encouraged by the critique were neither reflexive nor critical enough, leading to a spiralling array of discussions about insufficiencies and exclusions that had even more ideal reflexive practice in view.

The immediate effect of this period of critique were the changes in the ways that ethnographies were both written and discussed. But while the critique was developed through attention to texts and the way that anthropologists rhetorically established authority for them, the larger stake was the effort finally to justify them theoretically and ethically and expand anthropology as a critically reflexive field of inquiry. There can be little doubt that this much has been established as at least a long-term mainstream tendency in the discipline. This tendency has placed anthropology in much closer relation to such parallel interdisciplinary fields, themselves rooted in varieties of reflexive inquiry, as media studies, feminist studies, postcolonial studies, and most broadly, cultural studies, than to its historic partners in the other social sciences.

2. *The Incorporation of Reflexivity in the Mainstream of Anthropological Research*

Discussions about reflexivity, or at least the evaluation of ethnographic claims to knowledge in terms of the specific conditions and relations of inquiry that produced them from fieldwork, are not only highly visible and commonplace in anthropological discourse of the 1990s, they are *de rigueur*. Further, some form and degree of reflexive commentary is worked prominently into virtually every ethnography written these days. If not enacted in experimental text design, there is the presumption that all ethnography is produced collaboratively, and there are far richer and more probing discussions than ever before about the kinds of contexts which influence ethnographic representations of subjects and shape arguments from ethnographic data (see Marcus 1994). Concern for reflexivity has had a special appeal for ethnographic filmmakers, and some of the most cogent writing on the importance of reflexivity in the representation of other forms of life have come from this arena (e.g., MacDougall 1998). Current productions of ethnographic film and media demonstrate most clearly that the practice of reflex-

ivity crucially redefines and adapts the classic conditions of ethnographic inquiry to new conditions of fieldwork where anthropological research projects must negotiate different identities and roles in relation to the highly articulated projects of their subjects in the overlapping contexts of a globally interconnected world.

2.1 Variant Ideologies in the Practice and Form of Reflexivity

In sociology, discussion of reflexivity has tended to be integrated formally as a methodological tool or technique (e.g., see Bourdieu 1990), limiting its ability to affect fundamentally the forms and purposes of sociological research. In anthropology, the outcome has been quite different, generating a number of changes in the ways that ethnographies are written and fieldwork is conceived. This in turn has obviously had considerable implications for changes in both the form and content of the knowledge that anthropology's core research process generates.

In engagement with the terms of the 'Writing Culture' critique of the 1980s, the largest body of literature stimulated explicitly by reflexive inquiry examines in great detail the self-other relation in classic conditions and specific sites of fieldwork. While some have characterized this literature as narcissistic or merely self quests, in its most accomplished examples (e.g., Behar and Gordon 1995, Reed-Danahay 1997, Taylor 1999, Tsing 1993), it has addressed cogently issues of contemporary changes in concepts of self, personhood, and identity among many of the peoples who had been the subject of study by previous generations of ethnographers. At the microlevel of fieldwork, it has also clarified aspects of the history of anthropology as an academic enterprise and in relation to the broad range of effects that inquiry itself has on the peoples and subjects studied (e.g., Rosaldo 1989). While somewhat unruly and less governed by genre rules of form in social science writing, this literature has, in sum, been very useful in deepening and critiquing the complexities of constructs of subjectivity and otherness within their conventional usages in Western intellectual discourse—a long-term, continuing objective of anthropology as a discipline. It has also probed critically ethnographers' positions in relation to initial objects of study so as to transform the objects in novel ways and reconfigure the compass of research in response to radical contemporary changes in both the worlds of the academic and who is identified as subjects of study.

There has also been a strain of reflexive inquiry in anthropology for which reflexivity has been more distinctly a means by which to define an object of study or to circumscribe new temporal and spatial boundaries for a fieldwork project (Marcus 1998). Key to these works is clarity of the positioning or

location of ethnographic inquiry, which reflexivity enables, in relation to other historic and geographical agents in the same social field. Reflexivity as positioning not only serves the creation of new forms of objectivity in anthropology, sensitive to the issues of critique that discussions of reflexivity have raised, but redefines both the scope of ethnography and its arguments. In these works the limits and reach of once very locally focussed ethnographic arguments expand in unpredictable and intriguing ways (for a now classic experiment of this sort, see Taussig 1987; for more recent examples, see Martin 1994, Fortun 2000).

Finally, there is the presence of reflexivity in ethnography because of the evolution of certain realities on the ground over the course of career-long scholarly involvements with certain peoples and places. In recent decades, literally self-conscious cultural awareness has increased markedly and even been mobilized politically in many locales and regions such that the conditions of ethnographic research require a rethinking and reorientation toward one's subjects, now organized into social movements, nongovernmental organizations, and other groups involved in objectifying and representing themselves. Here, reflexive inquiry is the means to a complex and necessary politics of research which not only shapes fieldwork but makes its continuation possible at all (see Warren 1999 for an exemplar of this type of increasing variant of reflexive inquiry).

2.2 Reflexive Modernization and Reflexivity in the Changing Conditions of Anthropological Fieldwork

Broader changes in contemporary social conditions worldwide that stimulate the trend of reflexive inquiry in anthropology is encompassed in the concept of reflexive modernization (Beck et al. 1994), a development in social theory of the 1990s that responds to the postulation of a present era of postmodernity by trying to specify the characteristics of such an era for the pursuit of empirical inquiry. This construct proposes that the modernity characteristic of industrial society is succeeded by a modernity that involves living with irreducible contingency, living in a more complex and less controllable world. Most importantly, reflexivity as a self-monitoring process on the level of both institutions and individual persons becomes not only a pervasive aspect of society, but also a key focus of social thought itself.

This version of social theory suggests for the proliferation of styles of reflexive inquiry in anthropology that these are not driven only as a result of the internal critique of anthropology, as a seminal countertrend to a preceding era of positivist tendencies, but as a more generally shared condition with the societies and cultures which anthropology makes its subjects of study. This suggestion in turn has a potentially profound and enduring effect on the research proto-

cols of anthropology in recognizing certain affinities and identifications between the reflexive predicaments of ethnographers and those whom they study. Reflexivity is relevant not because it provides truer or more powerful explanatory models with which anthropologists can treat social facts among their subjects, but rather because reflexivity is also practiced differentially 'out there' on a widespread basis (see Marcus 1999). This fact suggests the breaking of the frame of conventional scholarly work altogether, at least in the anthropological tradition, rather than the demise and replacement of specific concepts and characteristics of this academic frame. Thus, reflexivity is no longer only a moment in the critique of disciplines but becomes more generally the object and medium of social and cultural analysis as well.

Reflexivity, in Science and Technology Studies

Considerations of reflexivity have salience in diverse intellectual practices and traditions: literature, philosophical logic, the visual arts, cybernetics, as well as social theory and sociology. Indeed, it is an issue with potential relevance for all modes of representational and performative practice. In the most general terms, considered as a feature or style of inquiry, reflexivity is a concept that expresses a concern to turn 'subject' into 'object,' to turn the activity of inquiry into a topic for (its own) inquiry. To 'be reflexive' is to bring the process of doing an activity into the purview of that activity as a feature of it. Thus, it implies a certain self-consciousness, and a certain paradoxical, even Zen-like, mode of operation: bootstrapping; attempting to see the flashlight that illuminates the scene as a part of the scene it illuminates; taking account of this moment as one writes of 'this moment.' This article details the ways in which reflexivity has featured in science and technology studies (STS), and speculates on the current and future status of reflexive study in STS.

1. Alternative Introduction

This heading is not to declare, exactly, that there is anything 'wrong' with that first introductory paragraph. It does the job, and it does it correctly; that is,

in accord with the 'Instructions for Manuscript Preparation' for this volume. It is just that in doing 'just that,' it is unable to acknowledge the conditions under which it does so. Thus, it leaves all those things out of (its) account; which is normal, and normally unobjectionable. Perhaps no other article in this *Encyclopedia* makes any reference to such things, preferring instead, perfectly 'obviously,' to concentrate on the primary task of speaking authoritatively (and, importantly, briefly) about its topic. Thus, the conditions of production of these particular texts are constructed as irrelevancies for, and obstacles to, the proper work. Social science inquiry that focuses on conditions of production has always acted (intentionally or not) to 'make trouble' of this kind: Marxist economics for capitalism; sociology of education for teaching; STS for science. Reflexivity adds a twist to this dynamic: in collapsing the external/internal, outsider/insider, on/in relation, the source of trouble, being as much 'here' as it is 'there,' is no longer clearly located or easily attacked. This, then, is the primary role for reflexive inquiry: to make things difficult; to enrich the process of inquiry; to go round and round in circles; to fill out the picture; to frustrate all action; to act authentically and without self-contradiction; to change the subject.

2. Reflexivity as a Problem

In STS, the impetus for explicitly reflexive studies has been felt most strongly in the important sub-field of STS known as the sociology of scientific knowledge (SSK) (see *Sociology, Epistemology of; Technology, Social Construction of*). Here, the reflexive tie between its subject (knowledge about scientific knowledge) and its object (scientific knowledge) is very marked. That is, SSK exhibits a strong 'X of X' structure. Because of this, and because SSK's epistemology is explicitly relativist, reflexivity in SSK has a 'bite' akin to classic philosophical skepticism.

Extremely crudely, and for illustrative purposes only, SSK's relativism with respect to scientific knowledge can be, and indeed has been, taken as equivalent to a statement of this kind: 'Scientific knowledge does not constitute truth because it is socially constructed.' Read this way, SSK then becomes vulnerable to the standard anti-relativist critique, the argument from self-refutation: 'If this statement is asserted as a (scientific) truth, then it suffers from performative self-contradiction, and thus refutes itself' (see, for example, Hollis and Lukes 1982). Note that the self-refutation argument uses reflexivity: it is through the process of turning its target onto itself that the demonstration of self-refutation is effected.

This is indeed one of the commonest modes in which reflexivity operates: as a weapon in the agonistic game of criticism. Thus, for those threatened with attack-by-reflexivity, it becomes a source of vulnerability to

be abjured and defended against. Reflexivity becomes, that is to say, a 'problem' to be 'managed.' The various ways that practitioners of SSK have done this have been one of the preoccupations of 'reflexivist' studies (see Sect. 2.3).

2.1 Logical Consistency: Bloor's Strong Programme

David Bloor's *Knowledge and Social Imagery* (1991), is one of the earliest texts to set out the elements of what has become known as the SSK. It contains an endorsement of reflexivity as the fourth and last of the 'tenets' for the 'strong programme in the sociology of knowledge' (see *Strong Program, in Sociology of Scientific Knowledge*):

In principle [the strong programme's] patterns of explanation would have to be applicable to sociology itself. Like the requirement of symmetry, this is a response to the need to seek for general explanations. It is an obvious requirement of principle because otherwise sociology would be a standing refutation of its own theories (1991, p. 7).

Here, Bloor's positive support for reflexivity is a matter of logical consistency and a creative way of managing the self-refutation charge. Rather than deny the reflexive applicability of the strong programme, he emphasizes it, secure in his understanding that the socially constructed character of all knowledge, including his own, does not count against its validity. Bloor's reflexivity, however, remains at this 'in principle' level. His negative attitude to any empirical instantiation of his reflexive programmatics is documented in a text that claims to be precisely that (Ashmore 1989). Thus for Bloor (as well as for his former 'Edinburgh school' colleague Barry Barnes 1974, Epilogue), reflexivity is an argument used to defend a position; it is certainly not a practice.

2.2 Harry Collins: Special Relativism and the Ban on Reflexivity

Not so for, perhaps, the most influential writer through the heyday of SSK (ca. 1975–90), Harry Collins (e.g., 1985). Collins's doctrine of 'special relativism' separates the natural world from the social world, and the distinctive tasks and 'natural attitudes' of the natural scientist from those of the social scientist. The sociologist of scientific knowledge should treat the natural world as socially constructed, while treating the social world as 'real' and a source of sound data. However, this sense of 'realism' is taken from a reading of how natural scientists act towards their realm of inquiry, namely, the natural world. In effect, what Collins is doing here is to deny the practical relevance of the purported reflexive similarity between subject and object in SSK for purposes of the conduct

of research. The result is the short-circuiting of attempts to apply Collins's conclusions about, for example, the replication of experiments to those conclusions themselves (nevertheless see Mulkay 1985, Chaps. 4 and 5, Ashmore 1989, Chap. 4). In short, Collins's 'management strategy' for reflexivity is to ban it altogether. This radical solution to the problem of reflexivity has laid Collins open to charges of inconsistency from both wings of the 'realist-relativist' continuum. The recommended moves for repairing this perceived inconsistency differ, however, with the 'realist' suggesting he abandon his problematic relativism about nature, and the 'more-radical-relativist' proposing the dropping of his social realism (see *Technology, Social Construction of*).

2.3 Relativist Consistency, Radical Reflexivity: The Reflexivists

In the late 1980s, a small number of 'full-blown' reflexive texts were published (Ashmore 1989, Mulkay 1985, Woolgar 1988). This group of writers became known as 'reflexivists.' Ashmore's *The Reflexive Thesis* is an SSK study of SSK, a general exploration of reflexivity, and an experiment in 'new literary forms.' Mulkay's *The Word and the World* is a series of 'explorations in the form of sociological analysis' that draws upon analyses of biochemists' discourse. Woolgar's *Knowledge and Reflexivity* is a collection of papers from a small group of regular contributors (including Ashmore, Mulkay, and Woolgar) to the Discourse and Reflexivity Workshops held in the UK in the early 1980s. What links all these texts together, apart from their authors' close socio-cognitive relation, is the common attempt to treat reflexivity as an opportunity; even, for celebration. What happens when one stops evading reflexivity, when one looks 'the monster' in the eye, when one gives it a place at the heart of the research process? Self-destruction? Massive irrelevance? Third apocalyptic simile?

Bruno Latour's contribution to *Knowledge and Reflexivity* (Latour 1988) is its exception. Latour argues that the 'meta-reflexive' writing strategies of the reflexivists is a solution to a false problem: the naiveté of readers who believe too much and too easily. On the contrary, the real problem that (scientific, factual) writers have is being believed, or indeed, read at all. Latour further claims that the reflexivists are searching, despite their own gestures at weakening their authorial privilege, for the final meta-level that leaves no remainder and from which vantage point, everything may be taken into (their) account. As an antidote to all this, Latour recommends a strategy of 'infra-reflexivity': just to tell stories, drawing upon the richness and variety of all the 'ordinary' resources available. Latour's *Aramis* (1992, 1996)—despite its appearance as an experiment in 'new literary forms'—is, perhaps, an example.

3. Criticisms: Pitfalls and Pratfalls

Reflexivity gets you nowhere. It is not a useful thing to do and its results cannot be used. It is impractical. As an activity, it immobilizes you. It leads to idle navel-gazing and foolish self-absorption. It is 'all pots and pans and no pudding' (Bloor, cited in Ashmore 1989, p. 20). Logically, it leads to the abyss of the infinite regress or the never-ending search for the perfect meta-level. Reflexivity is politically and morally irresponsible games playing, fiddling while Rome burns. It has no soul (to bare) and no wisdom (to distribute), just an overdose of clever-clever irony. It disables criticism by taking that role on for itself; in its attempt to play all the roles of the academic community at once, and all by itself, it betrays itself as deeply, and ironically, anti-social. Indeed, it appears to seek nothing from its readers but a kind of 'aesthetic' admiration marked by a knowing, and smug, and boyish, amusement.

However, for the larger STS community, reflexivity has had positive functions and effects. The reflexivist fulfils the important role of the jester at the court of STS. Moreover, the presence of reflexive work as part of the 'canon' of STS acts as a corrective to a kind of methodological overconfidence resulting from the recent success of the field. Reflexivity reminds us that the fundamental epistemic questions and quandaries that originally animated SSK are permanent features of the practice of 'inquiry into inquiry' epitomized by STS scholarship. The text that aspires to 'transparency,' that is blithely unconcerned with the conditions of its own production, is now, at the very least, 'visible,' a member of a marked, rather than unmarked category.

4. The Current Situation

If the work of the reflexivists is taken as the model for 'adequately' reflexive work in STS, then it has to be said that this style has been taken up on very few, if any, occasions between 1990 and 2000, Latour's *Aramis* (1992, 1996) being a possible exception (see Sect. 2.3). Nevertheless, interest in reflexivity has not vanished. Explicit discussions still appear (e.g., Pels 2000, Lynch 2000). Indeed, it can be argued that some new currents of work in STS appear animated by reflexive concerns, though couched in a new register. For example, the emphasis on the performativity of social objects, on the multiplicity of ontologies, and on the essential situatedness of (their and our) knowledge production, found in the work of John Law, Anne-marie Mol, and others attempting to move beyond actor network theory (Law and Hassard 1999) is implicitly deeply reflexive.

Reflexivity: Method and Evidence

Unity of Science, sometimes referred to as logical positivism, is the dominant paradigm in social science. It assumes a fundamental unity between the physical and social world, and the applicability of the same model of science and scientific inquiry. This unity derives from the belief that reality is ‘out there’ waiting to be described. The goal of science—physical and social—is the discovery of universal laws that allow us to predict and explain according to causes that are contained in the laws or some less demanding ‘mechanism.’ Reflexivism is a catchall term for a variety of approaches that deny that the main task of a social science is prediction or the discovery of universal laws. The world, and especially the social world, is not a container of things that have to be captured by our concepts, but is to a large degree constituted by our descriptions and theories. For this reason, most reflexivists see fundamental differences between the physical and social worlds and believe that our task in the latter is understanding (*verstehen*), and only secondarily, or derivatively, explanation (*erklären*).

According to Hans-Georg Gadamer, the principal difference between the natural and human sciences, is

not one of method but of the aims of knowledge (Gadamer 1987, Schutz, 1973a). Despite this fundamental difference in purpose, reflexivism and the ‘mainstream’—our shorthand for social scientists who embrace the unity of science position—share a significant number of methodological practices. These include a clear differentiation of premises from conclusions, respect for the canons of inference, recognition that some standards of validation must be established for data and source materials, differentiation of correlation from cause; the recognition of spuriousness problems when we rely on correlations, reliance on logic in establishing warrants for our assertions, and the belief that all findings can be contested. The deeper division about method is *within* the reflexivist community, between phenomenological, interpretivist, and hermeneutic approaches on the one hand and some postmodern or critical approaches on the other which do not subscribe to the above criteria. Jean-François Lyotard (1987), a representative of the latter tradition, asserts that ‘narrative knowledge certifies itself in the pragmatics of its own transmission without having recourse to argumentation and proof.

Because reflexivists are concerned with the social order and its reproduction through the behavior of actors, they have to be attentive to questions of context and meaning within which these actions take place. Context and meaning are principally shaped by language, and reflexivists accordingly recognize the importance of norms and problems of interpretation. This recognition has important implications for the constitution of facts and their evidentiary value, the problem of truth and its role in ‘theory- building.’

1. First: What is Evidence

Alfred Schutz (1973a) observed that all facts are created by cognitive processes. John Searle (1995) distinguished between ‘brute,’ or observable facts (e.g., a mountain), and ‘social,’ or intentional and institutional facts (e.g., an encyclopedia article). For the mainstream, facts are created by interpretation because they need to be detached from their context by intellectual abstraction. For reflexivists, they need to be considered in their particular setting. Neither the mainstream nor reflexivists can describe, let alone explain and theorize, without importing meaning. Reflexivists accept this as an epistemological given, not a corrupting intrusion to be ignored, controlled for, or explained away. Mainstream approaches, especially quantitative ones, often seem oblivious to the complications that arise from the impossibility of a pure empiricism. James Coleman has nevertheless shown that every measurement procedure that assigns a numerical value to a phenomenon has to be preceded by a qualitative comparison. While the assignment of

Table 1

What is evidence?

A	Mainstream—the observed, including the effects of social structures on behavior
B	Phenomenologists—subject's observations of self and structure
C	Interpretivists—B + observations of structure and subjects through each
D	Hermeneuticians—C + observer's relationship with subject and structure

numbers may permit powerful mathematical transformations, it is illicit to make such assignments if the antecedent qualitative comparison has not or cannot be completed (Coleman 1964). It is here that reflexivist and mainstreamers clash. The latter trying—illegitimately in the eyes of reflexivists—to apply the traditional measurement techniques and scientific operations to the social world, while the mainstream assert that even if the preconditions for successful measurements or causal modeling are not present, the 'scientific method' should serve as a regulative idea (see Table 1).

For the mainstream, the reality that matters most is usually that of the theorist who looks at the facts from an 'objective' point of view. Phenomenology, interpretivism and hermeneutics emphasize the subject's story, but treat this evidence differently. Interpretivists may or may not situate themselves in their own account of the evidence, whereas hermeneuticians are consistently reflexivist. Hermeneuticians may treat the social structure as a more or less autonomous evidence, and may or may not become evidence themselves as a result of changes they experience through the act of interpreting the subject.

The first move of the interpretivist is phenomenological. It is to gather inductively evidence that allows [the researcher] to evaluate the problem as understood by the actor (Ricoeur 1984, Berger and Luckmann 1966). This is not significantly different from applying a garden variety decision making approach to a social science problem. But the reconstruction of an actor's perspective and understanding may be only the first step. Treatments of evidence acquire validity when the subjects themselves recognize that understanding as adequate (Schutz 1973b, p. 64). Researchers must read back their interpretations to those who have been interpreted. This standard of validation is not uncontested, as it too is based on imputation. Paul Ricoeur insists that such interpretations as 'configurational acts'—might *not* be intelligible to the actors themselves, since they represent constructions that no actor or witness could have put together when the events occurred (Ricoeur 1984, p. 157).

Why not just ask people what their statements and behavior mean? Interpretivists and hermeneuticians

insist that unobservable social structures exist in all social contexts, and make the meaning of a peoples actions and words not theirs alone to interpret or control (Ricoeur 1971). The researcher's task is to reproduce both the subject's actions *and* the encompassing frames and social structures within which this action took place. Imagine asking a white woman why she moved her handbag from one side of her body to the other when a group of black men were approaching on the other side of the sidewalk. She would probably deny her action was racist. But irrespective of her actual intentions, her behavior may have reproduced a particular racist structure by typecasting those young black men as potentially dangerous felons.

Hermeneuticians go a step further and insist that the role of researchers must be included in accounts of actions. (That this is a big step away from and beyond phenomenology is obvious in Schutz's (1973a, 1973b) uncritical treatment.) Researchers must comprehend the evidence through their own conceptions, while simultaneously realizing the perspectives of actors (1973a, pp. 104–11). Gadamer describes this process as placing oneself in the position of the other not to generate empathy or to better apply one's own criteria, but to attain a higher universality that overcomes, not only our own particularity, but also that of the other. This is the fusion of horizons of observer and subject (Habermas 1994). The hermeneutic assumption of intertextuality calls for an understanding of an actor's story in its complete relationship to all other stories available in a site, as well as in its relationship to the observer.

2. *Second: Where is Evidence Found?*

In a certain sense it is unfair to compare main stream and interpretivist evidence selection strategies, because they have different objectives. The mainstream wishes to test theories, interpretivism intends to generate understandings. Reflexivism wants to expand the field of inquiry. Instead of focusing only on 'why' questions that automatically privilege causal accounts, reflexivists insist that 'how possible' and 'what questions are also legitimate objects of inquiry. 'Why' questions direct attention to the antecedent causes in a phenomenon, whereas 'how possible' and 'what' questions are what makes a phenomenon what it is. (For a fundamental discussion of the differences between 'what' and 'why' questions, see Alexander Wendt 1999.) Reflexivists who study sovereignty are not interested, at least not primarily, in what brought it about but rather in the generative logic of the concept, its various instantiations in institutions, and the constraining and enabling force of its norms that allow actors to reproduce domestic and international structures.

To the extent that mainstream rules are designed to promote the assessment of alternative theoretical

accounts of a phenomenon, whether in a single case, or across some universe, they do not address interpretivist concerns. Because reflexivists do not usually engage in the competitive testing of theories, they are on the whole uninterested in the method of difference, crucial cases, and statistical significance. While the mainstream generally treats the knowledge of what constitutes a case as self-evident, reflexivists contend that case selection pre-judges 'facts' not yet in evidence.

This difference in orientation has implications for the choice of methods. While the mainstream stresses the deductive rigor in the models they employ, or the somewhat more problematic justifications for inductive inference, reflexivists stress the role of analogies and of conceptual frames that are antecedent to any causal argument or inductive inference. Given its choice of methods, the mainstream must consider counterfactual alternatives to which it rarely assigns 'weight' to the several causes considered relevant and apply the standard statistical controls to large enough samples whose cases are independent of one another. In practice, the mainstream decision rules that establish a warrant for a particular interpretation resemble more a procedure of sequential exclusion of alternatives than a 'deductive' demonstration or a generalizing inference.

Reflexivists do not believe it possible to establish complete analytical or theoretical control over a subject and consequently regard the 'bivalence' principle of logic (either something is so, or not so, and no third possibility exists) as generally inapplicable. The best our explanations can do is offer plausible accounts, even though some accounts might be more persuasive than others. Here a variety of criteria might interact and any proposed solution is not only 'preliminary' but contestable from the outset. By reversing the default drive of the mainstream theorists, who believe that a case or subject is theoretically identical until shown to be meaningfully different, reflexivists *assume* such differences among subjects until they can be persuaded otherwise. Reflexivists expect to find heterogeneity in their evidence; this is not a problem to be solved, but justification for emphasizing interpretative methods. They do not expect to find evidence that would allow predictions about future behavior within a case, let alone about a class of subjects across the historical universe. They argue that their stance allows for a more appropriate heuristics and thereby for a stronger warrant for their assertions. Reflexivists also believe that the traditional trade-off between rigor and detail misstates the underlying epistemological problem.

To elaborate on this last point, let us consider the problem of predictive success as a warrant for 'science.' Some mainstream approaches assert that the only warrant for a theory is predictive success, and that concern for the appropriateness of characterization is misguided. Reflexivists—scientific realists as well as

logical positivists—counter this claim by pointing out that accurate predictions are sometimes made by demonstrably false theories, and that making predictions the only criterion for warranted knowledge discourages *systematic* search for mistakes when predictions fail. To that extent we are in danger of substituting *ad hocery* for disciplined inquiry. In short, reflexivists recognize control as a problem that is very hard to solve, and so reduce their claims about their theoretical constructs. The mainstream tends to see control as a technical problem, and so does not adjust its aspirations and expectations about evidence. (See, for example, the high level of attention 'omitted variable bias' receives in King et al. 1994, pp. 168–82, but how easily it is expected to succumb to simple techniques. On p. 172, we are reassured that it is possible to account for omitted variables because 'fortunately, in most cases, researchers have considerable information about variables outside their analysis.' Interpretivists recognize that such information is often impossible to obtain.)

3. Third: Evidence and Theory-building

The secret to mainstream confidence in using evidence to *test theories* and develop generalizations for use in other places and times is the implicit assumption of uniformity. This assumes that things, concepts, and people are meaningfully identical across time and space. Votes are votes, wars are wars, and power is power—everywhere and for all time. (This problem has long been recognized in political science. In 1970, Giovanni Sartori pointed out the perils of doing comparative research. He warned against 'stretching' the meanings of variables across contexts in order to achieve some contrived generalization.) Some mainstream scholars acknowledge that unit homogeneity is often impossible to attain, but argue that understanding the degree of unavoidable heterogeneity helps to estimate the degree of uncertainty or likely biases of inferences (King et al. 1994, pp. 93–4). They allow the theory being tested to determine if a feature is meaningful. But what if the theory—and in social science this is virtually always the case—is not perfectly specified so as to avoid omitting a meaningful source of variance?

For reflexivists, this misstates the problem and so offers a misguided solution. If we knew which untheorized features of the field were relevant to understanding social outcomes, presumably we would have accounted for them in the *a priori* theory. Reflexivists see no solution to this problem because it is impossible, logically, empirically, and theoretically, to specify a causal model that could possibly account for everything that is excluded outside its boundaries, and everything that is purportedly causally effective within those boundaries. Nevertheless, reflexivism is subject to the same tension between homogenization and

uniqueness. It objects to mainstream homogenization without often explicitly acknowledging that it also uses forms of homogenization to make sense of the social world. *Intersubjectivity* is really a way of homogenizing various parts of society or of historical developments through common webs of meaning. This is why common understandings and the practices based on institutional rules are so important. If people understand the same social practices in the same way, then they offer an example of sameness, of homogeneity or at least of comparability. It should be clear that we are not dealing with 'constant conjunctions' à la Hume, or antecedent (efficient) causes as in mainstream analysis. Common understandings or norms that are constitutive of practices (institutions) do not cause 'behavior.' They may provide weighty reasons, guide or inspire behavior, rationalize or justify it, or they may be ignored. They do not effect cause in the sense that a bullet through the heart causes death or an uncontrolled surge in the money supply causes price inflation (Kratochwil and Ruggie 1986, p. 767).

Reflexivists need a methodological technique to deal with both difference and similarity. (The difference between positivist and reflexivist homogenization of social reality is that positivism simply assumes homogeneity or uses prior theoretical categories to impose it on difference, while reflexivism theorizes about and uncovers homogeneity, treating it as a social phenomenon to be discovered and understood, not as one to be assumed and inflicted; see Habermas 1994, p. 108.) The image of a text, requiring both interpretation and an audience to which it is addressed and which brings to it certain pre-understandings that frame it, provides here their heuristic metaphor. Instead of viewing actors as simple 'throughputs' for norms and institutional rules, reflexivists point to the constraining and enabling functions of norms that cannot be reduced to a structure that determines behavior. Here the term 'actor' who has to act out or perform something rather than serve as a 'mechanism' or conveyor belt of forces is an alternative metaphor with considerable heuristic power. Reflexivist interrogation of mainstream homogenization is not always successful, but encourages us to guard against ad-ducing identity where meaningful difference exists and vice versa.

The differences between the mainstream and reflexivity on this issue are easily observed when we consider how each handles the anomaly, a piece of evidence that confounds its theory or understanding of some phenomenon. The mainstream response is similar to how nineteenth century naturalists and anatomists dealt with physical 'monstrosities.' Rather than indicating systematic chaos or contingency, an interpretation with which reflexivists would feel comfortable, these anomalies instead provided opportunities to reaffirm the natural order and to define it with more precision. They were incorporated into more elaborate and powerful taxonomies (Ritvo 1997, p.

137). (Based on an empirical evaluation of the history of science, Pierre Duhem 1962) pointed out the power of prior theories, methodological commitments, and other elements of the scientific project to ensure the rejection of anomalous findings. Lakatos, Kuhn, and Feyerabend have also offered different accounts of why theories are so sticky in the face of countervailing evidence. As if these were not sufficient, there are excellent motivated and cognitive reasons to restore balance and persevere in ones prior beliefs.) While interpretivists try to place any given historical event within a narrative, within a contextualized bounded social structure, the mainstream places that same event within the framework of an opposition between the particular and the universal (Ricoeur 1984, p. 112). It treats the historical event according to whether it is part of a more general story to tell about the world, or an idiosyncratic 'outlier' that needs to be explained away.

Mainstream theories are sticky, in the Lakatosian or Kuhnian sense. Single pieces of contrary evidence do not and must not be used to change the observer's account of the situation (Kuhn 1970). But, ironically, and perhaps only in this regard, reflexivism is truer to Popperian (logical) positivism than the mainstream which adopts the practical and sociological defenses of Lakatos and Kuhn. Popper offers an account of falsification that resembles that of an open market or Darwinian system. Explanations fail when they are no longer competitive, according to established falsification criteria, relative to the other available explanations. In other words, one's understandings are far more responsive to new evidence, no matter how anomalous, than would be the case in either a Lakatosian or Kuhnian world. The product could be called a relative working truth, or, as Popper called it, 'situational certainty' (Popper 1979, pp. 78–81). It is a relative truth in that its validity exists only in comparison to other possible accounts. It is a 'working truth' in the sense that its validity is acknowledged to be a pragmatic convention, rather than an absolute fact that is simply part of the world.

Since we never test our theories against a reality, but only against other theoretical interpretations of the world, two additional problems arise. The first is that truth is no longer a property of 'the world out there,' but of theoretically informed assertions for which we need warrants. Consequently, the bivalence principle that links data and theories is no longer applicable, since most questions in science remain undecidable. This makes all scientific statements subject to revisions and introduces a second important element of pragmatics into theorizing. A statement, or 'fact,' is true only in the sense that can be accepted in daily practice until something more satisfactory comes along. It is a 'truth' in the sense that it is believed to be contextually valid, within the prior two constraints.

Reflexivism is doubly Popperian. It resists both theoretical priors, sociological and institutional con-

sensus, and motivated and cognitive impulsion toward premature closure. It treats every anomaly as if it is, at least potentially, meaningful. (Of course, Popper was never the naïve falsificationist who argued that a single disconfirmation meant the abandonment of the imperfect theory. Disconfirmation had to be accompanied by an alternative theory that could account for all that the failed theory had accomplished, and then some.) The mainstream, on the contrary, rejects treating every disconfirming instance as a serious challenge, instead appearing to don the protective belts offered by a Lakatosian research program, or the Kuhnian mantle of normal science toiling on within a settled paradigm.

Reform: Political

In its most ordinary sense, political reform is any departure from the status quo that a proponent believes or represents as an improvement. But if reform is defined as those changes that democratic political systems have adopted in order to improve the legitimacy, accountability, and efficiency of modern government, it is possible to identify some common core values and reform actions in advanced democratic states. A recent survey of the 29 member states of the Organization for Economic Cooperation and Development (OECD) found that the most frequently stated public service values were (in order): impartiality, legality, integrity, transparency, efficiency, equality, responsibility, and justice (OECD 2000). Since to date less than half the OECD countries have explicitly adopted the last five of these core goals, they constitute the political reform frontier.

Democracies incorporate core values into their legal frameworks in the form of statutes, constitutions, civil service regulations, and public service acts. Reformers seek to change the legal framework in order to better realize one or more of the core values. The three main sources of these core values are general democratic principles (i.e., values consonant with systems in which citizens ultimately control governments), professional norms (i.e., standards for those who assume roles in the government), and prevailing ethical systems (i.e., societal conceptions of appropriate behavior).

The OECD survey discovered that impartiality is the most common core value held by its member states. This is defined as acting in a neutral or objective manner when dealing with various citizens and groups. The central idea embodied by this value is that states should not be partial towards specific persons in the administration of their laws. Examples of modern reforms that aim to increase impartiality are the creation of a neutral civil service, merit reviews for public employees, rules for bidding and winning public contracts, and judicial independence. It is not surprising that this is the most commonly stated value in advanced democracies. A government that administered its laws in a biased or partial fashion could not possibly act in the public interest. Partiality undermines democracy (by favoring the interests of the few over the majority's will), administrative professionalism (by violating the trust that citizens have in the government to act on their behalf), and conventional ethical norms (fair treatment as practiced in civil society).

Granting the importance of impartiality to modern governments, there is a serious debate as to how far impartiality should extend in public life. Elected officials and their top policy advisors are expected to represent the groups and individuals who put them in office so some forms of 'partiality' are routinely accepted in modern democracies. The key reform questions occur over when partiality is permissible and at what levels of government. In general, those who make policy are allowed to be partial to parties, constituents, and key support groups, while those who implement (i.e., public administrators below the highest levels) and those who interpret the laws (i.e., the judiciary or regulators) are expected to be more strictly impartial. But there is considerable cross-national variation in this rule as exemplified by the differences between the American and British Civil Service traditions (Kaufman 1956).

Closely related to the first value is a second: legality (a stated value in 22 of the 29 OECD countries). Legality means that decisions are incorporated into published laws and codes, and that there is due process protection for individuals when governments make decisions. It would be rare to find unpublished laws in advanced democracies although many, for instance, provide for relatively unlimited emergency powers in crises. More commonly, the reform focus is on due process—i.e., what constitutes a fair hearing for individuals who might be affected by government decisions. The problem with due process is that it can create highly complex and slow proceedings, greatly adding to the expense and untimeliness of government decisions. In politics like the USA where judicial due process is highly developed, reform means finding ways to adjudicate matters more informally and expeditiously (Kagan 1991), and in politics where due process is lacking, it might mean adopting an administrative procedures act (i.e., Greece and Portugal).

Integrity, the third most commonly stated value among OECD nations, is the subject of the most heated reform debates. It means that public office holders should not place their own interests above the public interest in the performance of official duties. When they do, this is usually considered corrupt behavior (Rose-Ackerman 1999). The most common forms of corruption are bribery, conflict of interest, extortion, and personal enrichment. Bribery is the exchange of something of personal value for the performance of an official act (Lowenstein 1985). It is almost universally proscribed in advanced democratic societies, but can take increasingly subtle forms. Hence, some bans on gifts, honoraria, and post-public service employment are attempts to prevent potential quid pro quo exchanges that might distort the judgment of public officials.

In the USA, this has led to increasing conflict of interest regulation, the purpose of which is to remove interests that might potentially seem to be corrupting (McAlevy 1988). Hence, officials have been required to

recuse themselves from participating in decisions that might directly and materially affect them. Alternatively, they might be asked to place their assets in a blind trust or even sell off potentially problematic holdings to prevent potential corrupt motives. Extortion and personal enrichment occur when public officials exploit the monopoly that the state has over some decision or service in order to extract rents. Some reforms that deal with this type of abuse include prohibitions against the unauthorized use of official or personal information, criminal penalties for those who misuse their office resources, anti-nepotism laws, limitations on accepting gifts, penalties for the failure to perform prescribed duties, bans against illicit enrichment, and laws against impeding or interfering with the public procurement process.

Corruption is a critical area of political reform. In Mexico, it has been a key issue for decades, and ultimately played a role in the *Partido Revolucionario Institucional's* demise in the 2000 national Presidential election. In the USA, anti-bribery logic has been widely incorporated into the campaign finance reform debate. As the modern state has assumed a wider regulatory and service provider role, the potential to use the state for corrupt purposes has grown. Nations that seek to enter into closer trading and political associations with OECD nations are under considerable pressure to address their unresolved corruption problems.

Another hotly contested area of political reform is transparency. Transparency (meaning the openness of the government to citizen observation and participation) is valued both for its own sake and for its instrumental value in promoting other core values. Full disclosure of government information helps to produce a more informed citizenry, which is a good in itself if it improves the quality of electoral decision-making. At the same time, full disclosure fosters greater accountability in the sense that it makes it harder for public officials to act in particularistic and corrupt ways without the public finding out and voting them out of office. Similarly, public participation can be beneficial to citizens, but also to the agency and decision making bodies that must make choices affecting real lives.

The most common transparency reforms are open meeting laws and freedom of information requirements (Thompson 1987, pp.116–122, Pupillo 1993). In the case of the former, so-called 'sunshine' laws require that the public and press be notified of impending meetings in which decisions might be taken. Citizens are given time to comment on the contemplated actions, and votes and discussions related to the meeting must be held in the open. 'Freedom of information' statutes require the government to release documents and information upon public request. Almost all advanced democracies have some restrictions on the release of confidential information that might compromise national security, police

actions, or personal privacy. As before, one can find considerable variation among advanced democracies. The Official Secrets Act in Great Britain gives government ministers much more ability to resist the disclosure of information that would be potentially damaging or embarrassing to the government. At the other extreme, some states in the USA have placed the right to request government information into their state constitutions.

The fifth value is efficiency. It is fair to say that this is a more contemporary reform goal. In an earlier period, public sector behavior was focused on the impartial administration of rules and programs, while private sector behavior was driven by market forces and profit. In the latter half of the twentieth century, private sector norms have been imported into public sector thinking. Government has been 'reinvented' to be more consumer-oriented and efficient. Efficiencies can be achieved by fostering competition through the contracting out of service activities to private firms, the promotion of inter-agency competition, and the benchmarking of government performance linked to outcome based rewards. One of the large issues this trend raises is whether accountability can be retained when activities are given over to private sector agents (OECD 1999).

Accountability is the ability to hold public officials responsible for their actions and decisions. Transparency is essential to a system of accountability in the sense that the public needs to know what officials are doing in order to hold them responsible for what the government does. While necessary, however, transparency is not sufficient for accountability; i.e., the public needs to be able to reward and punish officials for the consequences and quality of their actions and decisions. In democracies, this means that voters must have the ability to vote out incumbents who fail them (i.e., hence the need for truly competitive elections) and elected officials must be able to control the actions of those who administer the laws.

The problem that arises in advanced democracies is that incumbent officials and administrative officials often enjoy electoral advantages and legal protections that insulate them from the need to be highly responsive to public demands. In the USA, term limitations for legislators and campaign finance reform are seen as means to increase turnover and responsiveness. Critics charge that this greater responsiveness is purchased at the price of lower expertise and weaker judgment (Cain and Levin 1999).

The last two core values are equity and justice. Equity can mean either procedural or substantive equality. In the US for instance, the equity principle led to the 'one person, one vote' doctrine of the Supreme court—essentially requiring that all districts that elect officials for general governmental bodies must be equally populated to avoid diluting the vote of one individual vs. another. It also informs the desire to place limits on campaign contributions so that the

voice of one constituent is not unequal to that of another because the former has more wealth and resources than the latter (Cain 1995). The preoccupation with equity is stronger in the US than in most other advanced democracies.

Justice, on the other hand, refers to the substantive fairness of decisions that the government makes. Reform at this level begins to conflate with ideology, focusing on the government's obligation to make laws that provide positive opportunities for its citizens. Parties of the left and right will see these issues differently, and reform for one party can mean undoing the reforms of the other. The most general formulation that can be given to justice is that the laws accord with the common ethical and moral norms in civil society. Hence, where there is consensus in civil society about these norms, justice can be elevated beyond the merely political to broadly accepted goals.

1. Perspectives on Reform

This review of core values among OECD nations and the reforms that track those values is certainly not comprehensive. It merely illustrates the most common concerns. Apart from the debate over each of them, there are general differences among advanced democracies in reform orientations. They relate to the three sources of core goals: democratic, professional, and private ethical values.

With respect to the first, democratic values, there are important differences between those who interpret more democratic to be more majoritarian and those who resist such a formulation. American populists for instance prefer reforms that put more power directly in the hands of voters and less in the hands of elected and unelected officials. Neo-Madisonians in the US see popular control as lacking in the requisite checks against majority tyranny and in the expertise that representative government affords. Advocates of parliamentary systems prefer leaders to be chosen by (and therefore tied more directly to) other elected officials, and that the public show more deference to those in public office. Clearly, the position a society takes on this dimension strongly influences reforms that affect accountability, transparency, and equity.

Perspectives on professional values also shape modern governmental reforms. Systems that rely heavily on the socialization and training of public officials will tend to rely more on codes and internal monitoring (e.g., the British Civil Service). Politics that view professionalism as elitist or that are skeptical that people can be educated to high levels of public service, will rely on external checks and legal regulations (e.g., the American system).

There will also be important differences in the perspectives of those who believe that public ethics derives directly from private ethics vs. those who believe that the two differ in important ways. In the

view of the latter group, public officials need to be held to a higher standard and to ever growing scrutiny. In the view of the former, the two sectors can be analyzed within the same framework, and lessons learned from one sector can be imported to another. The shape of reforms to come will be determined by how future reformers situate themselves on these three continuums.

Reformation and Confessionalization

1. The Reformation or 'Temps des Réformes'

The term 'Reformation' traditionally refers to those events and changes which in sixteenth-century Europe originated in church and theology and then took hold of the social, political, and cultural order, reorienting the thinking and behavior of individuals as well as social groups. From this point of view, the originator of all these changes was the German Augustinian friar Martin Luther (1483–1546), who published his 95 theses against the system of indulgences on October

31, 1517. This date was for the first time celebrated by Protestants as a secular holiday in 1617, and has since the nineteenth century been celebrated yearly as 'Reformation day' in countries all over the world. This chronological, geographical, and theological restriction to Luther and 1517 corresponds neither to the historical facts nor is it confessionally or historiographically undisputed. Rather, it is the result of a double interpretation: on the one hand, the contemporary heroization of Luther by his adherents or his demonization as arch-heretic by Rome and Roman Catholic countries like Spain (the Reformation as *pestis Germaniae*), and on the other hand, the monopoly on interpretation by the Lesser German (*klein-deutsch*) Lutheran historiography, which gained worldwide acceptance, particularly in the United States. This interpretation continued to influence the so-called Luther Renaissance of the 1920s and 1930s.

After World War II Reformation historians became less deeply rooted in confessional traditions, and a pluralism of methods and theories gained acceptance in historiography. As a consequence, the traditional 'Lutheran restriction' (*lutherische Engführung*, Bernd Moeller 1998) lost influence, and the Reformation increasingly appeared as a chronologically and geographically wide-ranging phenomenon, as a 'temps des Réformes' (Jean Delumeau 1997), a period of change from the medieval *societas christiana* to the differentiated, multi-confessional society of the early modern period. It increasingly appeared as a period of several centuries, in which the Reformations of Luther, Zwingli, Calvin, and all the other sixteenth-century reformers represented an important phase which accelerated a long-term development. Under the specific historical and historiographical conditions of English history, there was recently also developed a revisionist historiography, which on the one hand proceeds from the assumption that there were a number of 'Reformations' in sixteenth-century England and which on the other hand stresses the continuity of late medieval conditions in church and religion, particularly in popular religion (Eamon Duffy 1992, Christopher Haigh 1993).

To describe the meaning of 'Reformation' in current scholarly discussions as well as from a broader cultural perspective, three main dimensions should be distinguished: first, the historical events; second, the myth of the Reformation in Protestant and 'Western' self-understanding and self-assurance; and third, the historiographical concepts and the main issues of current research.

2. The Historical Context

On the one hand, there were new beginnings in theology, piety, spirituality, and the social manifestations of religion in the highly urbanized zones of late medieval Europe, above all in Italy, in the

Netherlands, in central Europe including Bohemia, in England, France, and Spain (the reform crisis around archbishop Cisneros, 1436–1517). In the context of the Humanism of the *Devotio moderna* and similar currents of thought, the laity acquired a more important role in the church, rational forms of church service (preaching) and religious behavior were strengthened, and a ‘normative centeredness’ (*normative Zentrierung*, Berndt Hamm) as well as an organizational and spiritual formation set in.

On the other hand, decisive changes occurred in the organization and administration of the church as well as in the relationship between state and church. The development of early modern national and territorial states led to a regionalization—but not yet to a division—of the universal church into ‘national’, territorial, or town churches, in which the secular governments gained control over the church of their respective territories either through concordats with the Pope or through a revolution (as the Hussites in Bohemia).

The Roman curia had also changed dramatically since the fourteenth century, because of the formation and bureaucratization of its administration and because of the triumph of monarchical papalism over conciliarism after the Council of Basel. Recent research on the papacy therefore considers Rome to have been more advanced on the path of modernization, and sees Luther’s Wittenberg Reformation as the result of a crisis of modernization in a remote, backward area of Christendom. Through Luther and the other reformers the religious and ecclesiastical changes received a new direction, legitimacy, and dynamism, which since the middle of the sixteenth century also took hold of the Roman Catholic church and changed it further. In particular the *sola* formulas—only through faith, grace, and the reading of the Bible could human beings be justified before God (*sola fide, sola gratia, sola scriptura*)—focused the different reform attempts in a new and unique way. The widespread church criticism of the late Middle Ages was put on a new foundation. Medieval, accidental anticlericalism developed into early modern fundamental anticlericalism. The popes and the clergy were no longer criticized only for the neglect of their duties, but it was claimed that the priests and the pope were superfluous as intermediaries between God and human beings: indeed, that they were harmful to the salvation of the individual, the community, and society as a whole. In this way, the pope and the Roman church were—in the eyes of their opponents—for the first time completely de-legitimized and unmasked as the Antichrist.

This also meant that the state or other secular governments (town councils, estates, etc.) gained more power over the church. When there was no longer a difference between clergy and laity, the prince could claim to be *praecipuum membrum ecclesiae* (privileged member of the church) and administer and govern the

church as *summus episcopus* or ‘supreme head of the church.’ In the late Middle Ages, there existed territorial or national churches within the universal church. With the Reformation, Protestant territorial or state churches which no longer belonged to a universal church came into being.

Luther’s appearance (above all at the Imperial Diet of Worms in 1521), Zwingli’s appearance in Zurich, and Calvin’s appearance in Geneva in the 1540s, but also the appearance of several other reformers who had their own ideas about theology and church policy, thoroughly changed the intellectual and religious climate and opened up new perspectives in state and society. The printing press became decisive for the quick dissemination of the new teachings: not only were the writings of Luther and other reformers published in print runs of hundreds of thousands, but the mostly illustrated broadsheets constituted a new medium of mass communication. In this way, not only the intellectuals, the political elites, and the princes were seized by the new visions and ideas, but also the lower nobility, the burghers, and the peasants. In the Holy Roman Empire, the Reformation was a mass movement which climaxed in the rebellion of the imperial knights (Sickingen, Hutten), the Peasant’s War of 1525/26 and—until the 1540s—in burgher movements in the imperial and territorial towns.

Because of the close connection between religion and society in old Europe, the Reformation of the church inevitably led to a reformation of the political and social order. In this context, the idea of a communal church, decisively influenced by the laity, had a strong appeal. In the secular sphere, this corresponded with corporative (estate), communal, or republican (urban) concepts of order defended by the knights or the urban and rural communities (*Gemeinderreformation*, communal Reformation). Later, comparable reform movements occurred in the Netherlands, France (nobility and towns, above all in the south), Poland (nobility), with considerable delay also in England (in the seventeenth century, above all in London and among the gentry). These communal movements only had a lasting success in regions with favorable social, political, and constitutional preconditions, above all in Switzerland and the northern Netherlands.

In most of the states where the Protestant Reformation took hold, including the German territories, the princes and the officials of the central state defeated these Reformation movements of the nobility and the common man ‘from below.’ They took the Reformation into their hands and utilized it for their own interests, especially the formation of the early modern state and of an early modern society of disciplined subjects (*Fürstenreformation*, princely Reformation). As a consequence, early modern territorial churches (as in the Empire) or national churches (as in Scandinavia, England, etc.) came into being. These were increasingly staffed by a university educated and

married clergy, whose area of responsibility was identical with the territory of the respective state and who in numerous ways supported early modern state-building.

In this context, important developments were: First, the increase in funds and property assets through secularization; second, the extension of the activities of the state upon the so-called *res mixtae*, i.e., education, marriage and family, poor relief, and social welfare; third, the mutual strengthening of religious and political identities among the people; fourth, the increased legitimacy of the prince who as supreme head of the church or *summus episcopus* had a quasi-sacral quality; and fifth, the instruments of the state church (church discipline, visitations, sermons, and catechesis) which aimed at influencing the behavior and thinking of the people and which effectively supplemented secular forms of disciplining.

However, the climax of this connection between religious and political change was only brought about by the process of confessionalization between ca. 1550 and ca. 1650, which was a fundamental process of society on the basis of explicitly formulated confessions of faith. On the Protestant side these were the *Confessio Augustana* of 1530 and especially the *Book of Concord* of 1580 for Lutheranism, the *Helvetic Confessions* of 1536 and 1566 as well as the other 'national' confessions, but especially the *Canons of Dordrecht* of 1619 for Calvinism, the *Book of Common Prayer* of 1549, and the *Thirty-nine Articles* of 1563 for Anglicanism. By committing the subjects to a fixed set of norms concerning dogma, belief, and behavior, the different confessional churches became clearly delimited and this corresponded to a high degree of integration on the 'inside.' At the same time, the processes of formation in state and society became more dynamic and were given a new legitimacy.

As the Catholic church also went through such a process of confessionalization (based on the doctrinal canons of the Council of Trent, especially the *Professio Fidei Tridentina*), the Catholic and re-Catholicized countries of Europe (besides the German territories, e.g., Austria, Bavaria, and the prince bishoprics, above all Spain, Poland, France, and the Italian states) participated in the above-mentioned renewal of state and society in the wake of the reformation of the church. In contrast to Max Weber and the sociology of religion influenced by him, the historiography on confessionalization no longer assumes that only one of the early modern confessional churches—the Calvinist church—was the driving force of modernization, but that modernization resulted from the Calvinist, the Lutheran, and the Catholic confessionalization: in this respect, all three confessionalizations were functionally equivalent (Wolfgang Reinhard 1977).

However, in Catholic societies in particular there were often extra-confessional factors like geographical location, structure of the social elites, etc. that hampered the potential for modernization of the Catholic

confessionalization. In general, the state authorities, which in the course of the Reformation and the processes of confessionalization aimed at social, political, and cultural concentration and standardization as well as at the formation of an early modern society of disciplined subjects, were again and again confronted with the opposition of these subjects. Popular religion, including the belief in magic, remained widespread as did older forms of behavior which contradicted the norms of state and church. Changes in society more often than not lagged behind the normative aims of state and church. Moreover, it should not be forgotten that the differentiation of Latin Christendom had from the beginning overshot the Protestant Reformations accepted by the state. Already during the sixteenth century Baptists, Spiritualists, Anti-Trinitarians, etc. formed a big group of '*Chrétiens sans église*' (Kollakowski 1969) outside of the established confessional churches, and there were also some atheists. After the age of confessionalization in the second half of the seventeenth century, such trends became more and more important.

3. The 'Reformation' as Myth and Concept in Universal History

Just like the French Revolution, the Reformation also became a *lieu de memoir* and a myth: first of all for the Germans, but eventually with a universal claim. Luther was already made a hero by his contemporaries, for example as *Hercules Germanicus*, who fights against the clerical Hydra with a mace (woodcut by Hans Holbein, 1520). Especially, the nailing of the 95 theses to the door of the Castle Church in Wittenberg became an icon of modern times. However, this event appears only one generation later in one of Melanchthon's writings, and therefore probably never happened. But for generations of history teachers and the educated bourgeoisie the blows of Luther's hammer on the church door were a signal for the beginning of the modern period.

A critical distance to the religious meaning of the Reformation notwithstanding, the Enlightenment prized Luther and his rebellion against Rome as an important steppingstone towards liberty of conscience and the emancipation of the individual from authority, an interpretation further elaborated by Hegel and the liberals of the nineteenth century. Hegel identified the Reformation with the rise of modernity and saw it as '*die alles verklärende Sonne*,' which follows upon '*die Morgenröte des Mittelalters*.'

Leopold von Ranke's interpretation of the Reformation was even more influential in historiography. In his *Deutsche Geschichte im Zeitalter der Reformation*, which was first published in 1839, widely read and translated into several languages, Ranke interpreted the German Reformation of 1517 as a signifi-

cant turning point in universal history. Hegel's and Ranke's interpretations of course included the Calvinists and Western European Protestants, who called themselves 'églises réformées' or 'ceux de la religion réformée.' In a secularized form, this interpretation became one of the kernels of the concept of 'Western civilization,' particularly influential in the USA, as well as of the Marxist concept of human progress by revolutions (see Sect. 4, *frühbürgerliche Revolution*, early bourgeois revolution). In current historiography the term 'Reformation' remains relevant especially in the English-speaking world, where handbooks and encyclopedias are given the title 'of the Reformation,' even if they are equally concerned with the Renaissance and the period of confessionalization and cover much more than the history of religion and the churches.

4. Historiography and Issues of Current Research

In the research and interpretation of the Reformation and the period of confessionalization four main currents can be identified at present: first, church history in the stricter sense of the word; second, societal history (*Gesellschaftsgeschichte*), which modifies the classic sociology of religion in the tradition of Max Weber and Ernst Troeltsch and adapts their findings to the historiography of the early modern period; third, neo-Marxist interpretations; and fourth, post-modern approaches like cultural, gender, and ethno-history.

Its commitment to modern scholarly standards notwithstanding, church historians in theological seminaries are still oriented towards the meaning of the Reformation for the history of salvation as well as the historical background of the respective scholar's own confessional existence. In contrast to this, the other approaches emphasize the secular preconditions and consequences of the Reformation. Ranke's interpretation of the Reformation as a turning point in universal history pointed the way and was further developed by Max Weber, who brought the potential of the modern period for rationalization, discipline, and modernization in connection with the Reformation (*Die calvinistische Ethik und der Geist des Kapitalismus*).

The Marxist interpretation of the Reformation as an 'early bourgeois revolution' (*frühbürgerliche Revolution*, F. Engels, M. M. Smirin, M. Steinmetz) interpreted the role of the Reformation in universal history in a revolutionary, progressive sense. Moreover, in the historiography of the German Democratic Republic, the German nationalist perspective of the nineteenth century was retained: Reformation and 'early bourgeois revolution' were seen as compensations for the lack of a secular bourgeois revolution in Germany. At present these macro-historical interpretations continue to make themselves felt in two research para-

digms developed by German historians: in the thesis of 'the Revolution of 1525' and the interpretation of the Reformation as communalism by Peter Blickle and Thomas A. Brady on the one hand, and in the paradigm of confessionalization by Wolfgang Reinhard and Heinz Schilling on the other hand. The paradigm of confessionalization neutralizes Weber's fixation on Calvinism and instead sees the dynamism of change in the overarching process of confessionalization be it Lutheran, Catholic, or Calvinist. In France and in other Romance countries the history of the Reformation was and is not at the center of interest.

In the countries of Eastern central Europe a consciousness for the general importance of the early modern history of church and religion is only gradually developing. English historiography follows its pragmatic traditions also in this respect, and—apart from the revisionism of the English Reformation mostly lead by Catholic historians—it is little interested in the theoretical and methodological discussions about the macro-historical role of the Reformation. By contrast, the approaches of micro-history and cultural history, which claim to supplement or replace the traditional macro-historical interpretations and which have recently become the focus of attention, have their roots especially in Anglo-American historiography. On the one hand, the advocates of these approaches stress the continuous meaning of magic and popular religion (Bob Scribner 1981), which also in Protestant countries resisted the rationalization of the interpretation of the world as well as the disciplining of belief and behavior according to the norms of the respective confessional churches. On the other hand, they stress the long-term change in the meaning of rites and images, in the concepts of order, thinking, and behavior, etc., from the late Middle Ages until the eighteenth century, and they thereby open up new sources and further knowledge to the discussion about the character of the Reformation and its historical meaning.

Refugees: Geographical Aspects

Migrants are commonly differentiated based on their motivation for moving. The term 'refugee' is used to denote an individual who is forced flee in search of safety in contrast to someone who chooses of their own accord to relocate, i.e., a voluntary migrant. This entry examines geographical aspects of forced migration, a condition that applies to more than 34 million of the estimated 100 million permanent migrants worldwide.

1. The Term 'Refugee'

Legal distinctions regarding refugees can be traced to the United Nations Conference on the Status of

Refugees and Stateless Persons. Article 1 of the 1951 Geneva Convention Relating to the Status of Refugees applied the term to

[Any person who] ... owing to a well-founded fear of persecution for reasons of race, religion, nationality, membership of a particular social group, or political opinion is forced to migrate involuntarily across an international boundary and remain outside his country of nationality.

Cause, motive, and political boundary thus became the classic benchmark determiners of refugee status. The 1951 Refugee Convention specifically addressed the status of Europeans displaced by WWII.

An amended 1967 Protocol established legal standards for refugees in all world regions at any time. Although the 133 signatories are not required to provide asylum to refugees, they are prohibited against *refoulement*—expelling or returning refugees to countries where their life or freedom would be threatened (Hamilton 1999).

Under international law, final authority to grant refugee status rests in the hands of a given host government. Practically speaking, however, a branch of the United Nations bears the primary task of protecting refugees. In 1951, the UN General Assembly created the Office of the United Nations High Commissioner for Refugees with a brief three-year life span in mind. In 1954, however, the Assembly extended UNHCR's mandate for another five years. Successive five-year renewals have followed ever since.

Headquartered in Geneva, UNHCR is charged with refugee protection and the promotion of lasting solutions to their displacement. According to its statute, UNHCR is competent to assist:

[Any person who] ... owing to well founded fear of being persecuted for reasons of race, religion, nationality, or political opinion, is outside the country of his nationality and is unable or, owing to such fear or for reasons other than personal convenience, is unwilling to avail himself of the protection of that country; or who, not having a nationality and being outside the country of his former habitual residence, is unable or, owing to such fear or for reasons other than personal convenience, is unwilling to return to it (UNHCR 1993).

Protection remains UNHCR's *raison d'être*, but the complexities of post-Cold War conflicts have forced the agency to broaden its scope considerably. Whereas the Office of the United Nations High Commissioner for Refugees once restricted its concern to people outside their country of origin, it has become increasingly involved in assisting and protecting returnees who repatriate to their home countries as well as groups of people who face refugee-like situations within their country of origin (UNHCR 1993). As the dimensions and dynamics of forced migration change so the term 'refugee' has come to apply to other forms

Figure 1
Principal forms of refugee settlement in Africa, 1976 vs. 1994

of displacement. The discussion to follow examines 'classic' international refugees who cross a political boundary and then, several types of 'internal' refugees.

1.1 International Refugees

Although geographers, starting with Ravenstein's work in the late 1800s, have long studied voluntary migration, their analysis of forced migration lagged far behind. At the 1950 meetings of the Association of American Geographers, Proudfoot introduced a nine-fold categorization of refugee population. That paper constitutes an early example of geographic work on the specific topic of refugees. Geographers thus began documenting the flight and distribution of specific refugee populations, and, they have continued to do so ever since.

Kunz (1973) offered a set of conceptual postulates structured around the dimensions of space and time. That a sociologist provided the model of refugee flight patterns reflected that fact that geographers still gave limited attention to forced migration. In 1977, an article published in *The Professional Geographer* summarized the state of the refugee literature. Rogge concluded that geographers had produced a considerable volume of literature on human mobility, but that '... one form of mobility, however, namely the forced or impelled migration of refugees, has received only peripheral attention by the discipline.'

Refugee research, including that of geographers, has grown substantially during the last 25 years

(Hyndman 1999). Refugee study programs now exist at universities in Canada, Egypt, Great Britain, Kenya, Sweden, and the United States. Academic interest has correlated with the growing magnitude of refugee crises worldwide wherein the global total grew from less than 3.5 million in 1977 to a peak point of 18.2 million in 1992 (UNHCR 1993). Although media coverage tends to reinforce the perception that all refugees are in camps, most refugees—at least in the case of Africa—are still more likely to reside outside UN settlements (see Fig. 1).

During the 1980s, refugee research largely focused on the first and second stages of the refugee experience—the processes of flight and resettlement. Resettled Central Americans and Indochinese in the United States were the focus of study in the context of more developed countries. That East Africa had become the epicenter of refugee crisis in the developing world was reflected in books on Eritrean and Ugandan resettlement (see Rogge 1985, Harrell-Bond 1986, and Bulcha 1988). A basic distinction was frequently made between assisted refugees housed in UN-sanctioned camps or settlements and unassisted refugees who either self-settled in rural areas or in urban centers (Wijbrandi 1990).

In 1990, the locus of the global refugee population was predominantly in the global South. Developing countries hosted nearly 97 percent of all refugees. Conflicts in Afghanistan, Ethiopia, and Mozambique produced populations that each numbered in the millions apiece. The Palestinian community (2.48

million) had long since become permanent stateless exiles dispersed throughout the Middle East. Together, these four groups accounted for more than 13 million of the 16.6 million refugees worldwide. Yet, refugees could be found among more than one hundred different countries. And exile periods were extending longer and longer.

During the decade of the 1990s, geographers diversified their approach to match the growing complexities of the refugee picture worldwide (Black 1991 and Black and Robinson 1993). Refugee settlement was treated less and less often as if it were a self-contained process in isolation, thus moving beyond a 'refugee-centric' perspective (Chambers 1986). Bascom (1993), for example, related the larger processes of rural transformation and agrarian change to that of refugee settlement. Although media images give the impression that refugees are mass 'flows,' it became abundantly clear that ethnic, age, gender, and class differentiation all exist among uprooted populations (Bascom 1998).

Repatriation became a 'lead' research theme in the 1990s (Wood 1989 and Allen and Morsink 1994). As early as 1984, UNHCR had identified repatriation as one of three 'durable' solutions for refugees. The *de facto* solution is long-term integration of refugees in the country of first asylum. The exceptional solution, reserved for only a small percentage of asylum applicants, is resettlement to a third country of asylum. The optimum solution of the three is repatriation—the return migration of refugees from exile to their homeland. The UN High Commissioner for Refugees proclaimed the 1990s as the 'decade of repatriation.'

Repatriation research focused first on legal or logistical matters, then shifted to the socioeconomic and psychological dimensions of repatriations (Rogge 1991). Mozambique, Eritrea, and Afghanistan were some of the principal countries of concern. In theory, the repatriation decision is meant to be voluntary, fully informed, and only to occur when the conditions that prompted flight no longer exist. Practically, however, repatriations can involve different scenarios such as refugees choosing to return despite ongoing conflict or being forced to return home by host governments. Forced deportation, or *refoulement*, of refugees is the worst possible violation of the 1951 Refugee Convention.

The face of refugee studies changed dramatically during the last decade of the twentieth century. It began with the dissolution of the Soviet Union, whose fragmentation prefigured a pattern to come; states under siege amid competing national interests and thus producing complicated flows and counter-flows of displaced people. Wars in the Persian Gulf and Yugoslavia spiked the refugee total up to its record high. The year of 1994 marked the largest and fastest exodus in the modern history of refugee migration. More than 250,000 Rwandans fled the country in only 24 hours. Yet the era of mass movement across discrete

political boundaries was already giving way to more 'complex humanitarian emergencies' (Hyndman 1999).

The painful saga of intervention in Somalia followed by the Rwandan debacle have made the international community increasingly aware of the relationship of refugees to peacekeeping, peacemaking, political stability, and humanitarian action. The UN began emphasizing the need to:

(a) incite and expedite conflict resolution in source countries so refugees can return,

(b) take vigorous action—including emergency response to crises and the provision of international protection on site—to eradicate the causes of flight before refugees flee, and

(c) initiate more proactive intervention to prevent the development of conditions that might impel people to leave in the first place (UNHCR 1993).

The United Nations forged cross-mandate approaches to refugee crises. In the case of Somalia and Mozambique, for example, UNHCR sought collaboration with governments, the UN Department of Humanitarian Affairs (DHA), other concerned United Nations agencies, and NGOs to establish means of protection and assistance for all affected populations, i.e., returnees, internally displaced persons and other impoverished nationals. UNHCR has also increased assistance for refugees outside formal camps and settlements as well as to local populations in resettlement areas.

Meanwhile, the balance of the globe's refugee population began to swing toward Europe. People had come to think of refugees as a Third World problem, but the shattering of Yugoslavia forced Europeans and North Americans to engage with refugees much more directly. First, warfare sites moved closer. Then refugees turned to neighboring countries for protection, assistance, and asylum. And the need for political stability in southern Europe as well as ethnic links to Bosnians, Croatians, Slovenians, and Serbs could not be ignored. Whereas Europeans and North Americans enjoyed the luxury of modest refugee resettlement programs during the 1980s, they were inundated with asylum requests during the 1990s. The United States, Canada, and 17 European nations all received refugees from Bosnia. Meanwhile, the plight of Kurds entrapped within Iraq initiated a new debate about 'internal refugees.'

1.2 Internal Refugees

During the 1980s and 1990s, the character of war shifted in balance from conflict between sovereign states to civil conflict. International refugees now represent the smaller portion of the globe's displaced population. Internally displaced persons (20 million) outrank the number of 'classic' refugees—asylum-seekers who have involuntarily crossed an interna-

Table 1

Significant populations of internally displaced civilians, as of early 1999

Country	Total number
Sudan	4,000,000
Angola	1,000,000–1,500,000
Columbia	1,400,000
Iraq	1,000,000
Afghanistan	540,000–1,000,000
Burma	500,000–1,000,000
Turkey	400,000–1,000,000
Bosnia–Herzegovina	836,000
Azerbaijan	576,000
Sri Lanka	560,000
India	520,000
Burundi	500,000
Rwanda	500,000
Lebanon	400,000–500,000
Uganda	400,000
Russian Federation	350,000
Peru	340,000
Congo-Kinshasa	300,000
Sierra Leone	300,000
Georgia	280,000
Cyprus	265,000
Yugoslavia	257,000
Congo-Brazzaville	250,000
Somalia	250,000
Guinea-Bissau	200,000
Kenya	200,000
Ethiopia	150,000
Syria	125,000
Philippines	122,000
Algeria	100,000–200,000
Eritrea	100,000
Liberia	75,000
Croatia	61,000
Armenia	60,000
Bangladesh	50,000

tional boundary and remain outside their country of nationality. Sudan (4 million) tops the list of countries with large numbers of civilians displaced by persecution or armed conflict (see Table 1).

'Internal refugees,' more commonly known as internally displaced persons (IDPs), became a central focus of refugee research (see Bennett 1998, Cohen and Deng 1998, and Hampton 1998). In 1999, the IDP table in the *World Refugee Survey* included 41 countries as compared to only 25 in 1990. IDP growth reflects the pandemic of civil conflict as well as paramilitary activity in settings of chronic social anarchy like Somalia and Columbia. Most IDPs are refugees in every respect except that they have not, or, cannot cross an international boundary. Although civilians are more frequently targeted as a deliberate tactic of war, they have no right to protection or

humanitarian assistance as long as they remain inside their countries. Estimates of the number of internally displaced persons are often fragmentary and unreliable because they remain largely inaccessible to outside monitors and non-governmental relief organizations (Hamilton 1999). The total number of IDPs may be much higher than 17 million.

'Internal refugees' have become a central policy concern. In 1992, the secretary-general of the UN appointed a Representative on Internally Displaced Persons. Representative Francis Deng continues to parlay the status associated with his title into a limited protection framework for IDPs. The current working definition of IDP is that of a:

Person or group of people who have been forced to flee or to leave their homes or places of habitual residence as a result of, or in order to avoid, in particular, the effects of armed conflict, situations of generalized violence, violations of human rights or natural or human-made disasters, and who have not crossed an internationally recognized border (Bennett 1998).

Clearly, the locus of concern is limited to those forcibly uprooted within a given national territory. The working definition is broadly inclusive, combining several forms of internal migration, which can also be are treated as separate entities.

Most IDPs are forced to move due to explicit forms of persecution or armed conflict, but others migrate because of natural or man-made disasters. Victims of clear-cut natural catastrophes such as a hurricane in Honduras, massive mud slides in Venezuela, or repeated earthquakes in Turkey are sometimes referred to as 'environmental refugees.' Yet, famine-induced migrations often involve man-made factors. Drought, for example, was the immediate, observable cause of large population movements in Ethiopia and Sudan during 1984 and 1985. Poor rainfall may have prompted flight, but displacement within Ethiopia was amplified by the deliberate obstruction of food aid into stricken areas. In Sudan, more than 100,000 people left their homes. Largely at fault was the structure of the Sudanese political economy that set the stage for migration out of rural regions. For many who left, migration was but the culmination of an impoverishment process associated with the appropriation of labor and land by mechanized agricultural schemes, obstructionist tactics employed by merchants, and the state's long-term neglect of the rural sector. The flight of 'environmental refugees' like these is a symptomatic manifestation of oppressive economic and political conditions.

Two other forms of forced migration bear mention—migrants in refugee-like conditions and development-induced displacement. In its highly regarded annual *World Refugee Survey*, the US Committee for Refugees, a public information program of Immigration and Refugee Services of America, reserves a separate table entitled 'For people in refugee-like

Table 2
Significant groups of people in refugee-like situations, as of early 1999

Host country	Place of origin	Total number
Russian Federation	Former USSR	1,000,000
Jordan	Palestinians	800,000
Thailand	Burma	350,000
Bangladesh	Pakistan (Biharis)	238,000
Jordan	Iraq	150,000
Syria	Stateless Kurds	142,000
Kuwait	Kuwait (Bidoon)	117,000
Iraq	Kuwait (Bidoon)	100,000
Tanzania	Burundi	95,000
Ukraine	Stateless Tartars	91,000
Syria	Palestinians	64,000
Venezuela	Colombia	60,000
Eritrea	Ethiopia	35,000
Cameroon	Chad	30,000
Congo-Kinshasa	Rwanda	30,000
Ecuador	Columbia	30,000
Kyrgyzstan	Tajikistan	26,000
Syria	Iraq	23,000
Lebanon	Palestinians	22,000
Yemen	Iraq	20,000
Yemen	Somalia	15,500
Turkmenistan	Tajikistan	11,000
Slovenia	Former Yugoslavia	8,000
Kenya	Rwanda	7,000
Panama	Columbia	7,000
Congo-Brazzaville	Rwanda	5,000
Tanzania	Rwanda	5,000
Yemen	Sudan	5,000

conditions' (see Hamilton 1999 and Table 2). The 1999 report identifies more than 3.5 million such persons found within 28 countries. Some of these refugee-like people are stateless, denied the protection afforded by citizenship, e.g., Kurds in Syria or Tartars in Ukraine. Others are regarded by host governments as illegal aliens, or simply tolerated, or ignored (Hamilton 1999). Development-induced displacement is a final form of forced migration. Revolutionary governments in China and Ethiopia launched ambitious development programs that required resettlement of hundreds of thousands of people, some voluntarily, many not. Today in China, work continues on the largest dam resettlement project in history. Thus far, more than 1.2 million persons have been displaced in the wake of the Three Gorges Dam project.

2. Future Directions

At the end of the 1990s, the locus of the world's refugee population remained predominantly in the South, but 2.38 million of the world's 13.4 million refugees (18 percent) are settled in the First World.

Although the total number of refugees has decreased since 1992, the number of countries that host asylum-seekers increased to 125. Many countries host refugees from several countries simultaneously; thus 161 different populations of exiled refugees exist worldwide. Palestinians (3.8 million) and Afghans (2.6 million) still constitute the two largest refugee communities (see Table 3). Iraq, Sierra Leone, Bosnia and Herzegovina, Somalia, Sudan, Eritrea, Liberia, Croatia, Angola, Burundi, Vietnam, and El Salvador are also important source countries. At least 250,000 citizens from each one have fled into exile. Meanwhile, migration policies are tightening in Europe and North America. Geo-policing of migration poses new challenges to refugees who desire asylum and permanent residence in fortress Europe. In addition, the United States has placed some of the most severe restrictions on asylum procedures in its history.

Contemporary refugee flows are subject to far more complexity than prevailed in the earlier European context of World War II. The case of the Kurdish population entrapped within Iraq initiated a new debate about human rights, national sovereignty, and new modalities for international intervention. Massive upheaval in Kosovo and NATO's unprecedented level

Table 3
Principal locations of international refugees and asylum seekers, as of early 1999

Country of asylum	Place of origin	Total number
Jordan	Palestinians	1,463,000
Iran	Afghanistan	1,400,000
Pakistan	Afghanistan	1,200,000
Russian Federation	Former USSR	1,000,000
Jordan	Palestinians	800,000
Gaza Strip	Palestinians	773,000
West Bank	Palestinians	555,000
Syria	Palestinians	365,800
Guinea	Sierra Leone	350,000
Iran	Iraq	531,000
Lebanon	Palestinians	364,600
Thailand	Burma	350,000
China	Vietnam	281,000
Bangladesh	Pakistan (Biharis)	238,000
Armenia	Azerbaijan	218,000
Sudan	Eritrea	320,000
Yugoslavia	Croatia	279,000
Tanzania	Burundi	260,000
United States	El Salvador	242,500
Yugoslavia	Bosnia–Herzegovina	201,000
Azerbaijan	Armenia	180,000
Ethiopia	Somalia	180,000
Uganda	Sudan	170,000
Guinea	Liberia	160,000
United States	Guatemala	145,500
Congo–Kinshasa	Angola	140,000
Thailand	Burma	140,000
Zambia	Angola	140,000
Russian Federation	Former USSR	129,500
Côte d'Ivoire	Liberia	125,000
Saudi Arabia	Palestinians	122,500
Liberia	Sierra Leone	120,000
India	China (Tibet)	110,000
India	Sri Lanka	110,000
Nepal	Bhutan	100,000
Germany	Bosnia–Herzegovina	100,000

of intervention intensified the debate further. 'Safe havens' for Iraqi Kurds, 'zones of tranquility' for returning Afghan refugees, 'open relief centers' for would-be Sri Lankan refugees, and 'safe corridors' to Muslim enclaves in Bosnia exemplify 'new' spaces and discourses associated with refugees (Hyndman 1999).

Social scientists face major challenges and opportunities on many fronts. Longitudinal studies are needed to trace the refugee experience and associated processes through the 'full circle' of flight, resettlement, repatriation, and reintegration. The fourth stage of the refugee cycle—reintegration of former refugees after their return home – is especially in need of analysis. The use of remote sensing is a promising new research technique that geographers have begun em-

ploying to document displacement and to monitor environmental degradation around refugee sites (see Lodhi et al. 1998 and Bjorgo 2000). 'Refugeeism,' diaspora experiences, ethnic identity, de-territorialization, post-colonial expressions of place, and sense of home are important refugee related themes that social theorists in geography are well equipped to address.

The era of discrete refugee definitions is over. The traditional distinction between the refugee and voluntary migrant continues to be eroded in the face of new human dramas and political controversies. One need look no farther than the recent case of a Cuban six-year old rescued after his mother died in search of asylum or that of Chinese stowaways in container ships bound for America.

Refugees in Anthropology

People being forced to leave their homes to settle in new environments is nothing new. However, 'refugees' as a legal category and as the object of academic research are more recent phenomena. This article will outline the development of refugee studies, in response to global refugee crises of the twentieth century. It will also present some key concepts and theoretical influences and discuss some of the challenges to anthropology of refugee studies.

1. The Emergence of 'Refugees'

The historical context in which refugees emerged as an internationally recognized category was provided by the massive displacements in Europe following two world wars. The Geneva Convention of 1951 is the critical landmark of the establishment of institutions and legal instruments to protect and assist such populations. A convention refugee is an individual who has crossed a national boundary and has a well-founded fear of persecution in the country of origin for reasons of race, religion, nationality, membership of a particular social group, or political opinion. Subsequently, other, regionally based legal conventions, notably in Africa and Latin America, have adopted more inclusive definitions of refugees which better correspond to the manifold types of mass displacements that often follow war and social disruptions in their regions today. Categories outside of legal provisions but equally of concern to agencies of protection are internally displaced people, people who flee within their own countries. Others are humanitarian refugees—like those offered temporary protection, these are persons who are not personally persecuted but are victims of war or war-related conditions. Another category of displaced people with important parallels to the experience of refugees, but without a global agency to protect their interests, are those forcibly relocated by their governments for the purpose of development. Such development-induced displacement may result, for instance, from the acquisition of land to make way for commercial forestry or the construction of a dam.

Refugee studies developed in response to the changing realities of the global refugee crisis in the early 1980s. The escalation of violent conflicts and mass disruptions in many areas of the world had then, within three years, dramatically doubled the global

refugee population. New increases followed the political changes at the ending of the Cold War. At the end of the twentieth century, large numbers of refugees from national conflicts and upheavals in postcolonial states and from crumbling multiethnic federations in Europe still dominated the asylum claims. According to estimates of the United Nations Commission for Refugees (UNHCR), there were 12 million recognized refugees in the world in 1999. Adding the millions of internally displaced people and asylum seekers (persons whose petitions for asylum are still pending), the figure was 19 million. The majority of refugees are found in the regions of the southern hemisphere, in particular in Africa and Asia, where many seek refuge in neighboring states. Only a trickle of displaced people make their way to the more affluent but more restrictive host countries of the north, in Europe or in North America. Even fewer are allowed to settle there.

Until the early 1980s, when refugee studies emerged as an academic field of study, with academic degrees and international journals, 'international migration' had been the main academic context in which research in the social sciences on refugees was usually found. The field is largely interdisciplinary, drawing together a range of research from the behavioral and social sciences, but with a strong presence since its inception of international law and anthropology. The interdisciplinary nature of the field has also meant the fruitful confrontation of anthropology with other theoretical and methodological approaches and the need to clarify the nature of its specific contribution. Furthermore, with its clear relevance for the acute issues of many refugee situations, much anthropological research in the field has a strong focus on practical application and advocacy. However, depicting the severing of a community and culture from their place, refugees have also implied a challenge to some basic theoretical assumptions in anthropology.

1.1 Who is a Refugee? Moving Beyond Legal Definitions

The answer to the question 'Who is a refugee?' is a crucial one in today's world. For those being classified, it may be a matter of life or death, because of the exclusive rights and entitlements of humanitarian concern and international protection that come with the status. In the academic field, the question is a continuing concern as a matter of theoretical and conceptual delineation of its object of study. The definition of 'refugees' as given in the Geneva Convention is too narrow, both as a protection instrument (many would argue), and as a theoretical concept. There is an agreement that, as a useful academic tool, the concept needs to take account of the many different situations which force people to leave their homes, and the proliferation of other legal statuses that have developed in different countries for people moving in

'refugee-like circumstances' (Escalona and Black 1995). Another basis of definition on more theoretical grounds has to do with the cause of flight. Today, causes are often complex, involving multiple factors and the blurring of distinctions, such as that between economic and political motives (for instance, economic collapse may often follow from political change). It is clear that, given the complexity, monocausal explanations are not very useful, because one status may blend into another. For instance, the Palestinian guest workers in Kuwait, once ousted from their homeland, were again displaced during the Gulf War in the early 1990s. Such explanations tend to be simplistic and obscure important similarities in the experiences of the victims of these forces (Shami 1994). A broader definition, well accepted in the field today and better attuned to current realities of displacement in the world, is to consider as refugees those people who are forced to abandon their countries of origin due to violent conflict or insupportable living conditions (Zolberg et al. 1989). These new realities have also questioned the relevance of differentiating between refugees and economic migrants. Rather than being seen as dichotomous, categories can be defined along a continuum, based on the degree of force involved. This would range from voluntary, such as labor migrants moving to better their situation, to involuntary, those forcibly expelled from their home areas (Hansen and Oliver-Smith 1982). While comparative approaches to kinds of migrations are increasingly emphasized by researchers in the field, so is the importance of maintaining that which is specific to refugees and other forced migrants, in terms of human rights and other humanitarian provisions made in their name (Shami 1994). From a somewhat different position, Elizabeth Colson makes a similar plea: 'Despite their similarities with other migrants, refugees have a unique status and force themselves upon the world's attention, because they emerge from and provoke acute crisis' (Colson 1987, p. 4).

The burning question of who and what a refugee is, is also a matter of 'the politics of space and otherness' (Gupta and Ferguson 1992). Answers are sought by examining the powerful institutional contexts and discourses, national and international, in which the category of 'refugee' is construed and public policy shaped, often in ways that misrepresent and exclude refugees. Further, eschewing overgeneralizations of 'the refugee experience' that have emerged out of such contexts (Malkki 1995a), anthropologists today would rather ask what it means to be a refugee, given the specific history of displaced groups and the circumstances in which they find themselves.

2. The Dynamics of Displacement

As refugees, people and their communities are not only forcibly removed, they are also remade. Forced

migration is an important aspect of social change, and any theoretical approach to refugees necessarily engages with process. While the study of refugees shares some common ground with international migration, it must also respond to the realities of sudden, involuntary change and the different forms of power which act on refugees' lives. For those displaced, change is often multifaceted and compressed in time, thus also providing a theoretical challenge to anthropologists, more used in the past to study change as slow and cumulative. However, emerging theoretical frameworks can draw insights from a growing body of research in anthropology on war and violent conflicts, social collapse and reconstruction. As displacement affects most aspects of people's lives, it addresses core issues in the anthropological study of communities, such as patterns of subsistence and livelihood, kinship and family, social and political organization, as well as the systems of cultural meaning which produce a sense of coherence and predictability in everyday life.

These issues are embedded in the wider dynamics of social and political change which form important contexts for the analysis of refugee communities. Within these contexts, anthropological case studies typically focus on uncovering the perspectives and strategies through which displaced groups deal with their predicament, renegotiating livelihoods, relations, and identities in interaction with their hosts. Anthropologists also examine the making of refugee communities, exile cultures, and identities in the places of settlement, including the dilemmas of those refugees whose attachments to the homeland and to fellow countrymen in other parts of the world remain stronger than to the society in which they reside (Fuglerud 1999). For a political movement such as the Chilean left, exiled in the 1970s, this may be manifested as a conflict between political ideology and the realities of everyday life, between 'life as it is' and 'life as it should be' (Eastmond 1997).

3. The Diversity of Refugee Situations and Research Emphases

The great diversity of conditions, in particular the marked contrast between southern and northern host states, has meant the development of different emphases in the concerns and theoretical approaches applied to the problem of refugees in different parts of the world.

3.1 Northern Perspectives: Refugees in Resettlement

Issues of resettlement and integration are common in studies of refugees in North America or Western Europe, reflecting the legal provisions for permanent residence of most refugees into these societies. Much research on resettlement in the USA, for instance, seems to focus on sociocultural adaptation, which is a

conventional framework in the study of the immigrant experience. However, the analyses also draw fruitfully on current theories of ethnicity and identity, emphasizing agency and cultural construction in the process (e.g., DeVoe 1992). These concerns reveal that many exile communities are concerned with continuity but also that, despite their claims, exile cultures typically represent dynamic forms. In these fields, American anthropologists, like other Westerners in the profession, increasingly turn to study the institutions of their own societies and their interaction with refugees. Being a refugee often means something different in Western Europe, where large influxes of newcomers are relatively recent and where integration is often preceded by a long asylum-seeking process. An emphasis in much of the current research is the vicissitudes of integration in relation to policies and processes of social exclusion. Importantly, perspectives from the inside of diasporas, groups which maintain strong ties to the home country and to members in other parts of the world, indicate that full integration into the host country may not be a primary concern (Fuglerud 1999). However, more systematic and comparative studies of the experience of different groups in different countries and circumstances of reception in northern countries are called for (Escalona and Black 1995).

3.2 Southern Frameworks: Refugees and Development

In southern countries, particularly in Africa, displacement and refugees have frequently been studied as a problem of development. A general framework for analyzing displacement and involuntary resettlement with a focus on the responses of dislocated people and the role of the state in resettlement is provided by Hansen and Oliver-Smith (1982). This has been an important starting point for some of the comparative work in southern countries.

One theme is that of development schemes and modernization displacing large numbers of people within their countries. An early contribution from anthropology is Colson's (1971) study of the social consequences of the relocation of the Gwembe Tonga due to the building of the Kariba Dam in 1958. More recent analyses take account of power relations and local forms of resistance by those ousted from their home areas (McDowell 1996). Another theme is the critical evaluation of humanitarian assistance and the potential of more long-term development that also benefits the host population. Harrell-Bond's (1986) illuminating study analyzed the implications of relief operations on refugees and their hosts in Uganda. Neglecting refugees' own concerns and resources, the interventions of relief agencies were found to create conflicts and fragmentation both within refugee collectivities and with the local host population. Other critical studies have focused on camps as organized

solutions to refugee crises. Comparing the experience of camp-settled to self-settled Angolan refugees in Zambia over many years, Hansen (1992) found a preference for staying with kin even in meager and less secure circumstances, rather than submitting to the rigidly controlled but well-provisioned camps. While camp refugees remained strangers in the new country and wanted to return, most of the others did not. These studies highlight the problem of defining assistance in narrow economic terms without taking account of the perspectives and resources of refugees themselves. Malkki's ethnography (1995b) of displaced Hutu refugees from Burundi settled in Tanzania compared identity and historical memory of refugees in camps with those who had settled in a nearby town and relied on their own creative strategies for survival. Whereas the latter were pragmatically juggling social identities, in the diversity typical of many African towns, camp refugees were passionately concerned with creating their mythico-history as members of the Hutu nation.

4. Refugees as People Out of Place: Challenges to Anthropology

Camps, as a form of containment, also reveal something about the workings of power within the international refugee regime and the deeply cultural yet global notions of order which underpin it. In a world where nation-states are seen as the 'natural' basis of belonging, according to Malkki, refugees occupy an in-between or liminal position and as such challenge the dominant 'national order of things.' Drawing on theories of social classification and of the cultural constructions of nation-ness, such analyses of displacement have opened up new theoretical spaces of anthropological inquiry into the relationship between people and place, nationalism and history. Inquiries into the significance of place and the creative ways in which people come to see different places as 'home' also provide important theoretical frameworks for the study of repatriation of refugees. This applies both to international policy, in which going home is construed as the naturally desired end of 'the refugee cycle,' and to return as lived experience. Images of home, which are a central premise in much exile ideology and upheld in memories and claims to the homeland, cannot always be reconciled with the realities of life upon return (Black and Koser 1999).

Clearly, refugees present a challenge to nation-states, but they do so also to the social sciences and some of their cherished concepts. In anthropology, until recently, refugees and displacements were rather marginal as research themes, in interesting ways reflecting the position of displaced populations themselves. This neglect may be attributed to a theoretical bias in anthropology that has tended to downplay violence and suffering (Harrell-Bond and Voutira

1992). Other commentators, like Malkki (1995a) refer to a 'sedentary bias' in anthropology, meaning that communities and cultures have been assumed to be naturally located in a particular place. Studies of displacement thus require anthropologists to re-examine their concepts of culture and community as bounded and territorialized units. Also, with the growing theoretical interest in anthropology in globalization and transnational phenomena, nationalism and conflict, violence and social memory, the study of refugees and displacement is gaining new relevance and fresh theoretical insights. Taken together, these new challenges will contribute to the coming of age of the study of refugees as an academic field in anthropology with a more solid theoretical foundation. If, as it is often claimed, refugees are symptomatic of the state of the world, with global mobility, fluidity, and fragmentation, but also claims and allegiances to particular lands and cultural identities, then they may well occupy a central position in future anthropology.

Region: Geographical

Region is a concept of great significance that has a long and storied history in geography. When the discipline was becoming an organized field of study during the late nineteenth and early twentieth centuries in Europe and North America, regions were its principal subject matter. Two conceptions of the geographical region vied for legitimacy. The region's importance was eclipsed during the 1960s by new systematic and quantitative approaches. Regional synthesis did not disappear, but ceased to provide geography's unifying framework. By the end of the twentieth century, geography lost confidence in spatial science and unifying concepts and frameworks of most sorts. The region was rehabilitated and enjoyed something of a vogue as geographers and others refocused attention on the nature and meaning of space and place.

1. Regions for Everyone

Region is a concept both familiar and useful to fields of knowledge ranging across the arts and sciences. Distinctive resource endowments, climatic activity, and plant and animal life, along with widespread patterns of human occupancy all differentiate the earth's surface. That differentiation is the basis for identifying and naming regions: alpine forest; coal fields; wine country. Areas of the human body, too, are commonly referred to as regions; one of the most frequent physiological uses of region is in reference to the human brain, with distinct regions said to control discrete neurological functions. The essence of regions is the areal continuity (whether on the earth, the human body, or some other object of study, such as a painting) of some specified facts of interest to the observer (whether it be agricultural practices, digestion, or

brush stroke). Regions of all sorts are identified on the basis of areally associated common characteristics.

Despite its widespread parlance, region enjoys a special relevance in geography because of the concept's dictionary definition of and popular association with the earth's surface. Regions, *ipso facto*, are geographical regions. As a field of knowledge widely perceived to study the earth's natural and human variation, geography is similarly understood to rightly 'own' regions as its logical and meaningful object of study. Geography certainly has devoted itself to the continuing transformation and differentiation of global nature and society. Yet the discipline has had a problematic relationship with the region: an on-again, off-again love affair with its putative object of study.

2. The Region in Geography

The region has been such a troubled concept owing to geography's hybrid status as, at once, a natural and social science. When the great disciplines were borne during the late nineteenth century, geography came into being with its shoulders rubbing kindred disciplines of geology and anthropology. Geology laid claim to the scientific study of the origin, history, and structure of the earth, while anthropology claimed an equally scientific status for its study of the origin, cultural development, and behavior of humans.

Geography was the study of the earth and life on earth, especially human life and its capacity to change the face of the earth. More than a little geology, a little anthropology, geography on the continent, British Isles and in North America identified itself as the study of the relationships and interactions between nature and culture. Halford Mackinder, a founder of British academic geography and great champion of the regional approach, lamented in 1887 'one of the greatest of all gaps ... between the natural sciences and the study of humanity.' He went on to insist that it was 'the duty of the geographer to build one bridge over [this] abyss ...' (cited in Livingstone 1992, p. 190).

This early history of the discipline bore direct consequences for the conceptualization of regions, for what better place, quite literally, to examine such connections than in areas ostensibly characterized by common natural and human features—which is to say, than in regions? Geography neither invented the region nor wrested it away from a rival discipline. Rather, the region fell into the discipline's lap as the obvious focus for its pursuits.

The study of regions seemed a natural fit with the new discipline of geography not merely by default, however. Geographers attracted to the study of what were then called 'man-land' relations tended to focus, if not lavish, their attention on rural areas in an often deliberate rural bias. Well into the twentieth century, most people around the world lived in rural areas or small towns and to some extent, surely, geography was

simply following demography in its preoccupation with the countryside. But more willful considerations were also at play. The countryside offered an ostensibly more transparent scrim for observing interactions between nature and culture: it was easier to parse a relationship between soils and climate on the one hand, and cultivation, settlement, and even religious practices on the other in the countryside than to try to make analogous sense of the nature–culture nexus in burgeoning cities of the day. Livingstone (1992, p. 264–6) further suggests that geographers seeking a moral compass for their work deliberately sought out rural areas because of the perceived superiority of rural values in a rapidly changing world. Anti-urbanism was a conscious strategy, often fraught with political overtones, as was the case with regional geography in Germany and France. From the start, regional and rural geography were synonymous.

Early in the twentieth century, when geography was being established as a university discipline in Western Europe and the United States, the study of regions took place in service to geography's larger purpose of bridging the natural and human sciences. Regions were thought to disclose nature–culture relations with quintessential clarity and were a basis for the most hotly contested debates of the age, namely over the relative weights of nature and culture in determining the character of people and places. Regional geography supported a variety of positions about the degree and direction of what was somewhat delicately called environmental influence. Taking cues from a stringent reading of Darwin's principles, Huntington (1924) found evidence of a determining environmental influence on the fate of world regions through the instrumentality of race and intelligence, a determinist position staked out earlier in the influential work of German geographer Ratzel (1896–8). Elsewhere, a more nuanced approach was developed in France by Vidal de la Blache (1926). 'To him, the regional articulation of life-style consisted in the material expressions of human–land relationships' (Livingstone 1992, p. 267) which he explored in a series of essays about French *pays*. Vidal emphasized society's variable role in modifying nature and was concerned with investigating how different natural realms gave rise to what he called *genres de vie*, or different ways of living.

2.1 The Region is Geography

A subtle shift took place in the early twentieth century in the status accorded geographical regions. Debates over environmental influence waned with the inevitable rejection of crass determinism and the emergence of a possibilist consensus built around *Lamarckian* notions of human adaptation as an active rather than passive response to nature. Under these changing conditions, regions were no longer the mere

handmaidens of research but came to be the discipline's *raison d'être*. Regions held a newly intrinsic interest. In Germany, Alfred Hettner promulgated '... the principle of *chorology*—the explanatory investigation of terrestrial reality divided into a series of component regions—' as the only way 'geography could retain both its physical and human components because it was precisely in their dialectic that particular places acquired regional character' (Livingstone 1992, p. 263).

In the United States, two very different regional concepts competed for acceptance and legitimacy. The first was contained in the work of Sauer and the so-called Berkeley school of (cultural) geography. Borrowing from Germanic anthropology, Sauer translated the anthropologist (and Berkeley colleague) Alfred Kroeber's 'culture area' into the geographers' 'cultural landscape'—synonymous with then-contemporary meanings of region. In Sauer's conception, regions existed as organic wholes, awaiting discovery and interpretation through intensive geographical field work. Also presumed was the inherent uniqueness of regions in terms of the presence and combination of natural and cultural features. The Sauerian tradition rejected grand theorizing in favor of a particularism that found perfect expression in richly textured and seemingly exhaustive cultural landscape studies (Sauer 1963).

The rival regional concept was associated with areal differentiation as enunciated by Hartshorne in his exegetical *The Nature of Geography*, published in 1939. *Contra*-Sauerian particularism, Hartshorne rejected the heretofore common notion that regions existed as organic wholes. Regions might be observed and perhaps even experienced in a harmonious, holistic fashion, but otherwise such holism was 'not inherent in the world which the geographer studies—neither in the world of nature nor in the actual world which nature and man together have made' (Hartshorne 1961, p. 362). While denying regions an independent ontological status, Hartshorne sought to guide their study on to firmer ground. '(F)or him, the regional project consisted in determining how "particular elements and complexes of elements are related to those in others"' (Livingstone 1992, p. 310)—such particulars including relief, vegetation, climate, land use, etc. Hartshorne called for a formal process of *areal differentiation* to define geographical regions based on one or another consciously chosen geographical particular. Such a scheme would lay the systematic basis for areal classification (e.g., the agricultural/climatic/religious/botanical regions of the world), comparison, and mapping.

Until the mid-twentieth century, these two regional concepts uncomfortably co-existed with each other. 'In the first (Hartshornian) view, regions were a form of areal classification, and in the second (Sauerian), regions were relatively unique areas of the earth that possessed a geographic individuality' (En-

trikin 1991, p. 16). Hartshornian regions enjoyed a wider purchase in the discipline because they insinuated themselves easily in the discipline's burgeoning systematic subfields of cultural, social, and economic geography.

By all accounts, during the 1940s and 1930s regional geography turned formulaic, with material synthesized and presented in a numbingly predictable format, beginning with the physical environment (landforms and climate) and then moving through several layers, as it were, of human occupance (settlement patterns, house types, farming practices, barn and fence types, etc.). While some scholarship rose above this narrow groove, sadly much did not. '(A)s clearly illustrated by many of the regional texts that appeared during those decades, the result was a rather tedious catalogue of factual material within an uninspiring framework' (Johnson 1991, p. 40). Like an overly tended hothouse flower, regional geography withered at the very moment it enjoyed the discipline's central place.

2.2 *The Region is Dead! Long Live the Region!*

By the 1960s, many geographers openly questioned whether the region could any longer provide an integrative framework of study. The criticism leveled at regional geography was often upsparring, as when Peter Gould characterized it as 'shabby, parochial, and unintelligent' (cited in Johnston 1991, p. 40) and easily caricatured. Gould's comments contributed to a wider assault on regional geography by a new generation of geographers seeking to redefine the discipline as a spatial science. Through the very real weaknesses of the traditional regional approach, and the sheer hubris of geography's so-called young turks (such as Gould), spatial analysis decisively eclipsed regional synthesis as the discipline's heart and soul. Suddenly the strenuous disagreements about particularism and areal classification sounded oddly antiquarian compared with the clarion and oh-so-modern call of the quantitative revolution.

Amidst this upheaval, regional geography did not vanish. Quantitative methods lent the Hartshornian region something of a new lease on life. Those working in the Sauerian tradition simply ignored the spatial science gold rush and continued advocating their cultural landscape approach in what became something of a lively, though curious, intellectual backwater. But the region generated little in the way of theoretical or methodological debate until the late 1970s. By that time, the euphoria surrounding spatial science had run its course and quantification was finally understood as a tool, albeit a powerful one, rather than geography's *raison d'être*. A new methodological pluralism overtook geography and the region once again began inspiring fierce discussion and debate—the news of its death having been vastly overstated.

The 1980s witnessed a resurgence of interest in regional geography emanating from two disparate sources (Pudup 1988). The first was practitioners of traditional regional geography who shared an unwavering belief that geography's *modus vivendi* remained regional synthesis. Emblematic of the revived tradition was the election of two of its chief contemporary practitioners, John Fraser Hart and Peirce Lewis, to the Presidency of the Association of American Geographers (AAG) during the 1980s. Both used their AAG presidential addresses to celebrate traditional regional approaches. Hart called regional geography 'the highest form of the geographer's art' and the discipline's long neglected unifying theme: 'I know of no other theme that is even remotely so satisfying as the idea of the region. All of the different strands of geography converge when we try to understand regions, and we need the concept of the region in order to understand why we need the diverse and variegated systematic sub-fields of geography.' (Hart 1982, p. 18). Three years later, Peirce Lewis echoed Hart's sentiment in another spirited defense of synthetic description which he considered 'a kind of rough and ready definition of geography: describing the earth's surface and trying to make sense of it.' (Lewis 1985, p. 47).

Such 'back to basics' calls could be dismissed as pure nostalgia were it not for the equally spirited discussions about regions arising from a very different quarter—geographers who sought to rehabilitate the concept and create a 'reconstructed regional geography.' The new regional scholarship was pioneered, perhaps unsurprisingly, by a generational changing of the guard. Skeptical about both spatial science and regional synthesis, geographers coming of age in the 1980s brought to the study of regions a deep engagement with theoretical debates and philosophical discussions ranging across the social sciences (Thrift 1983). They also brought to the study of regions a consciousness borne from being living witnesses to dramatic changes wrought by globalization (Massey 1995, Allen et al. 1998, Storper 1997).

The study of regions underwent a profound transformation. Regions ceased to be a topic interesting chiefly to geographers and historians and became an object of fascination in mainstream social sciences. Economists, political scientists, sociologists and, of course, geographers began asserting 'that the region might be a fundamental basis of economic and social life "after mass production."' That is, since new successful forms of production—different from the canonical mass production systems of the postwar period—were emerging in some regions and not others, and since they seemed to involve both localization and regional differences and specificities (institutional, technological), it followed that there might be something fundamental that linked late 20th century capitalism to regionalism and regionalization' (Storper 1997, p. 3). The apparent *fin de siècle* tendency

toward regionalization of economic and social life, in places like 'the third Italy,' Baden-Württemberg, and Silicon Valley, was wildly at odds with post-World War II era expectations of global integration and homogeneity. The global village seemed to be giving way to a world of regions.

3. The Regional World

Reconstructed regional geography radically departs from traditional regional synthesis. Gone are assumptions of organic holism and naturalism, or that geographers take unmediated cues from the physical environment in discovering neatly packaged regions. Rural bias has given way to a plurality of spatial possibilities, including rural and urban but also sub- and ex-urban regions, as in the case of 'edge cities' like Orange County, California. Economic processes of trade and investment are accorded far greater importance in regional transformation, if not central importance, in contrast to traditional regional geography's emphasis on culture and its tendency to either ignore or collapse most aspects of social life into the material expressions of culture. Indeed social relations, understood as 'always inevitably spatialized' (Allen et al. 1998, p. 138) take on an unprecedented significance in the new regional geography. Regions are socially constructed and open to deconstruction through social relations both in- and outside the region. The brave new regional world is an unstable one: '... that process of construction is constantly evolving. The spatialities of our lives are the product of continual negotiation, the outcome of the articulation of differentially powerful social relations.... Any settlement of social relations into a spatial form is likely to be temporary. Some settlements will be longer lasting than others' (Allen et al. 1998, p. 138). Finally, regions are also discursively produced through cultural representations that imbue meanings differentiating one region from another, e.g., a 'core' vs. a 'peripheral' region. 'What is said' about a region can powerfully shape the form and content of its social relations and what literally takes place there. Another obvious change is the new regional geography's nomenclature. Perhaps because 'region' carries such bruised and battered baggage, concepts like space, place, locality, and even territory are typically used interchangeably with region. The long-standing question of the region's appropriate geographical scale appears moot.

But not all the hoary questions have gone away. As the twentieth century turns into the twenty-first, geographers continue to wrestle with how to understand regional difference and uniqueness. That places differ from one another—and not just in their landforms and climate—can no longer be assumed, as was the earlier luxury, but has to be explained in a world governed by recognizably systemic processes of global

capitalism. In this regard, regions continue to be human places where geographers explore relations between the general and the particular. And because such questions by definition defy agreement, the regional enterprise is guaranteed a long and storied future.

Regional Geography

1. Introduction

Regional geography is a field of study which strongly contrasts with systematic geography. While the latter is concerned with the distribution of certain characteristics, such as landforms, climate, vegetation, and

human activities, over the surface of the earth, regional geography looks into the relationships these phenomena have within the different regions. The prime interest in the systematic fields of geography is to describe the patterns certain phenomena display over the entire globe and to elucidate the (general) rules that govern these patterns. Regional geography, on the other hand—at least in the mainstream thinking of the nineteenth and early twentieth centuries—is not interested in general rules but, on the contrary, in the singularity or the specificity of regions. Thus, traditional regional geography is characterized by a synthetic view of the world, i.e., it tries to put things together in a regional context, and by the (epistemological) conviction that it needs to view the world as a mosaic of idiosyncratic, singular entities—the regions.

This understanding is deeply rooted in most people's everyday consciousness of the ways in which the world is structured. Thus, when we think of the American Midwest we conjure up images of commercial agriculture, endless cornfields, livestock production, and a predominance of white middle-class Protestants, whereas when we think of the Sahara or Central Australia we probably imagine little vegetation, heat, and dryness, and an environment hostile to most life-forms. The fact that people tend to be regional geographers in their everyday consciousness may be attributable to the fact that most of them were taught geography at school. It can also be seen as a strategy of the individual to simplify a complex world by structuring it along the lines of regional entities. Whichever the reason, the fact that we do tend to think in idiosyncratic ways helps to explain the lasting success of regional geography—at least in the form of regional monographs. In our age of extensive travel over the entire globe these monographs are useful backdrops for our encounters with strange environments, since they allow us quickly to attune to (rapidly) varying circumstances.

As an academic endeavor, determining geographers' shared conviction as to what constitutes the essence of the discipline, regional geography was not a lasting success story. However, after a period of strong rejection in the 1960s and 1970s there were signs of a renaissance in the last decades of the twentieth century. The following sections of this entry deal with the mixed press regional geography encountered in the past, with recent developments, and with the—possible—future(s).

2. Historical Development

Although regional geography can be traced back to ancient Greece, the 'classical' period was that of the late nineteenth and early twentieth centuries. The external factors explaining the success of geography as

a discipline and of regional geography as its center at the time were the rapid exploration (and exploitation) of the interior of continents, the setting up of a regular or more efficient administration in many countries, and the stronger ties that were forged between countries and places. All this necessitated the generation and dissemination of (geographical) knowledge, much of which was of a place-specific nature. Before geography was set up as a university discipline later in the nineteenth century, naturalists such as Alexander von Humboldt (together with Aimé Bonpland) ventured to study hitherto unexplored parts of the world. Von Humboldt supported a holistic understanding of (his) academic explorations: in his extensive research papers on South America, which covered more than 9,000 pages, for instance, natural and human phenomena were seen in context.

Thus, regional geography is associated with the early beginnings of geography as a university discipline and it was, in the case of von Humboldt, informed by the Enlightenment, as von Humboldt concerned himself critically with the situation in the South American colonies. However, later in the nineteenth century a holistic understanding of the (natural) sciences became increasingly marginal because they were undergoing a process of continuing specialization. In geography, on the other hand, the holistic approach experienced a sustained success as it influenced much of the mainstream methodological thinking well into the twentieth century.

In the German-speaking countries the Austrian Viktor Kraft (1929) offered his very influential epistemological analysis of the object, the aims, and the methods of geography. Following a neo-Kantian line of argument Kraft subdivided the discipline into 'general,' i.e., systematic, geography (as a nomothetic science), and regional geography ('Länderkunde'—as an idiographic science). In line with this view, it was maintained that the study of regions is the prime object of geography (an object truly exclusive to the discipline), that therefore regional geography is at the core of the discipline, and that, consequently, systematic geography and its branches are ancillary sciences. Moreover, regional geography had an integrating role to play as it incorporated physical as well as human geography under one epistemological roof. The fact that regional geography thus gave unity and an exclusive object to geography explains why it remained the hegemonic methodological discourse well into the twentieth century.

In Germany, Hettner (1927), amongst others, had successfully codified regional geography along the lines of Kraft's neo-Kantian epistemological reflections so that it occupied a pivotal position within geography from the 1920s onwards. In the USA, Richard Hartshorne's *The Nature of Geography* (1939) gave a similar importance to regional geography. The view that regional geography had an overarching, integrating role to play, however, came under in-

creasing attack in the 1950s and 1960s when the spread of an analytical-pragmatic and nomothetic paradigm reached the community of geographers.

In essence, practitioners of regional geography were accused of unscientific working practices, of gathering—and not analyzing—facts, and of emphasizing the ‘individuality’ of spatial units, the regions. The critics whose discourse on the philosophy of science was informed by logical positivism (cf. Harvey 1969) and critical rationalism pointed out that regional geography was lacking a theoretical foundation on which an explanation of empirical evidence could be grounded. Part of the criticism was directed at what the critics regarded to be a premodern frame of mind of regional geographers, who saw the world as a well-ordered mosaic (of regions) which the regional geographer’s ‘art’ had to put together, at the implicit geo-determinism and at the exclusion of social practices from academic work.

By the 1960s and early 1970s a nomothetic discourse had asserted itself in geography which was to form the mainstream methodological underpinning of the discipline for the next decades (Hanson 1999). As a consequence, from then on regional geography only played a minor role until the last decades of the twentieth century. This minor role, however, mainly expressed itself in the low esteem that regional geography enjoyed in the eyes of those geographers whose frame of mind was shaped by an understanding of academic work deeply rooted in logical positivism and critical rationalism. This state of affairs was sharply contrasted with the fact that at the same time many regional studies were being published (Gregory 1988). This is why it is not possible to infer from the (then) dominant paradigmatic understanding of the discipline the performance and the relevance of regional geography in the wider society.

The peripheral position of regional geography in academia during the 1970s did not change, despite the attempts of individuals to put it on a (new) epistemological foundation. In Germany, Wirth (1978), for example, in his endeavor to resurrect regional geography takes up certain key elements of critical rationalism as developed by Popper. According to Wirth, regional geography should be treated as a historical science which deduces singular events from general laws (which in the case of regional geography can be taken from the systematic fields of geography) and special antecedent conditions (which result from the unique situation under investigation). This approach will not only render a description but also provide the academic with an *explanation* of empirical phenomena. This view challenged other academics, notably Bahrenberg (1979). The dispute that evolved between the two antagonists did not, however, have a widespread impact. The fact that a broad discussion on the significance of regional geography did not take place at the time may have its roots in the repercussions of the ‘quantitative and theoretical revolution’ of the

1960s and 1970s, as well as in the growing inner diversity of the discipline as a whole.

3. Recent Trends: The Emergence of a ‘New Regional Geography’

In the 1980s there was a development, primarily taking place in the French- and English-speaking countries and in The Netherlands, which can be characterized as a trend back to the study of the specific, a renaissance of regional (human) geography (Gilbert 1988, Pudup 1988). This tendency can be seen as a reflection of a number of developments.

3.1 The Background

To begin with, a positivist mode of explanation in general and spatial analysis in particular were seen to be insufficient tools for geographical studies. The criticism leveled at the mainstream geography of the 1960s and 1970s was that it neglected humans as intentionally acting beings (‘structure–agency–debate’) and that it tended to reduce space to an entirely social construct (‘spatial exorcism’). Second, ‘space’ and ‘place’—key geographical concepts—gained in importance in the neighboring disciplines. This had repercussions on geography. Now geographers were able to point out that distinguished scholars, such as the sociologist A. Giddens, were borrowing from geography. And third, in the light of the crisis of the ‘grand narratives’ of humankind, such as religion, communism, science, etc. (and of ‘grand theories’ in the academic world), in the age of postmodernity there was an overall social trend which gave more importance to the special/specific (ideographic), and which acknowledged a greater diversity in regional cultures, ways of life, etc. Hence, a totalizing view as to the ways in which societies, economies, cultures, etc. should be seen and understood came under increasing pressure.

Regional specificity had reinstated itself on the methodological agenda because it was recognized by a growing number of academics that, as Massey (1984, p. 120) points out,

just as there are no purely spatial processes, neither are there any non-spatial social processes. Nothing much happens, bar angels dancing, on the head of a pin. ... The fact that processes take place over space, the facts of distance and closeness, of geographical variation between areas, of the individual character and meaning of specific places and regions—all these are essentials to the operation of social processes themselves.

3.2 The Different Approaches

According to Gilbert (1988) there are at least three different approaches dealing with regional specificity

that can be distinguished in the recent endeavor to promote a 'new regional geography': the political-economic, the humanistic-phenomenological, and the structurationist.

The political-economic approach is very much inspired by the tradition of dialectical materialism in Marxist geography. It focuses on the ways in which (global) mechanisms of capitalism take effect on the ground, in particular on the ways in which the division of labor is spatially structured in capitalist societies. This understanding of the spatial operation of capitalism is in essence based on two main premises: it rejects the notion of a linear realization of systemic processes in different spatial contexts ('regions') and it assumes a dialectical relationship between the systemic framework (of economic development) and the locally and regionally specific development trajectories. Hence, regions are not just spatial backdrops against which overall developments take place, they are the specific sociospatial, historically contingent context ('layer of history,' Massey 1984) which determines the specific pathways of capitalist development in the varying particular and the overall contexts.

According to Gilbert (1988, p. 219) the term 'region' is given a substantially different meaning and therefore a 'new regional geography' differs markedly from the traditional understanding: 'The traditional concern with the people/nature relation has widened to include society as the prime agent in region formation. Thus, the substance of regional geography has become the triangular relations between people, society and nature.'

The humanistic-phenomenological approach can best be understood as a multilevel change of perspective. It is a break with the established positivist methodology and it marks a different approach of the academic toward social reality. In their critique, Van der Laan and Piersma (1982, p. 416f.) emphasize the reductionism of quantitative geography which in essence meant that human beings were treated as 'things, as non-intentional materialistic research objects.' As a consequence—and in direct opposition to the positivist notion of *explanation*—the proponents of a humanistic approach place the intentionally acting human being at the center of academic inquiry. Furthermore, academics are to discard their 'classical' perspective as outsiders and to assume an insider's view of social reality in the sense of comprehending, *understanding* the meaning of social acts and the intentions of agents (Buttimer 1979). Only through this shift will social practice be rendered intelligible.

The humanistic approach looks into the cultural meaning of the 'region' which is being conceived of as the expression of a specific—culturally embedded—relationship between people and their spatial environment. The distinguishing quality of this relationship is the awareness of a shared culture among the population, and the associated distinct identity of that population as it is noticeable to outsiders. This

relationship also encompasses the resultant feeling within the population of belonging to 'their' region.

According to the programmatic considerations of its proponents, a humanistic-phenomenological approach has as its focal point individuals, their everyday view of the world, and the meaning which they attribute to their environment. However, the individual is not seen as a solitary agent but as a carrier of a shared cultural identity.

The most striking characteristic of the structurationist perspective, which is mainly based on Giddens's (1988) theory of structuration, is the dialectical understanding of the 'region' as the outcome and the producer of social practice. The 'region' is regarded as a specific spatial and temporal constellation of social relationships, and at the same time as a medium for these social relations. Pohl (1993) very aptly speaks of a 'co-reacting catalyst.' Behind this view is a comprehensive definition of the 'cultural region' in which elements of the political-economic approach are also incorporated.

3.3 *Their Conceptual Connections*

These different conceptional approaches do not in any way form coherent edifices of knowledge, nor are they as clearly demarcated as these few observations may suggest. Additionally, they are not at all canonized by the scientific community of geographers, particularly outside the French- and English-speaking countries. Notwithstanding these qualifications, there are a number of issues which link the different approaches on a conceptional level: it is the understanding of the term 'region' and of the central epistemological dimensions 'individual' and 'history.'

One of the outstanding arguments in the discussion is the ontological status being ascribed to the 'region.' According to a number of proponents of a new regional geography, regions are not only empirically important—as analytically relevant constructions of the academic—they are also the outcome of human history and therefore of an ontological nature (Pickles 1986). This is why the individual and history are at the core of a new, reconstituted regional geography. Another point which many advocates of a new regional geography agree with is the assumption that 'regions' are a persistent feature of societies. Contrary to the modernist conviction that regional differences will be eroded in the process of social modernization, these differences are assumed to remain, as spatial differentiation is seen as a central element of society (in the sense of social relations being spatially and temporally contingent phenomena). Such a notion of the 'region,' however, has little in common with the chorological view according to which the 'region' is an expression of the opposition against (or the inertia inherent in) the homogenizing trends of modernization. The third notion which runs through the debate

is the structural analogy of the three approaches. What is meant here is the mentioned dialectical concept of the regions being both the result and the 'medium' of social relations. As a co-reacting catalyst, the region has emergent powers as 'social relations within the region develop because of the specific way individuals and groups relate within the particular regional space' (Gilbert 1988, p. 215).

One distinctive feature of the debate about a new regional geography is the fact that it has a heavy theoretical and conceptual slant, whereas empirical studies are scarce. The existent empirical work does not exhibit a uniform approach toward method, but rather a certain methodical pluralism or voluntarism. There are basically two empirical approaches. Whereas one group of academics works historically by reinterpreting regional developments which have taken place (cf. for instance Gregory's outstanding work *Regional Transformation and Industrial Revolution: A Geography of the Yorkshire Woollen Industry*, 1982), the focus of the other group ('locality research'; cf. Cooke 1989, Harloe et al. 1990) lies on the present and on the examination of the consequences of (global) economic restructuring on 'localities.'

3.4 Unresolved Issues

After a fairly intensive (conceptual) debate in the 1980s and early 1990s the interest in a reconstituted regional geography waned somewhat in the late 1990s. The reasons behind this trend may have been a certain fatigue after a period of intensive debate, the fact that many geographers who have migrated to other fields of interest in the discipline do have strong reservations about (prejudices against) 'regional geography,' and the problematic or unresolved issues of the debate. All three are inter-related in various ways, and they need to be taken seriously if regional geography is to have a future as a stimulating, academically rewarding pursuit.

The interest of geographers—like that of other academics—usually is arrested by methodological debates which have the potential to renew the cognitive and the social system of which academics are members. However, fatigue sets in if these debates fail to live up to the expectations of the scientific community. In the case of a new regional geography this may be due to the fact that the promise of modernization was not convincing enough, both to those who took part and to the grant-giving bodies (who are operating on a system of academic self-control; thus colleagues with reservations about regional geography decide on submitted research proposals). As the new methodological direction is characterized not by one but by several approaches, it is hard to find sufficient collective support within the scientific community of geographers. What is more, despite their innovative

and stimulating new ideas, these approaches have inherent shortcomings which weaken the case for a new regional geography.

To begin with, there is, typical for a 'young' paradigm, the need to clarify the usage and meaning of key concepts and terms. This is particularly so in the case of the 'locality' debate, in which the usage of the term 'locality' leaves much to be desired. Most importantly, the usage of that term reproduces the casual handling of concepts that was typical of the 'old school' and that had received so much—deserved—criticism. Terminological constructs are taken as starting points without confronting these with the terms relevant for both the life world ('Lebenswelt') and the social systems. It was not the process and the outcome of the socially constructed spatial coding which was on the agenda but rather the examination of social interaction within the boundaries of the previously demarcated study areas ('localities'). This, however, bears the danger of reifying (predetermined) spatial concepts and thus of wasting a chance for epistemological progress.

This problem refers to another unresolved issue: the inadequate interaction between theory and empirical evidence. In the case of the locality studies, this becomes apparent due to the exclusive focus on the level of the locality and the exclusion of national or global economic development trajectories and their analytical framework. Because a new regional geography—rightly—assumes that phenomena cannot be explained by themselves, a stronger effort needs to be made to interrelate empirical description and theoretical abstraction.

The last point to be discussed here is as fundamental as the previous issues. What are the implications of a regional geography which is conceived of as a social science, thus relinquishing the former claim of giving unity to geography (by integrating physical and human geography)? Will a social scientific understanding of regional geography therefore lead to a loss of disciplinary unity? There can be little doubt that this issue is an important one as geographers have to compete with academics from other disciplines for funds, etc. Showing disciplinary unity can help to underscore the importance of the discipline and thereby demonstrate the importance of academic subjects as social systems which can effectively organize funds, support, and the like. However, as a cognitive system, geography has to approach the question of disciplinary unity via a different route. Unity is no value in itself, of course, so the issue at stake is whether there are social developments which suggest a holistic approach. One key area to be dealt with in such a way is the crisis of late modern societies effected by ecological and other human-made problems. Because of the complexity of these issues a comprehensive approach has to be taken in order to resolve the problems involved. Serious as these matters may be, they offer a chance for academics to cooperate

in various ways: amongst colleagues of the same subject, on an interdisciplinary level, and with the wider public. Only a concerted effort can help to come to grips with the numerous dangers inherent in the modern world we live in and which we helped to create.

4. *The Prospects of Regional Geography*

The future of geography as a whole and of regional geography as one of its branches will very much hinge on the ability of geographers to contribute to these and other socially relevant issues. Such an argument is based on pragmatic and normative considerations and not, as was the case with traditional regional geography, on the methodological neo-Kantian assumptions outlined above (the latter, however, having the normative implication as to how the subject, the methods, etc. of regional geography should be seen).

After the paradigmatic shifts in the twentieth century which first brought traditional regional geography into disrepute, and then questioned the hegemony of a positivist mode of explanation ('spatial analysis'), we now live in an era where the grand, all-encompassing theories have lost their authority and where different analytical frameworks (methodologies) coexist. It has become clear that there is not *one* way of coming to grips with the complexity academics (have to) deal with. It is understandable that the proponents of a positivist mode of explanation, in their wish to be accepted as equals by their colleagues from other (positivist) disciplines, broke with the regional tradition in the 1950s and 1960s. However, from the vantage point of the early twenty-first century, this development can now be seen as a certain stage in the development of the discipline which has evolved as the disciplinary discourse progressed. As Hanson (1999, p. 136) points out, there is now

a greater willingness to acknowledge complexity and to engage multiple approaches to understand that complexity. There is now a greater acceptance of the notion that people create knowledge rather than discovering objective truths ... and that taking advantage of what is useful in each of a number of approaches can yield greater understanding than does adhering only to one.

What are the implications of these considerations for the future of regional geography?

Taking up the line of argument presented by Hanson, an enlightened methodological understanding of a modern regional geography cannot afford to dismiss lightly any conceptual framework, as different perspectives may yield different facets of knowledge. If regional geography is to be taken seriously as a competitive academic subject, it needs to engage in the methodically controlled generation of knowledge, and it needs to do that by probing the relevance of different methodological approaches. This is no easy task as different understandings of what science is (or should

be) about rest upon different epistemological and methodological assumptions, for instance on contrasting concepts of knowledge or causality. But the options are much less attractive. Additionally, it needs to be pointed out that along with such a postmodern methodological understanding comes the inherent danger of warranting an 'anything goes' attitude (including a regional geography without or with implicit theory). A competitive regional geography, however, needs to take on board an explicit reference to theory, and it needs to take seriously the reciprocal relationship between theory and empirical evidence, as this is an important mechanism for expanding the theoretical foundation of the discipline.

At this point the above-mentioned pragmatic and normative considerations need to be reconsidered again. This is so because any definition of competitive research would be incomplete if it did not reflect the social contexts in which research agendas are being drawn up or in which research results are being applied. It is important that the value-free stance of traditional regional geography is given up because it would be a self-deception to believe that regional geography can do without explicitly referring to or incorporating normative issues. As academic disciplines are an intrinsic part of society, they need to reflect the origin and the legitimacy of research topics and the use of research results. But which questions are to be raised and which problems are to be tackled by regional geographers? A systematic discussion of this issue has not yet taken place. However, it needs to be addressed in the context of a concerted effort to bring to life a 'new' new regional geography as a theoretically informed empirical project (Thrift 1998). The debate of the 1980s and 1990s broke new ground and generated a number of stimulating (conceptual) ideas from where the debate could be taken.

Regional Government

Regional government analysis has traditionally been restricted to state politics in federal systems or to center-periphery relations in the integration of the nation-state. We focus in this entry on Western Europe and North America to show: (a) that the political and legal status of regional institutions is extremely diverse; (b) that the rationales for regionalization have to be referred to state traditions; (c) that these rationales converge to develop both regional politics and public policies; and (d) that transnational integration gives a new relevance and meaning to regionalism.

1. The Ambiguous Status of Regional Government

Regional government is among the topics in comparative politics that clearly reveal the contingency of political institutions and the diversity of political processes behind them. Some countries exhibit very strong subnational governments, such as states in federal political systems (e.g., the USA or Switzerland), while others do not have any regional institutions at all (in centralized states such as Greece or France until the Fifth Republic). When such institutions do exist they may range from weak administrative units without much social significance to real representative institutions with powerful political capacities. To enhance the complexity of the picture, regions often coexist with other subregional units (counties, provinces, and *départements*), and display very different legal and fiscal authorities over the lower levels of territorial governments.

This variance suggests that the analysis of regional government is anything but simple, and that the idea of a universal form or of a common feature of regional institutions, even in the limited area of Western democracies, is misleading. Regional government cannot be analyzed independently of the political context within which it is taking place. It has to be referred to the general process of state building and state tradition, and understood as the product of different trends of regionalization.

In a restrictive meaning, regional government can be defined as the activity of political authorities specifically designed as an intermediary level between the state and local governments, and grounded in legitimacy vested in regional forms of political rep-

resentation. Therefore, it involves the scale of political authority (the level where sovereignty is defined and bounded), the aims of government (whether it takes care of regional issues or not), and the tools used to fulfil these goals (centralized vs. decentralized means of authority). It is conceivable to observe a government of regional issues without corresponding mechanisms of political representation at the regional level (e.g., with the Scottish National Office before the devolution reforms in the United Kingdom or the regional *Préfets* before the decentralization reform in France). Nevertheless, most Western democracies have evolved since the 1980s towards a greater empowerment of regional levels of political representation (most dramatically in Spain, France, Belgium, Italy, Canada, and more recently the UK), while federal systems turned to more interdependent patterns of relations between states and federal governments (notably in Germany, the USA, and Switzerland). In a more extensive definition, it is therefore more appropriate to conceive regional government as a set of complex institutional interactions and social mobilizations around political representation and public policies defined at an intermediary level between the state and local governments. If all Western democracies do not display distinctive political institutions at the regional level, all of them nevertheless show strong tendencies towards social and political mobilizations, and adjustments in institutional settings at this mesolevel of government (Sharpe 1993). Thus, this extensive definition is more appropriate to capture the actual issues of regional government in its contemporary context.

2. State Traditions and Rationales for Regionalization

From this definition we can infer that different state traditions, that is, differences in historical paths of state building and related administrative cultures, will matter in defining regional government. In exploring this topic, Loughlin and Peters have identified four main state traditions. (i) The Anglo-Saxon tradition (including countries such as the USA, the UK until 1998, Ireland, and Canada with the exception of Quebec), where there is no (in the UK) or a limited (in the USA) legal basis for the state, and where regional government can be either the 'state power' of the federal system (the USA), or shadowed by the strength of local government (in the UK). (ii) The Germanic tradition (covering countries such as Germany, Austria, Spain after 1978, and Belgium after 1988), rooted in a strong legal status of a Weberian state and a co-operative federalism giving large powers to regional government. (iii) The French State tradition, which is Jacobean and centralist, and where regions appear as technocratic creations progressively building a regionalized unitary state (for example, France,

Spain until 1988, Portugal, Greece, Belgium until 1988, and Quebec). (iv) Finally, the Scandinavian state tradition of Sweden, Norway, and Denmark, which, like the Germanic one, is rooted in a strong legal basis of the state, but in which the territorial organization is based more on a strong local autonomy than on the development of regional government (Loughlin and Peters 1997).

State tradition conceptualized in this way does not explain everything regarding regional government. For instance, there are strong discrepancies in the Anglo-Saxon model between European and American countries, and The Netherlands appears as an exception in the Germanic tradition. But it helps nevertheless to understand the different territorial policy paradigms (Balme et al. 1994) and political rationales for regionalization, understood as the forces driving the creation and development of regional government.

The first of these rationales is strictly political and linked to the integration of the nation-state. Regionalism here is close to nationalism, and regional government can be seen either as a tool to sustain the integrity of the state or as the 'slippery slope' leading first to larger claims to regional autonomy and ultimately to separatism and independence. This issue is dependent on social and territorial contiguity, on the degree of economic integration of regions to the country, and on the use of political violence between protagonists. However, the meaning of institutional development at the regional level will be different in an Anglo-Saxon context, where it appears as explicitly political with devolution (Elcock and Keating 1998), from a continental one, where regional decentralization can also be justified by administrative arguments and in this respect be more easily acceptable.

The second form of regionalization is federalism. Here the rationale is not so much political as constitutional-legal. It refers not to its integrity or to the coexistence between different cultural communities as in the previous case, but to the structure of the state, to its territorial organization normatively defined. Again, the strengthening of regional government has different meanings in the Germanic and in the Anglo-Saxon tradition. When states gain in power in the co-operative federalism of Germany, it is understood as more political interlocking (*Politikverflechtung*) between federal and state levels of government. This process leads to complex patterns of interdependence, often sub-optimal and sometimes unable to avoid 'the joint decision-trap', that is, the impossibility to make any decision other than the smallest core for agreement (Scharpf et al. 1976). The governing capacity of the system is in this context limited by vetoing powers of territorial governments, but the general picture is nevertheless a context of 'big government', increasing public expenditure, and governmental overload. It is noticeable that this kind of analysis has been expanded by this author to European governance as a whole

(Scharpf 1988). In the European context, federalism has been transformed by European integration (Jeffery and Sturm 1993, Jeffery 1997).

The increase in regional government in an Anglo-Saxon 'disjoined' federal system would take a very different meaning, and does not appear likely in the contemporary context. In such a political system, states do not have an institutional access to federal government other than through the Senate. Federal and state policies are supposed to be distinct areas of government, and there is in principle no co-operation between the two levels of government in defining public policies, other than through judicial review. In fact, the 'marble cake' concept of federalism has long been violated by numerous overlaps, redundancies, and competition between federal and state administrations through the development of public policies (Gray et al. 1990, Wright 1988). Here the state tradition is liberal and rests on the idea of a minimal central government. Consequently, the empowerment of state governments would mean resisting the continuous development of federal policies, and saving the political system both from centralization and from 'big government'. Empirically, however, despite a lower level of public spending than in Europe and more limited welfare policies, the US political system has gradually evolved towards higher levels of public intervention and more overlap and interdependence between levels of government.

Finally, the third rationale for regionalization lies in public policies. Even in centralized states such as France, the development of the public sector during the decades after World War II, as well as changes in the economy associated with increased mobility, have often led to recognition of the need for a regional scale of decision making. In France, regions were first created as administrative bodies aimed at improving the territorial fitness of public investments and only gradually became political institutions, with the first election of their councils in 1986. Again, in a centralized state, the reform is mainly administrative (at least at the beginning), whereas in a federal system it is openly political with the transfer of the burden of public policy from federal to state governments.

3. Regional Politics and Policies

These three rationales have converged since the 1970s to strengthen in one way or another the political salience of regional government. This in no way means more autonomy at the regional level. It means, on the contrary, more interdependence in complex institutional settings, where regional specificities, be they economic, social, cultural, or political, have come to be recognized. This has also led to altogether fewer conflictual and hierarchical modes of integration between center and peripheries, defining new forms of public policies and political authority.

Regarding regional politics, political mobilization around regionalist parties was noticeably sustained in Quebec, Catalonia and the Basque Country, Corsica and Overseas French regions, Wallonia and Flanders, in Italy with the Northern League, and to a lesser extent in Wales and Scotland. More generally speaking, independently of quasinationalist movements, politics at the regional level gained in saliency with the development of public policies at the regional level. Regions more specifically develop public programs in education and professional training, culture, economic development, transportation, and regional policy. They answer in a way to a functional logic of public policy, where sectoral policies are selected by the relevance of the scale of government, but also and mainly by the opportunity structure defined by the existing institutional design and potential political support. Regional public policies are thus linked to mobilizations of social interests, sometimes through neo-corporatist modes of organization, and in any case to some forms of political exchange structuring political leadership (Koller-Koch 1997, Négrier and Jouve 1998). More controversially, the performance of regional institutions also refers to social capital and civic traditions (Putnam 1993). Without overestimating such a causality, the relation between regional sociality and identity on the one hand and regional governance on the other hand offers stimulating perspectives for analysis. Generally, societal mobilizations at the regional level tend to correspond to inter-institutional modes of regionalization of public policy.

4. Regional Government and Transnational Integration

Finally, regional government is affected by transnational integration in two different ways. First, economic globalization increasing the mobility of economic factors defines an opportunity for the development of regional policies aimed at managing the territorial consequences of these changes, both in attracting investments and in defending regional firms, industries, and social sectors. The creation of transnational markets such as the European community, NAFTA, and MERCOSUR transforms socioeconomic conditions and needs, most dramatically in the case of border territories and monoindustrial regions affected by international competition. Second, political integration at a supranational level, as it is best exemplified with the European Union, defines new issues for regions to get access to regional policy programs, and more generally to preserve their interests in the new political process. Getting involved in new public policies, regions also invent new channels of influence progressively designing a new political game made of transnational arenas and forums. The creation in 1992 by the Maastricht Treaty of the Comity of the Regions

reveals this logic of recognition of regions by European institutions and their inclusion in this political process. Even if their influence is extremely diverse (Keating and Jones 1985) and needs not to be understood to be an alternative to the power of nation-states (Le Galès and Lequesne 1998), it is nevertheless part of the more polycentric and multilevel forms of governance (Hooghe 1996) characteristic of the European Union. In the same way, the development of foreign relations (Keating and Aldecoa 1999) and of transnational co-operations between regions (Balme 1996) contributes to the bypassing of the Westphalian and exclusively interstate system of international relations, and defines regional collective action as an answer to globalization. This context defines a new relevance for regionalism, but also transforms its meaning (Letamendia 1999), as this new regionalism turns away from parochialism and tradition, and combines economic openness and cultural identity to sustain socioeconomic development in a more cosmopolitan way.

Regional Identity

1. Introduction

The concept 'identity' is concerned with the answer to the question: 'Who am I?' 'Place identity' and 'regional identity' are answers to the question: 'Where am I?' Sometimes this question is more differentiated: 'Where do I come from' and 'Where do I belong to?' The phenomenon regional identity has an enormous range: it stretches from the personal home to territorial politics (geopolitics), from self-consciousness up to the problem, how to cope with the impacts of globalization.

2. Definition

(a) Regional identity is part of the self-identity of the human being. Regional identity results from the close ties of an individual to a region. It may consist of different intensities: it reaches from (i) a vague sense of belonging to a particular region, (ii) a close attachment to a region, (iii) a deliberate confession to and identification with a region, up to (iv) an active engagement for the region. In each of these cases areas, which are defined emotionally or rationally, serve as an objective, relatively stable source of orientation for the behavior of the individual.

Regional identity is very close to personal identity. Personal identity does not exist for itself but is built—and permanently rebuilt—in social interactions. So there is a strong relation to the (social) environment of a person. In the same way regional identity is not only a personal feeling towards a place but is part—or counterpart—of the collective. There is no self-identity without embeddedness into a community and there is no identity of the collective without individuals.

Therefore regional identity is not only part of the personality which is bounded to the region, but also and particularly consists of the knowledge of others having similar feelings for the region as oneself.

(b) Regional identity is not always regarded as an

attitude or a characteristic of a person (or a group of persons). Sometimes it means a particular region as a whole. Then 'region' is regarded as an entity with special characteristics so far different from other regions. Although it obviously bases on individual attitudes, regional identity is regarded as a relatively autonomous social structural formation, which neither can be seen as the total of individual attitudes nor can be dissolved into society.

To this point there are different positions according to the underlying epistemological background. To declare regional identity as a structure of its own derives from the tradition of the 'physique sociale' founded by Emile Durkheim (1893) and—in a lower degree—from communitarism. Following the position of action theory this second definition of regional identity is seen as an improper naturalism or essentialism. But nevertheless it can be pointed out that a specific characteristic of regional identity obviously is the oscillation between the level of action of the individual and the level of structural formation of the society.

3. Special Aspects of Regional Identity

3.1 Characteristics of Regional Identity

Regional identity is not an isolated status quo of an individual, but is bounded to the development of social interactions as well as to the individual biography. Regional identity develops from different sources, from individual experiences during childhood, from the perception of the personal space, and other experiences. However, even more important are socially mediated aspects, because identity does not exist in individuals for itself, but develops, grows, and changes in social interactions. Therefore culture, tradition, landscape, and history of the region form regional identity and are part of it.

A decisive element of regional identity is the close relation between the region and the historical dimension. The common history is not only referred to as the history of a political territory, it may also refer to the affiliation to an unified confessional territory, a linguistic boundary or similar aspects. Normally there is a bundle of cultural elements important for the identity of a region and the identification of individuals with the region in question. Such elements can be:

(a) the economic basis, e.g. the production of coal and steel in the Ruhr area in West Germany. The popular name of the region 'Ruhrpott' (melting pot at the river Ruhr) reminds one of the process of melting ore with coal;

(b) the language or specific dialect, e.g. 'Languedoc' or 'Occitanie' in the south of France (where people say 'hoc' instead of 'oui' in the north of France), 'Catalunia' in the east of Spain, 'Friul' in the northeast of Italy;

(c) a particular landscape like an island, a big river, or a mountain area (Corsica, The Rhine Valley, the 'Padania' around the river Po, The Highlands);

(d) even specific regional dishes (Cornish pastry and Cornish cream, Tirolian 'Knoedel') can be part of the shared frame of reference. Of course regional identity rarely develops from that kind of particularity alone.

Abstract phenomena as well as objective elements can stand as objects of identity. Normally it is not a single element alone but several characteristics of a specific region which contribute to regional identity.

These shared symbols are normally grounded in the history and development of the region. But the historical dimension also may be an artificial 'myth' or an imagined community in the sense of Anderson (1996). What is really important is the belief in the common history and the existence of a collective. Following Weber (1922) this belief is called 'Gemeinsamkeitsglaube' (for details see Sect. 4). If these shared symbols become an important element of communication in the lifeworld or even in political discourse then there is a switch from regional identity (a) to (b).

3.2 Regional Identity and Scale

Regional identity is a kind of spatial identity on a certain scale called the meso-level. Regional identity is located between the national and the local level. To illustrate regional identity spatially the term 'county' should most likely fit.

Scale is helpful to distinguish regional identity from place identity. Although in some cases place identity is used as the overall term for the different levels of scale, place identity is normally associated with the directly perceived space.

An aspect which distinguishes regional identity from place identity is a higher degree of abstraction from the concrete space. To a lesser extent regional identity is bounded to the concrete perceived space, the personal perception and experience, and the co-presence of individuals. 'Local identity' is bounded to the network of friends and relatives, to the personal socialization of the individual and therefore people are deeply attached to particular places. Regional identity, however, is more abstract: it does not need an actual or the remembrance of a former co-presence of people at the same place. The person with close ties to the region normally knows the region, the physical space, and even more its inhabitants, only in part by personal experience. Particularly against this background symbols which are known and shared by a collective are quite important to establish a sense of community.

3.3 Regional Identity and Regionalism

Regional identity is different from localism as well as from nationalism or patriotism. Above all regional identity is a cultural, social, and psychological phenomenon and not a political one, but this depends on the

degree of the intensity described above. As far as regional identity includes a political dimension, it tends to keep cultural traditions or to blame economic disparities.

If the interest for regional issues leads to a strong political engagement the term 'regionalism' is used to describe this attitude which leads to a larger political movement. Regionalism is the political movement with the aim to preserve or to gain cultural or economic self-reliance (or both). Political autonomy is not the first aim but tends to develop during the history of a political movement. Regionalism often is marked by clear aims and strategies. If the intention is political autonomy one even has to talk about nationalism at least under the perspective of its supporters. These regional political movements can be organized like political parties. Examples are the 'Lega Lombarda' in Northern Italy, the 'Partis Quebecois' in Canada in a more traditional political sense on the one hand, and the liberation movements in Corsica or the Basque provinces in the north of Spain on the other hand.

The line between vague regional identity and active political regionalism is not sharp and the motifs are mixed together. See for instance the Occitanian case: on the one hand in the late 1960s the inhabitants of this region felt disadvantaged. The starting point of the protest was the bad situation of a region depending economically on the production of wine. Most people in that region were affected by this and it had little to do with regional culture and so forth. On the other hand, the regional protest led to much solidarity in the heart of France, especially in the intellectual milieu around the politically left students and academics. The engagement of these people for Occitanian, drinking Herault wine and spending their holidays at the Causse de Larzac, had little to do with their place of origin or the feeling-at-home in that region. The Occitanian identity of these intellectuals expressed their (general) political engagement in favor of disadvantaged regions and the utopia of an intact world. Regionalism unites individual interests and focuses people on common ends. Therefore, regional identity is to be seen as an element of the social system in the sense of the second definition given above.

3.4 Regional Identity and 'Real' Region

Talking about the Occitanian identity of the intellectuals at Paris has already expressed that the region as an area on the earth's surface and the region of the identity are not always congruent. Of course there must be a relation of a particular regional identity to a specific region. But this does not mean identical maps. For example, an administrative region like 'Bretagne' in France or 'Andalusia' in Spain is not congruent with the area of people calling themselves 'Bretons' or 'Andalusians' and is even less congruent with their regional identity. If people draw their mental maps of

the region in favor, the results differ considerably. Normally it can be assumed that the regional identity is more distinctive in the heartland than in the border area. In the center the regional language or dialect prevails and the specific traditions and rules of the lifeworld are cultivated. But even the contrary is possible: if the neighboring region seems to be strange or even hostile regional identity will be strongest at the border, e.g., this phenomenon can be found in the case of South Tyrol.

Another important point in this context is the personal absence from or presence in the region in question. Regional identity is not attached to the physical presence in that particular region. On the contrary, regional identity is sometimes stronger in foreign surroundings than at home: Friulians in Canada, people from Sicily in Torino, Bavarians in Hamburg, and so forth often feel and think more Friulian, Sicilian, and Bavarian than people who see their region as the natural place of the everyday life.

Finally, the Occitanian example shows that regional identity is not always a particular regional identity. Regional identity is an universal value too and not attached to a specific region. To prefer federalism to centralism in a political system expresses this attitude.

4. The Formation of Regional Identity

How does regional identity develop? According to the two aspects of the notion mentioned above in the definition, at least the answer to this question has to make a difference between two levels: the first is the anthropological aspect (in close relation to self-identity), the second is the social theory with special respect to social structural formation.

4.1 Regional Identity as a Basic Need of Human Beings

Regional identity is part of self-identity and therefore stretches from the unconsciousness to the rational consciousness. Especially an active political engagement for the reason in favor is already part of the discursive consciousness.

Above all regional identity is part of the practical consciousness in the sense of Giddens (1984). Among others practical consciousness means living and working in everyday life by routines. Therefore the surroundings and experiences in the places where people live form a stable frame for individual decisions and behavior. One can say that regional identity is built and permanently rebuilt in the social and spatial context of the individuals. The well-known region and its people give trust and security for the behavior of the individuals.

From a phenomenological point of view region has a similar function: at the heart of the lifeworld is the home world in contrast to the strange world outside.

Regional identity as a social process is constructed on different levels: in kindergartens, schools, clubs, and other institutions. Communication and experiences in everyday life form the attitude towards the region.

4.2 Regional Identity as an Element of Social Cohesion

In social theory the topic 'regional identity' is part of the discussion about inclusion and exclusion starting with the book of Ferdinand Tönnies *Gemeinschaft und Gesellschaft* (*Community and Society*) at the end of the nineteenth century (1887). Max Weber says that the formation of community (*Vergemeinschaftung*) and the formation of society (*Vergesellschaftung*) are two of the essential sociological notions. If people believe that there is a traditional or emotional feeling of togetherness then community can arise. To understand regional identity two points are of special interest. First, there must be a real starting point of a regional community (e.g. language, religion, origin) but it is just the belief in the force of this shared characteristic that can lead to the formation of a community. Therefore, even regional identity is socially constructed. Second, there is no need for the co-presence of individuals. The feeling of belonging together can be a powerful motor for the formation of inclusion, especially if there are no other characteristics easy to recognize and to manipulate. So the notion regional identity is not very different from the modern notion of ethnicity. The modern theory of ethnology too regards 'ethnicity' as a construct, while the traditional (primordial) notion of ethnicity is essentialistic and has a strong affinity to race.

From a systematic point of view social cohesion needs rationality as well as emotion. In a similar way to Weber, Emile Durkheim (1893) illustrates a difference between 'mechanical solidarity' and 'organic solidarity' in human societies. In the traditional 'Physique sociale' as well as in the modern 'New Social Physics' social integration is to be seen as a result of collective consciousness (on the basis of emotion, religion, and so forth) in the first case and of treaties between agents in the second. It helps people to avoid making arduous decisions if they follow the idea of 'natural cohesion'. Or as B. Anderson points out: 'In this way, nationness is assimilated to skin-colour, gender, parentage and birth-era—all those things one can not help. And in these "natural ties" one senses what one might call "the beauty of *gemeinschaft*"' (Anderson 1996, p. 143).

5. Regional Identity Between Modernism and Postmodernism

Is regional identity a relic of premodern societies disappearing during the process of modernization? Following the ideas of Giddens (1984), people are

more and more disembedded and this means that their activities and their thinking, that social relations in general, are no longer bound to the space-time-context. Time and space get more and more divided. The boundaries of the region and the self coincide no longer. The space of reference for the individual actor in the time of globalization finally is the whole earth. Therefore it is declared that regional identity loses its importance during the process of modernization. A similar position can be derived from the General Systems Theory of N. Luhmann (1994). According to Luhmann, the whole modern world is inter-related and regional worlds of their own no longer exist. Differentiation in the world is based on functions. Normally the same person belongs to different systems in different places depending on their role as a consumer, employee, or lover. M. Weber had a strong historical interest and regarded social change and the process of modernization but there is no clear statement that he regarded community as a—more and more disappearing—historical phase during the formation of (modern) society.

On the one hand one can be sure that there are no longer closed up regional worlds like in premodern times. On the other hand 'region' is a very simple and therefore very practical code to produce cohesion and identification. Even more: the more complicated and differentiated the modern world becomes the more we need simple possibilities to discern people, political subsystems, and so forth. Therefore regional identity is one of the powerful social bases for political movements, starting from regional protest based on environmental issues up to most of the wars in the late twentieth century. 'Belonging to'—not only same region, but also to the same religion, the same 'race' and so forth—is much more relevant than class differences or other social aspects to include or to exclude people. Such kinds of inclusions—and the corresponding exclusions—are responsible for most of the recent (violent) political developments especially in the east of Europe, but also in Africa or in the Near East.

Regional identity is embedded into the more general debate on the role of identities in relation to the universal values (of the Enlightenment). It is part of the debate which of these two basic values is of more importance: to respect individual historically grown traditions or to assert the general human rights all over the world. There is a strong political dimension connected to this subject: it stretches from the apparently simple question if Islamic girls are allowed to join school lessons with a scarf around their head in laizistic French schools up to the question if western politicians are allowed to claim the recognition of human rights in the People's Republic of China. The popular considerations of Finkelkraut (1989) in France and Germany and of Said (1978) and Bauman (1991) in the English speaking countries give new importance to this subject. The position of the—now

as accidental recognized—values of the Enlightenment has diminished and pluralism had to be put on the agenda. There are different ‘language games’ (in the words of Ludwig Wittgenstein) which are incomparable.

So it has to be pronounced that in the end regional identity is part of the postmodern debate. In a postmodern context regional identity can be submitted to the leading category of difference (and unity). In (post-)modern guise questions come back which were important already at the end of the eighteenth century: Immanuel Kant defended the achievements of the (French) Enlightenment, while John Gottfried Herder so preparing romanticism and historicism declared that these values are not valid for the rest of the world: in different regions develop different cultures which cannot be compared and ranked.

6. Relevance of Regional Identity Today

Following the theoretical considerations, regional identity as ‘a sentiment of belonging to’ always exists to a higher or lower degree at the individual level. Sometimes it is just folklore, but very often it gets at the heart of social and political issues. Regional identity is part of the general tendency in societies to construct social cohesion. Some examples are ecological and political movements, emigration colonies, and economic developments. For instance, political movements focused on ecological topics or resistance against nuclear power plants often affirm to defend ‘their’ region. As already shown in the example of Occitania there is often a mixture of political interest and traditional emotions: without doubt regional identity serves as symbolic arm in political discussions but without regional identity such political movements would not exist—or only for a short time.

People who are forced to emigrate try to keep their former identity in Little Sicily, in the Arabian ‘banlieue’ of Paris, in the Inner City Ghettos of the ‘Guest workers’ in Western Germany. Home is what you feel when you have lost it, so people try to keep their identity by staying together. In globalization, regional identity has a new dimension. On the one hand, people lose control to their surroundings more and more, so they try to keep regional traditions, on the other hand, it is much easier to get involved in the process of globalization and to keep its regional identity within a transnational space at the same time. Even more, jobs are more and more insecure, the firm is no longer the only center of thinking of the employees, while place gains new importance (Sennett 1997). So regional identity becomes more important.

In a similar way regional identity works in regional economics. The moral economy precedes the market economy and is still of importance. The success of industrial districts is sometimes an outcome of regional embeddedness of the entrepreneurs as well as

the employees of the region where it is located and where the network works. Shared rules and common values produce trust, confidence, and reciprocity which are regarded as the surplus making such specialized regions more successful than others. On the other hand it is also possible that there is an economic decline because of too much regional identity and following lock-in-effects: the Ruhr area in the 1970s and 1980s or—in a broader sense—Sicily and its whole Mafia problem may be seen as examples. Regional identity is therefore not a sentimental relic of premodern times. Regional identity is one of the geographical dimensions of the construction of modern society.

Regional Integration

1. Definition

The term 'regional integration' refers to the process whereby sovereign nation-states voluntarily establish common institutions for collective governance. This process is multifaceted. At the political level, regional integration involves the creation of supranational institutions, with executive, legislative and judicial powers, and the delegation of policy competences from domestic governance institutions to these institutions. On a legal level, regional integration involves the establishment of a new hierarchy of legal norms, where supranational law is not only an integral part of domestic law (the doctrine of 'direct effect') but is also sovereign over domestic law (the doctrine of 'supremacy'). At the economic level, regional integration involves the development from a common market (in parallel with existing national markets), through a single market (with the removal of barriers to the free circulation of goods, services, capital and labor), to a common or single currency (in parallel with, or replacing, national currencies), and eventually to full economic union (with common macroeconomic and fiscal policies). At the sociological level, regional integration involves the creation of new supranational identities, loyalties, interest groups, and social movements, in addition to and sometimes in opposition to existing national identities, interests, and movements.

2. The Early Study of Regional Integration

The first steps towards regional integration occurred in Europe in the immediate aftermath of the Second World War. This led to the establishment of the European Coal and Steel Community (ESRC) in 1952 by six states (Germany, France, Italy, and the Benelux countries), who then created the European Economic Community and the European Atomic Energy Community in 1958. Hence by the end of the 1950s, regional integration was more advanced in Europe than in any other region in the world. Nevertheless, modeled on the European process, inter-state agreements and supranational economic regimes began to emerge in South East Asia, Latin America and North America.

As a result, in the 1950s, the process of regional integration was regarded by most social scientists as a generalizable phenomenon. For example, Karl Deutsch and his colleagues (Deutsch et al. 1957)

developed a general 'transactions theory' of integration: as cross-border economic and social transactions increase, new regional identities and communities are created, which facilitate new institutions, and so on. The zenith of the early study was the 1970 special issue of the journal *International Organization*, which tried to develop and test theories that could explain the varying stages of regional integration throughout the world (Lindberg and Scheingold 1971).

3. European Integration: A Sui Generis Phenomenon

However, with the global economic crises in the early 1970s, it became clear that the experiments in regional integration outside Europe were not as deeply entrenched as the process within Western Europe. Ernst Haas, the founding father of 'regional integration theory,' consequently proclaimed that the generalizable study of regional integration was now 'obsolete' (Haas 1976). From the launch of European integration in the 1950s to the relaunch in the mid-1980s, there have been two dominant explanations of European integration.

3.1 Neofunctionalism

Neofunctionalism was first proposed by Haas (1958) to explain the establishment of the ECSC Treaty, and was developed by his disciples to explain subsequent integration steps. The basic argument of neofunctionalism is that European integration is a deterministic process, whereby 'a given action, related to a specific goal, creates a situation in which the original goal can be assured only by taking further actions, which in turn create a further condition and a need for more, and so forth' (Lindberg 1963, p. 9).

This 'spillover' process is promoted by two sets of actors. First, at the domestic level, societal and sectional interests promote integration of different policy sectors to achieve political advantage over their opponents or secure benefits already accrued by the integration of other policy sectors. For example, in the 1980s, multinational business interests lobbied for the establishment of a European-wide single market, to secure greater economies of scale and lower transactions costs in cross-border trade. Second, at the European level, the supranational institutions promoted further integration to increase their ability to shape policy outcomes. For example, in the 1960s the European Court of Justice consciously made rulings and established doctrines to promote legal integration in Europe, and in the mid-1980s the European Commission was instrumental in persuading governments to adopt the program for completing the single market.

3.2 Intergovernmentalism

Neofunctionalism's failure to explain the slowdown of European integration in the 1970s, and the subsequent strengthening of the 'intergovernmental' elements of the European Communities, led to the emergence of a starkly opposing theory of European integration, known as intergovernmentalism. In direct contrast with neofunctionalism's emphasis on nonstate interests at the domestic and supranational levels, intergovernmentalism argues that European integration is driven by the interests and actions of the European nation-states. In this interpretation, the main aim of nation-states is to protect their geopolitical interests, such as national security and 'sovereignty.' Also, interstate bargaining is a zero-sum game, where 'losses are not compensated by gains on other issues: nobody wants to be fooled' (Hoffmann 1966, p. 882). Consequently, against the neo-functional 'logic of integration,' intergovernmentalists see a 'logic of diversity [which] suggests that, in areas of key importance to the national interest, nations prefer the certainty, or the self-controlled uncertainty, of national self-reliance, to the uncontrolled uncertainty of the untested blunder' (Hoffmann 1966, p. 88). From the intergovernmentalist perspective, then, European integration was relaunched in the mid-1980s because the governments in the large member states shared the same policy preference for a single market and the governments in the periphery states were bought off through 'side payments,' such as regional transfers (e.g., Moravcsik 1991).

4. Reintegrating Regional Integration with General Social Science

Ironically, as European integration gathered pace at the end of the 1980s, regional integration began again to be understood as a general phenomenon in social science. There were three main reasons for this shift. First, with the Single European Act in 1987, the establishment of the EU in 1993, and the launch of European economic and monetary union in 1999, European integration began to have a significant impact on domestic political systems and on global political and economic relations. European integration and the EU hence became a major focus of research in a number of social science disciplines.

Second, in the 1990s, the success of the European single market encouraged regional integration in other parts of the world—where governments breathed new life into moribund regional organizations (such as the Association of South East Asian Nations) or created new regional governance regimes (such as the North American Free Trade Area). Once again, regional integration was a general rather than a *sui generis* phenomenon.

Third, and related to these two aspects, with this renewed interest in the European process came specialization, where scholarship focused on specific aspects of the integration process or the EU rather than on the broad historical development of regional integration. This specialization enabled scholars of European integration to apply general social science theories, e.g., of interstate bargaining, interest group behavior, legislative-judicial interactions, and monetary integration. Specialization consequently increased the subtlety and sophistication of our explanations of regional integration. It also enabled scholars of regional integration to be part of the mainstream study of these cross-systemic social science phenomena. This integration of regional integration and social science occurred in political science, legal studies, economics, and sociology.

4.1 Regional Integration in Political Science

In the International Relations subdiscipline of political science, regional integration is a particular type of supranational regime building between nation-states. For example, in his 'liberal intergovernmentalist' (LI) theory of regional integration, Andrew Moravcsik (Moravcsik 1998) deliberately places regional integration at the intersection between the two main approaches in international relations: liberalism and realism (see *International Organization*). From liberalism, LI argues that state preferences are formed through a process of domestic competition between rival economic interests in society. From realism, LI argues that once state preferences have been formed, states bargain to protect and promote their private interests, and cooperate to design institutions to reduce transactions costs, overcome collective action problems, and establish credible commitments (for example, by delegating agenda-setting and enforcement powers to supranational agents).

In the subdiscipline Comparative Politics, the EU, despite its peculiarity, possesses all the main attributes and processes of a political system. This enables the different elements of regional integration to be explained using general theories from comparative politics (Hix 1999). For example, the EU governments have delegated executive powers to the European Commission, and have designed institutions to control these powers, in the same way that legislative principals delegate to and control the powers of executive agencies in the domestic arena. Similarly, on the 'inputs' side of the political system, mass attitudes towards regional integration are shaped by the same utilitarian calculations and affective beliefs as the public show towards domestic institutions. Further, on the 'outputs' side, regulation (rather than redistribution) emerged as the central policy instrument of regional integration in parallel with the expansion of regulation and independent regulatory agencies in the domestic arena.

4.2 Regional Integration in Legal Studies

In legal studies, with the establishment of the doctrines of direct effect and supremacy, and the hierarchical relationship between the European Court of Justice and national courts (where national courts apply EU law in the domestic arena), the EU legal system is akin to a federal legal system (Weiler 1991). However, since the German Constitutional Court judgement on the legality of the 1992 Treaty on European Union (the Maastricht Treaty), there is not a clear hierarchy of norms in the EU system. EU law, in its primary form in the EU Treaty and in secondary legislation, is supreme over conflicting domestic statutes and legislation. However, according to the German Constitutional Court and similar constitutional authorities in other member states, EU law remains subservient to basic fundamental rights, as set out in domestic constitutions and the European Convention on Human Rights.

In the intersection between political science and legal studies, the interaction between the EU governments and the European Court of Justice is similar to the interaction between domestic legislative and judicial authorities. On one side, EU governments have delegated judicial power to the European Court of Justice to establish a rule of law, without which there would be little incentive for governments to implement EU legislation. On the other side, protected by the constitutional guarantees in the EU Treaty, the European Court of Justice has pursued the political strategies of many domestic constitutional courts, by reinforcing its legal authority versus lower courts and shaping political outcomes through the policy adjudication process.

4.3 Regional Integration in Economics

In economics, regional economic integration is a particular case of international economics and monetary economics. In international economics, states have liberalized trade to promote comparative advantage and economies of scale. From this perspective, the United States (in the nineteenth century), the European Union, the North American Free Trade Area and the World Trade Organization are all examples of the same phenomenon. In all these cases, the removal of barriers to the free circulation of factors of production was then followed, to a greater or lesser extent, by the creation of common regulations to address market failures, such as unfair competition (through merger rules), asymmetric information in market transactions (through rules on consumer protection), and negative externalities (through rules on environmental protection).

In monetary economics, the process of economic and monetary union in Europe, with the creation of the single currency, has led to the resurrection of the old 'Optimum Currency Area' (OCA) theory of

monetary unions (Eichengreen and Frieden 1994). In the OCA theory, nations decide to form a monetary union when the benefits of keeping independent exchange rates and interest rates (to address asymmetric demand shocks) are lower than the benefits of establishing a common currency (of lower transactions costs and greater certainty). However, through the empirical and theoretical study of monetary integration in Europe, this theory has been refined to take account of both political and economic calculations, how costs and benefits change with different levels of trade integration, and how different assumptions about the trade-off between inflation and unemployment change these calculations.

4.4 Regional Integration in Sociology

Although to a lesser extent than these other social science disciplines, regional integration has also become an important topic in sociology. For example, Soysal (1994) argues that supranational human rights norms—through the European Convention on Human Rights and the policies of the European Union—were as important as domestic factors in transforming the conception and operation of citizenship norms in Germany and France in the 1980s.

Regional Planning, History of

1. The Term 'Regional Planning'

'*Gallia est omnia in partes tres.*' All Gaul is divided into three parts. This command, from the reign of Julius Caesar in the first century BC, no doubt is one of the earliest example of regional planning. A region is a district or area defined by generally recognizable attributes, physical cultural, economic, or political. The word 'region' derives from the Latin '*regio*,' meaning direction or boundary, and from '*regere*,' to direct. Thus the concept of region embodies the interaction among place, people, and work or economy. A region may or may not be formally recognized as a political entity or sub-division. More likely a region is simply a shared mental construct of its constituents.

Regional planning then is the effort of the society or elements in the society to intervene in the integrated developmental evolution of the area in question. In ancient kingdoms, the wishes and wisdom of the ruler constituted the regional planning conception for the society. Values and objectives underlying regional planning and foresight particularly included protection from external threats, but also the provision of infrastructure—roads, water, the enhancement and protection of productive fields and forests, provision for population growth and economic development activities such as industry and trade, cultural enrichment, and provision for societal continuity in succeeding generations. These values and practices were often codified in religious beliefs and scripts. These values still underlie and are used to justify contemporary efforts to define and carry out regional planning.

At this point it will be helpful to discuss a few related words or concepts. We need first to distinguish regional from city planning. The concepts are related but city planning implies a *polis* or civic entity governed by elected or other recognized official bodies. A region does not necessarily have such official status. Indeed, often it does not.

Regional analysis is the study of the interaction of key variables—physical, social and economic—in a

regional context. Regional science, a relatively recent evolution founded upon economic location theory, seeks to describe and predict systemic regional phenomena.

We need also to distinguish types of regions. The European Community is a region comprised of nation states seeking to develop a commonality of purpose and policy, which presumably will result in superior outcomes for its constituent members. The European Union thus practices a kind of multi-state regional planning, much as the federal government in the United States does for the aggregate of its fifty constituent states. Parts of nation-states also may constitute regions. One thinks of Scotland and Wales in the United Kingdom or the Appalachian Region or the Great Plains of the United States.

Another distinction among regions is between mono-nodal, multi-nodal, and non-nodal regions. Metropolitan regions are examples of mono- and sometimes multi-nodal regions. Natural resource regions are often non-nodal. River basin regions are another category: linear regions.

Regions can also be distinguished as growth regions or as lagging regions. Regions may lag in development behind national averages, due to lack of natural resources, limited accessibility, or cultural or educational factors. Much attention has been given to assisting lagging regions to 'catch up,' with mixed results.

Today, we hear much about 'integrated regional resource management,' and 'sustainable development.' These concepts, while imprecise and difficult to measure, are increasingly shaping the directions towards which regional policy planning is moving.

We should also distinguish between 'regional planning,' and 'regional plan.' A regional plan is a specific document which lays out in physical detail a future desired end-state. It may also contain social and economic policy statements. The regional plan is typically based on a regional survey of social, economic, and physical factors. 'Regional planning' is the process by which regional plans are made. 'Regional policy' is a related concept. Regional policies are, in effect, guidelines to realize or implement regional plans.

2. Origins and Practice of Regional Planning

The origins of modern regional planning doctrine can be traced to reactions to the oppressive conditions created by the Industrial Revolution in nineteenth century England and France. Robert Owen and Charles Fourier proposed utopian schemes for alternative workers' housing and communities. Piotr Kropotkin's *Fields, Factories and Workshops* (1901) offered insights into the connections of people, land and labor. Charles Booth's *Life and Labor in London* (1892) systematically surveyed the conditions of work-

ing class people. Ebenezer Howard's 1902 *Garden Cities of Tomorrow* presented an influential alternative to unplanned metropolitan expansion. Patrick Geddes, a Scottish biologist, published his *Cities in Evolution* in 1915. Geddes' synthesis of the salient connections among people, land, economic activity, and natural systems greatly influenced the American essayist and critic, Lewis Mumford. Mumford, in turn promoted Geddes' integrative approach to social and public policy through such books as *The Culture of Cities* (1938). Through Mumford, Geddes' ideas influenced the Regional Planning Association of America (RPAA), a progressive private group concerned with development which was active in the 1920s and 1930s.

2.1 The Regional Planning Association of America

The RPAA embraced Ebenezer Howard's idea to siphon off and channel new growth at the suburban edges of existing large cities into planned garden cities. The group also espoused the notion that economic growth should be decentralized to smaller cities and towns and diverted from large metropolitan areas. The RPAA was especially influential in New York State, where Governor Al Smith appointed Stein and his fellow RPAA colleague, Henry Wright, to a newly-created Commission on Housing and Regional Planning. In 1926, the Commission issued a regional plan for the state that called for a concentrated grid of lines of transportation and communication along major corridors, separation of cities and highways, and the creation of independent communities away from the centralizing tendencies of its major cities. Protection of forest, farmlands and recreation areas were also proposed. The plan had considerable influence on policy and some of its proposals were ultimately carried out. What is notable is that these policies and issues are still under serious debate some 75 years later (Spann 1996).

The RPAA's conception of regional planning inevitably brought the group into conflict with the well-funded effort to create a Regional Plan for the New York metropolitan area begun in 1921 under the direction of Thomas Adams, a British town planner who had worked on plans for garden cities of Welwyn and Letchworth, and the Greater London region.

2.2 The Regional Plan of New York and Its Environs

The monumental Regional Plan of New York and Its Environs, begun in 1921 and published in 1929 (Committee on the Regional Plan of New York and Its Environs 1929). The plan brought together many of the development trends and proposals of the time and was underwritten by generous grants from the Russell Sage Foundation totaling some \$1.2 million. In 1990,

this would be equivalent to roughly \$20 million. The Regional Plan and Survey was and probably remains the best funded metropolitan regional plan ever undertaken (Hays 1965).

The plan, encompassing 22 counties surrounding the Port of New York and targeted on the year 1965, incorporated proposals of the Port Authority rail plans, including those for belt line freight rail lines. Schemes for rapid-transit improvements, highway construction, zoning rationalization, and parks and parkways were assembled from a variety of sources and agencies and synthesized into a unified conception. The plan called for a 're-centralization' of industry and business, involving, among other proposals, a shift of manufacturing outward from Manhattan and the core of the region. Whatever its flaws, the 1929 Regional Plan of New York and Its Environs left a significant imprint on Metropolitan New York. The plan's basic physical planning conceptions were reflected in the subsequent development of the region.

The Regional Plan of 1929 clearly had a significant effect on the physical development of the region. But it also brought important changes in the institutional and public bodies concerned with regional development. Numerous planning and zoning agencies were established at the county and municipal levels as a direct result of field work by the staff of the Regional Plan. State policies for regional development were also stimulated by the plan and its advocates. The plan also influenced the Depression-era New Deal policies of the Roosevelt Administration. President Roosevelt was well-aware of the ideas of both the RPAA and the Regional Plan of New York.

Roosevelt spoke at a Roundtable on Regionalism held at the University of Virginia on July 11, 1931 on the need for regional planning and development, aided by the initiatives of the federal government to lead the country out of the economic stagnation it had found itself. Thus Roosevelt was instrumental in getting the thought of Southern Regionalists, such as Howard Odum and Rupert Vance of the University of North Carolina, and the ideas of the RPAA group onto the agenda of the New Deal. This may have been the origin of the idea for a Tennessee Valley Authority (TVA) in Roosevelt's thinking. On a national scale, the New Deal also created a National Resources Committee to survey the needs and resources of the country.

2.3 The Tennessee Valley Authority

The Tennessee Valley Authority (TVA) was the first of the river basin or other large regional agencies to attempt to bring together the then-new concepts of integrated resource development, which was central to the conservation ideas of the time, and regional planning which was a part of the new city and area planning movement.

Roosevelt's early speeches and papers clearly reveal a deep-seated and long-standing concern with farm problems, rural poverty, and the inadequate methods of providing services to rural areas. He also saw these problems as coupled with those of overcrowding and poor living conditions for the working people in the big cities, which he believed were fueled in part by the migration from farms to cities. The emerging concepts of regional planning seemed to Roosevelt to provide the linkage between the two problems. It is within this context that the regional planning ideas of Roosevelt were appended to earlier ideas for a multi-purpose plan for the Tennessee River, which had focused on flood control, navigation, and power generation. The main body of the TVA Act, as introduced on March 9, 1933, consisted of a comprehensive river improvement program plus two sections which provided for surveys of regional development problems and for recommendations to Congress on necessary legislation to solve these problems. The river improvement sections of the TVA Act were very explicit and provided for a navigation channel from Knoxville to the Ohio River, flood control to protect valley cities and to help control floods on the Mississippi River, and power generation. In contrast, the regional planning sections were very general and thus susceptible to either broad or narrow interpretation. TVA's mandate to conduct and implement regional planning was never clear or unambiguous.

The National Resources Committee (later the National Resources Planning Board) envisioned TVA as the first of a nationwide array of river basin planning regions. TVA was viewed as a model for the rest and as a testing ground for new communities as originally proposed by the RPAA group. The first of these was Norris, Tennessee, built near the first hydroelectric dam, Norris Dam, originally to house construction workers, and then to be converted to housing for the local populations dislocated by the rising waters of Norris Lake. Roosevelt's grand vision for river basin regional planning initiatives was thwarted by the interventionist scale of the vision, in a country dominated by unregulated market forces, and by the outbreak of World War Two. TVA nevertheless became a model for numerous grand multi-purpose hydro-electric and irrigation projects around the world, some misconceived and contrary to sound, integrated regional resource planning and management principles. Sadly, TVA itself has relinquished any serious commitment to regional planning leadership and has become, in effect, primarily a publicly-owned wholesale electricity producer.

2.4 Appalachian Regional Commission

Besides TVA, America's other important multi-state regional planning effort has been the Appalachian Regional Commission (ARC). Like TVA, the ARC was created to deal with an economically lagging

region, the mountainous, relatively inaccessible chain of counties stretching from Alabama and Georgia to the Southern Tier of Upstate New York. The ARC began as an idea of President John Kennedy, who toured West Virginia's poverty-stricken mining towns in his campaign for the White House. The ARC was established in 1965 in the Johnson Administration. The ARC developed a plan for improving access and social services for isolated communities in parts of thirteen states. Highway improvement and infrastructure programs were central elements of ARC regional development. Thirty years later, assessments of the effectiveness of federal investments in the region are mixed. But according to one comprehensive study, the federal investment infusion seems to have been effective. Counties in the ARC program were noted on average to have developed faster economically than comparable counties not in the program (Bradshaw 1992, Isserman and Rephann 1995). ARC was still functioning in the year 2000 but other federal regional development efforts such as the eight Department of Commerce Title V regional commissions setup in other lagging regions of the US were not so fortunate. All were closed down in 1980.

2.5 Metropolitan Regional Planning

The post-war era in the United States, with its spreading suburbs and growing automobile dependency, raised new issues for regional planners, notably in the large metropolitan areas. Federal aid for metropolitan planning became available with the enactment of Section 701 of the Housing Act of 1954, stimulating the creation of planning commissions for the nation's metropolitan areas. By 1960, two-thirds of US metropolitan areas had some form of area-wide planning and, by 1971, thanks to federal grants and statutory requirements, all of the nation's 247 metropolitan areas had adopted official regional planning, mostly through elected, voluntary, Councils of Government (COGs). The A-95 review process, which required regional review and coordination to receive funding for large scale, federally-assisted projects, and Section 208 of the federal Clean Water Act of 1972 further stimulated the creation of regional planning bodies in metropolitan areas.

In the New York Metropolitan Region, the privately-supported Regional Plan Association produced a Second Regional Plan for the New York metropolitan area, released in November 1968. The Second Regional Plan emphasized the creation of regional sub-centers linked by fast rail to Manhattan to expand job opportunities for those trapped in the central cities. For the suburbs, these centers would provide an organizing focus for social and civic life, employment opportunities, and easy access to and from Manhattan. The centers would be composed of 'regional activities' which would have to be built in any event to

accommodate the expected additional twelve million people who would join the 18 million already in the 31-county region (expanded from the original 22-county definition) by the year 2000.

Forecasts for a large shift in employment away from manufacturing to service and white-collar jobs suggested the potential for significant office growth, some of which could go to centers outside of Manhattan. The plan proposed massive new office development for Manhattan, both in downtown and midtown but the plan also proposed that regional centers be built, both as redeveloped inner-city sub-centers such as Downtown Brooklyn, Jamaica and Newark, as older city centers in suburban cities, or as entirely new centers on open land. The centers idea took hold in a number of places, notably Jamaica, Queens, Downtown Brooklyn, and Fordham Road in the Bronx. Downtown Newark also experienced new central place development and expanded centers were developed in the outlying areas of White Plains, Stamford, and New Brunswick.

The Second Regional Plan draft addressed other issues as well. Its housing policies called for increased densities, a more compact region, better related to accessibility to jobs and activities, and more housing opportunities for lower-income and minority families. The draft also called attention to the continuing need to capture more open space and to deal with the increasingly difficult problem of waste management. The plan called for completion of the region's share of the interstate highway network but it also made a strong case for the preservation and enlargement of existing rail transit systems.

In the 1980s, regional planning in the United States suffered a severe setback when the federal government withdrew virtually all its support for regional planning agencies, resulting in the demise of many programs. Only the transportation planning function survived in most metropolitan areas. TVA and the Appalachian programs managed to continue, though their planning functions were greatly reduced. Some states replaced federal assistance for regional planning with state funds. Other regional agencies survived by becoming more entrepreneurial, focussing on service delivery. A few states such as Florida, Georgia and Massachusetts, concerned about the negative aspects of growth, have developed growth management or 'Smart Growth' initiatives, which require regional planning as a framework for development policies, in some cases.

Regional cooperation in politically fragmented metropolitan areas has generally proved difficult to realize in the United States. A number of metro areas, however, have managed to achieve success in facilitating regional planning consensus. The Twin Cities region of Minneapolis/St. Paul, and the Portland Oregon region are often cited as examples of successful regional initiatives. The Minnesota Twin Cities area created in 1967 through state legislation a seven-

county Metropolitan Council. The Council was created to address specific region-wide problems such as sewers and transportation. The Council has adopted a development guide for regional and local decision-making that identifies planned urban areas and growth centers. The Twin Cities regional initiative has enjoyed some major success, though its planning function has been scaled back in recent years.

The Portland Oregon three-county region in 1979 authorized by referendum a metropolitan service district. The district provides technical assistance and reviews local plans. In 1992, the Metro, as it is called, was given approval by charter to adopt a regional framework plan to guide regional development. The framework plan will address land use, development densities, housing, transportation, natural areas, and water supply. The Portland process is generally viewed as a successful example of the application of effective regional planning to control the negative aspects of rapid growth, though some concern has been raised about the impact of controls on the housing costs.

Metropolitan regional planning has experienced a resurgence in the 1990s in a number of American urban areas such as San Diego, California and Chattanooga, Tennessee, while, in the New York metropolitan region, the Regional Plan Association released in 1995 a Third Regional Plan, successor to the 1929 Regional Plan of New York and Its Environs, and to its Second Regional Plan of 1968 (Yaro and Hiss 1996). The Third Plan has focused on ways to help the region recover its momentum so as to maintain its faltering position in the global marketplace. To address the problems facing the region, the Third Regional Plan proposes five ambitious campaigns focussed on open and green space, transportation improvements, strengthening urban centers, improving workforce skills, and streamlining governance structures. It remains to be seen whether the Third Regional Plan will have as much impact as its two predecessors.

2.6 British and European Regional Planning

The trajectory of regional planning in Britain and Europe has somewhat paralleled that of the United States. Regional planning in post-World War II Britain found new support and momentum. The New Towns idea was re-embraced as a means to rebuild a Britain exhausted by war. Regional plans for the utilization of the old, lagging industrial regions of the North of England, Wales, and Scotland were adopted. These provided for decanting of populations into a new generation of expanded and new towns. Older urban areas would be contained within protected greenbelts.

In the 1960s, regional planning was further spurred by commission reports concerned about fast growing areas, notably in the Southeast of England. Metro-

politan regional planning, mainly advisory, was undertaken by county and regional councils. Their mandate was to:

(a) work out broad objectives for each region and provide a framework for detailed sectoral decision-making;

(b) advise on national policy-making where it could significantly affect regions;

(c) advise on the application of national policy in their region; and,

(d) help create a consensus within a region as to its problems and possible solutions.

Regional planning tended to be more favored by the Labour Party, less so by the Conservatives. The Conservatives tended to view taxation for social schemes and infrastructure as a burden on business and regulation and control of development as disincentives to market responses to problems of growth. The Thatcher government in the 1980s reconfigured regional planning bodies and responsibilities: the Greater London Council and other regional councils were abolished and regional planning was transformed into a mechanism for assisting large-scale private redevelopment schemes.

With the return of a more liberal-left government in the 1990s, there has been a modest return to regional planning initiatives. These initiatives, however, have continued the private/public partnership approach promoted by the Thatcher government. The central government places more emphasis on local government bodies. Grand regional planning schemes are not in vogue, as pragmatism and incremental and market approaches are more the order of the day. Whether this approach will enable the UK to meet the challenges of the first decades of the new century remains to be seen. With continuing population growth, a deteriorating environment, limited local resources, and continued un- and under-employment in some regions, together with a need for further integration into the European system, Britain faces hard choices. Robust, effective regional planning and implementation intermediate between the central government and local governments would appear to be a prerequisite for meeting these challenges. Whether the political climate will permit and support an articulated interventionist approach remains to be seen.

On the European continent, regional planning has been practiced with considerable success in both France and the Netherlands. France, with its strong provincial history and identities, has been able to focus its regional planning efforts on channeling excessive growth away from the Paris region towards second- and third-order city-regions. Meanwhile, the Paris region has benefited from metropolitan region planning and development that has focused on transit-based development and suburban centers. Regional planning in the Netherlands has emphasized a '*Randstad*' plan which focuses development on the ring of cities surrounding a protected green center in

the middle of the country. The European Union has fostered regional cooperation among regions that share common characteristics. An example is the Atlantic Arc Region, the grouping of the regions of EU member country fronting the Atlantic Ocean, which share technologies and cooperative approaches to managing planning and development.

3. Future Prospects for Regional Planning

To summarize, it is reasonable to say that regional planning in western industrialized countries has historically had a checkered history of meeting the challenges of growth and decay at the sub-national level. But it is also accurate to point out that those areas that adopted and tried to carry out regional planning schemes have often achieved better results than those which simply drifted into incremental, piecemeal development. It is almost always an advantage to have some systematic framework and political consensus on which to build, even if all relevant variables cannot be predicted or controlled.

There is reason to believe that regional planning will enjoy new vitality and acceptance. Powerful new forces, needs, and demands are compelling a renewed look at the desirability of regional planning approaches. Globalization trends are fostering the integration of economies on an international basis. Metropolitan economies are increasing seen as the building blocks of a world trading system. The communication and air travel revolutions have reduced the accessibility advantages enjoyed by a few large cities. Competitiveness will require regions to make the most of their assets, and grow new ones. This will take conscious, deliberate, smart planning. Environmental pressures and the deterioration of air, water, and land have reached serious proportions in many countries. Regional approaches will be needed to address the pollution of air and water sheds, which rarely conform to the boundaries of local jurisdictions. Global warming and the need to reduce carbon emissions will inevitably require regional approaches to the transportation and land-use interface. Sustainability is becoming the norm by which regional development decisions increasingly are being judged. More attention is being paid to the protection of natural and cultural amenities, natural habitat, green areas, wetlands and waterways, which, by their scale, mandate regional approaches. At the same time, the digital revolution has provided policy-makers and the public with new tools to collect, manage, and display vast amounts of relevant data, in ways only dreamed of in the early years of regional planning. Powerful computer-based geographic information systems (GIS) now permit mapping and analysis of trends, projection of impacts, and improved understanding of alternatives by regional bodies. This new capacity will surely enhance regional planning possibilities and effectiveness in many areas and countries.

Regional Science

Economists pay too little attention to the location of economic activity and the effects of distance on economic systems. Geographers focus on the spatial dimension but lack rigorous tools to study the effects of location and distance on human behavior or explain why activities are located where they are. Urban and regional planners need a stronger analytical foundation to go beyond the physical and aesthetic aspects of urban form to consider social and economic dimensions of city and region. With such premises, 60 economists, geographers, political scientists, sociologists, and planners gathered at the annual meeting of the Allied Social Science Associations in 1954 and founded the Regional Science Association. Its objective was ‘to promote studies focusing on the region.’ Envisioned were the use of theoretical frameworks and methods of the social and other sciences and the development of new ones specifically for regional analysis.

This interest in the region as a subject of study had important and immediate political and intellectual antecedents in the United States. In 1927 the regional plan for New York considered economic factors in metropolitan growth and spatial form, largely through the work of Robert Haig. In 1933 the Tennessee Valley Authority became the nation’s first major regional development program, arguably since the western expansion. In 1935, asserting that policies of national development depend on regional factors, the US National Resources Committee asked ‘modern students of regional science’ (10 regional geographers and two regional sociologists) to identify the best type of region to use for regional planning and development. In 1942, Alvin Hansen, perhaps the leading American Keynesian economist and a Harvard professor, advocated a comprehensive postwar expansionary program of regional development on the premise that the effective utilization of resources in any region makes the whole nation richer.

Two organized, interdisciplinary efforts with very different intellectual roots had focused on regions. In the 1920s Lewis Mumford and his colleagues in the Regional Planning Association of America saw cities

as congested and unmanageable. They advocated a mode of thinking and procedural methods aimed at seeing the region as a whole—integrating city and region, and utilizing, not destroying, the natural environment. Closer to the regional scientists because of their emphasis on both science and the region and their scholarly, university base were the southern regionalists. Centered at the University of North Carolina, they were well established by 1931 in terms of research achievements, agendas, and infrastructure. Howard Odum, the acknowledged leader of the effort and a sociologist, argued in 1945 that the nation owes the fullest development of the South not only to the South but also to the nation itself. Similar in ambition but predating the Regional Science Association by a quarter century, Odum advocated a regional approach to the scientific study of human society, arguing that it would entail the integration of method and theory, require the joint effort of the traditional social science disciplines, and create fundamental new understanding of all society, not just its regions.

Members of the Regional Science Association from the outset debated whether regional science would become a new discipline or an interdisciplinary activity. Walter Isard, widely recognized as the father of regional science, was the leading proponent of the disciplinary view. In 1956, he became an economics professor at the University of Pennsylvania, where he formed the Department of Regional Science in 1958. By then he had published 23 papers in the leading economics journals (acknowledging the help of Alvin Hansen in the first five). Yet the Regional Science program would go far beyond economics in its scope and impact. In 1960 the first Ph.D. in Regional Science was awarded to William Alonso, later regional planning professor at Berkeley and Saltonstall Professor of Population Studies at Harvard. Subsequent doctoral recipients took positions in economics, engineering, geography, planning, and other university faculties as well as public agencies and consulting firms.

Isard's prediction that regional science programs would emerge from geography departments and achieve wide recognition before 2000 was not realized. In the 1970s Cornell University established the second Regional Science Ph.D. program, and the University of Illinois initiated a multidepartmental program requiring completion of the Ph.D. in a participating department. By 1976, regional science degree programs or specializations existed at 14 universities internationally. The lone department devoted exclusively to regional science remained the one at Pennsylvania until it was closed during university retrenchment in 1994.

Among the early challengers of the disciplinary view was Lloyd Rodwin, a planning professor at the Massachusetts Institute of Technology. He envisioned the social sciences developing more systematic spatial studies, geography becoming more analytical, and regional science becoming 'a generic name for regional

studies.' This vision has become reality, but not fully. Regional science has become a generic name for a certain kind of regional studies, one whose origin is in mathematical abstraction and quantitative modeling.

Today regional science is an international, interdisciplinary endeavor. It brings together economists, geographers, planners, and others whose research has a regional dimension. It is the confluence of many streams, but arguably also the origin of a few. Each discipline brings different theoretical and methodological approaches to regional science, and each typically has different substantive concerns within a given topic. Migration, for example, interests several disciplines. An economist might focus on migration behavior as a way of measuring quality of life in cities, a demographer on regularities in the age pattern of migration, a geographer on turnarounds in core-periphery migration, a planner in forecasting migration for land use and transportation modeling, a sociologist on the effect of kinship links on migration destinations, and a real estate specialist on the relationship between housing prices and migration.

The numerous scholarly regional science journals and annual conferences create effective forums for exchanging ideas among disciplines. Although dominated by the abstraction and modeling inherited from economics, these forums are eclectic and open. They have been helpful incubators for scholarly groups who went on to create their own forums, be they input-output analysts, spatial social theorists, urban economists, or transportation modelers. Collectively regional scientists actively borrow ideas from a wide range of sources and combine, adapt, and extend them to regional research.

The recognition Isard anticipated has materialized in many ways other than through a proliferation of university departments. The Regional Science Association became the Regional Science Association International (RSAI), an umbrella organization overseeing three major supraregional organizations, the North American, European, and Pacific coordinating councils. Most countries in Asia, Europe, and North America have active regional science associations, and there are several multinational ones, including the British-Irish, French-language, German-speaking, and Australia-New Zealand organizations. Most sponsor annual meetings, and several have journals.

A widely accepted notion is that almost all regional scientists have dual identities, economist and regional scientist, geographer and regional scientist, and so on. For many, the regional science meetings and journals provide the best audience for honing and distributing their research. Others' participation ebbs and flows with changes in their immediate research agendas. No complete census of this fluid regional science community exists. The associations, including those in China, India, and Brazil, may have over 10,000 members combined. RSAI itself has about 2,000 dues-paying members annually.

Regional science journals have become numerous and well established. Five international ones with regional science in their titles are now published by major commercial presses: *Annals of Regional Science*, *International Regional Science Review*, *Journal of Regional Science*, *Papers in Regional Science*, and *Regional Science and Urban Economics*. Echoing the debate a half century ago about the name 'regional science,' some regional science associations leave it out of their journal titles, for example, *Journal of Regional Analysis and Policy*, *Review of Urban and Regional Development Studies*, or *Review of Regional Studies*.

Book series, position announcements, honorary degrees, and external research prizes are other marks of regional science's role within the social sciences. Noteworthy, too, are the National Science Foundations program in Geography and Regional Science in the US and similar ones in other countries. Perhaps the most spectacular recognition of regional science occurred when the Emperor and Empress of Japan personally welcomed participants to the RSAI World Congress in 1996.

1. Subject Matter

The international regional science community studies a wide range of topics, sometimes ambitiously defined as those social, economic, political, and behavioral phenomena that have a spatial dimension. A common, narrower view groups regional science research under three themes: location theory, methods of regional and spatial analysis, and regional development and policy.

Location theory is the study of what social and economic activities are located where and why. Traditionally, emphasis has been on the location of firms and households. The latter considers inter-regional and international migration and labor markets, as well as intrametropolitan residential mobility and housing markets. Early contributions focused on the role of transportation costs and proximity to suppliers and markets. Recognizing interdependencies of behavior focuses attention on agglomerations or clusters in space, as well as questions of land use, urban form, housing markets, city size, hierarchies among and systems of cities, market thresholds, and market boundaries. Recognizing interactions among activities and individuals distributed over space raises questions about commuting, trade flows, congestion, transportation, other infrastructure, facility location, taxes, user fees, local public finance, and diffusion of innovations and growth.

The phrase, methods of regional analysis, describes a growing set of techniques used to identify, analyze, or forecast key regional characteristics or changes. Among the methods are three invented to study national economies but adapted to regions. The inventors received Nobel Prizes in Economic Sciences:

Wassily Leontief (1973) 'for the development of the input-output method and for its application to important economic problems,' Lawrence Klein (1980) 'for the creation of econometric models and their application to the analysis of economic fluctuations and economic policies,' and Sir Richard Stone (1984) 'for having made fundamental contributions to the development of systems of national accounts.' Regional scientists have adapted and extended techniques from demography. The cohort-component model focuses on the components of population change and their probabilities (births, deaths, and migration), grouping the population into cohorts by age, sex, and often race or ethnicity. Regional scientists borrowed the gravity and entropy models directly from physics and found that they described certain aggregate human behavior well. Migration, trade, transportation flows, and other interaction between two places tend to increase with the product of their masses (e.g., populations) and decrease with distance between them. Regional scientists have also adapted and applied optimization techniques to contexts in which spatial interaction is important, such as transportation networks, location of facilities, and land use.

Regional scientists use statistical methods extensively. Yet here, too, important adaptations and extensions permit the study of spatial and regional phenomena. Geographers, in particular, have extended standard statistical concepts to situations where observations have locations, for example, to draw random samples over space or to determine the likelihood that an observed locational pattern could have occurred by chance. Spatial statistics, spatial econometrics, geographical information systems, and other methods of spatial statistical analysis have become major parts of regional science—for economists, planners, engineers, and others as well as geographers. In the case of statistical methods widely used to study travel demand, residential location, migration, and other behavior with a spatial dimension, the pioneer was an economist, Daniel McFadden, who won the Nobel Prize in 2000 'for his development of theory and methods for analyzing discrete choice.'

Regional development and policy focuses on why some regions grow and prosper while others lag and even decline. Research ranges from theories of growth and development to evaluation of specific policies. Persistent questions deal with the divergence and convergence of regional growth rates and incomes, the relationships between core regions and peripheral regions, and the geography and timing of the spread of growth. Other long-standing questions deal with regional labor markets, including the relationship between growth and unemployment and the persistence of wage differences among regions. Key policy issues concern people prosperity vs. place prosperity (should the focus be on helping people directly, for example, through education or out-migration incen-

tives or on helping people indirectly by making the region more competitive through infrastructure, tax incentives, or other actions), ways of making lagging regions more competitive and prosperous, the rationales for regional policy, and the roles of different levels of government.

Policy evaluation has attracted much attention as well. Commonly the objective is to measure the effects of various (nonregional) national policies on regions, for example, free trade treaties, defense spending, or tax reductions. Other times the objective is to evaluate regional policies, for example, by estimating what would have happened to lagging regions in the absence of the regional support programs. Sometimes the emphasis is on comparing alternative regional plans or policy instruments before they are implemented, generally using cost-benefit, cost-effectiveness, or goals achievement methods augmented to include policy objectives, distributional issues, and hard to quantify outcomes.

2. Intellectual Progress

Two easily contested, unavoidable decisions must be made before discussing the intellectual progress of regional science. The first is whose contributions should be counted. The open, fluid nature of the regional science community makes this decision difficult, and the early claims to disciplinary status make it controversial. The perspective here is that the idea itself is more important than the primary tribal self-affiliation of its originator. The key criterion is whether the idea is part of the scholarly conversation in regional science meetings and journals. Mention of an individual's contribution does not imply that the person considers him or herself a regional scientist, although each person mentioned has participated in regional science meetings or published in regional science journals. Debates about whether particular intellectual contributions were initiated by regional scientists, borrowed by regional scientists, or adapted by regional scientists, and who is really a regional scientist are fruitless. The gravity model provides an early case in point. One observer described it as work that may clearly be termed regional science, while another argued that it had been pioneered by outsiders and applied in many disciplines. By far the most interesting fact here is how understanding and use of an idea have evolved.

The second decision concerns the scope of regional science. Something narrower than human activities and phenomena with an important spatial dimension must bound this discussion, but many offer too incomplete a view. Some describe regional science as a toolbox for practical analysis that lacks rigorous theory, while others decry it as a theoretical never-never land with too little realism. The path chosen here recognizes Isard's deliberate efforts to nurture the field

of regional science. He edited several of its journals, commissioned papers, supported dissertations, organized meetings, and shaped an influential book series. Three of those books frame a useful way of discussing regional science: Isard's *Location and Space-Economy* (1956), the Isard-led collaborative effort, *Methods of Regional Analysis* (1960), and a reader edited by John Friedmann and William Alonso and dedicated to Isard, *Regional Planning and Development* (1964). The books' foci—theory, method, and policy—frame the discussion of intellectual progress well.

2.1 Location and the Spatial Economy

The quest here is to model mathematically and show graphically both the determinants and consequences of individual location decisions. Regularities in spatial patterns are readily observable, among them, the emergence and persistence of large cities, clusters of related industries, relatively homogenous residential areas within cities, and regularities in city size distributions. The goal, chiefly of economists who work in this tradition, is to show how these agglomerations materialize from the interaction of self-serving decisions of individuals and firms. Isard's book drew on the pioneering German contributions by Johann Heinrich von Thünen, Alfred Weber, August Lösch, and Walter Christaller.

Two works from the birth period of modern regional science were extraordinarily seminal. Alonso's dissertation, *Location and Land Use*, focuses on transportation costs and its role in residential decisions and the resultant land use patterns within a metropolitan area. Concentric rings of land use emerge from the behavior of utility maximizing individuals. Alonso's starting point like von Thünen's is the existence of an agglomeration, in this case the central business district of a monocentric city. Charles Tiebout, a founding member of the Regional Science Association, argued that 'people vote with their feet' by choosing locations within the metropolitan area that offer the combination of revenue and expenditure patterns that appeal most to them. Thus, spatial mobility among diverse communities within an urban area provides a solution to the collective consumption problem posed by Samuelson and another mechanism by which individual preferences create spatial variation. Much of today's field of urban economics builds on these two contributions.

A contemporary contribution of this genre is *The Spatial Economy* (1999) by Masahisa Fujita, Paul Krugman, and Anthony Venables, which they describe as a continuation and possible validation of Isard's project. It derives agglomerations instead of positing them as a starting point (e.g., Alonso's central business district around which commuters organize themselves). In the 'new economic geography,' as Krugman

calls it, agglomerations result from the tension between centripetal forces that promote concentration of economic activities and centrifugal forces that oppose it. Of key interest is when a spatial concentration of economic activity is sustainable, and when a system without spatial concentration breaks down and concentration emerges. Combining formal theoretical models that include increasing returns to scale and computer simulations to study nonlinear dynamic properties, this work links urban, regional, and trade economics in a way that exceeds the dreams of the formal modelers of a half-century ago. As was the case then, however, many geographers and others within the regional science community do not embrace this formal mathematical, theoretical mainstream economics approach. They are far more interested in the social, cultural, and institutional factors involved in spatial development and in the study of real places and real regional histories in contrast to abstract ones. The new *Journal of Economic Geography* hopes to encourage dialogue among the groups.

2.2 *Methods of Regional Analysis*

A very different early quest of modern regional science was the creation of practical tools for the study of real places, and here regional science has had spectacular success. The input-output model attracted early attention. A series of regional input-output articles appeared in the *Review of Economics and Statistics* between 1951 and 1971. Their foci ranged from the theoretical specifications of the models and the definitions of concepts to studies of the nature of metropolitan economies, the location of a major steel complex, and the effects of arms reduction. This initial period culminated in the creation of two landmark regional input-output models constructed from survey-based data, the Philadelphia model of Isard and Thomas Langford and the West Virginia model of William Miernyk. The next three decades focused on building and using models, with attention paid to the treatment of households and consumption, economic-demographic linkages, and strategies for building the models in a cost-effective way. Here too progress exceeded the dreams of the 1950s, with regional input-output models now widely used for impact studies in the private and public sectors in many countries of the world. In fact, this method of regional analysis has become an industry with data and software readily available from commercial firms, most notably the IMPLAN system within the United States.

Econometric modeling similarly saw astonishing progress from the efforts of pioneering scholars to the commonplace of professional practice. Lawrence Klein sketched out how regional econometric models might be developed as satellites of national models, and his student Norman Glickman developed a fully

operational landmark model of the Philadelphia economy. For roughly a decade, many others built regional econometric models as doctoral dissertations, one becoming the blueprint for the National Regional Impact evaluation system of the US Department of Commerce. Today most states and many companies maintain such forecasting models. This method, too, has become an industry with many companies selling forecasts to private subscribers. A particular noteworthy case is the eclectic REMI model of George Treyz, which grew from a design at a regional science meeting in 1978 into a widely used commercial product.

Modeling land use and transportation flows within a metropolitan region proved to be arguably the most ambitious search for practical methods, and the most spatially explicit. Its intellectual scope is daunting: understanding the determinants of the location of industrial, commercial, residential, and other activities and of the movement of people among those locations. It combined five elements: the theoretical urban economic framework of Alonso and Lowdon Wingo, mathematical programming methods to make them operational starting with the Herbert-Stevens model of land use, gravity models of spatial interaction eventually enriched by the entropy formulations of Alan Wilson, discrete choice statistical methods eventually incorporating McFadden's work, and the transportation forecasting framework established by Robert Mitchell and Chester Rapkin. For four decades, university research groups, notably those led by Britton Harris, Alan Wilson, and David Boyce, have produced a sustained flow of dissertations and other contributions. Yet, unlike the cases of input-output and econometric models, the pioneering research phase did not lead to widespread adoption in routine public and private practice. Dominant practice remains a set of incremental steps—predict population and employment change, decide (usually unaided by models) where those activities will locate, and then use transportation modeling software to forecast the flows among the locations. The research quest continues, large-scale operational models continue to be built (about a dozen were in use in the early 1990s), and the research leads to improvements in the transportation modeling software and other elements of the incremental approach.

2.3 *Regional Development*

The basic quest here is to understand differences in regional growth and development. During the early years of modern regional science it attracted the attention of two more Nobel Laureates in Economics. Gunnar Myrdal was honored in 1974 for his 'penetrating analysis of the interdependence of economic, social and institutional phenomena.' His work on economic theory and underdeveloped regions centered

on the principle of cumulative causation, a 'vicious circle' of economic and noneconomic factors that led activities to cluster in certain regions and caused regional inequalities. Douglass North was honored in 1993 for 'for having renewed research in economic history by applying economic theory and quantitative methods in order to explain economic and institutional change.' He studied regional economic growth using exportable commodities or the export base as the key concept, pointing out the incentives regions have to reduce their processing and transportation costs to better the competitive position of their exports. An influential book by Michael Porter, *The Competitive Advantage of Nations* (1990), builds on these notions of clusters of activities and competitiveness of export industries. He argues that national advantage derives from successful firms concentrating geographically within a country, their competitive success stimulated by their local environment, including government policy at the regional and local level. An earlier formulation remains popular in regional policy. Based on the growth pole research initiated by Francois Perroux, governments concentrate investment in selected urban centers to stimulate the economies of their surrounding areas or draw population away from the crowded, larger metropolitan areas.

2.4 Other

Brief mention of some other work completes a broader picture of regional science. RSAI has awarded its Founder's Medal to Martin Beckmann for research in transportation network theory, location theory, and spatial economics; William Alonso for urban economics, spatial demography, and regional development; Jean Paelinck for methods of regional analysis, spatial econometrics, and regional policy; and David Boyce for transportation network models and urban transportation planning methods. The three most cited articles in the *International Regional Science Review* are on population dispersal from major metropolitan regions internationally (D. Vining 1978), intra-urban residential mobility (J. Quigley and D. Weinberg 1977), and the shift of the US population to nonmetropolitan areas (C. Beale 1977). In the *Journal of Regional Science* they are on the distribution of residential activity in urban areas (J. Herbert and B. Stevens 1960), determinants and consequences of migration (M. Greenwood 1985), and an efficient algorithm to solve the Weber location problem (H. Kuhn and R. Kuenne 1962). In *Regional Science and Urban Economics*, they are on the baby boom and the housing market (N. Mankiw and D. Weil 1989), the demand for housing characteristics (J. Follain and E. Jimenez 1985), and publicly provided inputs and economic growth (T. Garcia-Mila and T. McGuire 1992). The supplementary Bibliography includes well-cited books and recent overviews of aspects of regional science.

A. Isserman

Regionalism and Cultural Expression

A region is a geographic concept that denotes a set of places understood as having something in common. While this common ground is typically geographic, political, and/or economic, it gives rise to shared forms of cultural expression as well; conversely, shared culture may encourage political or economic linkage, even perceived geographic unity. Regional culture refers to these shared cultural patterns most generally, while regionalism is reserved for a highly favorable evaluation of the culture of place. Research has

addressed questions about regionalism's political implications, its persistence under conditions of modernity, and its capacity to ground identities under conditions of postmodernity.

1. Definitions

When people refer to a region, they are indicating a set of places that they view as having some common characteristic. Regions can be specific to a small group or organization; for example a regional sales manager might cover a specific territory that no one outside the firm would think of as a region. They can be individual, as in 'the region where I grew up.' And they may involve an exquisite local knowledge. This essay concerns regions having a wider application than these.

Usually the places included in a region are contiguous; if they are not, the plural form gets used, as in the 'polar regions.' The basis for defining a region may be purely geographic (the Mediterranean region) or historical (the Spanish empire), but the places within any single region usually come to share more than geography or history. Regions are or tend to become economic (the Ruhr (*Ruhrgebiet*)), ethnic (Yorubaland in West Africa), or cultural (the Bible Belt of the American South). Political boundaries may or may not contain a region, which can include all or parts of different nation states. Bound by their common characteristics, regions are often at odds with the political unit(s) that claims sovereignty over them (e.g., the Kurdish region of Turkey and Iraq).

Even in the case of regions defined strictly by geography or political necessity, some degree of common culture emerges. Climate, topography, and relationships to the sea will influence agricultural and commercial activities. Thus, in the most obvious illustration of this point, political antagonists like the Palestinians and Jews of the Middle East prepare similar food in similar ways. For this reason scholarship on such regional forms of cultural expression once took them as natural, the straightforward products of material circumstances and history. Such shared characteristics are weak versions of regional culture.

Cultural regions typically derive from a preexisting geographic, economic, or political region, but in some cases the cultural common ground can come first. Nations that share the same language become trading partners, for example, and elaborate other ties; even here, however, there is usually the prior political connection of colonialism. Religion would offer another example of this potential, for example in the Organization of the Islamic Conference. Stretching from Indonesia to Nigeria, this is hardly a territorial region but is sometimes envisioned as such, and it constitutes the potential for economic and political links.

Regional culture comes in a strong version as well. Geographer D. W. Meinig (1986) defined regional culture as, 'that which is characteristic of a group of people who are deep-rooted and dominant in a particular territory, who are conscious of their identity as deriving from a common heritage, and who share a common language and basic patterns of life' (p. 80). He contrasts the seventeenth-century Welsh region, which shares geography, ethnicity, language, and a sense of self-identity, with the West Country, a much vaguer region with its own traditions, dialect, and ancestral families but no unmistakable 'ethnic' distinctions. The West Country was a 'relatively subdued form of regional culture, one which its members are conscious of but not normally militant about, though strong feelings of identity may be aroused under special circumstances' (p. 81).

In light of this distinction between strong and weak regional cultures, manifest versus latent, regionalism is a strong and self-aware form of regional culture, and sectionalism is an intolerant and divisive form of regionalism. The term regionalism generally has a positive connotation, referring to things that win local and often external approval; other strong but destructive manifestations of regional culture, such as the vendetta tradition in Corsica, are not usually designated as regionalism. Regionalism aggressively promotes its own symbolic expression, which can reinforce, or even generate, social and political bonds.

2. Real Regionalism, Debatable Impact

Considerations of regionalism used to begin from a bimodal model: urban culture versus folk culture; cosmopolitan versus provincial; center versus periphery. In this view regionalism was often conflated with localism, the residual cultural forms that hegemonic centralized culture had not yet obliterated. Regional culture, although it made meaningful the lives of people in the region and perhaps enriched the larger cultural pool, was one of those things that was likely to fade away under industrial capitalism and centralized political authority. Research mapped (and sometimes celebrated) regional differences, and it also addressed the impact of these cultural differences on the larger political units.

For example, in the 1930s, sociologist Howard W. Odum argued that the American South remained backward because it lacked social institutions that could facilitate social change while protecting traditional culture; the pro-business New South could not reconcile change with continuity. Odum concluded that the South must reinvent its debilitating local culture by blending it with national culture into regionalism, whereby (in his somewhat idiosyncratic definition) the local was part of the larger unity. In Odum's view, sectionalism was a pathological form of localism, the result of cultural inbreeding (Odum and

Moore 1938, p. 43), although many contended that this regional/sectional distinction was hard to maintain. Odum saw literary and aesthetic regionalism as an undeniable fact—he catalogued over two thousand regionalist titles from two decades of *Publishers' Weekly*—but rather than local color provincialism, which would smack of sectionalism, he maintained that 'regional portraiture is only fundamental units in the great American literary fabric.' True regionalism, in other words, contributes to the health of both region and nation.

As the New South has become both established and even normative on a national level, the regionalism/sectionalism distinction has faded. Social scientists like John Shelton Reed (1986) have continued to assess the degree of Southern regional variation that persists. Analyzing the economic and political differences among a nation's regions is a standard activity on the part of both social scientists and the popular press.

A contemporary political scientist who has made a strong case for the political impact of regional culture is Robert Putnam (1993). Using data from Italy's twenty administrative regions, Putnam shows how 'institutional performance'—effectiveness of and satisfaction with regional government—is high in Italy's north and low in the south. He connects this with presence or absence of civic traditions, which he traces back to medieval period; 'the astonishing tensile strength of civic traditions testifies to the power of the past' (p. 162). Why is the past so powerful? Putnam draws on theories of social capital to show how norms, whether of 'never cooperate' or of trust and reciprocity, produce stable cultures, with only the latter—'civic equilibrium'—able to solve the collective action problem. Culture and structure reinforce each other.

Sociology and urban studies have renewed attention to place as a variable, as in Douglas Massey and Nancy Denton's study of the devastating impact that inner-city spatial isolation—'American apartheid'—has on African-Americans (see also Gieryn 2000). Ethnographers study the symbolic and aesthetic worlds such conditions produce, as when Elijah Anderson analyses the intricate set of signs and behaviors that black youth must master to steer between trouble with the police and with their peers (E. Anderson 1999). While this type of research is often at the level of neighborhood, some employ a broader, regional canvas.

A good example of regional cultural analysis is Francis Violich's 'urban readings,' in which he offers a phenomenological account of the intersection of ecology, urban functions, and cultural history on the Dalmatian coast, now in Croatia (1998). Ecologically, the region possesses rich sea resources along with a poor, mountainous land where the limestone foundation makes water collection a societal preoccupation. Isolation and the need to manage their water supply and harbors has produced strong urban cul-

tures, independent of one another and of whichever regime—in the past thousand years these have been Hungarian, Venetian, French, Austrian, Marxist, and Croatian—was currently in power. A regional culture of autonomy, tradition, and resistance to change has been the result, making Dalmatian cities like Dubrovnik both elegant and backward. Violich is not just describing regional culture but is also making the case for regionalism, for he is concerned about the human cost of losing our 'rootedness to place.' Older towns that reflect regional aesthetics and local building materials become 'treasures of the past,' standing in sharp contrast with the anesthesia of today's cities, 'hodge-podges of synthetic eclecticism and tiresome look-alikes, grown too large to allow the common citizen to claim a sense of identity with them or pride of belonging' (p. 51). This association of identity with territory, the spiritual nourishment that comes from being 'at home' somewhere, is characteristic of regionalism. It is surprisingly parallel to the inner-city gang members' desire to be with their 'homies' in a secure and familiar territory.

3. *Debatable Regionalism, Real Impact*

Scholars of regionalism like Putnam or Violich assume that regions are both naturally based and historically configured. They are materialist in that they see the natural features of the land as encouraging certain economic formations, and these in turn give rise to political and cultural patterns distinctive to the region. Yet even these scholars recognize that human ties to any particular region have become far more optional than in the past. In his discussion of identity, Violich points out that people seek environments compatible with their desired self-images in a way that was not necessary in earlier, more homogeneous cultures that provided a secure sense of belonging. 'Today, in contrast, with great individual opportunities for regional mobility, one can choose among diverse physical and cultural environments in various parts of a large city or metropolitan area as a way of individualizing one's cultural expression' (p. 59).

This is not something new, some scholars have asserted. Spatial boundaries and their cultural representations have always been subject to decisions made in the pursuit of interests. Beginning in the 1970s the view emerged that politics and the power of dominant groups, not geography, has always shaped humanity's mental and physical maps. Much of this literature centered on the origins of nationalism, as in the theses of 'the imagined community' (B. Anderson 1991) or 'the invention of tradition' (Hobsbaum and Ranger 1983), although smaller communities were similarly fictitious (Laitin 1986, Griswold 1992). Once in place, the arbitrary or fanciful boundaries could have powerful and lasting consequences, and indeed some like 'the nation' became unavoidable, as the 'world culture'

thesis pointed out. Cultural expression played a role in such inventions, both encouraging them, as in Benedict Anderson's discussion of the role of newspapers, and in sustaining them, as in critiques of heritage movements.

Revisionist historical and sociological research, such as that of the New Western Historians, has focused on the manipulation of collective memory (Ayers et al. 1996). Regional representations, in this view, are highly suspect. For example, a universally recognized regional symbol is the New England village with its white steeples and town commons. Stephen Nissenbaum (1996) contends that New England towns were originally not different that other towns in British North America, for there was no reason for farmers to live in villages. The compact village arrangement was a consequence of the commercial revolution in the late eighteenth and early nineteenth centuries, when it made sense for merchants and professionals both to set up business in and live in villages. And the 'pastoralization' of town commons—previously they had been bare patches, rather like parking lots—didn't take place until after the Civil War where local Village Improvement Societies, 'usually dominated by businessmen or newcomers to the community,' began to plant grass and elm trees. Litchfield, Connecticut actually hired Frederick Law Olmstead, designer of Central Park, to 'restore' their common.

Once region became seen as subject to human agency, the door was open to a lively debate on the relationship between regionalism and modernism, no longer assuming that the latter simply came along and eclipsed the former. Yatsuka (1998) describes how internationalist architects believed modernism to be 'globally shared beyond a regional understanding.' In architecture, unlike in politics, the international (modernist) preceded the regional: 'contrary to the simple notion of "regional things," the idea of "regionalism" arose due to the appearance of "internationalism"' (p. 167). Regional reaction—'a romantic nationalism'—arose in response to modernism, as in the case of the Finnish modernist Alvar Aalto. Yatsuka cites 'critical regionalism'—Kenneth Frampton's term for resistance against corporate modernism on the one hand and the postmodern reaction (compensatory façade) on the other—critical regionalism couldn't have been conceived of without modernism. He looks at Japanese architects such as Kenzo Tange, who both used and altered traditional (regional) forms such as the *sukiya* (sixteenth-century teahouse) and *shinden-zukuri* (nobleman's palace), grafting elements onto modernist layouts; by asserting 'we inherit spirit, not individual idioms' (p. 177), Tange avoided nostalgia just as he avoided placeless internationalism. Along similar lines James Dennis (1998) shows how the regionalist painters of the thirties, despite being given to bouts of antimodernist rhetoric, demonstrated strong modernist influences. The dichotomy between regionalist and modernist, like that between provincial

and cosmopolitan, has been not just overdrawn but misconceived.

During the 1970s and 1980s some theorists of postmodernity argued that in the world of electronic communications and unrestricted cultural flows, place-based notions like 'region' and 'regional culture' were irrelevancies, at best productions for a tourist market intent on collecting scenic memorabilia (MacCannell 1976). The 'no sense of place' thesis maintained that electronic media has severed the link between social place and physical place. '[A]s place and information access become disconnected, place-specific behaviors and activities begin to fade' (Meyrowitz 1985, p. 148). This was something of a return to the bi-model model, only instead of industrialization, capitalism and imperialism, now electronic media and globalization were bleaching regional cultures out of the postmodern fabric.

More recent research has drawn back from this position, in part due to the undeniable assertiveness of place-based social formations, traditional or new-mint (Logan and Molotch 1987). Indeed, globalization itself, to the degree that it makes state boundaries less significant, gives rise to place-specific formations like the much discussed 'Europe of the regions.' Proliferation of communications channels encourages formation of new possibilities for the assertion and communication of cultural identities, and in some cases regionalism seems to find new life through these media (Griswold and Engelstad 1998).

4. Future Research Directions

Research at the end of the twentieth century accepts the constructed nature of regional cultures but takes a W. I. Thomas view that such regional cultures are real in their consequences, regardless of their origins. Making space into place, 'mapping the invisible landscape' through words and symbols (Ryden 1993), is a cultural process that, while by no means innocent of politics and economics, seems to fulfill a human need for meaningful spatial orientation. Regionalism and the culture of place represent, following this line of thought, a psychologically fundamental dimension of cultural expression. Thus, the regionalist impulse is not likely to atrophy, regardless of changes in mobility or communications technology.

Scholars have been addressing the lines along which regionalism gets configured (Ayers et al. 1996), the circumstances under which regionalism expands (Griswold and Engelstad 1998), the ability of regional culture to offer a viable alternative to class and racial hierarchies (Stack 1996), and the degree to which regionalism influences social and political behavior (Putnam 1993). Particular attention is being paid to how a regional culture is apt to be less the result of shared local experience, as celebrators of regionalism have maintained, and more the consequence of elite

conflicts brought about by external social changes. Anthony Cosgrove (1993) describes how the sixteenth-century Venetian elite still had its fortune tied to maritime power, and felt increasingly insecure due to French pressure. One response was a rash of estate construction in the rural interior, 'terra firma.' While these were working estates, they were ideological as well, representations of the harmony of various spheres: macrocosm, microcosm, divine will, world, theatre, human body, buildings, and lands. In an era when professionals were rising in status, architects like Andrea Palladio (1508–1580) created this regional culture of harmony and control. Palladio's use of classical forms and his emphasis on harmonizing buildings with landscape combined 'Roman imperial grandeur [with] Venetian sensitivity to atmosphere, site, and situation' (p. 20). Thus, the Palladian rural landscape both expressed the unease of the urban regional elite and reassured them of their centrality within an orderly cosmos.

This type of analysis, while recognizing the fundamental human desire to connect to place, looks for how political and economic struggles shape the way this connection gets articulated as regional cultural expression. This is one of the liveliest lines of research at the beginning of the twenty-first century and seems likely to continue. A second direction for the future is a renewed interest in the relationship between technology and regionalism. Studies of how elite conflicts and the pursuit of economic interests mold regional culture have tended to downplay the impact of new communications media, but the question of technological change is being revived by the Internet. The impact of the Internet on regionalism is unclear, with possibilities ranging from the theory that it will constitute the final blow to 'place' and other material forms of identity to the theory that it will encourage new 'tribal' groupings, including those of region. A new generation of researchers, unconstrained by former assumptions about how modernization would devastate regional culture but also largely free from a romanticist reverence for the traditional, will undoubtedly explore these possibilities.

Regression Discontinuity Design

1. Definition

The regression discontinuity (RD) research design is a quasi-experimental design that can be used to assess the effects of a treatment or intervention. Unique to the RD design is that participants are assigned to groups solely on the basis of a pretreatment cutoff score. The name ‘regression discontinuity’ indicates that a treatment effect appears as a ‘jump’ or *discontinuity* at the cutoff point in the *regression* function linking the assignment variable to the outcome. In its simplest form, the design has two groups (those scoring above and below the cutoff), a pretest (the assignment variable) and a post-test (the outcome). More complex variations are also possible.

To many, the RD design seems counterintuitive. Using a cutoff to assign participants to the treatment and comparison groups creates a pretreatment group nonequivalence that seems like it should lead to selection bias. But while the design does induce initial nonequivalence, it does not necessarily lead to biased treatment effect estimates. Instead of assuming pretreatment equivalence in measured and unmeasured means and variances—as with the randomized experiment—in the absence of a treatment effect the RD design requires the two groups to be equivalent in their pre–post regression functions. This assumption can be tested.

The major attraction of RD designs is that they can be used to estimate the effects of treatments given to those who most need or deserve them, provided that need or merit is determined as a qualification score on the assignment variable (i.e., the cutoff) and nothing else. Because the design does not require some needy individuals being assigned to a no-treatment group, it has ethical advantages over experiments for assessing treatment effects.

2. History

The RD design was first used in psychology by Thistlethwaite and Campbell (1960) and was first discussed in detail in Campbell and Stanley (1963). It has been repeatedly reinvented—by the economist Goldberger (1972), the statistician Rubin (1977), the educators Tallmadge and Horst (1976), and by the public health researchers Finkelstein et al. (1996). Despite such independent reinvention, the RD design has not been used much outside of compensatory education where students scoring below some predetermined cutoff value on an achievement test are then assigned to remedial training (Trochim 1984). But it has also been used to study how unemployment benefits influence recently released prisoners (Berk and Rauma 1983) and how different levels of in-

carceration affect those in prison (Berk and de Leeuw 1999). A variation was also used to study how class size affects test scores (Angrist and Lavy 1999).

The low frequency of published examples may be due to several factors. One is its recency. Another is that RD designs require administrators to assign participants to conditions *solely* on the basis of quantitative indicators, restricting the role of judgment, discretion, or favoritism. Finally, understanding the design depends on some familiarity with regression analysis, making the strategy difficult to convey to nonstatistical audiences.

3. The Basic RD Design Structure

Simulated data for an RD design are shown in Fig. 1. It depicts the example of a compensatory treatment—perhaps a reading program designed to help students who initially score poorly (defined as below the cutoff) on a standardized reading measure. The figure depicts the standard bivariate plot of post-test and pretest for 500 simulated participants. Data points for the treatment recipients are represented with ‘+’ while the comparison cases are ‘o.’ The cutoff value in this example occurs at the middle of the pretest distribution (pretest = 50) and is indicated by the vertical line. All students scoring below 50 are defined as needing compensatory training and get the treatment, while the remainder (i.e., those to the right of the cutoff) are assigned to the comparison group.

The solid lines represent the straight-line regression of post-test on pretest for each group. In the absence of a treatment effect, the critical assumption is that the regression line in the comparison group would continue to the left of the cutoff into the treatment group region, as indicated by the heavy dashed line. That is,

Figure 1

Basic regression discontinuity design for a compensatory treatment showing a positive effect

if the reading program does not work, then the observed treatment group regression line would be where the dashed line is. The fact that the observed treatment group line is displaced from this 'expected' line suggests a treatment effect—treatment group participants scored higher on the post-test (i.e., vertically) than would have been predicted from the comparison group pre-post relationship. The size of the treatment main effect is estimated as the vertical jump or discontinuity between the regression lines at the cutoff. Assuming that higher scores on both measures indicate better performance, one can conclude from the figure that the treatment improved participant performance by the amount of the vertical discontinuity.

In experimental designs one assures through random assignment or otherwise that the treatment and comparison groups are initially equivalent. Otherwise, post-treatment differences can be attributed to the intervention. In the RD design one obviously does not expect this kind of equivalence. Instead, it is assumed that the *relationship* between the assignment variable and the outcome is equivalent for the two groups—that is, the same continuous regression line describes both groups. Thus, interpretation of the RD design depends mostly on two factors: (a) that no alternative cause operates at or near the cutoff; and (b) that we can perfectly model the pre-post relationship. These issues constitute the major problems in the statistical analysis of the RD design, particularly the second one.

4. Design Considerations and Variations

4.1 Selection of the Cutoff

The choice of cutoff value can be made solely on the basis of available resources. If a program can only handle 25 persons and 70 apply, then a cutoff point can be selected that distinguishes the 25 most 'needy' persons from the rest. The cutoff can also be chosen on substantive grounds. If the assignment measure is an indication of severity of illness measured on a 1–7 scale, relevant experts might contend that all those scoring 5 or more are ill enough to deserve treatment. So, a theoretically justified cutoff of 5 is used.

4.2 Assignment Variations

While the use of a pretreatment cutoff value distinguishes the RD design, it is often difficult to implement. In many situations it does not appear to allow room for professional judgment or discretion. In fact, the design does not preclude incorporating such judgment so long as it can be quantified or explicitly accounted for when specifying the cutoff value.

Violation of the assignment rule leads to 'mis-assignment.' It seems to be most prevalent at scores around the cutoff and is often labeled as the 'fuzzy' RD design. Standard analyses will yield biased estimates of treatment effect in the fuzzy RD case. While statistical procedures for dealing with mis-assignment have been suggested (Trochim 1984), mis-assignment is better avoided if possible.

4.2.1 Multiple cutoff points. RD designs are not limited to a single cutoff value. In the absence of treatment the assumption is that the pre-post relationship can be described as a single continuous regression line extending over the entire range of the assignment scores. Even when multiple cutoff points are used, the comparison group's pre-post relationship is still used as the counterfactual for projecting where other groups' regression lines should be if there is no treatment effect.

The simplest multiple cutoff case involves two cutoff scores. In this variant, persons scoring above the higher cutoff might be assigned to one treatment, those scoring below the lower cutoff to another, and those scoring within the cutoff interval might be controls. The assignment of treatments to each part of the assignment distribution can be made in many ways, including by random assignment.

Considerable work has been done on another way of 'coupling' the RD design to the randomized experiment. This is when individuals scoring in a range just above or below an originally selected cutoff value are randomly assigned to conditions, while those scoring further below and further above the cutoff are analyzed as from an RD design (Boruch 1973). Trochim and Cappelleri (1992) discuss four other ways of coupling random assignment to RD design features.

Multiple cutoff points are also involved in designs where the treatment is implemented a series of times (i.e., in phases), perhaps beginning with the most needy before successively giving it to those less needy. In the first phase, one uses a single cutoff value, assigning those most in need to the treatment and then measuring post-treatment performance. Then the cutoff value would be moved to include the next most needy group on the assignment measure. Eventually, everybody could receive the treatment, but in groups ordered by need and phase. This is particularly useful in organizations seeking to 'roll-out' a treatment over time, but eventually serving all.

4.2.2 Multiple assignment measures. The requirement of strict adherence to the cutoff criterion entails a single quantitative indicator. When this does not capture the degree of pretreatment need well, Trochim (1990) discusses two multivariate strategies.

The first involves the use of several separate measures, each having its own cutoff value. This is most feasible when a prospective participant must meet the different cutoff criteria on measure 1 ‘and’ measure 2 ‘and’ measure 3, etc. Less feasible is an ‘or’ rule when assignment depends on meeting a fixed number of criteria from a larger set—say, 5 out of 10. The second involves assignment according to a new variable that is a composite of several individual measures. Using multiple measures this way can help incorporate more judgment into a quantitative assignment strategy.

4.3 Treatment Variations

When treatment comparisons are absolute, the control group receives no formal treatment or a placebo treatment. When they are relative, the comparison group receives an alternative treatment, very often the current treatment to which a novelty is to be compared.

An advantage of the RD design is that it enables assignment of progressively riskier treatments to those in greater need. Assume three treatment programs: the standard, plus two increasingly riskier experimental ones. It is then possible to have two cutoff points and to assign the riskiest treatment to the neediest patients, the least risky (i.e., standard) treatment assigned to the least needy, and the moderately risky treatment assigned to those falling between the two cutoffs. (If no *a priori* basis exists for making risk judgments, an alternative would be to use a single cutoff and to assign those least in need to standard treatment while randomly assigning those on the other side of the cutoff into one of the two experimental protocols.) RD designs are flexible for examining treatment variations.

5. Post-treatment Measurement Variations

In RD designs, pre- and postmeasures do not have to be on the same or equivalent measures. For instance, one might assign persons to a health education treatment on the basis of household income but then examine its effects on attitudes towards health. The assignment variable is an economic indicator and the outcome is a cognitive one.

The RD design is not restricted to a single outcome, and for each post-treatment measure there can be a separate RD design and analysis. But it will often be useful to create an aggregate outcome or outcomes. For instance, we may have many knowledge items that are scaled to give a total and subtest scores for mathematical reasoning, computational skills, verbal reasoning, analogies, and so on. We might then conduct separate analyses for both the total score and each subtest.

Outcome measures need not be continuous normal variables. While such distributions facilitate RD anal-

ysis, they are not necessary for it. Thus, Berk and Rauma (1983) evaluated the effects of a California law that extended unemployment benefits to released prisoners who had not previously been eligible. In order to qualify, prisoners had to earn at least \$1,500 working in the prison over the 12 months prior to release. Would extending these benefits reduce subsequent recidivism—a dichotomous outcome where 1 indicated recidivism and 0 staying out of prison? To analyze this outcome, Berk and Rauma (1983) relied on a linear random utility model related to the binary logit model. When continuous normal outcomes are not feasible, the analyst must specify a statistical model to account for the specified distributional form of the outcome.

5.1 Internal Validity

Internal validity refers to the degree to which causal inference is reasonable because all alternative explanations for an apparent treatment effect can be ruled out. The RD design is very strong with respect to internal validity because the process of selection into treatments is fully known and only factors that would serendipitously induce a discontinuity in the pre-post relationship at the cutoff can be considered threats. However, validity also depends on how well the analyst can model the true pre-post relationship so that underlying nonlinear relationships do not masquerade as discontinuities at the cutoff point.

5.2 Measurement Error

Stanley (1991) has argued that the RD design yields biased estimates of the treatment effect when the assignment variable is measured with error. Cappelleri et al. (1991) refuted this for situations with no interaction effects and Trochim et al. (1991) for the interaction case. The reason such error does not induce bias here although it does in quasiexperiments is that assignment to treatment is by the fallible assignment variable and not by some latent underlying selection process, as happens in quasiexperiments.

5.3 Statistical Power

It takes approximately 2.75 times as many participants in an RD design to achieve statistical power comparable to a simple randomized experiment (Goldberger 1972). When RD is combined with random assignment within an interval around this cutoff, 2.48 times the number of respondents are needed if 20 percent of participants are randomized; 1.96 times with 40 percent randomization; 1.46 with 60 percent; and 1.14 with 80 percent (Cappelleri and Trochim 1994, 1995).

6. Analysis

6.1 Assumptions of RD Analysis

Five central assumptions must be made in order for responsible analysis of data from an RD design:

(a) *The cutoff criterion.* The cutoff criterion must be followed without exception. Otherwise, a selection threat arises and estimates of the treatment effect are likely to be biased.

(b) *The pre-post distribution.* The true pre-post distribution must be known and correctly specified as linear, polynomial, logarithmic, or the like. Reichardt et al. (1995) point out the difficulties in specifying the appropriate model, especially when some curvilinearity exists in the pre-post relationship.

(c) *Comparison group pretest variance.* There must be a sufficient range of pretest values in the comparison group to enable adequate estimation of the pre-post regression line for that group. Variability in the treatment group is also desirable, though not strictly required because one can project the comparison group line even to a single treatment group point.

(d) *Continuous pretest distribution.* Both groups must come from a single continuous pretest distribution. In some cases one might find intact groups that serendipitously divide on a measure so as to imply some cutoff (e.g., pents from two different geographic locations). But such naturally discontinuous groups must be used with caution.

(e) *Treatment implementation.* It is assumed that the treatment is uniformly delivered to all recipients—that is, they all receive the same dosage, length of stay, amount of training, or whatever. If not, it is necessary to model explicitly the treatment as implemented, thus complicating the analysis considerably.

6.2 A Model for the Basic RD Design

The model presented here is for the basic RD design. Given a pretest assignment measure, x_i , and a post-treatment measure, y_i , the model can be stated as follows:

$$y_i = \beta_0 + \beta_1 \tilde{x}_i + \beta_2 z_i + \beta_3 \tilde{x}_i z_i + \dots + \beta_{n-1} \tilde{x}_i^s z_i + e_i$$

Where $\tilde{x}_i$ = pretreatment measure for individual i minus the value of the cutoff, x_0 (i.e., $\tilde{x}_i = x_i - x_0$); y_i = post-treatment measure for individual i ; z_i = assignment variable (1 if treatment participant; 0 if comparison participant); s = the degree of the polynomial for the associated $\tilde{x}_i$; β_0 = parameter for comparison group intercept at cutoff x_0 ; β_1 = linear slope parameter; β_2 = treatment effect estimate; β_n = parameter for the s th polynomial or interaction terms if paired with z ; e_i = random error.

The major hypothesis of interest is: $H_0: \beta_2 = 0$ tested against the alternative: $H_1: \beta_2 \neq 0$. This model estimates both main and interaction effects at the cutoff point in order to examine changes in means and

slopes. It postulates a pre-post relationship that is polynomial at the cutoff. It also requires subtracting the cutoff score from each pretest score. The term $\tilde{x}_i$ has a superscript tilde to indicate this transformation of the pretest x_i . Finally, the model allows for any order of polynomial function (although certain restrictions are made in specifying the function as described below). Thus, the true pre-post relationship can in theory be linear, quadratic, cubic, quartic, and so on, or any combinations of these.

6.3 Model Specification

The key analytic problem is correctly specifying the model for the data—in this example, as a polynomial model. No simple or mechanical way exists to determine definitively the appropriate model. As with any statistical modeling, the RD analysis requires judgment and discretion and conducting multiple analyses based on different assumptions about the true pre-post relationship.

6.4 Steps in the Analysis

Recall what data the basic RD design provides on each unit. There is a pretest assignment value x_i in the model. Knowing this and the cutoff value allows creation of a new variable, z_i , which is equal to 1 in the treatment group and 0 if not. Finally, there is a post-test score labeled y_i in the model. Given the variables x_i , z_i , and y_i , the steps to be followed in the polynomial analysis are:

(a) *Transform the pretest.* The analysis begins by subtracting the cutoff value from each pretest score, thus creating the term as in the model. This sets the intercept equal to the cutoff so that estimates of effect are made at the cutoff rather than at $x_i = 0$.

(b) *Examine the relationship visually.* It is important to determine whether there is any visually discernable discontinuity at the cutoff. It could be a change in level, in slope, or both. If a discontinuity is visually clear at the cutoff one should not be satisfied with analytic results that indicate no effect. However, if no discontinuity is apparent, variability in the data may be masking an effect and one must attend carefully to the analytic results.

The second thing to look for is the degree of polynomial that may be required as indicated by the overall slope of the distribution, but particularly in the comparison group part. A good approach is to count the number of flexion points (how often the distribution ‘flexes’ or ‘bends’). A linear distribution implies no flexion points, while a single flexion point could indicate a quadratic function. This information is used to specify the initial model.

(c) *Create higher-order terms and interactions.* Depending on the number of flexion points, create transformations of the transformed assignment variable, $\tilde{x}_i$. The rule of thumb is that one goes two orders

of polynomial higher than indicated by the number of flexion points. Thus, if the bivariate relationship appeared linear (i.e., no flexion points), one would want to create transformations up to a second-order $(0 + 2)$ polynomial. The first-order polynomial already exists in the model ($\tilde{x}_i$) and so one would only have to create the second-order polynomial by squaring $\tilde{x}_i$ to obtain $\tilde{x}_i^2$. For each transformation of $\tilde{x}_i$ one also creates the interaction term by multiplying the polynomial by z_i . In this example there would be two interaction terms: $\tilde{x}_i z_i$ and $\tilde{x}_i^2 z_i$. If there seem to be two flexion points in the bivariate distribution, one would then create transformations up to the fourth $(2 + 2)$ power and their interactions. This rule of thumb errs towards overestimating the true polynomial function needed, for reasons outlined in Trochim (1984).

(d) *Estimate the initial model.* The true analysis can now begin. One simply regresses the post-test scores, y_i , on $\tilde{x}_i$, z_i and all higher-order transformations and interactions created in step (c) above. The regression coefficient associated with the z_i term (i.e., the group membership variable) is the estimate of the main effect of the treatment. If there is a vertical discontinuity at the cutoff it will be estimated by this coefficient. One can test the significance of the coefficient (or any other) by constructing a standard t -test. If the analyst correctly overestimated the polynomial function required to model the distribution at step (c), then the treatment effect estimate will be unbiased. However, by initially including terms that may not be needed in the true model, the estimate is likely to be inefficient—that is, standard error terms will be inflated and statistical significance underestimated. But if the coefficient for the effect is highly significant, it would be reasonable to conclude there is an effect. Interaction effects can also be examined. A linear interaction is implied by a significant coefficient for the $\tilde{x}_i z_i$ term.

(e) *Refining the model.* The procedure described thus far is conservative, designed to reduce the chances of a biased treatment effect estimate even at the risk of increasing the error of the estimate (Trochim 1984). So, on the basis of the results of step (d) one might wish to attempt to remove apparently unnecessary terms and re-estimate the treatment effect with greater efficiency. This is tricky and should be approached with caution lest it introduces bias. One should certainly examine the regression results from step (d), noting the degree to which the overall model fit the data, the presence of any insignificant coefficients, and the pattern of residuals. One might examine the highest-order term in the current model and its interaction. If both coefficients are nonsignificant, and the goodness-of-fit measures and pattern of residuals indicate a good fit, one might then drop these two terms and re-estimate the model. One would repeat this procedure until either: (i) all of the coefficients are significant; (ii) the goodness-of-fit measure drops appreciably; or (iii) the pattern of residuals indicates a poor fit.

6.5 Analyses with Multiple Cutoff Points

The basic model described above can be applied directly when multiple cutoff points are used and random assignment is used within cutoff intervals. If assignment within intervals is nonrandom, one must also address the potential for selection bias in the analysis. When multiple cutoffs are used to distinguish separate treatments (i.e., multiple treatments are not assigned within the same cutoff interval), one would have to construct multiple treatment assignment variables for the analytic model (e.g., z_1, z_2, z_3) and all necessary interaction terms. Clearly, as more cutoffs and groups are added, model specification becomes more complex.

6.6 Analyses with Multiple Assignment Measures

Imagine having multiple measures, each with its own cutoff. Each assignment measure is then transformed by having its own cutoff value subtracted from it to create $\tilde{x}_i$. The analysis would then include all transformed assignment measures, group membership, higher-order terms, and interactions. For the simple first-order (or linear) case, one could use the model:

$$y_i = \beta_0 + \beta_1 z_i + \beta_2 \tilde{x}_{1i} + \beta_3 \tilde{x}_{2i} + \beta_4 \tilde{x}_{3i} \\ + \beta_5 \tilde{x}_{1i} z_i + \beta_6 \tilde{x}_{2i} z_i + \beta_7 \tilde{x}_{3i} z_i + e_i$$

This model does not include any two-way assignment variable interactions terms (e.g., $\beta_i \tilde{x}_{1i} \tilde{x}_{2i}$ or $\beta_i \tilde{x}_{1i} \tilde{x}_{2i} z_i$) or any three-way terms (e.g., $\beta_i \tilde{x}_{1i} \tilde{x}_{2i} \tilde{x}_{3i}$ and $\beta_i \tilde{x}_{1i} \tilde{x}_{2i} \tilde{x}_{3i} z_i$) but such an assumption may be reasonable where primary interest is in estimating β_1 , the treatment effect, and not interactions. Clearly, though, the use of multiple assignment variables with higher-order polynomial models will quickly lead to an unwieldy analysis.

The situation is simpler when multiple assignment variables are rescaled to reflect ‘number of assignment variables on which a person meets the criterion’ (e.g., on 5 of 10). This number then becomes the x_i variable and one would conduct the basic analysis described earlier. When multiple assignment variables are combined into a single index, the analysis is also a straightforward application of the basic procedures described initially.

7. Conclusions

From a methodological point of view, inferences drawn from a well-implemented RD design are considered comparable in internal validity to conclusions from randomized experiments. However, the lower statistical efficiency of RD designs, and the resulting sample size demands, may limit the design’s utility. From an ethical perspective, RD designs are com-

patible with the goal of getting the treatment to those most in need. It is not necessary to deny the treatment from potentially deserving recipients simply for the sake of a scientific test. From an administrative viewpoint, the RD design may be directly usable when allocation formulas are the basis for assigning treatments or programs.

With all of these considerations in mind, the RD design must be used judiciously. In general, the randomized experiment is still the first method of choice when assessing causal hypotheses (Cappelleri and Trochim 2000). However, where they are ruled out as impractical, the RD design should be considered as a practical alternative.

W. M. Trochim

Regulation and Administration

Regulation is the effort to shape significant institutions—industry, universities, immigration—to serve some social concerns that might not be taken into account in the ordinary process of doing business. According to one definition, it is the imposition of legal orders on those engaged in economic activity (Kagan 1978). States regulate capitalist enterprises within capitalist or mixed economies.

1. Emergence and Justification

Bureaucratic regulation of industries emerged in the nineteenth century with the rise of industrial capitalism and the bureaucratic division of labor. Britain established a factory inspectorate for the textile industry as early as 1832. The use of inspectorates to address the more dangerous conditions at work—in match factories, in tenement labor—expanded dramatically throughout the Western world in the 1890s (Rodgers 1998, pp. 254–9).

Regulation has proven to be at least partly reversible: central trends in capitalist economies during the 1970s and 1980s included both privatization of

state-owned industries (see e.g., Graham and Prosser 1988, Pistula and Rasmussen 1990) and political pressure toward deregulating already regulated industries (Derthick and Quirk 1985, Harris and Milkis 1996).

Economists have thought it important to explain why regulation is necessary within a capitalist economy, given that neoclassical economic theory holds that social purposes are best accomplished by markets. The importance of neoclassical theory has meant that advocates and critics of regulation have also expended effort understanding the justifications (see e.g., Breyer 1982). Justification has sometimes centered on the concept of 'externalities.' A market requires that business pays for some components, for example, steel in manufacturing a car. However, the manufacturer does not have to buy the air that it pollutes in the process of making cars, and in turn, neither do consumers who drive the cars. In the United States in the 1960s and 1970s in particular, concern about the inability of companies to take into account the social costs of doing business was used to justify regulating products and processes in manufacturing.

In addition to regulating products and processes, governments regulate price and entry: the price that an industry may charge and the requirements to enter into the business. The justification of price and entry regulation does not rely upon the concept of externalities. Rather, the argument is that some industries take on the characteristics of monopoly, whether as a natural monopoly or because there are very high barriers to entry. For example, it could be inefficient to have multiple railways competing against each other since the costs of laying railroad track are very high. What is more, because it is expensive to build a railway, it is extremely difficult to enter the business, which means that the competition that is supposed to ensure that prices and services are responsive to consumer demand does not exist. Without competition, railroads could charge what they would for services. Thus railroads, the first industry subject to national bureaucratic regulation, in the United States would charge more for short-haul than for long-haul trips because there was much less competition in short haul (Skowronek 1982, pp. 124–5, 141–50). In air transport, too, the barriers to entry are high because airspace is limited and in any one airport runways and gates are limited. Someone must allocate the space and ensure that once the airline has the space it does not ignore what customers want. Economists also note the importance of 'network effects' in monopoly. If having compatible computer systems facilitates the exchange of information, each person buying a computer system has an incentive to buy one compatible with those people already have, whether or not that is the best system. Advocates assert that professions like medicine and law require regulation because expertise is required to assess whether the profession is being practiced correctly. Consumers cannot assess whether

a surgeon knows what she is doing until it might be too late.

These justifications for regulation have been subject to serious critique from those who believe that markets should be unregulated and from those who believe that regulation is ineffective because industries have special access to the state not shared by their workers or customers (Derthick and Quirk 1985). In this view regulatory bureaucracies, designed to incorporate public concerns into capitalist economies, become 'captured' by the industries they are to regulate. The regulatory bureaucracies then act largely to insulate the industries from competition and protect their interests. Sometimes that has happened by design: railroad regulators meant to maintain and steady the railroad industry. In the late nineteenth century railroads in the United States wanted to be regulated to moderate the incentives to cut prices that were putting railroads out of business (Skowronek 1982). In France *notaires* welcome regulation to preserve their monopoly on drawing up legal contracts; opening that monopoly would have meant decreasing income as a result of competition (Suleiman 1987).

Economists call the effort to gain protection from the market by legislative or bureaucratic intervention 'rent-seeking behavior'—that is, an effort to gain a return beyond what is required to keep one in the business—and many have argued that rent-seeking is the heart of regulation. For example, lawyers benefit from the licensing of lawyers; it restricts the numbers of lawyers available and thereby maintains a higher price than would be the case if anyone could practice law. The claim that regulation protected inefficient industries from competition and used state power to keep prices artificially high provided a substantial part of the support for deregulation in the United States. In the late 1970s and 1980s (Derthick and Quirk 1985, Harris and Milkis 1996). In other nations, critiques of state ownership of industries led to privatization, which in turn entailed regulation (Graham and Prosser 1988). Across the industrialized Second World, industries differed in their ability to maintain monopolies or other advantages regulation provides (Derthick and Quirk 1985, Suleiman 1987).

In the United States, deregulation seems to have promoted consolidation in the airline industry and the trucking industry just as understandings of 'natural monopolies' might have predicted. Perhaps surprisingly, the strength of the pro-environmental regulation lobby meant that environmental deregulation did not go far (Harris and Milkis 1996). Those advocating a more market-based approach in pollution rights gained recognition in Clean Air Act Amendments, but government officials were still deeply involved in regulation (Harris and Milkis 1996). Presidents elected on antiregulation platforms do not completely control the political environment in which they work. The American federal system also provides access in the states when people have lost at the federal level. For

example, when the federal government tried to limit the regulation of advertising, activists turned to the more sympathetic state governments.

States approach regulation relying on different institutions that have, in turn, different styles. Courts, legislatures, local governments, marketing boards, and bureaucratic agencies all can (and have) imposed orders on capitalist enterprise. In the United States before the Civil War, rather than relying on negotiations between business and bureaucrats, or on rules from bureaucrats that were enforced in the courts, the United States relied on courts—largely state courts—to enforce statutes or common law duties. In addition, state legislatures granted charters to businesses and in return exacted some form of regulation: limits on what entrepreneurs could charge to cross a bridge or use a road (Hartz 1948), or requirements that those who owned docks contribute toward keeping harbors dredged and open (Hartog 1983). Such regulation is not a matter of general rules implemented through a bureaucracy, but it was an effort to require businesses to take into account public concerns not readily addressed in the market. By the late nineteenth century most states had instituted some bewildering array of boards, commissions, and special courts to instead ensure that a broader public interest was taken into account.

2. Institutions that Regulate

The first American federal regulatory agency, the Interstate Commerce Commission, was created in 1887. It was unusual in that it established an agency independent of immediate control by ministers, responsible for making a framework of policy through trial-type procedures, with decisions that could be appealed to general jurisdiction courts (Baldwin 1985, p. 7). The United States' official regulatory procedure is more rule-oriented than those in other Western industrialized states, and courts are more deeply involved in making policy. The American system also allows for much more public participation and opportunity to argue against regulations both within an administrative agency and through courts after administrative agencies have decided.

After World War Two regulation in the United States became open to wider public participation. Administrative agencies must hold public hearings after announcing the topic of a rule they are considering. They must then justify the rule they issue according to the evidence they have. Often an organization concerned with the rule will bring the regulatory agency to court. Federal courts usually review the processes by which the rules were promulgated and decide whether the rule or decision is justified according to the evidence. What lawyers have won in the United States has been observed sometimes with horror, sometimes with envy in other nations.

Other nations do not rely so extensively on the equivalent of generalist courts to assess the procedures by which rules are enacted. The French have a specialized court that hears challenges to administrative decisionmaking, the *Conseil d'Etat*, or Council of State. The *Conseil d'Etat* is staffed with people who have built careers within administration; the purpose is to have a court that will take into account public purposes, or the interests of the state, in deciding cases brought by individual challengers. In Britain, practitioners in regulation were frustrated enough with how their general jurisdiction courts supervised administrative decisions that the state created a version of a specialized administrative court in the 1970s (Sterett 1997). Particular judges specialize in hearing complaints about administrators. The political justification for both courts is that specialization in administrative complaints will lead to sensitivity to public purpose and an awareness of what can go wrong in administration. Germany, also, relies on a specialized administrative court staffed by a trained civil service judiciary that lies above a system of specialized tribunals.

A further contribution to the complexity of regulation in the United States is the extent of interest group litigation. Interest group challenges to the general rules under which administrators work are far more numerous than in any other nation. However, social welfare groups have in recent years organized to challenge rules concerning immigration and environmental regulation in Western Europe. The expansion of standards via the European Court of Justice and directives via the European Union have made it more possible to challenge domestic regulation, or refusals to regulate, in Europe. Finally, cross national treaties or other agreements also shape domestic regulation, for example in ozone regulation (Braithwaite and Drahos 2000; Canan and Reichman 1993).

In most countries there are specialized courts between generalist courts or the upper level administrative court and front line administrators. These specialized courts usually include representatives of relevant sectors (e.g., employers and union representatives in labor tribunals) in their staff. Members of specialized courts are not always legally trained. Their procedures are often less formal than those of generalist courts, and those before them do not always have legal representation. The informality and discretion allowed most tribunals provides substantial opportunity for a slip between formal statement of government policy and its meaning in particular cases.

3. What Does it Cost?

Line items in government budgets for regulatory agencies do not actually tell what regulation costs. To comply with regulatory requirements, businesses incur the costs of improving safety or documenting that they

are trying to. To the extent that regulation requires businesses to internalize their externalities, to pay for pollution abatements, for example, there is no one thing to measure. Business representatives have argued that the processes of American regulation are more difficult than those in other Western postindustrial states: compliance requires more documentation, inspectors more readily impose fines, businesses can expect more public interest group confrontation, hearings, and possibly court battles (Kagan and Axelrad 2000). The outcomes in Western states—the regulatory standards that are imposed—tend to converge. (Kagan and Axelrad 2000). It is unclear whether this means that other states achieve comparable standards without the process costs incurred in the United States or that the United States through its extensive procedures sets standards that are copied elsewhere.

Regulation involves trade-offs between effectiveness and other considerations. For example, we might want nursing homes to provide good care for people, but that is hard to measure. To the extent that we try to enforce it, we might direct effort in an organization toward documenting practices that do not quite get at caring, such as providing meals on time (Braithwaite 1993). A more substantive mandate to care might better capture what we want, but it would be unenforceable. In addition, different substantive regulations are acceptable to businesses and broader publics in different countries. For example, American commitments to nondiscrimination, which critics see as more extensive than those in most other countries, impose costs through requirements of documentation of fair procedures. Such provisions do not require any particular substantive outcome. Other countries, however, employ approaches that would be unacceptable in the United States. For example, Sweden tried to implement employment equality in a way that could keep administrative costs low while resulting in real change, by setting employment quotas for women in jobs in which they were underrepresented (Brown and Wilcher 1987). Britain, on the other hand, has relied on loose and open-ended definitions of nondiscrimination implemented through tribunals whose members are not legally trained and whose primary jurisdiction is not nondiscrimination law. The result seems to be a relatively inexpensive system that has done little to challenge discriminatory practices in the workplace (Kenney 1992).

Globalization has increased the importance of legal rules and lawyers in regulation in national states outside the United States, raising questions about the costs of more formal styles of regulation (Kagan 1997, Kagan 2000). Despite concerns about the expense of regulation, enterprises sometimes choose to pursue the goals of regulation beyond what governments require, because compliance offices sometimes employ people who take the goals of regulation to be their mission, or because large corporations concern themselves with

their public image as good citizens (Edelman 1990; Rees 1988). Compliance is not always a matter of direct orders.

4. *Explaining Regulation: Political Institutions and Political Culture*

Explanations for the different approaches to regulation—contentious, and emphasizing public procedures and rules as against consensual, and without formal rules—across postindustrial states are of two different types. The first explanation emphasizes the historical emergence of governance in different countries. The second explanation emphasizes cultural predilections such as individualism as against faith in authority.

A historical-institutional approach holds that political institutions have shaped the emergence of different regulatory regimes. Those political institutions are in turn the result of large-scale historical processes. In particular, in much of Western Europe, a career civil service insulated from politics was created in the nineteenth century (Kelman 1981). Administrative arms of government often started as the personal servants of the monarch; the political environment within which they worked did not include mass electorates. Governments could develop bureaucracies insulated from political pressure, setting in place systems difficult to disrupt, no matter what cultural preferences there might be for a broader or more accessible or more aggressive system of regulation. Alternatively, the incorporation of political fragmentation also has a history necessary, for example, to understand affirmative action policy in India (Parikh 1997).

Parliamentary systems, in which the government controls the legislative agenda, provide the government substantial control over how a regulator bureaucracy will be organized and the forms accountability will take. Should a government believe it is best to include only responsible-seeming or moderate interest groups in their discussion of regulation, they will find little institutionalized opposition (Vogel 1986). Parliaments see little reason to institute checks on administrators that can be invoked directly by interest groups, such as a right to sue. From the point of view of government ministers, both in charge of government departments and sitting in parliament, such a capability only makes regulation more difficult.

In addition to administrators and their ministerial supervisors, courts participate in regulation, to a different extent in different national states. In civil law systems, judging is a career to which people are trained. The highest level administrative court in France, the *Conseil d'Etat*, is staffed with top-level civil servants. Their charge is quite clearly to attend to complaints against administrators with an eye to maintaining the

effectiveness of a regulatory regime; it is not a system designed to allow confrontation over the fundamentals of public policy. Even within British-style common law systems, judges in the general legal system are selected from the elite of the bar, who are narrowly trained and disinclined to confront administrators. The insulation from the electoral politics that so profoundly shapes the civil services includes the judiciary.

The historical-institutional explanation points us toward the very different institutional development in the United States in order to understand differences in the contentiousness of regulation. In the American presidential and federal system, the legislatures—Congress and the states—are not wholly within the control of the executive. Those who wish to insist on visions of regulation different from that of the executive can gain leverage in the legislature to do so, not least through mobilizing popular mistrust of closed procedures. The American system of formal rulemaking procedures and some openness in administration resulted first from the American Bar Association's mistrust of regulation and then from the politically distinct mistrust emergent in the 1960s and 1970s. Both gained leverage through Congress and through the courts, which had more generous standards for allowing people to sue than did courts in other nations.

In contrast, cultural explanation for differences in regulation among states focuses more on shared meanings and less on the institutional sources of those meanings. American culture is individualist and assertive according to this interpretation, while cultures in other Western countries are more deferential, in part based on a monarchical past and strong social hierarchies (Vogel 1986). Deference, however, hardly characterizes the upheavals of the 1960s and 1970s, pervasive throughout Western industrialized states. Demands for participation were institutionalized in law in the United States but not in other nation-states in that period. In other nation-states attempts to make the government more responsive included instituting ombudsmen, state institutions to listen to complaints about administration in particular cases. Responses did not include a fundamental change in how rules were instituted, though they did in the United States.

Further evidence raises questions concerning the completeness of the cultural explanation. In Britain, for example, a country cited as having informal regulatory practices in comparison to the United States (Vogel 1986), land-use planning has been contentious, rule-bound, and full of litigation. A cultural explanation arguing that the British are more deferential than Americans cannot account for that contentiousness. An alternative institutional and historical explanation is relatively simple. The legal profession long made most of its income in land. By the time bureaucratic land-use regulation emerged, the

government had to take into account the interests of an already organized legal profession accustomed to litigating land disputes. In attending to national cultures as a basis for explanation, tensions within cultures require scholars to attempt to explain why some cultural preferences have been enacted into law and some have not.

Supranational courts shape regulation within the European Union. Both the European Court of Human Rights and the European Court of Justice make decisions concerning the rules that nation-states use in admitting immigrants, limiting sex discrimination, and determining the right to a family life or the right to travel. The European Court of Justice also decides cases concerning environmental regulation, based on directives from the Council of Ministers. The context for regulatory bodies therefore includes not only the businesses and practices that they regulate, alongside the attentive publics following regulation and their domestic political institutions. Increasingly, it includes supranational institutions harmonizing requirements cross-nationally. A perspective that takes nation-states as monolithic entities would see the supranational courts as an imposition on national autonomy. Since, however, not everyone within a nation-state agrees—some political activists want stricter regulation of pollution, or more openness to the families of settled immigrants—the introduction of supranational institutions makes for more complex alliances. State officials themselves are often not united, so supranational decisions can strengthen the hand of one administrative office over another.

5. *Constituting Regulation: Rules and Discretion*

National legislatures and executives may state general rules for regulation: that sex discrimination in employment is illegal, that businesses must reduce air pollution. Regulation is a complex task in which goals are often in tension—for example, to clean the air while ensuring that businesses that pollute do not have to close, or without severely curtailing driving. Multiple and conflicting goals for complex organizations mean that what counts as compliance requires interpretation. Even in the United States, where the courts are in the business of continually clarifying the rules, the facts of a situation can be complicated enough that compliance with a rule is something that will entail negotiation between the regulator and regulated, which a court then only ratifies. An order to emit less smoke can easily become subject to negotiations regarding the kind of scrubbers to install (Melnick 1983). Distinguishing between general rules and decision making in individual cases is difficult. In regulation, general rules often emerge out of particular decisions.

Where officials have substantial discretion in determining compliance, the meaning of regulation emerges

in negotiations with the regulated company. Case-level administrators interpret their instructions in light of what regulated businesses ordinarily do. For example, in Britain, specialized courts (or tribunals) that were responsible for hearing labor complaints interpreted discrimination law so to prohibit *unreasonable* unfavorable treatment of women, even though the sex discrimination statute did not rely upon a standard of reasonableness. 'Reasonableness' was a standard in unfair dismissal cases outside of sex discrimination. Common sense told tribunal members that reasonableness must be part of the sex discrimination statute; in practice the tribunals ratified most of what businesses had been doing (Kenney 1992, pp. 104–8).

Changing the ordinary practices of an organization is difficult. Where there are applicable rules or direct court orders against an organization, the organization must construe what it means to comply. Organizations have every reason to interpret decisions so that they fit with organizational priorities. For example, a court order to pay women equally with men in comparable jobs still leaves open what count as equivalent jobs, how equal the pay must be, and over how long a period it must be equalized, all of which will be up to an employer to determine (McCann 1994). Administrative agency decisions or court interpretations of them gain meaning in their application.

The professional training of decision-makers shapes what regulations mean. In employment discrimination law in the United States, personnel administrators interpret the law so as to require what they see as good management practices, which requires that people who work together get along. They do not often interpret the law as a matter of legal right, that is, as an enforceable claim that someone can make against his or her employer. Rather, personnel administrators are more likely to interpret problems as matters of personality conflicts (Edelman 1993). Thus the presence of enforceable rights does not necessarily make regulation very different from, for example, enforcement of water pollution laws in Britain, where there are no clear rules and enforcement officials negotiate and bluff (Hawkins 1984, see also Graboski and Braithwaite 1986). A substantial difference is whether officials can enlist courts in enforcement efforts.

Recent scholarship focuses on both business organizations and administrative officials working in complex environments in which they mutually shape meanings of the law (Edelman 1993, Harris and Milkis 1996). Charting variation across sectors requires attending to that environment in which regulation works, including the variation in attentive publics as well as the organization of the state. While national states sometimes do have national approaches shared across regulatory sectors, the emergent supranational context is shaping regulation so as to require analysts to attend to reasons for convergence as much as differences between nation-states.

Differences could result less from differences between postindustrial states; the global context of operation might lead to convergence among First World states (Draho and Braithwaite 2000), while Third World countries produce goods, often in conditions much worse for workers. Regulation there could depend as much on global political forces as on internal political dynamics.

Regulation, Economic Theory of

Regulation is defined as ‘the act of controlling or directing by a rule, principle, [or] method’ (Webster 1989). This definition encompasses many forms of control by a variety of actors. The ensuing discussion will focus on the important form of economic regu-

lation in which the government controls the activities of producers in order to enhance the well being of the customers they serve.

1. Regulating with Accurate Information

When the average cost that each firm incurs in serving customers (i.e., the firm’s cost per customer) declines as the firm serves more customers, industry costs will be minimized when only one producer serves all customers. For example, the cost of providing local telephone service to a community is often lower when a single telecommunications network is constructed and operated than when multiple networks are operated. Similarly, because of declining average costs, the local distribution of electricity, water, and gas is often provided at minimum cost by a single firm. But if a single profit-maximizing firm faces no competition, consumers will have no alternative source of supply, and so an unregulated sole producer may have considerable freedom to charge high prices for its services. Regulation of the prices charged by a single (monopoly) supplier can help to protect consumers while permitting the industry configuration that minimizes the costs of serving customers.

Consumer protection can take many forms, particularly when the regulated supplier provides more than one service. To illustrate this fact, consider the mandate of the US Postal Rate Commission. When it sets the prices that the US Postal Service charges for the services it delivers, the Commission is required to ensure that the pricing structure is simple and that prices are fair and equitable. The Commission must also ensure that established prices reflect the value of the service rendered and cover the costs of providing each service (Postal Reorganization Act 1970, § 3622(b)).

To determine how a regulatory body (hereafter, a regulator) might attempt to satisfy such mandates, consider first, the case of an omniscient regulator who knows both how highly consumers value the services produced by the regulated firm and the minimum possible costs that the firm incurs in serving customers.

1.1 Linear Pricing with a Single Output

Initially suppose that the regulated firm produces only one product. Also suppose that the regulator desires to set the price for this product so as to maximize the aggregate welfare of all consumers, while delivering sufficient profit to the firm to guarantee that it will voluntarily serve customers at the established price. Consumer welfare measures the total value that consumers derive from their purchase and consumption of the product. A firm’s profit is the difference

between the revenues it receives and the costs it incurs. Profit is a measure of producer welfare.

To maximize consumer welfare while delivering at least the minimum required level of producer welfare, the regulator must set the price that consumers pay for each unit of the product they purchase so as to deliver the largest possible sum of consumer and producer welfare. This welfare-maximizing price is the one that equals the extra (or marginal) cost the firm incurs in producing the last unit of the product it sells. This is because consumers will continue to buy more of the product as long as the extra value they receive from doing so exceeds the price they must pay for an additional unit of the product. Therefore, when the price reflects the producer's marginal cost of production, consumers will purchase additional units of the product whenever the value they derive from consumption exceeds the cost of allowing that consumption. Consequently, a regulated price that reflects the producer's marginal cost of production will ensure the level of output that maximizes the combined welfare of consumers and the firm.

However, when unit production costs decline as the firm produces more output, a price set equal to the marginal cost of producing the last unit of output will cause the firm to suffer a financial loss. For all but the last unit produced, the compensation the firm receives (i.e., the price) will be less than the incremental production cost it incurs. To ensure that the total revenue the firm receives does not fall below the total production cost it incurs, the regulator must raise the authorized price above the level of marginal cost. A price equal to the firm's average cost of production at the prevailing level of production will deliver the highest possible level of welfare to consumers while ensuring that the regulated firm's costs do not exceed its revenues.

1.2 Nonlinear Pricing

A regulator might contemplate implementing a pricing structure in which customers do not simply pay the same unit price for each unit of the product they purchase. For example, each customer might be charged both a fixed participation fee that does not vary with the amount of the product purchased and a constant unit price for each unit that is purchased. Under such a pricing structure, the unit price might be set equal to the regulated supplier's marginal cost of producing the last unit of output it sells and the participation fee might be set to recover exactly the deficit the firm incurs (i.e., the difference between the total revenue it receives from sales and the total production costs it incurs) when it sells its product at the specified unit price. This pricing structure would deliver the maximum possible level of consumer welfare while ensuring non-negative profit for the firm, provided the participation fee is not so onerous

as to compel some customers to terminate all purchases of the regulated product (Wilson 1993). In practice, large participation fees are often viewed as unduly onerous for consumers with limited resources. Consequently, particular concern for the well being of these consumers or general concerns with equity and fairness can limit the use of participation fees and other alternatives to constant unit prices.

1.3 Linear Pricing with Multiple Outputs

Now consider the more common setting in which the regulated firm produces multiple products (for example, both rural and urban telephone services). Also suppose the regulator chooses to implement only a constant unit price for each regulated product. Since the prices charged for different products can vary, there are many different ways in which the regulator can raise prices above marginal production costs while ensuring that revenues match total operating costs exactly. To maximize the combined welfare of all consumers, the regulator will implement proportionate mark-ups ($(p_i - c_i)/p_i$) of price (p_i) above marginal cost (c_i) that vary inversely with the sensitivity of consumer demand to price (Ramsey 1927, Baumol and Bradford 1970). The regulator will set the price of a product close to its marginal cost of production when a larger price increase would cause consumers to severely curtail their purchases of the product. In contrast, the regulator will raise the price of a product well above its marginal cost of production when doing so does not cause consumers to reduce their purchases of the product significantly. This pricing policy secures the greatest combined welfare for consumers by limiting the aggregate reduction in consumption that arises as prices are raised sufficiently far above marginal production costs to generate revenues that match production costs.

1.4 Quality Deterioration and Cream Skimming

As noted above, regulators do not always seek solely to maximize the aggregate welfare of consumers. Consequently, in practice, regulated prices are not always raised above marginal costs by greater amounts the less sensitive consumer demand is to price. In fact, some prices (e.g., those for rural, residential telephone service) may be set below marginal production costs while other prices (e.g., those for telephone service to urban business customers) may be set well above marginal production costs. Such prices may arise from fairness and equity concerns, for example. Pricing patterns of this sort can introduce two important problems: quality deterioration and cream skimming.

When the price of a product is set below its marginal cost of production, each extra unit of the product that the firm sells causes its profit to decline. Consequently,

the firm would secure greater profit if consumers purchased fewer units of the product. One way to induce consumers to purchase fewer units of a product is to reduce the quality of the product. Therefore, when prices are set below marginal production costs, the regulator may need to impose penalties on the firm if the level of service quality it delivers is found to be inadequate.

When prices are set above cost for some products and below cost for other products, competitors may find it profitable to supply only those products for which price exceeds cost and leave the incumbent regulated firm to supply those services for which price is set below cost. For example, unless they are prohibited from doing so, competitors may provide telecommunications service only to large businesses in urban areas. This practice is known as cream skimming. A regulator can prevent cream skimming by barring potential competitors of the incumbent regulated firm from providing services in the regulated industry. Such entry prohibitions, though, can hinder industry performance by precluding the operation of firms that have lower operating costs than the incumbent supplier and by removing the discipline that the threat of entry can impose on the incumbent firm. Furthermore, competitors are sometimes able to circumvent prohibitions on entry by developing and marketing substitute products. A regulator can limit incentives for cream skimming by setting prices that more closely reflect the incumbent firm's operating costs. When prices reflect costs in this manner, entry will typically be encouraged only when a competitor can satisfy consumers' needs at lower cost than the incumbent supplier can.

2. Regulating With Limited Information: Incentive Regulation

When, as presumed above, the regulator is well informed about the firm's operating capabilities, the regulator can set prices to generate revenues that exactly match production costs when the firm operates efficiently (i.e., when it incurs only the minimum possible cost required to serve customers). When the regulator is not perfectly informed about the firm's capabilities, the regulator cannot simply mandate that the firm operates efficiently. Instead, the regulator must induce the firm to minimize its operating costs. There are a variety of techniques the regulator can employ to do so. These techniques constitute elements of what is termed incentive regulation.

2.1 Regulatory Lag

When prices are set to match realized production costs only periodically (e.g., once every three or four years) rather than continually, the firm derives some financial

benefit from reducing its operating costs. The larger the period of time before prices are reduced to match lower realized operating costs, the more pronounced is the firm's incentive to reduce its costs. On the other hand, the longer prices are permitted to remain above operating costs, the longer consumer welfare is held below the level that could be secured given the firm's realized costs. This tradeoff determines the optimal length of time between price revisions, i.e., the optimal regulatory lag.

2.2 Price Cap Regulation

Price cap regulation has enjoyed increasing popularity in recent years. It incorporates a form of regulatory lag while delegating some pricing discretion to the regulated firm. The typical price cap regulation plan specifies a price cap period (often four or five years) and a maximum rate at which the regulated firm's inflation-adjusted prices can rise annually, on average, during this period (Sappington in press). The firm's realized costs and earnings are usually reviewed at the end of the specified price cap period, and often employed to update estimates of the pricing restriction that would allow the regulated firm to secure a reasonable level of earnings in the next price cap period. When the firm's realized performance is employed to set future standards, the firm's incentives for exceptional performance are dulled. However, price cap regulation provides some incentives for cost reduction by instituting an explicit regulatory lag.

By controlling the rate at which regulated prices can increase on average, price cap regulation affords the firm some discretion in setting prices for individual services. This discretion can help the regulated firm to limit undesirable cream skimming by realigning prices to more closely match production costs. However, this discretion can also enable the firm to raise certain prices that the regulator prefers to remain low (e.g., the price of local telephone service to rural residential customers). To limit the firm's ability to implement undesired pricing structures, price cap regulation plans often prohibit the firm from raising significantly the prices of certain specified products.

2.3 Earnings Sharing Regulation

By providing incentives to reduce operating costs, price cap regulation can simultaneously provide incentives to reduce service quality, since superior quality is often more costly to provide. By allowing prices to diverge from realized costs for considerable periods of time, price cap regulation can also admit earnings that depart significantly from expected levels. To mitigate these potential problems, an earnings sharing plan is sometimes appended to price cap regulation. An earnings sharing plan requires the firm to share with its customers a fraction of realized earnings above (and

often below) specified thresholds. Such sharing helps to insure the firm and the regulator against extremely high (and low) earnings, but at the expense of reduced incentives for exceptional performance (Lyon 1996).

2.4 Yardstick Regulation

In certain settings, yardstick regulation can be employed to provide strong incentives for superior performance while limiting the risk of extreme earnings. Under yardstick regulation, the standards to which one firm is held are based upon the performance levels achieved by other firms. To illustrate, in the British water industry, the prices and service quality standards that are imposed on the monopoly provider in one jurisdiction are linked to the costs and service quality levels achieved by monopoly producers in other geographic regions (Cubbin and Tzanidakis 1998).

When firms face similar operating circumstances, yardstick regulation can enable the regulator to impose a reasonable but challenging performance standard on the regulated firm without basing this standard on the firm's own historic performance. Consequently, yardstick regulation can ensure reasonable earnings for the regulated firm while providing the firm with strong incentives for superior performance. However, these desirable outcomes can only be secured via yardstick regulation if the firms are known to face similar operating circumstances or if all relevant differences in their operating circumstances are well understood (Shleifer 1985). In the absence of this knowledge, the standards imposed under yardstick regulation can result in extreme earnings, much like under price cap regulation. Yardstick regulation may also encourage collusion among the firms that are implicitly being compared. By agreeing to reduce their performance below achievable levels, the firms can effectively relax the constraints imposed by yardstick regulation.

2.5 Franchise Bidding

Even when there is a single regulatory jurisdiction and a single producer in the industry, a regulator may still be able to harness the discipline of competition by structuring competition for the industry. The regulator may allow potential producers to bid for the right to serve as the sole producer in the industry. When the potential producers have similar abilities and similar information about operating circumstances, intense bidding competition for the market can secure for consumers the low prices and high service quality that competition among producers in the market might otherwise provide. However, successful franchise bidding requires that all relevant performance requirements be specified completely in advance, and that the

regulator and firm both adhere precisely to the terms of the franchise contract once a producer has been selected. If the regulated firm can renege on its responsibilities after it is installed as the sole producer, or if the regulator can demand more services from the selected producer than it originally agreed to provide, franchise bidding can fail to deliver the maximum possible attainable level of consumer welfare (Williamson 1976).

2.6 Regulatory Options

When the regulated firm has better information than the regulator about its operating capabilities, consumers are often best served when the regulator allows the firm a choice among regulatory plans. A careful structuring of the options afforded the firm can induce it to employ its superior information to choose a plan that best serves consumers (Laffont and Tirole 1993, Armstrong and Sappington in press).

To illustrate this point, suppose that a regulator decides to impose price cap regulation on a firm rather than allow the firm to choose between price cap regulation and cost-plus regulation, whereby prices are re-set frequently to match realized production costs. To limit the likelihood of financial distress, the regulator may not insist that prices decline rapidly. In contrast, when the firm has the option to choose cost-plus regulation, the regulator can impose more stringent limits on price increases under price cap regulation without the fear of causing financial distress. If the firm believes that it will be unable to realize adequate earnings under the proposed price cap regime, it will choose to operate under cost-plus regulation instead. But if the regulator has not overestimated the firm's capabilities in setting the challenging requirements of the price cap regime, the firm will choose this regime and deliver its pronounced benefits to consumers.

3. Regulation in Vertically Related Industries

Sometimes, a regulated firm may have the ability to supply both inputs and final products. Inputs are products that firms employ to make other products. Final products are those that customers consume, and that are not used to make other products. For example, a local telecommunications network operator may sell to long-distance telecommunications firms the local network access (an input) they must have to complete the long-distance messages they transport. In addition, the local network operator may have the ability to deliver long-distance telephone calls (a final product) itself. Two fundamental questions arise in such settings: (a) should the monopoly supplier of an essential

input be permitted to compete downstream, i.e., against the firms to which it sells the input? (b) how should the price of the essential input be regulated?

3.1 Regulating Industry Structure

One potential benefit of allowing an input supplier to operate downstream is the additional competitive pressure that the input supplier may impose on other downstream producers. The additional competitive pressure can serve to reduce industry prices, and thereby enhance consumer welfare. An input supplier may be a particularly strong competitor when economies of scope are present. Economies of scope exist if multiple products can be supplied at lower cost when they are produced simultaneously by a single firm rather than when they are produced in isolation by distinct firms (Baumol et al. 1982 p.71).

A potential cost of authorizing downstream participation is that it may encourage the input supplier to disadvantage its downstream rivals unfairly. For example, the input supplier may intentionally reduce the quality of the essential input that it sells to its downstream competitors in order to make it more difficult for the competitors to provide high quality service at low cost. However, the input supplier may not have an unambiguous incentive to disadvantage its downstream rivals, because their demand for the essential input typically declines as the quality of the input declines. This reduced demand can reduce the profit derived from supplying the essential input (Weisman in press). The magnitude of the profit the input supplier foregoes by reducing the demand for the input it supplies is greater the higher the price the firm is permitted to charge for the input, *ceteris paribus*. Consequently, raising the price of an essential input above its marginal cost of production can reduce the incentive of an input supplier to disadvantage its downstream rivals.

3.2 Regulating Input Prices

Raising the price of the essential input above its marginal cost of production can also help to limit cream skimming and ensure that downstream production is carried out by the least-cost suppliers. To illustrate this point, suppose that if the input supplier operates downstream, the prices it charges there are regulated. Further suppose that the price of one downstream product (called product A) is set at a level (p^A) that exceeds the supplier's marginal cost of production (perhaps to facilitate a price below marginal cost for another product). If the price of the essential input is set equal to its marginal cost of production in this setting, a downstream producer may be able to serve all consumer demand for product

A profitably even though its marginal cost of production ($\tilde{c}^A$) exceeds the corresponding cost (c^A) of the input supplier. The higher-cost producer can set a price below the regulated price for product A and still secure positive profit if its cost disadvantage ($\tilde{c}^A - c^A$) is smaller than the regulated profit margin on product A ($p^A - c^A$). To preclude operation by higher-cost competitors, the price of the essential input can be raised above its marginal cost of production by the amount of profit ($p^A - c^A$) the input supplier foregoes when it provides the input to competitors (Laffont and Tirole 1994, Baumol et al. 1997, Armstrong in press). One potential drawback to this pricing policy, though, is that it provides little incentive for the input supplier to reduce its operating costs.

4. Additional Forms of Regulation

Regulation of producers' activities can help to enhance consumer welfare even when industry cost minimization does not require operation by a single producer. To illustrate this fact, consider the potential value of environmental regulation and health and safety regulation.

4.1 Environmental Regulation

In certain instances, production activity can impose costs on society in addition to the direct physical costs of the inputs used in production. For example, some production processes may expel harmful pollutants into the surrounding land, water, or air. If no restrictions are placed on producers' rights to expel pollutants into the environment, producers may produce more than the surplus-maximizing level of pollution. This is the level of pollution at which the social damage that would be caused by an additional unit of pollution is exactly equal to the social cost that must be incurred to eliminate that additional unit of pollution. Pollution in excess of the surplus-maximizing level imposes social damage that exceeds the cost of eliminating the extra pollution. In contrast, the cost of reducing pollution below the surplus-maximizing level exceeds the social benefits derived from the reduction in pollution.

Various regulatory policies can be employed to control environmental pollution. For instance, direct taxes (effluent fees) can be imposed on pollution when it is readily observed and measured. By setting the tax on pollution equal to the marginal social damage caused by the pollution, the producer can be induced to realize the surplus-maximizing level of pollution. When the level of pollution produced by a firm is difficult to measure, taxes can be imposed instead on the products whose production causes pollution, or on inputs (such as gasoline) to the activity (automobile driving) that causes pollution. The use of specific

pollution abatement technologies can also be mandated.

Recently, some governments have introduced tradable pollution permits. Each permit entitles its bearer to emit one unit of pollution (e.g., one ton of sulfur dioxide). Polluting firms are able to buy and sell permits at prices determined by the available supply of and demand for these permits. A key potential benefit of tradable permits is that they promote pollution abatement at minimum cost. Producers that are able to reduce the pollutants they expel at a cost below the prevailing price of a permit will find it profitable to do so and sell any permits that they own. In contrast, producers for whom pollution abatement is more costly than the price of a permit will continue to expel pollutants but will pay for the right to do so (Schmalensee et al. 1998).

4.2 Health and Safety Regulation

Pollution abatement regulation is often intended to improve the health and well being of citizens. Other forms of health and safety regulation can serve this same purpose. The regulations come in many forms, including information requirements, standards, and prohibitions.

Regulations that require manufacturers to provide relevant product information to consumers can help consumers choose among available products. These regulations include requirements that product contents be fully specified and that the potential health risks associated with consumption be stated clearly. In contrast, direct regulation of product standards and outright prohibitions on the sale of certain products can substitute information collection and decision-making by a regulatory body for decision-making by consumers. For example, when the government imposes minimum home construction standards or when it bans certain drugs from the marketplace, the government eliminates the option a consumer might otherwise have to purchase below-standard homes or banned drugs. One rationale for such regulations is that they can implement the decisions that consumers would make if they were fully informed about all relevant benefits and costs of consumption, without requiring consumers to develop the expertise and obtain and evaluate the information required to assess the benefits and costs (Viscusi 1992).

5. Competing for Regulatory Benefits

The preceding discussion illustrates some of the ways in which government regulation of producers can be designed to benefit consumers. It is important to note, however, that regulation need not only serve this role in practice. Since regulators typically have the power to deliver benefits to some parties and impose costs on others, the affected parties will have an incentive to try

to secure favorable treatment from regulators. When industry producers are better organized and have more at stake than industry consumers, regulation that benefits producers at the expense of consumers can arise (Stigler 1971, Peltzman 1989). For example, new competitors may be barred from an industry even though their entry and operation would be in the best interest of consumers. These realistic possibilities merit careful consideration when evaluating the benefits and costs of existing and proposed regulations.

Regulation: Empirical Analysis

The economic regulation of firms and industries constitutes an extreme form of government intervention in markets. Government antitrust, competition, tax, and trade policies, as well as most environmental, health, safety, and information regulations, shape but do not replace the market, although the most severe of these policies may blur that distinction. Economic regulation stands in sharp contrast. In industries subject to economic regulation, government agencies or departments exercise considerable control over firms' entry, pricing, investment, and product choice decisions, and administrative decisions replace market outcomes. Intervention may go as far as replacing private ownership with government-owned and -operated enterprises.

The modern field of empirical regulatory economics developed during the 1960s and early 1970s, as economists began 'to apply the familiar principles of microeconomics in comprehensive fashion to the subject' (Kahn 1988, p. xv). George Stigler, whose contributions to the field were recognized in his 1982 Economics Nobel prize citation, sparked much of this growth. Through the 1980s, economists focused on quantifying the effect of regulation on firm behavior, industry outcomes, and consumer welfare. The diversity of regulatory forms and industry characteristics across the transportation, energy, utility, financial, and communication sectors provided a rich set of institutions for investigation. Significant policy reforms, even deregulation, in structurally competitive sectors during the 1970s and 1980s provided new sources of variation in the regulatory environment and

invigorated empirical regulatory research. More recent attention has turned to the traditional 'public utility' sector, particularly the telecommunication and electric utility industries. Market-based institutions have begun to replace state-ownership and regulation, as technological change called into question the natural monopoly assumption in many of these industries and policy interest in privatization raised questions of how best to restructure and sell-off vertically-integrated monopolies. Analyzing the operation of these redesigned markets has become a main focus of empirical regulatory research.

This article focuses on empirical analysis of the effects and reform of economic regulation. Section 1 describes the dominant empirical methodologies. Section 2 sketches the evidence on the effects of traditional economic regulation. Section 3 discusses recent analyses of market design and regulatory scope. To keep the reference list manageable, readers are referred to surveys and collective volumes wherever possible. These guide readers interested in delving more deeply into particular issues to a wealth of primary studies.

1. Empirical Methodologies

Measuring the effect of economic regulation requires the establishment of a counterfactual benchmark: what would firm or industry performance look like in the absence of regulation? A variety of approaches to this have been used. The most compelling lesson of the existing literature is that the impact of economic regulation depends critically upon its particular institutional form and the characteristics of the industry under study. Measuring the impact of regulation requires as much attention to the details of how regulators operate in practice as to the prescribed legal form of the regulation. Paul Joskow's (1974) study of electric utility regulation in the US provides a persuasive exposition of this argument.

The most common methodology used to measure regulatory effects compares outcomes in regulated markets with those in unregulated markets. Time series variation may facilitate this comparison; the wave of US deregulation in the late 1970s and early 1980s generated numerous 'before-and-after' studies of regulation. Differences across political jurisdictions, e.g., across states within a country or across countries, may provide another source of variation in regulatory regimes. Empirical studies also may use differences in the intensity or form of regulation to infer its effects, particularly if regulation is likely to bind only under certain well-defined circumstances.

Two conditions limit the usefulness of this approach. First, unregulated comparisons may not exist. Industries that are regulated in one political jurisdiction tend to be regulated or government-owned in other political jurisdictions. Regulation may be so

long-lived that comparing current regulated performance with historical unregulated performance is meaningless. Second, this method implicitly assumes that differences in regulatory regimes are exogenous to firm or market performance. This is often false. If, for example, jurisdictions impose electricity regulation in response to high or rapidly increasing local electricity rates, comparing price levels in regulated and unregulated locales might suggest no effect even if regulation does, in fact, constrain prices. Using panel data to estimate effects from 'differences in differences' econometric models may be useful in some cases, as may developing more complete models of the determinants of regulation.

A second methodology estimates a structural model of the market, forms assumptions about behavior in the absence of regulation, and compares simulated unregulated outcomes with those observed under regulation. This technique may be useful even in the absence of regulatory variation. It is most appropriate when regulatory constraints can be clearly specified. Suppose regulators constrain prices but do not influence investment or factor use decisions. Structural estimates of underlying demand and cost functions permit one to predict unregulated profit-maximizing prices and compare these with current regulated prices. If regulated firms do not minimize costs, however, or if regulatory intervention alters investment decisions in a systematic way, then the regulated cost function may be a poor estimate of the unregulated long-run cost function, and the implied price comparison will be misleading.

A third approach uses experimental data to measure regulatory effects. Field experiments, such as the time-of-use electricity pricing studies conducted in the US during the early 1970s, can reveal responses to alternative regulatory or market designs. In the best of circumstances, these can provide information on how market outcomes respond to exogenous variation in regulatory mechanisms, holding other economic conditions constant. Their cost limits their widespread use, however, and their temporary nature may preclude an assessment of long-run equilibrium responses to alternative policies. Laboratory experiments, which present volunteers (often students) with a set of objectives, operating guidelines, and payoffs, also have been used in a limited way to simulate responses to alternative regulatory designs.

2. The Effects of Traditional Economic Regulation

It is impossible to describe succinctly the full effects of economic regulation across industries, over time, and through space. Regulation may influence prices, costs, and the pace of technological change in an industry. This may lead to the creation or suppression of

economic rents, and change the distribution of rents across various stakeholders or interests in the industry. These effects are likely to vary considerably across markets and regulatory forms, and preclude simple generalizations. This article highlights some illustrative results. Further detail is provided in the many reviews referenced at the end of this article and the primary sources they cite.

2.1 Empirical Analysis of Natural Monopoly Regulation

Industries such as electricity supply, telecommunications, natural gas transmission and distribution, water and sewer service, cable television service, and to some extent railroads have historically been considered 'natural monopolies.' This applies when total production costs are minimized by providing service to all customers in a given market through a single firm. As economists since Adam Smith have recognized, minimizing production cost may not minimize price, since monopolies use their market power to mark up price above competitive levels and earn monopoly rents. This historically engendered one of two policy responses. Government ownership in natural monopoly sectors was typical outside the USA, and was used frequently in the USA for water and sewer service, but less so for electric utilities and cable television service. Government regulation of privately-owned firms was the dominant US response in most other cases. In this scheme, regulators typically grant a legal, 'franchise' monopoly to a single provider in a geographic market, but retain control over price to mitigate the monopoly mark-ups that an unconstrained legal monopolist would choose. Prices are determined generally by commissions that review costs, and often investment decisions, and set prices to cover allowable costs and a 'fair rate of return' on 'prudent' capital investments.

Early economic research on the regulated public utility sector was generally theoretical and focused on how to perfect regulatory pricing, treating as given the desirability and general effectiveness of government regulation. Optimal pricing questions also arose for state-owned utility enterprises, and French and British economists were in the vanguard of research in this area (Kahn 1988, Laffont 1994, and *Poverty: Measurement and Analysis*). Stigler and Friedland's (1962) study of the early electricity industry was one of the first empirical analyses of the actual effect of utility regulation, and concluded that regulation did little to reduce prices below unregulated monopoly levels. While the particulars of this research generated controversy at the time, and subsequent work suggests that electricity prices in the Friedland-Stigler sample were, in fact, lower for regulated firms (Peltzman 1993), the notion that regulation might not improve

upon market outcomes even in those sectors with the strongest public interest rationale stimulated considerable additional research.

The literature subsequent to Stigler and Friedland (1962) suggests generally that price regulation, particularly in the electricity and cable television industries, has constrained average prices below the level an unconstrained legal monopolist would choose. Analysis of average price levels masks the effect of regulation on price structures, however. Price structure analyses in electricity and telephone industries suggest redistributive rather than Ramsey-like efficient pricing objectives, often with considerable transfers from customers with relatively elastic demands to those with relatively inelastic demands. For example, regulatory cross-subsidies from long-distance telephone rates to basic residential telephone service and from urban to rural telephone customers were a major force driving new entry into the US long-distance sector, leading ultimately to the 1984 divestiture of AT&T and the regulatory reform of the telephone industry. The tenacity of these cross-subsidies more than 15 years later testifies to the strength of political interests supporting these policies. Some economists have estimated the social welfare cost of the residential service cross-subsidy to be as high as \$7.0 billion per year (in Peltzman and Winston 2000, p. 78).

The effect of natural monopoly regulation on static production costs is less well-measured. One of the most developed theoretical and empirical literatures on incentives for excessive capital investment in rate-of-return regulated industries proved largely inconclusive (Averch and Johnson 1962, Joskow and Rose 1989). There is some evidence of higher wages in firms that expect regulators to flow increased labor costs through to higher consumer prices, though wages do not tend to be higher overall in regulated sectors (Hendricks 1975, Peoples 1998). In the railroad industry, low regulated profit rates led to underinvestment in track maintenance and repair on many lines, reducing efficiency and increasing average transit time over the track.

Of particular concern is the effect of regulation on the pace of technological innovation. This may occur from direct regulatory constraints on new process or product introductions, such as the Federal Communications Commission's delay in allocating radio spectrum to wireless telephone systems in the USA and its restrictions on enhanced telephone service offerings. Indirect regulatory effects may also influence the pace of technological change by altering expected payoffs to investment in new technology. While often difficult to measure, these costs can be enormous. For example, Hausman estimated lost surplus from the delayed introduction of wireless phone service in the USA at more than \$30 billion annually (in Peltzman and Winston 2000, p. 80).

The ambiguity of cost and innovation effects may arise in part from the difficulty of establishing an

appropriate empirical counterfactual benchmark to regulation, an essential prerequisite to measuring either static or dynamic efficiency effects. Nevertheless, ongoing policy concerns about the efficiency of production, investment incentives, and the pace of technological change in natural monopoly sectors have fueled much of the recent movement toward market-based reforms, discussed in Sect. 3.

2.2 Empirical Analysis of Regulation in Multifirm Industries

A substantial portion of the regulatory apparatus built during the twentieth century involved multifirm industries, such as trucking, airlines, natural gas and oil production, property and liability insurance, and banking. Regulation in many of these was rationalized by the deleterious effects of excessive, rather than insufficient, competition, particularly during the depression of the 1930s. In others, such as airlines, regulation was advocated to promote the orderly development of an emerging commercial industry. Many of these regulatory systems were dismantled or reformed substantially between 1975 and 1985, reflecting a broad consensus on its social costs.

Multifirm price regulation usually requires all firms serving a given market to adhere to a standard tariff. In some industries, this tariff was set by the regulatory commission, as the Civil Aeronautics Board did for the US airline industry. In others, tariffs were set collectively by the firms and ratified by the regulatory commission, as the Interstate Commerce Commission did for trucking rate bureau filings. Regulation generally discourages entry or market extension. By eliminating the ability of existing firms to discount rates and the ability of new firms to enter the market, regulation limits competition and tends to raise prices significantly. For example, economists estimate that regulated prices in the late 1970s were at least 15–20 percent above competitive levels in the trucking industry and 25–30 percent above unregulated prices in the airline industry.

High prices generate significant potential rents. The value of these rents is embodied frequently in the market value of regulatory assets, such as taxicab medallions, operating certificates for regulated trucking firms, or state liquor licenses. Asset values may reflect only a portion of the rents generated by regulation, however. In some sectors, organized labor was able to garnish a substantial share of regulatory rents (Rose 1987, Peoples 1998). Members of the Teamsters Union, for example, were a major beneficiary of trucking regulation, with wages 50 percent above those for nonunion truck drivers and drivers outside the regulated industry. In other industries, regulatory rents were dissipated through various rent-seeking behaviors. This seems to have been particularly

acute in the airline industry, where nonprice competition repeatedly eroded load factors and profit margins despite increasing regulated prices. In the rare situations in which regulatory policy effectively constrains maximum prices and exit from markets, rents may be negative. In the short-run, this can transfer quasi-rents from owners of regulated capital to consumers of their products. Over the longer-run, its adverse effect on investment tends to erode both the quantity and quality of service provided. The rash of bankruptcies in the US railroad industry during the 1970s and early 1980s, and natural gas shortages during periods of below-market ceiling prices in the 1960s and 1970s, were consequences of this type of policy.

As in the natural monopoly sectors, regulation influences the structure of prices as well as the average price level. Economic regulation often leads to a more uniform price structure than in unregulated markets. Prices tend to be less responsive to cost differences across consumers or over time, due in part to cross-subsidies for favored higher-cost consumer groups and to aversion to congestion-based or peak-load pricing. This distorts both capacity utilization and firms' investment incentives. These effects have been analyzed in the context of traffic mix distortions between railroads and trucking firms, provision of air service to small communities, and excessive pooling in insurance markets.

Postderegulation experience suggests that regulation often suppressed variation due to price discrimination, relative to the unregulated market. Airlines are perhaps the best example of this. It is important to recognize that price discrimination, while controversial, may enhance overall welfare relative to a uniform price structure; see the literature on Ramsey-Boiteaux pricing (Kahn 1988). In airline markets, for example, the pervasive use of low discount fares to fill seats that would otherwise depart vacant increases substantially the population for whom air travel is viable, and raises airline revenue per available seat-mile. The net welfare effect of current levels of price discrimination is difficult to measure, and has not been directly calculated for any deregulated market.

Economic regulation in multifirm industries has been associated with both direct and indirect cost effects. Regulatory restrictions and rigidities may prevent firms from optimizing production in both static and dynamic contexts. For example, entry restrictions in the trucking industry led to high rates of partial or empty backhauls and circuitous routings, raising the cost of transporting a given commodity flow. Unit banking regulations, which restrict a firm to a single physical location in one state, both limit realizations of economies of scale in provision of service and insulate less efficient banks from takeovers by more efficient competitors. Inefficiencies such as these generate potentially huge regulatory deadweight losses (Winston 1998).

The welfare effects of cost increases may be difficult to quantify when associated with offsetting changes in the product provided to consumers. For example, the suppression of price competition may encourage nonprice competition, increasing both costs and quality relative to outcomes in unregulated markets. In the regulated airline industry, increased flight frequency and rapid adoption of new aircraft increased both costs and value to passengers. Measuring cost or productivity effects without controlling for the value of higher service quality leads one to overstate the adverse welfare effects of regulation in situations like this. Recent advances in structural demand estimation may help to quantify the value of particular quality attributes, though both data and modeling limitations continue to make this one of the weaker empirical links in most assessments of the overall effects of regulation.

3. The Effects of Restructuring Regulated Natural Monopolies

The focus of regulatory policy and research changed sharply in the late 1980s and 1990s, with the ascendancy of market-based institutions over state-ownership and regulation in even traditional 'natural monopoly' sectors. Restructuring, requiring firms to divest along vertical segment lines, has become common. Segments viewed as structurally competitive, such as electricity generation, have been increasingly deregulated. Network segments that continue to operate under natural monopoly cost conditions, such as electricity transmission grids or distribution systems, generally are required to provide access to competitive suppliers, often at terms subject to continued regulatory oversight. Where economic regulation has been retained, it has become more market-oriented. This reflects both dissatisfaction with recent performance under regulation and a response to theoretical research emphasizing attractive properties of incentive-based regulatory schemes (see *Poverty: Measurement and Analysis*)

These changes raise new questions about market design and regulatory interfaces. The emerging empirical literature has focused on three main issues: the impact of privatization, the performance of restructured sectors, and the effects of incentive-based regulation. Policy in this area is very much in flux, as the initial wave of enthusiasm for market solutions confronts unanticipated consequences from their implementation.

3.1 The Impact of Privatization

Privatization has been motivated by a range of concerns including the cost of service, pace of technological innovation, and impact of continuing subsidies on government budget deficits. A review of the

voluminous literature on privatization is beyond the scope of the present article; see Vickers and Yarrow (1991), La Porta and López-de-Silanes (1999), and their references. Because privatization has been so closely linked with restructuring and regulatory reform initiatives over the past quarter-century, however, it is useful to highlight key empirical results.

One of the most robust empirical results from this literature is the dramatic impact privatization typically has on cost reduction. This is particularly evident in labor costs. Substantial labor shedding has accompanied privatization almost everywhere, with labor force reductions of 50 percent or more a common result. Where comparisons with privately-owned firms are feasible, studies suggest that postprivatization labor rates approach those at firms that were never government-owned. This suggests considerable excess labor in state-owned enterprises. This may reflect the use of state-owned enterprise to promote certain social policies as well as direct operating inefficiencies, suggesting that excess labor costs may include both transfers as well as social dead-weight loss.

Privatization often leads to both price and output increases. Rising output despite higher prices suggests the elimination of artificial constraints, such as rationing, or higher quality service for which consumers are willing to pay more. In numerous studies of utility sectors, waiting time for service falls and investment and service quality increase following privatization. This seems most common in sectors that were capital-starved or in which service was underpriced under state-ownership. Even in countries where state-owned utilities were perceived to be functioning relatively well, however, increased investment and innovation may be important benefits of privatization.

One caveat is in order: the frequent concurrence of privatization with changes in the competitive environment can make it difficult to empirically disentangle the relative contributions of ownership change, hard budget constraints, and increased competition to improved performance. Moreover, it appears that the benefits of privatization may be greater when accompanied by increased competition or deregulation. Studies vary considerably in their recognition and successful treatment of this problem.

3.2 *Performance in Restructured Natural Monopoly Sectors*

Vertical restructuring has become common in natural monopoly industries worldwide. In telecommunications, equipment provision and long-distance service were among the first to be carved out of vertically-integrated telecommunications firms and opened to competitive suppliers. Power generation has been divested from transmission and distribution functions and opened to competition in many electricity systems. Much of this policy movement appears stimulated by

concerns that prices charged by monopoly providers were too high, relative to those attainable by privately-owned firms operating in competitive sectors. In some cases, this reflects real operating inefficiencies and reduced innovation under monopoly. In other cases, apparently high prices may in part reflect perverse regulatory pricing schemes. Action on these concerns was facilitated by technological innovations that reduced scale economies at certain production stages and enabled decentralized operations to achieve many of the economies of scope previously attained by vertically integrated firms.

Economists have been especially interested in assessing the competitiveness of restructured markets. Empirical research suggests these markets have yet to converge to competitive ideals. In the US long-distance telephone market, for example, AT&T lost its sanctioned monopoly provider status in 1984, following the earlier technological erosion of its 'natural monopoly.' While long-distance prices have declined, the convergence to competitive norms has been relatively slow, with average per-minute prices more than double estimated long-run incremental costs as late as 1998 (Peltzman and Winston 2000, p. 77). Some economists have suggested that this reflects relatively weak competition among the small and decreasing number of existing long-distance providers.

Analyses of electricity markets echo this theme. In most restructured electricity markets, unregulated generators bid to supply electricity to the system operator, which determines the dispatch order of generators to supply the electricity demanded at each moment in time. There is considerable evidence of generator market power in many markets, with generators bidding above their marginal generation costs and strategically withholding capacity from the market to increase prices (see Wolfram 1999, Borenstein et al. 2000, Joskow in Peltzman and Winston 2000, and Joskow and Kahn 2001).

While many restructured markets have been prone to supracompetitive prices, the extent to which price exceeds cost varies tremendously across different settings. There is growing evidence that performance variations are heavily dependent upon the institutional details of the market's design. These include the way the competitive sector is structured, the terms on which suppliers interface with their customers and the network, and the management of network investments. In electricity markets, for example, the relative sizes of different suppliers, their inframarginal capacity, the use of long-term hedging contracts between generators and their customers, and the degree to which customers see and can respond to real-time price variation have all been demonstrated to influence the exercise of market power.

While competition may enhance cost efficiency in the deregulated sector, restructuring may increase other costs. For example, substitution of market mechanisms for internal decision-making or 'com-

mand and control' by a vertically integrated firm may increase coordination costs in electricity markets (Joskow in Peltman and Winston 2000). In California, for example, reserve margins and hence system operating costs have increased as a result of moving to a dispatch market. Local distribution companies may face difficulties when their requirement to serve, which was imposed in exchange for franchise monopoly in many utility sectors, is maintained, but restructuring eliminates their direct control over electricity supplies, as evidenced by California utilities in 2000–2001.

In telecommunications, access issues focus on pricing and interconnection requirements for the 'local loop,' the set of wires connecting individual subscribers to the local network. These problems are magnified by the potential for local exchange carriers to compete with other firms for services beyond the local loop. The determination of access terms has substantial effects for investment incentives by incumbent exchange companies and potential competitors, entry into local, long-distance, and enhanced services, and the performance of competitive markets where entry occurs. This is the focus of much current regulatory policy and some empirical analysis (Crandall and Hausman in Peltzman and Winston 2000).

3.3 Effects of Incentive-based Regulation

While regulatory reform over the past two decades has been substantial, economic regulation continues to play an important role in many sectors. Economic regulation in the new millennium is more market-based than its counterpart of 1970, but less market-driven than current rhetoric would suggest. Policy innovation has been particularly notable outside the USA, perhaps because these systems were being designed *de novo* rather than patched on to existing regulatory practices. Regulation has moved away from traditional rate-of-return regulation, which determined prices through cost-based mark-up rules (Kahn 1988). More common are higher-powered incentive schemes such as price caps, which fix price levels or rates of change, and allow firms to keep the surplus generated from unanticipated improvements in efficiency, at least until the next review of the cap or its adjustment factor. The models behind these schemes are discussed elsewhere (see *Poverty: Measurement and Analysis*). It is important to recognize that implementation, however, generally deviates considerably from the theoretical construct.

Many researchers have attempted to measure the impact of incentive-based regulation, particularly in the telecommunications sector. This literature broadly suggests that incentive regulation is accompanied by lower prices. Kridel et al. (1996) suggest that these effects may reflect coincident policies that increase competition more than the incentive effects of incentive regulation itself, however. This interpretation

is particularly suggested by the difficulty in finding consistent effects of incentive regulation on costs or productivity, although the short time span of many studies may impede detection of such effects. As earlier empirical work in regulation suggests, one should exercise great caution in affirming the superiority of incentive-based policies based on the theoretical properties of idealized schemes.

4. Conclusion

The reforms of the 1990s have created a vast new set of institutions and regulatory policies. This is an area in which empirical analysis greatly lags behind the theoretical literature, and the returns to additional careful work are likely to be significant. Empirical research in regulatory economics, argued by some in the 1980s to belong to the domain of economic history, remains vital to guiding, understanding, and evaluating policy initiatives today.

Regulation: Family and Gender

There are few more politically sensitive areas than the role the state should play in regard to 'the family.' It is not easy for liberal democratic states to justify intervention in the private sphere of personal relationships and family life. In the first place memories of extreme examples of state intervention during the twentieth century, most notably in Nazi Germany, where the state dictated who married and who had the right to reproduce, make this difficult territory. Second, even when governments have little by way of explicit family policies, they usually make implicit assumptions about what families should look like, which in pluralist societies are bound to be at odds with the way in which some people organize their affairs. Not only have modern Western states tended to assume that the family will consist of two parents and children, but historically both government policies and the professional experts employed by the state have also made gendered assumptions about the part played by men and women in family life, particularly in respect of responsibilities for earning and for caring, which are increasingly at odds with the social reality.

Feminists have been one of the most vocal groups criticizing government policies on the family, but the relationship between parents, children, and the state has been one of the most hotly debated issues of the twentieth century, as important as the more common touchstone of individualism vs. collectivism. Gender,

understood as a fundamental organizing principle in society (Scott 1988), is crucial to the analysis of the relationship between the state and the family. The concept of 'gendered divisions,' particularly in respect of resources, labor, and investments, is key to understanding the development and impact of the public policies and family law that regulate the family.

1. Ideas about the Nature of State Regulation and the Family

The debate about state regulation, the family, and gender in the last quarter of the twentieth century has revolved around the extent to which states have propped up a particular family form, but the positions taken are complicated and do not follow a simple political division between Left and Right.

Feminists have argued that for governments, family policy all too often meant ways of bolstering the traditional two-parent family, with a male breadwinner and an economically dependent female carer, and that policies rarely impacted on different family members in the same way. For example, in the 1970s, Scandinavian feminist writers proposed that the modern welfare state amounted to a new form of 'public patriarchy,' the argument being that the dramatic increase in women's employment, which began in Sweden and Denmark in the 1970s, involved for the most part women leaving their homes to engage in similar caring work, often for children, in the service of the state. In the UK, Wilson (1977) suggested that the postwar welfare state amounted to nothing less than the state organization of domestic life, by which she meant that state policies, for example in respect of cash benefit entitlements, sought to reinforce the male breadwinner family model. A few years later, a similar kind of criticism was made from an entirely different quarter.

Arguing from a 1980s New Right position, Mount (1982) suggested that the family had been in 'permanent revolution' against the unwarranted intrusions of the state. In his view, even apparently helpful public visitors, such as home nurses, were essentially seeking to impose standardized modes of care on families and were able to invoke a wide range of powers if they deemed the family to have 'failed' in some respect. Mount's view keyed into the long-standing suspicions of working people, especially in the English-speaking countries, of officialdom. However, this does not mean that nonintrusive, nonstigmatizing state intervention has not been welcomed. The panoply of Swedish collective social provision has been referred to by the citizens of that country as 'the people's home.'

The idea that state officials practice some kind of surveillance over the family also found favor with followers of Foucault, although Donzelot (1979) stressed the extent to which the professionals in emerging welfare states formed alliances with women

in order to do so. In her history of domestic violence, Gordon (1990) also stressed the extent to which social workers had sided with the weaker family members against the more powerful, thus questioning the extent to which state regulation worked to reinforce traditional power relationships within the family. Indeed, most feminists, while criticizing the kinds of assumptions about the family inherent in social policies, have also looked to the state to work for gender justice (Okin 1989). Few have followed Elshtain (1981) in defending the family as a separate, private sphere, outside the reach of the state.

In recent years the very different idea that the state has played a part in deregulating family life has gained in strength. The argument is that rather than working to uphold traditional family patterns, the state has effectively underpinned a trend towards individualistic behavior that is essentially selfish. This view has been formulated in the context of the dramatic postwar statistics on family change. Marriage rates have fallen in most Western countries; people are marrying later; fertility rates (especially in some Western European countries) have fallen well below replacement rates; divorce rates have increased since the 1970s and remain high and stable in Northern Europe and the US; rates of extramarital childbearing have increased; and behind these changes lies the huge increase in cohabitation. In addition, all Western states have seen an increase in women's employment, albeit predominantly part-time in many countries. These changes in behavior appear to signal greater sexual and economic autonomy on the part of women and, in the view of some, more irresponsible behavior on the part of men. Together with a shift in attitudes towards individualism, which has been documented for a large number of Western countries (Inglehart 1997), the changes in behavior have been widely interpreted as signaling that men and women are less prepared to commit to, and to invest in, family life.

The optimism of academics in the 1960s and early 1970s about the fundamental stability of the traditional two-parent family has given way to profound pessimism at the end of the twentieth century. Bellah et al.'s (1985, p.85) influential study of middle America concluded that 'if love and marriage are seen primarily in terms of psychological gratification, they may fail to fulfil their older social function of providing people with stable, committed relationships that tie them into the larger society.' The causes of behavioral and attitudinal change are extremely complex, but the fear of many commentators is that both public policy and family law have encouraged rather than countered them.

In respect of public policy, Murray (1984) proved particularly influential in the English-speaking world in arguing that the provision of welfare benefits, far from sustaining the male breadwinner model family, allowed women a measure of financial autonomy and thus promoted family breakdown. In respect of family

law, Glendon (1981) argued strongly that legal ties among family members in the postwar period were loosened. In particular, the move that took place in most Western countries towards the implementation of no-fault divorce in the 1960s and 1970s has been interpreted in terms of the withdrawal of government from the attempt to impose an external moral code in favor of allowing the parties to a marriage to work out their own destiny. A similar view has been taken by leading commentators in non-English speaking countries with very different legal traditions. Thus Thery (1994) has suggested that marriage has become a private choice and that marriage as an institution has become disengaged from wider social structures, the law included.

In whatever way the role of the state in regulating the family is interpreted, the solutions are far from easy to determine. Those who are suspicious of the state, whether because they feel that it has perpetuated traditional family forms and gender roles, or because they feel that these have been effectively undermined by the state, have difficulty in trusting government to do better, and in any case will demand radically different kinds of action. However, the picture of a homogenous state acting either to support or to undermine traditional family patterns is in all probability too simple. In the first place, the relationship between law and behavior is very difficult to determine. For example, Phillips' (1988) comparative study of divorce has shown that levels of marital breakdown are not dependent on legal change, and may be high in the absence of a liberal divorce law. Nor should people's resistance in the face of legal change be underestimated. Mount's account of the family resisting state interference is supported by findings from comparative studies that show legal change to have less effect on family behavior than on other areas of human activity. Second, the various departments of Western liberal governments rarely act coherently. Different departments may pursue very different agendas in respect of an issue such as childcare, for example.

Indeed, it may be more helpful to think of government regulation in the area of the family as layered. In all probability, Western governments in the twentieth century have tended to be Janus-faced in regard to family policy and law. While most have had a clear idea of the (traditional, two-parent) family form they wish to promote, policies have often pulled in a different direction. Thus, for example, while most income maintenance systems have a cohabitation rule, which prohibits the payment of welfare benefits to lone mothers who have a 'man in the house' (in accordance with the assumptions of the male breadwinner model family), they have also served to facilitate and legitimate, if not actually cause, the formation of lone mother families (Kiernan et al. 1998). The means of regulating the family have been many and various and certainly include the huge and

vexed area of birth control, abortion, and reproduction (see *Regulation: Sexual Behavior*). Historically, public policy and family law have sought to impose two powerful prescriptive frameworks on the family: that of the male breadwinner model, which has had a considerable impact on the gendered division of labor, and a strict moral code, which resulted in the stigmatizing of divorce and extramarital births. These frameworks were embodied in legislation but were also internalized by ordinary men and women. Their erosion in the late twentieth century has meant that increasingly people must negotiate their own solutions.

2. Public Policy

Given that in modern societies independence derives primarily from wage-earning, the assumption that women are located mainly in the private sphere as wives and mothers, supported by breadwinning husbands, has also meant that women have only been partially individualized for the purposes of public policy making (Pateman 1989). The liberal dilemma first described by Okin (1979), whereby for the purposes of determining political citizenship 'individual' effectively meant 'male head of household,' persisted. Thus most Western states have subscribed to some degree to the idea of a male breadwinner model family and have therefore treated women as dependants of men, although this set of assumptions has been modified to very different degrees in different countries (Lewis 1993). In its pure form, the male breadwinner model assumes that married women will not engage in paid work but will rather undertake the work of caring for children and other dependants at home without the support of collectively provided services, and that they will be subservient to their husbands for the purposes of social security entitlements and tax. In reality, such a model never existed; working class women have always gone out to work as and when the family economy demanded it. However, the model matched the social reality of middle class women fairly closely at the turn of the century. For the late nineteenth century social theorist Herbert Spencer, society was 'progressing' towards a position whereby all women would be able to stay at home in their 'natural sphere.'

It is no coincidence that the foundations of most Western European and Australasian welfare states were also laid down at the turn of the century, when the ideology of 'separate spheres' for men and women was at its height. Skocpol (1992) has argued that the core program of modern welfare states—social insurance against sickness and unemployment—is fundamentally 'paternalist.' The program sought to protect the full-time, respectable male worker. Women were rarely covered as workers in their own right and were usually eligible for benefits only as the wives of

male employees, the justification being a division of labor that was perceived to follow 'naturally' from their capacity for motherhood. Women have thus tended to make (smaller) contributions and draw (smaller) benefits via their husbands. Furthermore, in welfare regimes such as that of the US and early and mid-twentieth century Britain, where the social security systems developed dual social insurance and social assistance benefits, this provision was gendered, with first class (insurance) benefits going mainly to men as workers, and second class (assistance) benefits, such as aid to families with dependent children in the US, to women, usually in their capacity as mothers.

Nevertheless the male breadwinner logic that informed most early twentieth century social protection was broadly accepted, not just by men and by policy makers who regarded the responsibility for dependants as a guarantor of male work incentives, but by women themselves. In the context of hard household labor and frequent pregnancy the male breadwinner model was a shared ideal. This changed in the postwar period as fertility rates fell and housework became less onerous. Assumptions regarding the existence of a male breadwinner model were eroded to different degrees in different countries, but the assumptions informing public policy usually lagged behind behavioral change. In France, because of the very different occupational structure (of family farms and firms), women tended to gain entitlements both as wives and mothers on the one hand, and as paid workers on the other.

Given the additional importance of pronatalism in France, the former tended to be more generous, but abundant public child care provision made possible a long tradition of full-time work for women. The Scandinavian countries moved furthest away from the male breadwinner logic in terms of public policy provision, deliberately pulling women into paid employment from the 1970s by the introduction of separate taxation and parental leaves and by increasing child care provision, to the point where the dual-breadwinner family became the norm. The contrast with Britain and Germany is striking. The latter has no independent taxation, which works against female employment when there are high marginal rates of tax, and a strong social insurance welfare system, in which women's eligibility remains tied to that of their husbands. Until very recently neither country made a significant commitment to collectively provided care services. In Germany female labor market participation rates have been low in the postwar period, while British women have tended to work short, part-time hours. In the US, where collective provision for able bodied adults did not develop beyond assistance benefits for lone mothers, state policy has played little part in determining how male and female members of the household decide the division of paid and unpaid work. However, the absence of explicit policies does not mean the absence

of a regulatory framework. The policy logic operates to constrain choices: adult women who are also mothers must depend on either men or on their own efforts in the labor market.

Policies towards lone mothers provide a particularly striking illustration of the extent to which public policy frameworks do have an impact on behavior. In the context of assumptions regarding the traditional two-parent family, the problem of lone motherhood becomes that of women with children and without men. In the absence of a male breadwinner, the state has to decide to what extent and under what conditions it will step in to fill the place of the missing husband; how far it will exert pressure on an able-bodied absent father to support his child and possibly its mother; and how far it will expect the lone mother to support the child by herself becoming a breadwinner. Policies in respect of each of these have varied enormously between countries and over time. But broadly speaking there has been a pendulum effect.

In the nineteenth century, lone mothers were treated as workers and were expected to support as many children as they could; by the mid-twentieth century they were more likely to be treated as mothers and permitted to draw benefits for as long as they had children under a particular age, and by the end of the century policy in most Western countries has veered again towards treating them as workers, although only in the US has the right to draw benefit been removed (see *Lone Mothers in Affluent Nations* and *Lone Mothers in Nations of the South*).

3. Family Law

The family has been seen both as bedrock and yet as fragile. Historically, the stability of marriage and the family has been seen as fundamental to the stability of the *polis*. Sociologists have suggested that marriage has moved from institution to relationship. In fact it remains both, but the regulation of the institution in accordance with an externally prescribed moral code has been substantially eroded. In the last quarter of the twentieth century Western states have largely ceased to regulate the role of men and women as husbands and wives. In respect of family law, the attention of the state has turned to regulating their roles as fathers and mothers.

Whereas the erosion of the male breadwinner model lagged behind social change, many would argue that changes in family law have run ahead of the social reality, certainly in terms of mentalities if not behavior. The reasons for abandoning the attempt to impose a strict moral code have been attributed to changing moral beliefs with an increased tolerance for pluralism, the rise of a psychological view of personal affairs, and the increased emphasis on individual rights. Nevertheless, most of those campaigning for reform of the

divorce laws in the 1960s were convinced that they were proposing a higher form of morality that would be based on love and that would come from within, rather than being imposed from outside. The removal of fault from divorce law made it impossible to allocate blame and then, as a matter of course, to award long-term financial support to 'innocent' female spouses. Reform of family law meant that the state ceased to regulate the dissolution of marriage and concentrated on adjustment between the parties. Under a no-fault regime, a marriage without children is effectively terminable at will. The import of the process of liberalization has been to let men and women as husbands and wives order their own affairs, in other words to assume the existence of a degree of individualization, while also putting in place measures that seek to regulate them as fathers and mothers. The problem is that it has been difficult to make a neat separation between these two sets of roles, not least because of the need of children for caretakers and the tendency for women to perform more of this unpaid work.

The idea that divorcing couples should be treated in exactly the same way, thereby ignoring the different nature of their contributions to the marriage and the inequalities resulting from women's greater investment in childbearing and childrearing, followed the introduction of no-fault divorce. By the 1980s, in the English-speaking countries, the presumption of female dependence had been replaced in family law by the equally problematic assumption that husbands and wives were equal members of a partnership. This ignored the substantive inequalities which meant both that the view of the more powerful party as to the desirability of continuing the relationship might prevail, and that the outcomes for the economically weaker partner were likely to be poor. As academic research sounded the alarm about the latter (Weitzman 1985), and about the effects of divorce on children (Wallerstein and Kelly 1980), so the state made greater efforts to regulate the roles of men and women as fathers and mothers, focusing particularly on fathers.

In the face of rapid family change, the growing numbers of lone mother families and the resulting rise in the burden on public expenditure, governments sought to enforce the responsibility of men for their biological children. In the US, Australia, and the UK in the 1980s and 1990s new child support legislation was passed to this effect. Continental European countries had a much longer history of efforts to secure maintenance from absent fathers. A government-appointed commission in the UK examined these in the early 1970s, but rejected them as too intrusive, which indicates how far opinion moved in the last quarter of the century. If husbands and wives were to be left alone, parents were not. Fathers were also increasingly expected to have contact with their children, in part because the psychological evidence showed this was important for children, in part

because policy analysis showed that fathers who maintained contact were also more likely to pay for their children, and in part as a response to fathers' rights campaigners.

However, it has not been easy to deal with children separately from their carers. No-fault divorce removed the link between the grounds for divorce and maintenance without substituting any alternative principle to justify the latter. The relaxation of the divorce law took place in Western liberal democracies which felt that it was neither possible nor desirable to regulate the marriage system such that men's right to remarry and further reproduce was curtailed. This made it difficult to enforce the responsibilities of men in relation to their biological children, and by extension, those children's carers.

4. Future Prospects

The assumptions lying behind traditional marriage constructed husbands and wives as equal-but-different partners, something public policy accepted when it assumed the existence of the male breadwinner model family. In so doing, it constructed women as dependants and ran the risk of failing to recognize either the nature of their contribution as both paid and unpaid workers or the entitlements that were their due. Family law, on the other hand, moved towards a construction of marriage as a partnership of formal equals after the 1960s, which ran the risk of ignoring the substantive inequalities between men and women. Thus the problems of the relationship between the state and the family in regard to gender hinge on the larger problem of equality and difference.

Faced with family change that has been both dramatic and rapid in the last quarter of the twentieth century, Western governments have two basic options: to recognize the social reality and work with it or to seek to put the clock back. Just as it is possible to see the state acting both to bolster the traditional family and to transform it, so it is possible to identify ways in which the state is recognizing and resisting change. To move towards an emphasis on the responsibilities of men and women as parents is to recognize the changes that have taken place in the marriage system, but as Smart and Neale (1999) have argued, at the same time public policy and family law have attempted to perpetuate the traditional responsibilities of men for maintenance and women for care beyond the life of their intimate relationships.

Regulation, Political Economy of

Government regulation of firms uses the 'coercive power' of the state to alter firms' pricing, entry, production, investment, or product choice decisions. An extensive empirical literature analyzes the effects of

'economic regulation' of price and entry as well as environmental, health, safety, and information regulation. These analyses amassed substantial evidence of high prices, excess profits, and production inefficiencies under economic regulation (see Joskow and Rose 1989, Joskow and Noll 1994; and *Regulation: Empirical Analysis*). Studies of environmental, health, and safety regulation revealed substantial deviations from least-cost solutions and dramatic variation in measures such as expected cost per life saved across regulatory interventions (see Viscusi 1994, Gruenspecht and Lave 1989). These outcomes, so systematic and pervasive, were difficult to reconcile with 'public interest' models of regulatory intervention. Examination of regulatory systems further suggested that they often deviated from cost minimization or efficiency objectives by design. This begged for an explanation beyond bureaucratic incompetence or malfeasance, common to earlier Marxian or 'capture' theories of government. Stigler's (1971) *Economic Theory of Regulation* provided the conceptual underpinnings of what has become a vast enterprise among economists and political scientists to understand the origin, objectives, maintenance, and reversal of regulatory policy in the context of rational choice models of political behavior. These simple insights stimulated a substantial theoretical and empirical literature (Noll 1989, Peltzman 1993).

Theories of legislative and bureaucratic behavior have become increasingly sophisticated since the 1980s. The literature has moved well beyond Stigler's simple model to incorporate the role of competing interests, policy entrepreneurs, majoritarian political institutions, legislative oversight of regulatory agencies and commissions, and asymmetric information (see Noll 1989, Joskow and Noll 1994, Laffont 1999, and *Regulatory Agencies*). The empirical literature has struggled to keep pace with these developments.

Common to virtually all empirical studies in this area is the importance, and difficulty, of defining well-specified alternatives to the political economy model under investigation. To test a given model of political behavior, or to interpret results as consistent with a given model, one must understand how predicted outcomes differ between competing hypotheses of behavior and the model being tested. For example, there is a natural tendency to identify rent conveyance with rent-seeking activity. In some cases, however, increased rents for regulated firms may be consistent with both successful rent-seeking behavior by those firms and elimination of some market inefficiency. It is important, though often quite difficult, for empirical analyses to identify and attempt to distinguish alternatives such as these. Studies vary considerably in the degree to which they meet this standard.

This article introduces the main empirical methodologies used to explore the political economy of economic, environmental, health and safety regu-

lation. Examples of their applications are briefly discussed. Interested readers are urged to pursue the surveys listed in the references for more complete discussions of this literature.

1. Measuring Distributional Effects

Empirical studies of political economy generally begin with estimates of the distributional effects of a given policy. While many empirical methods may be used (see Joskow and Rose 1989 and *Regulation: Empirical Analysis*), asset market 'event studies' have been particularly popular. These measure price movements in capital assets, such as company share prices, at the time policy changes are first announced. If the announcement is not previously anticipated, and asset markets efficiently process information, these price changes provide estimates of the policy's effect on the capitalized value of expected rent streams. This method may be used to measure the effects of the policy change on firms within a regulated industry, corporate customers and suppliers, and possible competitors. The distributional implications for individual or small business customers, employee groups, and other noncorporate interests usually must be measured using alternative methods.

The simplest political economy studies use measured distributional effects to infer the relative influence of different interest groups in the political process. These implicitly assume that the observed changes in rent distribution are anticipated and intentional, and that larger rent gains reflect greater political power. Consider, for example, the extensive debate over the origin of the first federal economic regulatory commission in the US, the Interstate Commerce Commission created in 1887 to regulate railroads. Was this legislation intended to solve an inefficiency in an industry characterized by large sunk costs and natural monopoly conditions? If the legislation was a response to interest group politics, did it respond to agrarian interests and other shippers' demands to constrain monopoly pricing by railroads, or was it a railroad-sponsored effort to establish a government-enforced cartel? Did legislation intend one outcome, only to be thwarted by the regulatory agency's subsequent behavior? There have been numerous empirical studies attempting to answer these questions, many using railroad share price responses to various regulatory 'events' (e.g., Prager 1989, Mullin 2000). In these, railroad share price gains in response to the Interstate Commerce Act, for example, have been interpreted as evidence that the regulation was intended to benefit railroads, supporting Stiglerian models of regulatory politics. While it may be reasonable to assume that *ex post* gains identify *ex ante* intended beneficiaries, this should be made explicit and considered against alternative explanations. To move convincingly from a positive

statement about the distributional consequences of a policy to an inference about its political motivation requires an understanding of distributional effects under leading alternative models.

2. Estimating Political Support for Regulation

A second empirical methodology estimates the determinants of regulatory incidence or political support as a function of underlying economic interests. These studies generally involve three steps. First, *ex ante* winners and losers of a regulatory policy are identified, using either prior estimates or a model of the regulation's effect. For example, Stigler's (1971) analysis of truck weight laws modeled state truck weight and size limits as raising the cost of trucking service, particularly over longer hauls. Truckers therefore lose from lower limits, as do their current customers, businesses using their own trucks, and potential customers for whom trucking rates constrain alternative transportation rates. Competitors to trucks, such as railroads, gain from tighter restrictions. There may be diffuse 'public interests' as well, for example, in limiting damage to roadbeds and reducing congestion, though these may well be endogenous.

Second, the importance of the identified economic interests within a given jurisdiction or at a particular point in time is measured. There is considerable variation in how this is done. For example, the number of trucks, scaled or unscaled, the dollar volume of activity in trucking, and the fraction of freight hauls susceptible to potential truck competition are all possible measures of the importance of trucking interests in a jurisdiction.

Finally, the incidence or intensity of regulation, or the political support for regulation, is estimated to be a function of the measured economic interests and any other relevant factors. Stigler used this method to explain differences in the intensity of truck weight limitations across states, for example. Other studies apply this technique to model variation in political support, such as voting records, as a function of constituent economic interests in the policy, *inter alia*.

Most studies in this area find that constituent interests are significant determinants of regulatory policy, though interests must be defined broadly to include constituent preferences (such as conservation or environmental preferences) as well as direct economic interests. Detailed studies of voting behavior suggest that the underlying models may be quite complex, however; see, for example, Joskow and Schmalensee (1998) on the US acid rain program. The significant impact of legislators' ideology on their voting behavior (e.g., Kalt and Zupan 1984) suggests possible slack in the agency relationship between constituents and their legislators, as well support for more sophisticated models of voting in majoritarian systems across issues and over time.

3. Modeling Regulatory Agency Behavior

A final strand of empirical work in political economy begins with the recognition that most regulatory legislation leaves considerable discretion over its implementation to regulatory agencies or commissions. Early work on regulatory 'capture' assumed that industry groups could influence regulators to use this discretion to benefit the industry in direct contravention to legislative intent. As economists and political scientists began to explore the extent to which apparent regulatory capture was instead a reflection of legislative intent, they confronted the questions of how much discretion regulators retain and how regulators use that discretion to form policy (e.g., McCubbins et al. 1987). This led to an extensive literature on the operation and oversight of the administrative process, most of it within political science. This area remains one of the least-developed empirical literatures in regulatory economics.

While some early analyses explored the responsiveness of regulatory agency decision-making to congressional preferences, most economics research in this area analyzes the responsiveness of agency decision-making to interest groups and various measures of efficiency or social welfare. This is methodologically quite similar to the legislative studies described in Sect. 2, with individual regulatory decisions as the unit of observation. As in those studies, the results suggest a role for concentrated economic interests to influence regulatory outcomes. This does not itself demonstrate that regulators respond to interest groups in contravention with broader social objectives, however. For example, studies have found that despite significant overall delays in the process by which the Food and Drug Administration (FDA) controls entry of new pharmaceutical products, the FDA responds more quickly to drugs with greater market potential (Dranove and Meltzer 1994). In this case, both producer and social interests are aligned with reducing delay of an innovation.

4. Conclusion

While research on the political economy of regulation has made significant progress since the 1970s, fundamental questions remain unanswered by either theoretical or empirical work (Peltzman 1993, Joskow and Noll 1994). One of the most basic is why some industries are regulated (or deregulated) and others are not. Another is why regulatory policy seems characterized by 'waves' or cycles: changes tend to occur across broad ranges of industries and sectors within fairly short periods, separated by longer periods of relative inactivity. Considerable scope remains for additional work in this area.

Regulation: Sexual Behavior

The regulation of sexual behavior refers to the enactment of laws and legal codes at the federal, state, or local level whose intent is to define and restrict specific sexual conduct. Sexual conduct encompasses a range

of behaviors and activities, only some of which are regulated by law depending on the age, marital status, and legal residence of the individual. Sexual behaviors include those practiced between individuals—as in any intimate bodily contact such as kissing, touching, intercourse, oral and/or anal sex—and those practices, usually solitary, such as masturbation and nude public exposure. While all societies have enacted some form of a regulatory mechanism to prohibit sexual behaviors considered socially offensive or physically and/or psychologically harmful to its members, the regulation of sexual behaviors typically reflects ‘a society’s particular vision of sex, marriage, and the family’ (Francoeur 1991a, p. 583). In the case of the USA, sexual regulations have historically served to reinforce traditional moral values in the form of social and religious taboos proscribing non-procreative sexual behaviors, including those practiced within and outside of marriage. Changes in social relations and in the expanding configurations of coupling, marriage, and family structure since around 1950, have resulted in more tolerant and permissive attitudes about sexuality and more diverse sexual lifestyles (D’Emilio and Freedman 1988). Many of the existing legal regulations are either not enforced, in the process of reform or repeal, or are confronting considerable resistance. Moreover, cultural forces, such as changing gender roles and norms of sexual development, influences of mass media, popular culture, information technology, and Internet access, as well as alterations in the workplace have provided new issues with regard to the regulation of sexual behavior, which continue to be intensely contested in the political and legal arenas in the USA. Since around 1980, such issues as sexual harassment, the sexual abuse of women and girls, the role of sexually explicit materials in public and private life, government policy regarding sexual orientation and military personnel, and the prevention and treatment of HIV/AIDS have placed this issue at the center of social controversy (Gagnon 1991).

1. The Legal Sphere: Protection vs. Restriction

The multifaceted role of our legal system is particularly evident in this complex process of enacting, interpreting, and/or disputing the laws regulating sexual behavior. In this process, the legal system is intermittently supported or challenged by a myriad of cultural, social and political forces that view this system either as an appropriate and necessary force enacting restrictive laws in the interest of individual safety, family cohesion, and societal order, a system that arbitrarily applies laws to certain individuals or groups of individuals, or conversely, as an ameliorating one that can redress the loss of individual right to privacy and consensual sexual expression.

In the USA, sexual behaviors are primarily regulated by way of a legal process that restricts what it

defines as either harmful or socially unacceptable sexual conduct, both in private and public. More specifically, it is the general consensus that certain sexual behaviors merit prohibiting. In these instances, the laws are typically viewed as necessary and justifiable because they either provide parameters for sexual relations, as with regulations dictating the age of majority, or they prohibit coerced sexual contact between individuals, unsolicited sexual behavior on the part of the individual, and sexual exploitation, such as laws prohibiting rape, coerced nudity, sexual exploitation of an incapacitated individual, sexual contact between family members (incest), sexual contact between adults and children (pedophilia), sexual exposure to another individual (exhibitionist/indecent exposure), or the unsolicited sexual attention and/or pursuit by another individual (sexual harassment) (Leonard 1993). Other regulations are controversial because they restrict consensual sexual behavior and/or private sexual activity that is subjectively defined as socially offensive, inappropriate or immoral, as in sexual relations between: individuals married to other partners (laws prohibiting adultery); sexual relations between homosexual partners (laws targeting homosexual sodomy); oral or anal sex between heterosexual individuals, married or unmarried (those targeting heterosexual sodomy); and sexual relations exchanged for payment (prostitution). Resistance to these regulations and increasing controversy regarding their enactment has emerged from a growing awareness of one's right to privacy and the constitutional requirement that any restriction must be justified by compelling social need and benefit.

A related set of controversial regulations pertaining to sexuality but not directly involving sexual behaviors are those whose objective is to limit the production of and access to, sexual 'entertainment' and sexually explicit material. Operating in both the private and public sphere, these regulations focus on the right of the individual to access or 'consume' sexual entertainment and/or sexually explicit material in a variety of venues and mass cultural mediums—including various entertainment spheres, TV, movies, video, and via the Internet. Also restricting private, consensual behavior, these regulations range from censoring sexually explicit material in print to banishing live entertainment shows to peripheral locations in urban centers to confining sexually explicit content on cable TV to specific channels and hours (Communications Decency Act of 1995, Telecommunications Act of 1996).

2. Sexual Regulations that 'Protect'

Even regulations whose objective is to protect the individual from harm have a history of vague legal definitions and arbitrary enforcement. A case in point is the discrepancies in the penalties attached to

violations of sexual regulations and other criminal laws such as rape vs. murder, the disproportionate penalties given to minority vs. non-minority individuals charged with rape, and the increasingly subjective determination of incidents of sexual harassment.

More often, regulations pertaining to sexual behavior are applied to some but not others, and in many instances the determination is made on the basis of sexual orientation, sexual preferences or to behaviors considered outside of normative heterosexual activity. Individuals who fall into any one of these categories are then part of a 'sexual minority' with the unequal application of laws to these persons often questioned as to its constitutional legality.

3. Regulations that Restrict: A Normative View of Sexuality

In the legal enactment and interpretation of these regulations, rarely does the body of scientific and accurate knowledge about sexuality inform this process, a body of knowledge best represented by the repository of scholarly contributions on the subject from the social, biological and physical sciences, and from the humanities. As a result, knowledge of sexuality has had limited influence on developing a meaningful public and legislative discussion and coherent public policy regarding the regulation of sexual behaviors. Instead, the regulations of behaviors, especially those conducted in private between consenting adults, are typically based on a normative, procreative view of sexuality originating in English common law. This view approaches human sexuality as a potentially uncontrollable, inherently deviant and socially disruptive force in need of restraint, one rightfully subject to stigma, penalty, and criminalization, especially outside of marriage. In the USA it has resulted in very clear demarcations of appropriate and inappropriate sexual behavior in which fornication between married, heterosexual partners is considered a sexual behavior worthy of protection under the law. However, at the same time other sexual behaviors, such as those between homosexual partners or oral/anal sex between married or unmarried partners, are determined to be immoral and illegal. Some laws do not specify 'non-reproductive sex, but use laws against disorderly conduct, carnal abuse, lewdness, lascivious behavior, public indecency, loitering, and indecent exposure to prosecute crimes of oral and anal sex' (Franceour 1991a, p. 588).

Regulations based on a normative, procreative view of sexuality typically target adult behavior inherently private and consensual. As they become increasingly at odds with the sexual practices of the population and are enacted against an increasingly vocal sexual minority (more typically evident in the western world), their application and enactment becomes not

only controversial, but often arbitrary. Two examples stand out as particularly incongruent with actual sexual practices—the state sodomy laws and the military law regarding homosexual behavior among its members—and their application has become increasingly both controversial and unworkable. Forces supporting their enactment have confronted and continue to confront those seeking their revocation; a conflict played out in the courts, in the media, and in strategy meetings by opposing teams of legal experts and community activists. In both examples, the point of contention is whether their continued enforcement either ensures the ‘common good’ and protects someone from harm, or whether it promotes intolerance and violence against a sexual minority who are the target of their enactment. To illustrate this point, a brief history of these two regulations follows.

4. State Sodomy Laws

State sodomy laws criminalize certain sexual behaviors within heterosexual marriage and all sexual behaviors occurring between individuals of the same gender. More specifically, sodomy is often defined as deviate sexual intercourse, including genital–anal, genital–mouth, manual–anal, or manual–genital contact. Sodomy laws are any one of the many laws, which criminalize non-reproductive, non-commercial sexual behavior between adults in private. Since their enactment, restrictions against sodomy between unmarried individuals have typically served the purpose of dictating ‘normative heterosexuality.’ This is clear when reviewing their application, as sodomy laws are rarely enforced in the case of married, heterosexual couples engaging in oral or anal sex. Not only are they primarily enacted in those cases when sexual acts occur between members of the same gender, but they have been used to justify legal discrimination against homosexual people (Cain 1993, Copelon 1990) and to deny lesbians and gay men a range of other rights. This occurred when the laws were introduced as relevant evidence in adoption and custody cases and they have justified the taking of children away from gay and lesbian parents.

5. The History of Sodomy Law Repeal

The original 13 colonies continued the English tradition in which sodomy carried the penalty of death and every state adopted some form of a sodomy law as it joined the USA. By 1960, all states had some form of sodomy law in place, although their terms were often vague and they rarely stated clearly what the law prohibited. Throughout the long period of their enactment state by state, sodomy laws covered a variety of sexual behaviors, including oral sexual

relations between two men, two women or between a man and a woman; anal intercourse was included either under sodomy or buggery laws, without distinction as to whether the two persons are heterosexual or gay, married or unmarried (Franceour 1991a, p. 587).

It was not until 1961 that the first state repealed its law when the Illinois legislature revised their criminal code without prohibiting sodomy. Other states followed soon afterward, although this movement significantly tapered off in the 1970s and 1980s during which time a spate of ‘homosexual-only’ sodomy laws were introduced. These laws were quickly, and in a number of cases successfully, challenged for their constitutionality under equal protection and privacy rights at the state level. The brief movement toward repeal came to a standstill in the 1980s as it coincided with the early stages of the HIV/AIDS crisis and courts and lawmakers withdrew from [such] efforts in light of the potential criticism of promoting homosexual sex at a time that the HIV transmission modes were becoming known.

In 1986, the US Supreme Court upheld a Georgia anti-sodomy law in the case of *Bowers vs. Hardwick*, ruling that the constitution ‘does not protect homosexual relations between adults even in the privacy of their own homes’ claiming that (a) homosexual couples did not have a constitutional right to engage in acts of consensual sexual acts, and (b) oral and anal sex is a criminal offense ‘regardless of whether the parties who engage in it are married or unmarried, or of the same or different sexes’ (Franceour 1991a, p. 587). It was not until the 1990s that the HIV/AIDS transmission was more clearly understood and the changing political climate allowed for repeal legislation to move forward.

Repeal legislation has continued to slowly dismantle state sodomy laws one by one, and in the process often unveils the weak foundation upon which the pro-sodomy camp stands. A telling example is the recent case argued by the state of Montana in defending its ‘Deviate Sexual Conduct Law’ to the Montana Supreme Court. Here, the state argued that there is no right to privacy when it comes to sexual conduct; some of the justices, not persuaded by this argument asked, ‘what could citizens in the state expect to be covered under the privacy clause if it was not sexual activity?’ (ACLU Newswire, 1997).

At the beginning of the twenty-first century, 16 states plus Puerto Rico have sodomy laws; 11 states plus Puerto Rico have sodomy laws which apply to both heterosexuals and homosexuals, and five states have laws, which apply only to homosexuals. The growing movement for repeal has been successful in 34 states: 27 states have repealed the law through legislative action, and seven states have had their laws invalidated by courts. Sodomy laws are primarily being challenged in state courts on the basis that state constitutions can provide greater rights than does the

federal constitution. One brief in support of repeal states said: 'When considering a public morality justification for (sodomy laws), it is important for the Court to recall that prohibitions on interracial marriage, and the segregation of races generally, were values deeply imbedded in social morality and were values that invoked both God and nature.' But appeals to natural or theological ethics cannot constitutionally be used to legitimate laws whose sole function is to give effect to private citizens' prejudice or conviction (ACLU Newswire 2000).

6. Military Law Regulating Sexual Behavior

The most significant military law enacted to regulate the sexual behavior of military personnel in active service is the Pentagon policy of 'don't ask, don't tell' regarding the sexual behavior of homosexual service personnel. Enacted on July 19, 1993, this rule specifically forbade US military commanders from asking, pursuing, or harassing homosexual service members regarding their orientation. More significantly, it codified the same restrictions for homosexual service members as had existed before 1994 under Pentagon policy, requiring secrecy and celibacy as a condition of their military service, under penalty of being fired or imprisoned. It also openly barred homosexual individuals from serving in the military. Five years later, the 1998 discharge figures have shown a record high of 1145 individuals discharged under the current policy, a 92 percent increase in homosexual discharges since the law was implemented (Service members Legal Defense Network).

When challenged on the figures, Pentagon spokespersons indicated that the high number of discharges was due to an increase in 'voluntary' statements made by service members; what they failed to state was that the overwhelming majority of such statements were made to psychotherapists, in personal diaries, contained in anonymous online profiles, or, in direct violation of the law, constituted responses to direct questions about one's orientation. During that time, service members have indicated that they were coerced to make such statements due to hostile command climates characterized by fear, intimidation, and threat of assault, death and/or criminal prosecution. This was evidenced by the documented cases of physical assault and the brutal murder of Private Barry Winchell at Fort in Campbell, KY, which marked a turning point in the debate over the Pentagon's policy.

Coming under considerable pressure, the Pentagon initiated a series of measures in 1998 designed to 'improve' policy implementation by incorporating such measures as: prohibiting 'plea bargains' to obtain evidence of consensual homosexual conduct; protecting service members from investigations in order to encourage the reporting of anti-gay harassment or

lesbian-baiting without fear of reprisal; limiting the scope of investigations to prevent fishing expeditions; requiring commanders to consult with higher headquarters before initiating investigations into alleged homosexuality, and providing necessary and effective training on investigation parameters under the policy. Moreover, in December 1998, the Pentagon implemented a first-of-its-kind survey to determine the views of its service members about anti-gay discrimination evident in the military. It additionally required universal training on the 'don't ask, don't tell' policy of all military personnel with the intent to promote full compliance with military policy that anti-gay threats and harassment will not be tolerated and to educate all service members on policy's parameters.

In issuing the results of its survey, the Pentagon indicated that disparaging, anti-gay remarks, hostile attitudes and harassment are commonplace in the American military, with a majority of the service members stating that they believed that superiors and colleagues tolerated it. Such behavior has been confirmed by independent investigatory reports indicating those incidents of verbal abuse and physical assault in 1999 more than doubled from the year before. Placing the discharge figures in realistic terms, the report specified that on average, the policy has resulted in three persons per day being discharged after declaring they are gay, with a 142 percent increase in harassment reports for 2000 (SMDN, March 10, 2000).

The regulation of sexual behaviors is ultimately an issue of privacy, consent, and choice. In the US 'there is no shortage of opinions on what constitutes acceptable or unacceptable sexual behavior or what justifies regulating or prohibiting a particular behavior or activity' (Francoeur 1991a, p. 583). Yet the legal process of regulation enactment or revocation inevitably provides crucial opportunities for engaging public discourse, refining strategies to promote social change, and questioning ideological assumptions about sexuality and morality. A continuing challenge is to effectuate the appropriate balance between the common good and individual rights, privacy, and the social/personal cost exacted for laws that unnecessarily restrict sexual behavior.

D. Di Mauro

Regulation Theory in Geography

1. Introduction and General Argument

The regulation theory aims to understand the economic and extra-economic mechanisms which, relatively, stabilize capitalistic societies despite the fundamental contradictions generating crisis and disintegration. The regulation approach (RA) originated in French academic debates about the economic and social changes of the 1970s. Thirty years after World War II, a first serious structural crisis affected western societies indicating the end of the dream of a never-ending prosperity ('the golden age'). New forms of conflict configuration and new balances of power arose—without undermining the fundamental principles of capitalist societies altogether.

To understand the restructuring of postwar capitalism, neither the equilibrium models of orthodox economies nor the traditional concepts of Marxism seemed to be satisfactory. In this context an integrative approach has been developed—combining the analysis of political economy with that of civil society and the state, sometimes looking like a kind of institutional economies. But the term 'regulation' within RA may not be understood as an authoritative direction in order to govern the economy. Instead a process of self-regulating is addressed to conceptualize the evolution and temporary stability of a crisis-driven capitalist society. Four core concepts help one to understand processes of regulation (Boyer 1990, Boyer and Sallard 1995, Jessop 1997):

(a) an 'industrial paradigm' as a model governing the technical and social divisions of labor;

(b) an 'accumulation regime' as a complementary pattern of production and consumption which is reproducible over a long period;

(c) a 'mode of regulation' as an emergent ensemble of rules, norms, conventions, patterns of conduct, social networks, organizational forms and institutions which can stabilize an accumulation regime; and

(d) a 'model of development' as the result when an industrial paradigm, an accumulation regime and a mode of regulation complement each other sufficiently.

These four aspects of capitalist societies are differently configured in successive stages. As the most

discussed and inquired, the term 'Fordism' refers to a new production concept, introduced by Henry Ford between 1908 and 1925. The Fordist accumulation regime is characterized by a specific combination of mass production and mass consumption. Purchasing power has to be sustained by appropriate wages to ensure demand. This process depends on continuous productivity growth. The corresponding type of state is an intervening welfare state ('Keynesian welfare state') that aims to adjust demand to the supply-driven needs of mass production.

Fordism entered into structural crisis in the 1970s. The regulationists discussed several arguments to understand this phenomenon: differentiation of consumer behavior; rising wages, caused by the bargaining power of strong trade unions, but without a corresponding increase of productivity; the internationalization of economy, especially an increasing low cost production in developing countries; and a lack of a corresponding internationalization of politics and policy.

The stage after Fordism is characterized by productivity gains, ideologies and constraints of 'flexibilization.' Fordist mass production seems to disappear whereas flexible networks of decentralized production units, partly hierarchically controlled, are significant for the new stage using new technologies and new forms of production organization which enable 'flexible specialization.' At the same time there are strong attempts to deregulate the labor market while collective wage bargaining, rigid work relations, and intervening legal forms as institutionalized compromise between capital and labor have been serious constraints for the flexibilization of economy and society. Further, objectives of state acting have changed in order to strengthen the international competitiveness of the national economy. At the same time redistributive welfare rights have been subordinated to a productionist reordering of social policy.

This rather rough sketch of 'post-Fordism' is differentiated in the regulationist debate. Thus, it is not possible to identify a definite post-Fordist model of development. Some authors have distinguished two main directions of post-Fordist development (Leborgne and Lipietz 1994): 'neo-Taylorism' (deregulation and flexibilization without major constraints; for example, in the UK and USA) and 'Toyotism' (decentralization and flexibilization while keeping a high degree of social cohesion; for example, in Japan and Northern Europe).

Spatial patterns are varying between the different stages. The Fordist stage is characterized by strong spatial divisions of labor, homogenization, and core-periphery differentials on all spatial scales (for example, city-suburb, north-south divide). Post-Fordist spatial development is characterized by heterogeneity on all scales: different types of spatial structures (industrial districts, global cities, high-tech regions,

regions with functional mixtures, etc.) built up 'patchworks.' Definite trends of spatial structures are hard to recognize.

2. *Origins and Development of the Approach*

Today there are several RA directions. In the beginning at least two schools of regulationist thinking evolved in France; the 'Groupe de Recherche sur la Régulation de l'Economie Capitaliste' (GRREC) based in Grenoble, and the 'Centre d'étude Prospective d'Economie Mathématique Appliquées à la Planification' (CEPREMAP) in Paris. An important input to both approaches has been the work of François Perroux. Whereas the work of the GRREC is characterized by an elaboration within a more traditional Marxism, the Parisian RA, especially Michel Aglietta, Robert Boyer, and Alain Lipietz, have been basically involved in a renewal of Marxist thought and Althusserian structuralism with respect to evolutionary and institutional economics. Their contributions mark the beginning of the globalization of the RA (see reviews by Jessop 1997, MacLeod 1997). Since the mid-1970s and especially in the 1980s, their ideas spread, leading to new schools of innovation within the RA. A closer look at these discussion groups reveals a broad heterogeneity, bound together by common understandings of basic elements of radical political economy and the ability of social groups to act in order to transform society and economy.

Up to now, three periods of the RA with changing topics are observable: the first one may be labeled as the formative period that is characterized by theoretical and empirical work by the French regulationists. Among others, Aglietta's outline of the theory of regulation based on an analysis of the evolution and crisis of US capitalism in the twentieth century is usually seen as a well recognized starting point (published in French in 1976; in English in 1979, reprinted 2000). In general the formative period delivered the basic concepts of the RA and a deep understanding of Fordism including its crisis in the 1960s and 1970s.

A second period may be characterized by an intensive search and controversial debate around the term 'post Fordism.' Though often rejected as a misleading concept, post-Fordism served as a focus for those who looked after new economic and social principles of capitalist development in the late 1980s and 1990s. Examples are:

- (a) the search for the microfoundation of regulation using convention theory or Bourdieu's concept of habitus (e.g. Painter 1997, Jenson 1993);
- (b) debates about new organizational patterns of enterprises and the internationalization of production (e.g. Waringo 1998);
- (c) attempts to overcome structuralist shortcomings and a reflection of the structure-agency debate;

(d) comparative perspectives on modes of regulation in order to understand crisis and changes of the welfare state more profoundly (e.g., the concept of the workfare state by Jessop (1995) or the 'Wettbewerbsstaat' (competition state) by Hirsch 1995); and

(e) the question of scale related to the diminishing power of the nation state and the growing importance of substates (regional, urban) and supranational levels (international regimes) (e.g., Boyer and Hollingsworth 1997).

As outlined above, these attempts to understand the new (flexible) regime of accumulation and new (deconcentrated) mode of regulation indicate a thematic and regional expansion of the original French RA—a globalization of a theoretical program. However, the critical notes about the term post-Fordism—whether it is the guiding concept of a new development model as temporal spatial fix of capitalism evolved at the end of the twentieth century or it is an overloaded catchword demonstrating the inability of the RA to deliver a consistent explanation of changes—illustrate severe difficulties to open and use the RA for new topics and problems.

A regional perspective within RA has been introduced by different authors like Leborgne and Lipietz (1988), Esser and Hirsch (1994), or (Moulaert 1996). More recently Jessop and colleagues have announced what they call a 'third generation' of regulationists. They emphasize the ability of RA especially to answer questions of the changing form of the state and the relations between scale, space, and time. In their recent reviews (see Jessop 1997, MacLeod 1997), the RA is located between political science, geography, and sociology leaving the traditional macroeconomic perspectives of RA behind. However, in the new edition of Aglietta, the start-up analysis indicates an ongoing interest in macroeconomic regulation (Aglietta 2000).

We may conclude that the RA has experienced a remarkable differentiation in the last two decades of the twentieth century. This diffusion process did not favor a consistent body of thinking—one theory or school—but has led to a range of different concepts which today form the components of the RA. Though these concepts are far away from being parts of a whole, they are proofs of an ongoing interest of academics to organize their thinking around this approach. But there is also a tendency of the spatial and thematic diffusion of RA to a dissolution of the specialties of this approach into the broad stream of critical social science.

3. *Examples of Special Topics*

The diffusion process of the RA makes it difficult to focus on special topics. The following selection tries to outline those we think are probable pathways for future work, especially in geography. The common

question of the first body of literature that we would like to emphasize here is addressing problems and changes of scale-dependant institutional arrangements. One of the major changes between the period of Fordism and today is the dissolution of the former regulatory fix that is grounded on the temporal compromise between capital and labor (based on rising wages related to productivity growth), and on macroeconomic regulation (based on the defined territoriality and relatively autonomous power of the nation state). Owing to the loss of importance of the concept of the welfare state as the democratic form of the 'golden age' of Fordism, a debate about new forms of institutional arrangements has evolved. Deregulation, privatization, and the evolution of new political regimes at local as well as at the international level have resulted in the debate about the concept of governance, which includes new public, private interrelations beyond and within the old concept of nation state.

Within this context, the work of Jessop is of particular interest. The shift from—what he calls—'the Keynesian welfare national state' to an emergent 'Schumpeterian workfare postnational regime' forms the center of his analysis. Three changes are emphasized:

(a) New state activities evolve which should strengthen the competitiveness of state spaces by stimulating and promoting permanent innovation processes. Besides direct incentives to create national systems of technological innovation, new institutional forms, resources, and values are invented in order to create a 'Schumpeterian' mode of regulation.

(b) System competitiveness and labor market flexibility are accompanied by a subordination of social policy to imperatives of the new economic orientation. The term workfare is used to underline a general tendency of post-Fordism to cut back welfare expenditures and to redirect social assistance in order to promote individualistic responsibilities and risk acceptance.

(c) The state itself changes its form substantially. The 'hollowing out' of the national state apparatus favors subnational as well as supranational levels. Though the nation state remains important, new state activities emerge on different scales. This deconcentration of state power is accompanied by a shift 'from government to governance' which reflects a growing importance of semi-public and private actors, illustrated by new urban and international regimes. At the same time, trends towards de-statization or decentralization are counteracted by new state functions (metagovernance), addressing activities such as self-organization of partnerships, networks, and governance regimes.

The concept of the 'Schumpeterian workfare postnational regime' is a promising and far reaching concept of regulation under post-Fordist conditions. Yet, though well elaborated in relation towards RA

and state theory (especially Poulantzas position), the concept has to be grounded in empirical work. In particular, the reconfiguration of scales and state activities need further analysis in order to improve our understanding of new organizational principles beyond the nation state.

A second promising body of literature has drawn attention to local and regional modes of social regulation (Tickell and Peck 1992). There are approaches which address urban management and politics (Mayer 1994), and urban social movements (Hitz 1995), local labor markets (Peck 1996) and regional development in a postsocialist environment (Krätke et al. 1997). In particular, in reaction to challenges of urban regime theory, a new theory has set in (a) to conceptualize the relationships between accumulation and regulation on urban and regional scale; (b) to find adequate solutions for structure–agency problems which are inherent in the RA; and (c) to direct concrete research (Goodwin and Painter 1997). According to Goodwin and Painter, the concept of regulation should not be viewed as a static and stable, but as a process which is constituted by material and discursive practices. Because these practices are temporally and spatially embedded, there are many possible patterns of regulation as contingent combinations that might operate to support accumulation. This variety of modes of regulation is enlarged by the possibility that quality and intensity of regulation might differ due to spatial differentiation and uneven development. Therefore, the process of regulation is constituted geographically as result ‘of the contingent interaction of disparate practices’ (Goodwin and Painter 1997, p. 21).

To view regulation as a process, rather than as a fixed mode, and to conceptualize the process as contingent practices is an important contribution to reduce missing links in RA. But new problems arise when these suggestions are followed. For example, in applying the concept of Goodwin and Painter, it becomes difficult to decide what kind of social practices might be relevant in order to reveal processes of regulation. If it is assumed that regulation might be a result of intended and unintended consequences of social practices, we are trapped in the universe of possible practices. Though the introduction of the habitus concept of Bourdieu may serve as a micro-foundation of the RA and the identification of structures beyond the variety of practices (Painter 1997), the relationships between habitus and fields, on the one hand, and the concept of regulation as process, on the other, remain undefined. Therefore, if we give up the idea that the mode of regulation is like a development model beyond Bourdieu’s fields of political contest, e.g., as a spatially and temporally defined class compromises, which the subjects are reflecting, the term regulation receives a technical connotation of a self-organized system that creates order out of nowhere.

4. Future Directions

There are several missing links and open questions within RA often partly addressed as a general critique. Some of the important deficits are as follows.

The theoretical status of the terms Fordism and especially post-Fordism has become unclear. Some of the regulationist thinkers seem to give up the idea of development models serving as a background necessary for the evolution of structural coherence in time and space.

The ecological question is still neglected in the majority of contributions to the RA and a further concept is needed within RA, addressing an economic–ecological compromise. The evidence that the Western mode of production is self-neglecting in terms of sustainability of ecological resources and is partly elaborated in the work of Alain Lipietz, who has become one of the major political leaders of the red–green movement in France and Europe (Lipietz 1995).

The immanent functionalism of the RA has to be overcome in order to refuse reductionist explanations of modes of regulation for stabilizing capitalist development.

Though the listed deficits are already challenges for future work within RA, some directions are addressed here because they should receive major attention. The first perspective for future research reflects the growing integration of RA, evolutionary economics and institutional approaches in the social sciences. Within this broad field, the term regulation as a mode or as a process has to be worked out in a more detailed way in relation to state theory and the growing body of literature dealing with ‘governance’ approaches. Whereas RA usually puts more emphasis on structure, macroeconomic forces and large-scale institutional mediations, the post-Fordist variety requires differentiated concepts (a) of the enabling and restricting qualities of institutionalized systems of norms and rules, (b) of forms of leaderships and regimes on different scales, and (c) of forms of social network integration through conventions, coercion, and strategic behavior. As we have shown, there are some promising starting points in RA, but a comprehensive approach on regulation is missing. Further, it is rather unclear what a geographical perspective might look like. Interpretations like reterritorialization and politics of scale (Brenner 1999) as a dominant feature of current restructuring of capitalist society, as well as the notion that ‘all regulation is generated in temporally and spatially embedded social contexts’ (Goodwin and Painter 1997, p. 13), are still beyond a clear understanding of the role of space and scale.

A second promising field of future research evolves within the debate about poststructuralism and the societal paradigm of the mode of regulation (e.g., Scherrer 1995, Jenson 1993). Though the more recent literature is very aware of the problem of economic

determinism and the latent functionalism of the RA, it seems to be promising to review the concepts of the RA using discourse analysis (e.g., Laclau and Mouffe 1985). This methodological inquiry may not only serve as a reformulation of basic approaches within RA (like the refusal of a mode of regulation in favor of a process, or a more cautious usage of the term Fordism), but also may lead to (new) answers of the question of political practices deriving from RA analysis.

Regulation: Working Conditions

Working conditions encompass the aspects of work ranging from the terms under which workers enter the employment relationship to the environment in which they perform their tasks. Historically, working conditions have varied widely across countries and across time within each country in terms of their quality—from the workers' vantage point. Working conditions have been subject to regulation to varied degrees, a situation which accounts for variability in their quality.

Working conditions are part of employment systems that have been shaped by actions, rules, and regulation emanating from several spheres of society. These include the legal, judiciary, administrative, and collective bargaining spheres as well as personnel policies and informal social norms. All of these spheres shape

the 'way of doing business' (Piore 1990) as well as working conditions for workers. This article reviews how working conditions are shaped by regulation. In industrialized societies, the regulation of working conditions has primarily affected people in waged or salaried employment, that is, those who are in a relationship, recognized legally as economically dependent, with an employer who usually controls the means of production.

1. Working Conditions, Definition

Working conditions consist of the following elements:

(a) *The terms of the employment relationship.* They include whether the employment relationship is durable or short-term, formal or informal. The terms of employment may be explicit or implicit.

(b) *Access to employment.* This access may be equitable or discriminatory. In this latter case, groups of workers may be excluded from employment or have differential access based on their race/ethnicity, gender, age, or other characteristic.

(c) *The workplace itself.* Work may be performed in a single site, multiple sites, or from the worker's home.

(d) *The wage level.*

(e) *Time at work and away from work.* This includes the daily, weekly, and yearly number of work hours as well as their scheduling. It also includes provisions for time away from work due to illness, vacation, or leave for family or medical reasons or for training.

(f) *The supervisory structure and mechanisms.* This structure may or may not include procedures for due process in disciplining, discharges, and layoffs. It may entail varied degrees of protection from supervisory arbitrariness.

(g) *Health and safety conditions in the workplace.* These include occupational health, that is, the ways in which the performance of work tasks affects worker physical health and well-being, and environmental health, that is, whether the environment in which the work is performed has negative effects on physical health.

(h) *Voice at work.* This encompasses access to worker representation and the shape of representation structures. These structures may include representative organizations such as labor/trade unions or worker associations as well as participatory structures such as workplace councils.

(i) *Social protection/social insurance benefits for the individual and their dependents that have been tied to waged employment and are administered through payroll systems.* These include, for example, health insurance and pension plans.

Some of the elements of working conditions listed above have a direct relationship to employment and the performance of work, e.g., health and safety conditions at work. Others have been historically tied to employment with a particular employer in the USA

and to labor market participation in Western European countries but do not have to be. For example, health insurance coverage can also be provided as a universal benefit regardless of work activity.

2. Systems of Employment and Working Conditions

National systems of employment, of which the US system is one example, can be viewed as a whole which provides degrees of regulation and of protection to workers and employers in a variety of ways (Jacoby 1982, Boyer 1986, Piore 1986). Systems of employment can be seen as a conjunction of 'spheres' which contribute to varied degrees toward shaping working conditions over time. These 'spheres' are legal, executive/administrative, judiciary, collective bargaining, and employer personnel policies to the extent that they embody 'social protection' norms, as well as informal social norms. Different countries have a varied mix of reliance upon these spheres to affect working conditions. Some rely on collective bargaining approaches whereas others favor the action of the legislative and executive spheres combined. The regulation of working conditions can therefore be achieved through these spheres in a different manner across countries as well as across time in one country.

3. The Purpose of Regulation on Working Conditions

The regulation of working conditions has several purposes. Most commonly, it establishes labor standards, that is, set minima for wage, hours, or health and safety conditions that employers are mandated to respect and that are enforced through prohibition and penalties. This corresponds to the narrowest role of regulation.

Regulation can permit the formation of structures for negotiation, mediation, or problem solving that contribute to shaping working conditions in varied ways and with diverse outcomes across industrial sectors and occupations (Weiler 1990). One example of such regulation is the federal and state statutes governing worker representation and collective bargaining (e.g., National Labor Relations Act of 1935).

4. The Regulation of Working Conditions

Most narrowly and conventionally, regulation is understood as emanating from government (national, state, local) through laws and statutes (legislative branch), as well as administrative rules (executive). In the USA, separate agencies have been established over

time to develop enforcement mechanisms. For example, the Wages and Hours Division in the US Department of Labor enforces the Fair Labor Standards Act of 1938 and related legislation on minimum wages and overtime pay for hourly workers. Through inspectors and administrative courts, violations are verified and penalties issued for responsible employers. Enforcement mechanisms and their effectiveness play a key role in the shaping of working conditions. Conversely, the work setting affects the effectiveness of enforcement. For example, if workplaces are small, scattered, and numerous, it is difficult for an enforcement agency that relies on visits by inspectors to monitor work conditions and enforce a specific law.

The court system is another feature of the regulation of working conditions. Courts contribute to enforcing existing laws and statutes. For example, an employer responsible for hazardous working conditions having resulted in worker death may be sued. Sometimes, in response to cases initiated by workers, courts issue decisions in areas of working conditions where government legislation and executive enforcement have not acted yet. In this case, court actions precede legislative action.

Working conditions are also affected by the relative bargaining power of workers and their organizations. In turn, this bargaining power is shaped partly by the provisions made in legislation for worker voice and representation. For example, the National Labor Relations Act of 1935 established a mechanism for representation for many US workers in the post-World War II years and also shaped the form that labor unions took. The relative bargaining power of labor unions and worker organizations affects the ability of workers to bargain for improvements, the thoroughness of enforcement of existing laws, and the ability to obtain new laws.

Lastly, social norms and customs along with worker relative bargaining power are reflected in personnel policies and employer practices; these also affect working conditions. In the USA, many aspects of working conditions are shaped by personnel policy rather than law or collective bargaining and thus vary greatly across employers.

In sum, working conditions are shaped by the totality of action in these respective spheres and by the interaction of actions from these spheres. For example, in the USA, provisions in collective bargaining agreements or in innovative personnel policies that affect an aspect of working conditions that is not the subject of government regulation may serve as a model for state or federal legislation.

In other national systems, such as France, national sectoral bargaining in lead industrial sectors on a particular aspect of working conditions often precedes national legislation. National sectoral bargaining is a negotiation of large employers and their federations with national unions that is sometimes mediated by government and whose outcome is extended to an

entire industry. In some countries, national sectoral bargaining on a particular issue (e.g., implementing shift work) is used sometimes as an alternative to government regulation.

5. The Long-standing Debate on the Regulation of Working Conditions

The role and benefits of the regulation of working conditions have been the subject of long-standing debate. One view sees regulation, particularly regulation on labor standards, as an externally imposed cost and/or as having a distorting effect on the operation of the labor market. This view stems from the neoclassical school of economics whose core perspective—presented here in stylized fashion—is that markets are self-regulating and that prices must be allowed to vary freely in order to be efficient allocators of human and capital resources. This view also tends to assume there is no significant conflict or power differential between workers as a group and employers as a group. Rather, workers and employers are individual decision makers who make choices unhampered by power differentials. Critics of federal and state minimum wage laws have argued that the laws push wages above the ‘market clearing’ level and thus cause unemployment. Other analysts have taken a more benign view of their impacts on firm decisions and employment levels. The research literature has centered on the empirical measurement of the relative magnitude of effects on employer costs and employment levels (Card and Krueger 1995, Houseman 1998).

Another view in this debate sees the regulation of working conditions and its effects as a special case in economic analysis because labor markets are deemed the least self-regulating among all markets. In this view, the regulation of labor markets cannot easily be analyzed with the conventional tools of economic analysis.

Consistent with this view, another perspective sees regulation as a reflection of customs and social norms and of power relations between employers and workers—all of which vary across countries. In this view, regulation may permit, hinder, add costs to, or facilitate greater efficiency in production. In other words, the effects of the regulation of working conditions are not conceived as unidirectional. They are expected to vary widely depending on the contents of regulation, the structure of particular industries, and their production organization. For example, minimal labor standard on wages, hours, or health and safety have been argued to discourage ‘sweatshops’ and favor other business strategies that are less onerous to workers (Piore 1990). In sweatshops, workers are unprotected because employers are insulated from the economic impact of variations in productivity among workers and over time thanks to the piece-rate system (workers are paid for measurable units of output). A

minimum wage rate which is high enough to create employer concern with productivity may compel a change in a firm's practice and working conditions; it may deter the use of low-productivity workers such as young children.

In the USA, recent debates on the regulation of working conditions have been colored by the general policy trend toward deregulation of markets. Laws on hours and scheduling, and those on worker representation structures have been questioned. Advocates of deregulation have argued that existing regulations fit an old order of production organization, and market structure and must be removed. Others have called for their replacement with different standards and representation systems that provide equivalent protections for workers but through new means that are more appropriate for contemporary forms of production and work organization.

6. Future Trends and Research Issues

6.1 New Forms of Employment

In the post-World War II period, the contents and enforcement of the regulation of working conditions in late industrialized countries have been constructed, albeit in different ways, around a certain notion of the employment relationship as a relatively long-term, stable attachment to a single employer with the work tasks being performed on the employer's work site. While there were always exceptions to this notion—for example, farm labor, construction, expert consulting, or domestic labor—the bulk of post-war regulatory attention to working conditions has been structured around this employment arrangement.

In the future, most observers expect less employer commitment to long-term employment relationships, less worker attachment to particular employers, and greater lateral mobility (across firms, industries, and possibly occupation). This is due to changes in the organization of production and employment structures within firms; increasingly, firms recruit workers from the outside labor market rather than rely on internal training and promotion. Career paths for workers will become less predictable and may span several companies and industries (Arthur and Rousseau 1996, Cappelli et al. 1997).

The manifestations of these transformations include the emergence and establishment of varied forms of employment which are explicitly short term (limited-duration hiring, temporary assignment), may be brokered by an intermediary (a for-profit or nonprofit temporary/staffing service), or may be the result of contracting arrangements between two businesses (e.g., workforce of a janitorial subcontractor), thus creating a triangulated employment relationship. Independent contracting has also

appeared—a situation where individual workers are treated as self-employed under the law, that is, not wage/salary employees, while they have a sole purchaser of their service and are economically dependent on the relationship.

Short-term employment relationships may render existing regulations and their enforcement ineffective; workers may not stay long enough in a particular job to bring a complaint about a violation of a labor standard. Triangulated employment relationships entail ambiguities as to employer responsibility for compliance with particular laws. Independent contracting means that there is no employment relationship and therefore no option for regulation under most labor and employment law. In practice, the financing and implementation of social protection benefits such as health insurance and pension through employment relationships are weakened if not rendered ineffectual.

As employment relationships change in these ways, the contents and means of the regulation of working conditions will likely change. The regulation of working conditions will require a reconceptualization and analysis.

Although employment relationships change in these ways, they still remain the primary means through which core social protection benefits continue to be provided. In the USA, which has relied on social protection benefits being provided by employers either voluntarily (fostered by tax deduction incentives) or through rare mandates, regulatory attention has focused on mechanisms to enable workers better to meet their responsibilities to family. For example, family leave—time off for caring for a child or sick relative—has been the subject of US legislation (in 1993), of continued activism at the state and federal level, and of innovative benefit policies by some large employers. These developments reflect the increased presence of members of dual earning couples as well as that of single parents (mostly female) in the workforce (Blau and Ehrenberg 1997).

6.2 The Regulation of Working Conditions and Globalization of Production

International economic integration has accelerated in recent years and is expected to continue. Its main features include the reduction or removal of trade tariffs and of restrictions on capital flows either by policy change or simply through the use of new communication technologies (which put distant production areas directly in competition). It has resulted in greater international capital mobility, the freer movement of goods, and the development of production processes ('production chains') that span national boundaries. This pattern holds particularly for manufacturing and, increasingly, for service activities (Whitman 1999).

In this context, the issue of the regulation of working conditions will take on new facets requiring further consideration and research. First, the adaptation and strategic responses of firms in industrialized countries to minimal labor standards were developed during the post-World War II period when mass production was in expansion, and domestic markets were relatively sheltered from foreign competition. Growing product competition from countries with dramatically lower wages and fewer regulations of working conditions, as well as the increased opportunities for firms to expand their production processes cross-nationally, are changing the parameters that affect working conditions for workers in both industrialized and developing countries. These developments challenge the ability of national and local governments to regulate working conditions in ways that provide for effective enforcement.

Second, in developing countries, the development of activities linked to the production processes of cross-national firms has given rise to forms of employment (e.g., electronic parts assembly at home) which are not subject to existing national regulation of working conditions, or which take place in settings and on terms in which monitoring and enforcement are difficult (see debates on the 'informal economy').

Additionally, the ability of countries enforce the regulation of working conditions through labor standards in those developing countries with low wages and low-quality working conditions is weakened by the ability of cross-national firms to shift production to another low-wage country with a workforce of similar skill level.

Three groups of issues will need to be considered in future research. First, the parameters of firms' choices will need to be documented in the context of particular countries and for specific activities, contrasting capital-intensive and labor-intensive manufacturing as well as comparing manufacturing with service activities.

Second, future research on regulation will increasingly examine the sphere of international organizations (e.g., World Trade Organization, Organization for Economic Cooperation and Development, International Labor Organization), the process of international negotiation of conventions on working conditions, and the impacts of these conventions, first, on national regulation efforts and, second, on firm strategies and practices regarding working conditions.

Lastly, for policy analysis and discussion, the core question will be what *should* be the complex of regulation of working conditions that is most compatible with new forms of cross-national production, the productive use of new production and communication technologies, and the well-being of workers in industrialized and developing countries?

Regulatory Agencies

Broadly defined, regulation includes any governmental effort to control behavior by other entities, including business firms, subordinate levels of government, or individuals. Sovereign governments may cooperate under regimes of mutually-recognized restraint, the rules or decisions of which might also be characterized as regulations. Campaigns for elective office may likewise be subject to controls on spending

and advertising. However, in most public discourse and social science inquiry, the term refers more narrowly to formal government programs (or to specific implementing decisions) intended to constrain economic activity in accord with some public-interest justification.

Four primary concerns of regulation in this sense may be distinguished (Breyer 1982, Stone 1982). First, regulation may control (as in the case of occupational licensing) market entry. Second, it may (as in the case of electricity utilities and other 'natural monopolies') establish directly the prices that firms can charge customers. Third, it may limit the competitive practices available to firms, especially as regards price-setting (e.g., the law of antitrust), advertising, and disclosure. Fourth, regulation may aim to improve the quality of specific work practices or products, often in the interest of protecting human health and safety, or the environment. These activities are sometimes subsumed under two more general headings—'economic' (i.e., price, entry, and competitive practices), and 'social' (meaning generally health, safety, and environmental) regulation.

Social scientists have posed three primary empirical questions about regulatory programs. First, what forces lead to the creation of such programs? Second, and most commonly, they have asked what constellation of factors influences program behavior? Third, under what conditions may regulatory programs be significantly scaled-back or terminated? Normative questions also proliferate. Some varieties of regulation, especially in the United States, have been prone to intense controversy. Both business representatives and policy-focused academics have pursued long-running debates about the merits of various regulatory programs, the quality of their specific decisions, and possible institutional alternatives to the status quo.

1. *Empirical Inquiry*

Students of regulation have long found the formally-stated public goals of regulation inadequate to explain program creation and maintenance. From the 1950s to the 1970s, working within disciplines as diverse as economics, political science, and historical analysis, commentators viewed regulatory programs frequently as being prone to 'capture' by regulated interests (Huntington 1952, Bernstein 1955, Kolko 1965, Stigler 1971). By some accounts, regulation was said to have arisen because a diffuse majority favoring regulation (and motivated by a 'public interest' rationale, such as the elimination of predatory pricing or consumer fraud) succeeded, at least briefly, in obtaining legislative consensus, often in the wake of well-publicized scandal. Over time, however, according to this 'life cycle theory' of regulation posited by Bernstein (1955), waning public attention and media scrutiny was said

to have allowed resourceful regulated interests, whose attention to regulatory program activity did not wane, to exercise a strong (even dominant) influence over the program, thus thwarting its original intent. A different version of capture analysis suggested that such programs were sometimes created, at least partially, at the behest of economic interests. Agencies might thus, in effect, be 'born captured' due to business incentives to seek stable and reliably profitable operating environments. The capture model of regulation is in some respects akin to a traditional political science metaphor, widely employed during the same period, that described the politics of narrowly distributive public policies in terms of mutually-reinforcing 'iron triangles' or subgovernments composed of interest groups, legislative committees, and agencies (Freeman 1965). The similarity is striking, even though an analytic scheme widely appropriated among political scientists (Lowi 1964) highlighted a distinction between 'distributive' and 'regulatory' politics.

During the 1970s and thereafter, however, scholars challenged increasingly the descriptive accuracy of both the capture theory and the 'iron triangle' metaphor. In the United States especially, this challenge stemmed importantly from the creation of regulatory programs (e.g., in environmental, consumer, and worker protection) where lack of media scrutiny, public indifference, and business dominance plainly did not apply over the long run (Wilson 1980). Indeed, the creation of these programs often represented sustained triumphs by idea-driven policy entrepreneurs over business interests that had to adjust to the presence of long-term political competitors. In one prominent instance, the regulation of nuclear power generation, a policy milieu changed dramatically from one to which the term 'capture' could arguably have applied in the 1950s. By 1980, the politics of nuclear power in the United States had evolved into a far more complicated set of power relations, in which environmental advocates and citizen groups competed effectively with the nuclear industry (Temples 1980).

Throughout the 1980s, political science commented increasingly about the inadequacy of broad generalizations regarding regulatory politics as a whole. The concentration of costs and benefits prevailing in regulation were found to differ importantly among agencies, and across issues within a single agency (Wilson 1980). The politics of broadcast regulation, pursued within a markedly vague standard of 'public interest, convenience, and necessity,' clearly varied between technical industry structure matters and issues of program content (Krasnow et al. 1982). Within public utility regulation, not only were issues determined to differ in complexity and conflict, with significant implications for the power of different kinds of advocates (Gormley 1983), but the characteristics of commission personnel were also found to vary in ways important to generating distinctive regulatory outputs (Berry 1984).

Regulatory policy also became the staging ground for scholarly argument over the relative influence of various political institutions. A conventional position among journalists and political scientists had for many years held that Congress does little to oversee bureaucratic behavior, largely because of the modest political incentives said to prevail (Scher 1963). In arguing against what he called 'interest-group liberalism,' Lowi (1969) bemoaned the vagueness that had crept into legislative delegations for regulatory and other programs.

A later principal-agent perspective on the legislative-executive relationship argued for the existence of a more robust oversight mechanism grounded in a rational legislative approach to structure and procedure that appeared only superficially to be weak (McCubbins and Schwartz 1984). Careful sifting of agency case histories determined that widely-trumpeted accusations of 'runaway bureaucracy' often directed at regulation were misplaced (Foreman 1988).

Because regulation is politically contentious and generates substantial numbers of comparable implementation and enforcement decisions over time, political scientists (often working within the tradition of rational-choice models and principal-agent theory) have gravitated to regulation as a window on relative institutional influence more generally. Some analysts have emphasized the power of legislative principals (activated by the material stakes of affected parties) over agency behavior (Weingast and Moran 1983, Weingast 1984). Meanwhile, Moe (1982), examining time series data drawn from three US regulatory commissions, concluded that presidential power deserved emphasis. On the other hand, some analysts have looked inside regulatory bureaucracies, to the professional worldviews and incentives of staff members, as key drivers of agency behavior. In antitrust enforcement, economists and attorneys are among those professionals whose views have been found to have a profound impact on agencies, both in case studies (Katzmann 1980, Weaver 1977) and in quantitative analysis (Eisner and Meier 1990). On the other hand, the theory of overhead democracy embraced by Wood and Anderson (1993) ascribed variation in both the level and substance of antitrust regulation to a complex set of institutional forces; changing presidential administrations, congressional committee preferences, and court decisions all helped to mold antitrust activity.

Deregulation is rarer, and politically more problematic, than regulatory initiatives. As regards social regulation, such goals as a clean environment, and safe workplaces and pharmaceutical products, are popular with the mass of the public. In economic regulation, organized stakeholders would be expected to resist unfavorable change (i.e., alteration of profitable regulated environments). Given such forces, it is worth emphasizing that deregulation has occurred on occasion, and asking how this has come about. Political

scientists Derthick and Quirk (1985) point to the power of both ideas and effective leadership. They observe that, by the late 1970s, economists had mounted a sustained, coherent, and nearly unanimous attack on the underlying justifications for price and entry regulation in the transportation sector. This pro-competition critique gained added political impetus from the increasing visibility of economists in national policy debates, from the infiltration of economists into leadership of the regulatory apparatus, and from the transformation of deregulation into an anti-inflation and consumerist cause that both liberals and conservatives could support. Strong presidential and legislative leadership also proved to be pivotal.

2. Normative Assessments

Nearly all regulatory programs will find supporters and detractors in the social sciences. Unlike price and entry regulation, which regularly has found advocates of abolition in the economics profession, other types of regulation enjoy strong academic support on principle (e.g., recognition of 'market failure') though often not in specific detail.

Leading the charge for varieties of regulatory reform have been economists and economically-oriented analysts associated with policy research institutions or 'think tanks.' Criticisms of environmental policy stress varieties of putative inefficiency or irrationality. Costs are said to exceed benefits, to be higher than necessary to achieve a given level of environmental benefit, and perhaps to be masked altogether by inadequate economic analysis (Kraft 1996, pp. 165-6, Litan and Nordhaus 1983, Lave 1981). Inefficiency is sometimes argued to have been caused by the logic of political compromise (Ackerman and Hassler 1981), or by unwillingness to impose overtly visible losses on large numbers of voters (Nivola and Crandall 1995). Inadequate monitoring has long been said to bedevil assessment of pollution control efficacy (Crandall 1983, Davies and Mazurek 1998).

A broader, efficiency-based critique encompasses additional concerns, including the discordant, meandering, and arguably even panic-stricken character of regulatory politics and policy (Breyer 1993). Critics point to a chronic inability to set risk priorities, to confront risk-benefit and risk-risk tradeoffs (Graham and Wiener 1995), and to reconsider regulatory statutes in the light of such concerns.

3. International Perspectives

All developed nations regulate, but they vary substantially in both regulatory structure and regulatory political culture. The United States is often portrayed as having a markedly more adversarial and legalistic system than other countries. One study concluded that

while 'regulatory power has been directed at very similar ends [i.e., control of carcinogens]' in Britain, France, Germany, and the United States, 'the openness, complexity and divisiveness of American decision making have no parallel in Europe' (Brickman et al. 1985, pp. 301–2). It is not clear, however, that the American style of regulation is necessarily more stringent than that of other nations. Conceding the more open regulatory style of the United States in comparison with Canada, Harrison and Hoberg (1994) nevertheless do not find the latter consistently less stringent than the former. Although institutions matter, their effects are 'contingent on a number of other variables that influence policy, such as the balance of power between competing interest groups and the interests of the party in power' (p. 181). Nevertheless there can be little doubt of the generally greater levels of hierarchy, and the more tightly-woven informal networks of personal relations, that characterize regulatory regimes in other advanced democracies in comparison with the United States (Badaracco 1985).

Rehabilitation (Cardiac): Psychosocial Aspects

The primary aim of rehabilitation of patients with physical conditions such as skeletal, spinal, or brain injuries, or following a cardiac event such as a myocardial infarction, is to enable the patient to return to as near their level of pre-morbid functioning as their physical condition allows. Since much heart disease is a product of an unhealthy life-style, an important secondary aim in cardiac rehabilitation is to enable the patient to change their behavior to reduce the risk of further arterial damage and recurrent cardiac events.

Cardiovascular disease is a major problem in most industrialized countries. Currently in the UK approximately 300,000 people per year have myocardial infarction, of whom 50 percent survive for at least 28 days. There are also large numbers with the disabling symptoms of coronary disease such as the 1.4 million individuals in Britain with angina. While there has been progress in the prevention of coronary artery disease in most countries with a high incidence of heart disease, an aging population and advances in medical treatments mean the number of people with coronary disease and its consequences is in fact increasing. A sizeable proportion of these people would benefit from cardiac rehabilitation. While prolonged inpatient rehabilitation—often in sanatoriums in country environments thought to be healthy—has been common in some countries for many years, the development of intensive outpatient programs is a product of the last quarter of the twentieth century. Founded with great enthusiasm, the early results from cardiac rehabilitation programs were disappointing but developments in therapeutic and data analytic techniques have led to a much more positive picture emerging since the mid-1990s. Many now hold that that comprehensive cardiac rehabilitation can improve the quality of life and physical health of patients with coronary heart disease and most sophisticated systems of healthcare aim to offer rehabilitation to patients suffering the effects of cardiovascular disease (see *Chronic Illness: Quality of Life*).

1. Main Features of Cardiac Rehabilitation

The main group of patients who receive cardiac rehabilitation comprises survivors of acute myocardial infarction, although patients who have undergone coronary bypass surgery or angioplasty may also receive it. Since the latter are often elective procedures, rather than the unpredicted disaster of a heart attack, the patients' problems may differ and less is known about the most appropriate forms of rehabilitation for them. The first cardiac rehabilitation programs were primarily based around exercise regimes and this remains the core of many programs. However with the

increasing understanding of the psychological effects of myocardial infarction and the psychological and behavioral determinants of coronary heart disease (Krantz and Lundgren 1998), programs have widened to include many psychosocial components. There is no agreed standard program of cardiac rehabilitation, and programs vary widely in practice, but a modal program would be offered in an outpatient setting, starting six to eight weeks after discharge from hospital, would run for two or three months and would include regular exercise, an educational component about life-style change, and some procedures—such as relaxation training—to reduce distress. Exercise is usually conducted in specialist hospital gymnasiums, often with careful monitoring of the heart rate to diminish the risk to the patient. Rehabilitation programs are usually offered to middle-aged patients but might not be offered to the elderly, although they are the main sufferers from heart disease. Uptake of rehabilitation can be poor, especially in older patients. Such rehabilitation programs are expensive and difficult to deliver to the infirm, the socially disadvantaged, or those who live far from a specialist centre. Fortunately, effective versions of some aspects of rehabilitation can also be delivered by manual and supplementary telephone contact (Lewin et al. 1992), or by brief educational or counselling interventions while the patient is still in hospital (Johnston et al. 1999).

2. The Effects of Cardiac Rehabilitation

2.1 Psychosocial Outcomes

It would appear self-evident that patients will be distressed immediately after an unexpected, painful, and life-threatening event such as an acute myocardial infarction, and that this distress will continue for some time. While this is true of perhaps 15 to 30 percent of patients, a number of studies have shown that anxiety and depression are only slightly raised in most patients while still in hospital, but rise several weeks later and may remain elevated for at least a year (Johnston et al. 1999). Perhaps as significant is the finding that anxiety and depression are very high in the patients' partners while the patients are in hospital and these remain high—higher than that of the patients—for at least the subsequent year. There are many studies using rehabilitative techniques designed to reduce the distress associated with an infarction. Issues covered in such interventions will typically include an explanation of the attack and the healing process, including medical treatments and investigations, information on resumption of activities, and material on the emotional effects of a heart attack and the management of stress. Many recent studies of such interventions are positive and until recently there was a clear consensus, which had been confirmed by meta-analysis (Linden et al.

1996), that anxiety and distress could be reduced by appropriate rehabilitation programs, including programs that focused primarily on exercise (Kugler et al. 1994). However, an analysis by Dusseldorp et al. (1999) failed to confirm this finding. This is almost certainly because of the inclusion of two major studies with substantial samples that failed to find a reliable effect of psychosocial rehabilitation on distress (Jones and West 1996, Frasure-Smith et al. 1997). These studies are aberrant, and while their impressive size (which came about because they were primarily designed to detect effects on reinfarction rate) means that they have a substantial effect on summary analyses, few in the field accept that distress cannot be reduced after a myocardial infarction. Other studies have shown highly significant effects of simple interventions (Lewin et al. 1992, Johnston et al. 1999) on distress and on the resumption of the normal activities of daily life. Johnston et al. also showed that anxiety and depression was greatly reduced in the partners of patients if they were included in the rehabilitation program.

2.2 Risk Factor Reduction

A substantial proportion of heart disease is predicted by a few well-recognized and modifiable risk factors, all of which relate to some extent to behavior. These are elevated blood pressure, some lipids (including cholesterol), and cigarette smoking. Dusseldorp et al. (1999) have provided the most complete account of the effects of psychoeducational programs on the reduction of these conventional risk factors. All were reliably reduced by the interventions.

As well as these well-accepted risk factors there are a number of psychological risk factors that, although not necessarily accepted by the whole medical community, have substantial epidemiological support. Currently the most prominent of these are Type A behavior and depression (see Krantz and Lundgren 1998), and there is increasing interest in social support. Type A behavior, a pattern of behavior characterized by competitiveness, time pressure, and hostility, has been recognized as a risk factor for myocardial infarction for some time. However, possibly because of continuing controversy over which component of this complex behavior pattern is actually harmful, there have been few studies that both modified the behavior and were large enough to detect any effect on physical health. By far the largest of such studies is the Recurrent Coronary Prevention Project (Friedman et al. 1986) in which nearly 900 patients were randomized to either a prolonged program of Type A modification using cognitive behavioral techniques (see *Cognitive Behavioral Therapy*) or an alternative treatment emphasizing cardiological care and information. The behavioral intervention led to substantial reductions in Type A behavior and in recurrent myocardial infarction. There have been a number of successful

small-scale replications of this study, but it does not seem to have been incorporated into clinical practice to a significant extent. Future studies may concentrate more on hostility than the complete range of Type A behavior, since it is generally held that hostility is the component of Type A most reliably related to cardiovascular disease. Depression has emerged much more recently than Type A as a risk factor for heart disease (and indeed other physical conditions) and appears to be finding widespread acceptance. While studies are ongoing, there are no completed studies of the effects of treating depression on recurrent heart disease. Frasure-Smith, one of the leading advocates of depression as a risk factor in recurrent heart disease, has described interventions for related states with disappointingly mixed effects. In an early study she found that distress (which could include both anxiety and depression) could be successfully treated in patients after a myocardial infarction and that this was associated with reductions in morbidity and mortality over the subsequent seven years. However in a substantial replication (Frasure-Smith et al. 1997) she was unable to either reduce distress or affect the recurrence rate.

3. Morbidity and Mortality

Few studies of rehabilitation have large enough samples to demonstrate reliable changes in morbidity or mortality, but meta-analytic techniques enable independent studies to be combined. Oldridge et al. (1988), in a highly influential analysis of exercise and life-style change programs, showed a reduction in mortality, but not reinfarction rate, following rehabilitation. Subsequent meta-analyses incorporating more studies of exercise have largely confirmed these findings and also shown effects on reinfarction, as have the meta-analyses of life-style change and stress management programs (Dusseldorp et al. 1999). They show that such programs were associated with a 34 percent reduction in mortality and a 29 percent reduction in reinfarction rate. The findings were most persuasive in studies in which there was evidence of change in life-style-related risk factors such as blood pressure, cholesterol, and cigarette smoking.

4. The Future

The outstanding issues for the future are effectiveness, efficiency, and access. While it is clear that effective programs exist, the results from ineffective trials are still reported and the critical components have yet to be isolated. In addition we can anticipate increasing efforts to incorporate modifications of the newer psychological risk factors such as depression, hostility and, very probably, social support. Many programs are expensive to implement, they require gymnasiums, physiotherapists and other health professionals, and

time—all scarce resources. Increasingly complex programs will have to be delivered in ever more efficient ways. This will surely involve close targeting of interventions to patients' particular problems and risks as well as more efficient methods of delivery such as patient manuals, both printed and computerized, and the use of the internet. Perhaps the greatest advances need to be made in increasing access. In many countries with otherwise sophisticated healthcare systems, too few people are offered cardiac rehabilitation, and many find it difficult to accept because of factors such as other commitments, poverty, and, no doubt, a failure to realize or accept the possible benefits. In England and Wales 40 percent of centers restrict rehabilitation to those aged below 60, and when it is offered to the elderly it is not geared to their special needs. The situation may be a little different in the USA, where Richardson et al. (2000) report an increase in the uptake of rehabilitation in those aged 65 and over, from 28.3 percent in 1986 to 52.1 percent in 1996 for one particular service. Cardiac rehabilitation in the elderly appears to be safe and of value (Foreman and Farquhar 2000), but Oldridge (1998) has pointed to the lack of good, controlled studies. Most studies, like most rehabilitation programs, have focused on the middle-aged. We can expect to see in the near future a change in both access and a strengthening of the scientific basis of cardiac rehabilitation for the elderly.

D. W. Johnston

Rehabilitation of the Offender

The ways in which societies react to those who break criminal laws show major historical changes. In most civilized countries, corporal punishment and the death penalty have been replaced by prison sentences, fines, and a broad range of diversion programs, alternative sanctions, and community treatment (Tonry 1998). The latter include, for example, restitution, offender–victim mediation, social training courses, community service, intensive supervision, electronic monitoring, boot camps, day treatment centers, and other alternatives to institutionalization and routine probation.

Although the scope of criminal justice interventions has broadened, the ‘right way’ forward for crime policy is still controversial in many countries. The respective opinions are related to general political attitudes. They emphasize different aims in reactions to criminal behavior, such as compensation by the guilty, safety of the public, deterrence of other people from similar crimes, and prevention of future law breaking in the offender. The last aim is central to offender rehabilitation and relates to similar concepts such as resocialization or correctional treatment. These concepts refer to educational, psychological, and medical measures that are delivered in a systematic

way to reduce the risk of recidivism and contribute to (re-)integration in society.

During the 1960s and early 1970s, this idea became a centerpiece of crime policy in many countries. However, the concept of rehabilitation was also criticized from different perspectives that emphasized the other aims mentioned above. In the mid-1970s, a comprehensive review of offender rehabilitation programs concluded that the majority of available studies were methodologically too weak to prove treatment success (Lipton et al. 1975). Although this and other reviews revealed various positive effects, the slogan of 'nothing works' in offender rehabilitation became widespread. However, the 1990s saw a re-emergence of the issue of offender rehabilitation. Among other reasons, this was due to systematic research integrations via meta-analyses that led to a more differentiated discussion in research and practice (McGuire 1995, Palmer 1992).

1. General Efficacy

There are now hundreds of evaluations of offender treatment that include an untreated comparison group. The outcomes differ somewhat depending on

the age of offenders, previous criminality, offense types, modes of treatment, criteria of success, length of follow-up, and other issues. For example, various studies of sexual offender treatment revealed sexual reoffending rates between 3 percent and 44 percent with a mean of 18.8 percent (Hall 1995). The respective data for untreated control groups were 6 percent to 75 percent with a mean of 26.8 percent. Therefore, a single study cannot be generalized, and it is necessary to base research syntheses on common measures of effect size (ES). Such an indicator is the correlation coefficient *phi* or *r*. Table 1 summarizes the results of a number of recent meta-analyses on offender rehabilitation.

Although effects differ according to study samples and methods of computation, all mean ESs are positive. However, they are generally small. A realistic estimate of overall effectiveness is only approximately 0.10 or a little less. Taking the example of a control group with 50 percent reoffending, such an effect size of 0.10 would indicate a reduction to 40 percent recidivism. This is a 10 percentage points or 20 percent difference in comparison with the untreated group. Such a small effect may well be relevant in terms of cost utility. A realistic evaluation of correctional programs also has to take into account that the

Table 1
Selected meta-analyses on offender rehabilitation

Authors and topics of meta-analyses	Studies	ES (r)
Andrews et al. 1990 Community/institutional programs for juvenile/adult offenders	154	0.10

Polizzi et al. 1999 Prison- and nonprison-based programs for sex offenders	13	0.09

optimum ES is not 1. Depending on the recidivism rate in the untreated group, 0.30 may already represent the maximum possible efficacy.

2. Different Types of Program

Most research reviews reveal significant differences between kinds of programs: the largest effects come from theoretically well-founded, multimodal, cognitive-behavioral, and skill-oriented programs. Also promising are family-oriented programs in ambulatory treatment for serious juvenile offenders and clearly structured therapeutic communities in the institutional treatment of adult offenders. Successful interventions fit the level of offenders' risk, address criminogenic needs precisely (instead of vague personality changes), and take into account the specific learning styles of the offenders (responsivity principle). Such programs are founded on empirical knowledge about the causes and development of the respective criminal behavior and are not just derived unspecifically from psychotherapeutic 'schools.' They address, for example, motivation for change, self-control, crime-related beliefs and attitudes, social skills, interpersonal problem-solving, self-critical thinking, moral reasoning, anger management, victim awareness, and coping with risk situations for relapse (e.g., Ross and Ross 1995). Cognitive-behavioral and relapse prevention approaches are not only most appropriate for the treatment of 'ordinary,' violent, and personality-disordered offenders but also for sexual offenders (Marshall et al. 1998). Here, combinations with hormonal measures seem to be relatively successful as well.

Effect sizes in the most appropriate programs can be twice as high as the average. In contrast, unstructured case work, traditional psychodynamic, and non-directive approaches show smaller effects than the overall mean. Relatively low-structured, self-governing, permissive therapeutic communities and milieu therapy also seem to range at the lower end of effectivity. The same holds for merely formal variations in punishment or probation; diversion without any educational or psychosocial component; deterrence, boot camps, and other measures of smarter punishment or intermediate sanctions. Aversive behavioral methods for sex offenders are also not successful. In some studies, the effects of inappropriate treatment are even negative.

3. Methodological Issues

Methodological features explain a substantial part of outcome variance. For example, studies with random assignment tend to produce smaller effects than quasi-experimental designs. There are also smaller effects in studies with larger samples, higher statistical power, and low rates of attrition between subject assignment

and outcome measurement. Juridically-proven recidivism shows somewhat smaller effects than measures of institutional adaptation or attitude change. Outcome criteria with good reliability and longer follow-up periods also tend to be associated with smaller effects.

Although the number of evaluations with reasonable methodological quality has increased, there are still very few well-controlled studies on specific modes of treatment and specific offender groups. This is particularly the case for the institutional treatment of serious adult offenders, psychopaths, and sex offenders. In these cases, it can be rather difficult to form equivalent control groups that do not receive any kind of treatment. So far, evaluations often address different degrees or modes of treatment and not an all-or-none dichotomy.

4. Program Integrity and Intensity

A certain treatment label may be misleading with respect to what actually happens in a program. However, high integrity (reliability) of program delivery is necessary for good outcomes. Naturally, this holds only for programs that are successful in principle. Low integrity may result from, for example, weakly-structured programs with no treatment manuals, organizational barriers and staff resistance, or insufficient staff training and supervision. Although psychosocial interventions are basically an individual process and not a standardized technique, it is important to assess and monitor program implementation systematically. Doing this may be one reason why studies in which researchers were involved in program delivery show better effects than other evaluations.

Treatment intensity and dosage also relate to outcome. Lipsey and Wilson (1998), for example, found that the duration of treatment correlated positively with effect size, whereas the mean number of hours a week correlated negatively with outcome. The latter result may be due to problems of implementation and some satiation in very compact programs.

5. Offender Characteristics

The efficacy of rehabilitation programs depends not least on the characteristics of the offenders. For example, child molesters seem to benefit more from sex offender treatment than rapists. In juvenile offenders, Lipsey and Wilson (1998) found that samples with mixed prior offense types (including violent offenses) had better outcomes than those containing primarily property offenders. Effects were also larger when all offenders had prior sentences. These and other data suggest that serious and violent offenders may benefit more from treatment than less serious ones. This is plausible when considered in light of the risk principle: offenders with various prior offenses

are more often at risk of life-long persistent antisocial behavior. In contrast, offenders with fewer prior offenses more often belong to the type of adolescence-limited antisocial behavior. In these cases, natural protective factors in everyday life counteract recidivism in the untreated control groups as well.

However, the finding that high-risk groups benefit most from rehabilitation programs cannot be generalized to very high-risk cases such as psychopaths. These offenders lack the interpersonal and motivational characteristics that are essential for successful treatment, and thus rarely show a good outcome (Lösel 1998). This would indicate that a nonlinear, U-shaped function may be an adequate description of the relationship between risk and treatment efficacy. It is in particular the low-risk and very high-risk cases that show the weakest effects.

The need principle and responsivity principle can be applied adequately only when a systematic assessment of the offender is performed. This should be based not only on static variables such as offender age or criminal history but also on dynamic characteristics that are accessible to change. A thorough assessment is necessary for adequate placement decisions, for example, in the case of dangerous offenders. This should also reduce the number of treatment dropouts. Most studies have shown that the latter group is particularly at risk for reoffending.

6. *Setting Characteristics*

Overall, there seem to be larger effects in community programs than in institutional treatment. As a result, custody should be the last resort (for financial reasons as well). However, placement in a closed setting is normally confounded with a higher risk of reoffending. Sweeping assumptions that successful treatment is not possible within prison or other institutional settings are not supported by empirical research. Negative incarceration effects may depend on personal, situational, and organizational moderators that can be addressed at least partially by adequate programs. In cases of drug use and other dangerous lifestyles, institutions may even have some protective effects. The alternative therefore of 'community vs. institution' is too undifferentiated. The systematic assessment of risk can contribute to a stepwise reduction of custody to accompany positive developments in the offender (e.g., Quinsey et al. 1998).

7. *Organizational Climate and Regime*

Perhaps, it is not institutionalization by itself but the quality of regime and social climate that accounts for positive or negative effects. Although institutional features vary widely even under similar formal conditions, they have not yet been investigated to any great extent. A regime that is emotionally and socially responsive as well as structured, norm-oriented, and

controlling is most promising. From process research on general psychotherapy, it is known that the relations between clients and therapists are very important for efficacy. Similarly, correctional programming requires well-selected, specifically trained, highly motivated, and continuously supervised staff. Attitudes and competencies that are not in line with the aims and content of a program may not only lower treatment integrity but even counterbalance potential efficacy.

8. *Aftercare and Relapse Prevention*

Even intensive rehabilitation programs make up only a small part of the factors that impact on the clients' thinking and behavior. It is therefore necessary to deliver services that consolidate the competencies acquired during treatment, to provide control over risks, and to cope with crises that may arise afterwards. Without such measures, treatment efficacy often can be demonstrated only during short follow-up periods. Although systematic programs of through-care, aftercare, and relapse prevention are particularly emphasized for the treatment of drug-addicted and sexual delinquents (Annis 1986, Laws 1999), they are relevant for other violent and personality-disordered offenders as well. Thorough planning and monitoring of relapse prevention refers to type and intensity of services, cooperation routines between the institutions, probation officers, and other staff involved. These multiagency networks are very important for preventing recidivism (Spencer 1999).

9. *Natural Protective Factors*

Even without any rehabilitation program, a subgroup of high-risk offenders desists from criminal behavior. In these cases, natural protective mechanisms make delinquent behavior less attractive. Although our knowledge about such processes is still rudimentary, various personal and social resources have repeatedly shown a protective function against criminality (see *Religiosity, Sociology of; Non-violence: Protective Factors*): for example, bonds to nondeviant family members or other reference persons; cognitive competencies, school achievement, and planning for the future; nondeviant peer groups; work motivation, vocational skills, and employment; or a supportive and prosocial intimate partner. Such protective factors are relevant for positive turning points in criminal careers. Therefore they need to be assessed and integrated into program planning and delivery.

10. *Community Features*

Individual and microsocial risk and protective factors also interact with the broader social context. Therefore community features such as the concentration of

poverty, unemployment, multiproblem families, violence, drug use, and other deficits in 'social capital' must be taken into account in offender rehabilitation. If, for example, a program promotes vocational skills, it may be particularly successful in communities with low unemployment rates (Sherman et al. 1997). In other contexts, the skills acquired will be less useful. Counterproductive influences may result from neighborhoods with high criminality and violence. In a community in which peers and neighbors model and reinforce deviant behavior, it is more difficult to preserve program effects than in a social context with less negative influences. Offender treatment and relapse prevention should therefore be integrated into broader community programs of crime prevention.

11. Conclusions and Perspectives

During the last decade, there has been growing evidence that some programs of offender rehabilitation work and others are promising. However, there is still a lack of methodologically sound evaluation, particularly of complex programs and multiple services for specific adult and serious offender groups and of the service delivery in everyday practice. More process data are needed on the content of program delivery, staff characteristics, and dimensions of the institutional regime. It is also necessary to assess control group conditions in a similar way. The dropout problem must be tackled more effectively. Adequate assessment procedures, program modules on motivation, and flexible procedures of case management are suggested here. Outcome evaluation should not rely primarily on one-shot studies but refer to a theoretically-based chain of various change measures, including longer follow-up periods. Last but not least, practice-oriented evaluations must place offender rehabilitation programs in their wider social context.

Although more systematic research is needed, empirical program evaluations and experiences from practice already suggest guidelines for effective rehabilitation. These include, for example:

- (a) Realistic expectancies regarding possible efficacy.
- (b) Theoretically sound concept (social learning, multimodal approach).
- (c) Systematic assessment of offenders' risk and matching to service level.
- (d) Appropriate targeting of specific criminogenic needs and not unspecific personality characteristics.
- (e) Teaching of self-control, nondeviant thinking, and social skills.
- (f) Consequence in applying reinforcement.
- (g) Matching of program type, offender, and staff.
- (h) Thorough selection, training, and supervision of staff.
- (i) Development of a supportive institutional climate and regime.

- (j) Neutralization of criminogenic social networks.
- (k) Strengthening of 'natural' protective factors.
- (l) Attainment of high program integrity and adequate intensity.
- (m) Dynamic assessment and monitoring of offender change.
- (n) Provision of systematic through-care, aftercare, and relapse prevention.
- (o) Continuous process and outcome evaluation of the program.

Countries such as Canada, England, and Scotland use similar guidelines for program accreditation. Naturally, we cannot expect that one specific type of program will emerge as the gold standard for successful offender rehabilitation. However, the current empirically-based knowledge on 'what works' is promising in securing service quality for both the society and the offender.

Reification: History of the Concept

Notwithstanding its esoteric overtones and philosophical intricacies, reification (*Verdinglichung*) is a central concept of social theory in general and of critical theory in particular. Although reification has received the greatest attention in Western Marxism, and above all in Lukács' *History and Class Consciousness* (1923), it is important not to restrict the use of the concept to that tradition but to see that it can also and already be found in the work of Kant, Hegel, Nietzsche, Dilthey, Husserl, Heidegger, Simmel, and Max Weber to criticize the dehumanizing, rationalizing, and alienating tendencies of modernity.

As a technical term, the term reification emerged in the English language in the 1860s out of the contraction of the verb *facere* (to make) and the substantive *res* (thing), which can refer both to concrete and empirically observable things (*ens*) and to ab-

stract, indeterminate things (*aliquid*). As a synonym of 'thingification,' the inverse of personification, reification metaphorically refers to the transformation of human properties, relations, processes, actions, concepts, etc. into *res*, into things that act as pseudopersons, endowed with a life of their own. This material transmutation of persons, relations, processes, concepts, etc. into thing-like entities that act like pseudopersons can operate both on a methodological and a social level. In both cases, however, the concept is usually used as a *Kampfwort* to denounce the 'violence of abstractions,' either of conceptual abstractions (Sohn-Rethel's *Denkabstraktionen*) that suppress the reflexive embeddedness of concepts into their social context, treat social facts as things, and transform metasubjects into megasubjects, or of real abstractions (Marx's *Realabstraktionen*) that strip individuals of their autonomy and reduce them to cogs of an abstract social machinery. This reference to the Kantian notion of autonomy is important. Outside of the normative context of an 'enlightened critique of the Enlightenment,' the notion of reification hardly makes sense, as can be gathered from the fact that conservative, skeptical, and ultraliberal theorists such as Gehlen, Luhmann, and Hayek have a theory of the autonomization of social structures but no theory of reification to connect it to the alienation of individuals in modern capitalist industrial societies.

1. Methodological Reification—or the Critique of Conceptual Abstractions

In the philosophy of the social sciences, the concept of reification is used (a) to denounce the hypostasis or substantialization of concepts (nominalist critique of reism), (b) the naturalization of the subject and the life-world (humanist critique of naturalism), and (c) the ideological justification of the status quo (dialectical critique of fetishism).

1.1 Nominalist Critique of Reism

In the case of the critique of reism (or naive conceptual realism), the notion of reification of concepts is used to denounce, from a nominalist, vitalist, or criticist perspective, the categorical error of transforming abstractions (notions, representations, concepts) into a material reality, in a concrete object 'out there.' Reification is here understood as a synonym of the 'fallacy of misplaced concreteness' (Whitehead). What is criticized is the hypostasis of concepts, analytical constructs, and ideal types, the sliding from the substantive to the substance, which involves a subreption of the categorical thing with the 'thing in itself.' This is, for instance, the case with macrosociologists who transform their own conceptual constructs or those of

the actors ('the State,' the *Bourgeoisie*, the 'Proletariat') into historical subjects capable of agency and of determining their own ends ('the State decides,' 'the Anglican Church resists,' 'the glorious Proletariat triumphs,' etc.). It should, however, be noted that due to the absence of a consensus on the ultimate referents of reality and the fact that one can always submit the concepts of the scientist to a neo-Kantian critique of ontology, the charge of reification is almost inevitable. Given that one's typification is another's reification, the critique of 'false conceptual realism' (Weber) is endemic in sociology.

1.2 Humanist Critique of Naturalism

The critique of positivist naturalism in terms of reification of the subject and the life-world is linked to the series of methodological disputes (*Methodenstreit*) which, since the double foundation of sociology by Comte and Dilthey in the nineteenth century, have opposed the partisans of the method of causal explanation (*Erklären*) to the partisans of the interpretative methods (*Verstehen*). Drawing on Vico's principle of the *verum factum* (*verum et factum convertuntur*), according to which we can understand the sociohistorical reality because it is a human product, but not nature which is a divine product, humanists claim that the appropriate method of sociology is interpretative in that it aims to understand, by means of a phenomenological and hermeneutic reconstitution of the meaning of action, the social-historical world (Hegel's objective spirit) as an objectivation of subjective actions. Social facts thus have a meaning and cannot be treated 'as if they were things' (Durkheim). The naturalistic elimination of the meaningfulness of action through statistical observation is reifying in that it transforms psychic acts into pseudophysical facts and reduces culture to (second) nature. Against Durkheim and his fellow 'factists' who 'change the subject' of the human sciences by substituting factors for actors, humanists thus argue that social facts are not things but that things are social facts whose meaning can be understood and which can be interpreted as an 'ongoing accomplishment of the concerted activities of daily life' (Garfinkel).

1.3 Dialectical Critique of Fetishism

The dialectical critique of fetishism offers a meta-theoretical critique of the ideological implications of *bourgeois* theories and methodologies of the social that, due to a lack of reflexivity on their context of genesis and application, legitimize the status quo. Dialecticians accept the limits of 'hermeneutic idealism.' When social relations have crystallized into a

'second nature' and social subsystems follow their own pseudonatural laws, 'dehumanizing' theories (e.g., functionalism, structuralism, systems theory) and methods (e.g., linear modeling, statistical regression) can and have to be applied. But if one does not want to fall prey to a 'reification of the second order' and give a 'reified perception of the reifying' (Adorno) that willy-nilly endorses the reality it registers, the observed facts have to be 'mediated by the totality' (Lukács 1923) and defetishized in such a way that the tension between the real and the possible, between what is and what could or should be, becomes perceptible within the facts themselves.

2. Social Reification—or the Critique of Real Abstractions

In the tradition of Western Marxism, Marx's theories of alienation and the fetishism of commodities are combined with Hegel's dialectical phenomenology of spirit, Simmel's theory of the tragedy of culture, and Max Weber's theory of formal rationalization to form a critical theory of society. The concept of reification is used to refer to the relatively autonomous, alienating and alienated functioning of the social and cultural (sub-) systems of modern capitalist societies that impose their constraints from without on individuals, limit their freedom and tend to reduce them to powerless 'carriers' or passive 'executioners' of the system. As products of praxis, institutions and organizations are human objectivations, but in the course of their development, the cultural and social (sub)systems have been complexified, formalized, rationalized, and depersonalized to such an extent that eventually they have been transmuted into self-referentially closed systems that function independently of the will and the consciousness of individuals, thwart their plans, threaten their autonomy, and perhaps even their existence. The critique of reification is dialectical and thus somewhat paradoxical: the insistence on the alienating autonomy of the system, which is an objectivation of action, aims to reactivate the autonomy of the individuals and to overcome their alienation.

Although the concept of reification (*Verdinglichung*) can already be found in Hegel's *Philosophy of Right*, the real history of the concept begins with Marx and with Lukács's Hegelian interpretation of Marx. The origins of the theory of reification are usually found just where the word itself is absent, namely in the famous section on the fetishism of commodities (Marx 1869, Chap. 1, Sect. 4). Analyzing capitalism as a system of generalized exchange, Marx notes that the commodity has become the universal form of the product of labor, with the result that the exchange value of the commodity supplants the use value. Consequently, the exchange value appears to those

who exchange goods as a property of the commodity itself, whereas in reality it is the result of the labor that is incorporated in the commodity and that expresses itself as a quantitative relationship between the exchanged goods. 'It is nothing but the definite social relation between men themselves which assumes here, for them, the phantasmagoric form of a relation between things' (Marx 1869, pp. 23, 86). This inversion of humans and things is not simply an illusion, however, but an expression of the real nature of social relations in a competitive market environment. In the absence of a central organism that regulates both the production and the distribution of the products of labor, the social integration of humans is imposed from without by the systemic interconnection of things.

In 'Reification and the Consciousness of the Proletariat,' the central chapter of *History and Class Consciousness*, Lukács, a Hegelian Marxist who was once a student of Simmel and Max Weber, presents the classic formulation of the theory of reification. Synthesizing Weber's theory of formal rationalization with Marx's theory of commodity fetishism, Lukács generalizes the theory of commodity fetishism beyond the sphere of circulation. In the problem of fetishism, which he immediately identifies with the phenomenon of reification, he discovers the 'central, structural problem of capitalist societies in all its aspects' (Lukács 1923/1968, p. 257). The universality of the commodity form, conceived as the prototype of all the forms of objectivity that follow their own laws and dissimulate the traces of human relations that subtend them, affects the life of everybody, both in its objective and subjective manifestations. Objectively, individuals are confronted with a second nature of pseudo-things against which they are powerless; subjectively, they are estranged from their own activity, apprehending the products of their own activity in an alienated mode—'as if they were something else than human products' (Berger and Luckmann). Moving from the sphere of circulation to the sphere of production, Lukács rediscovers the theory of the alienation of labor which the young Marx had developed but not published in the *Parisian Manuscripts* of 1844 (see *Alienation, Sociology of*). In the sphere of material production, reification expresses itself most clearly in the reduction of labor power to a commodity and of the laborer to an appendix of the machine. In capitalism, reification is generalized and the fate of the worker becomes paradigmatic of the fate of everyone. Expressing the Messianism of the oppressed, Lukács eventually reintroduces the Proletariat as the 'identical subject-object' of history whose revolutionary actions overcome alienation and reification and thus realize the Hegelian dream of the restoration of the 'beautiful totality.'

The development of the so-called Critical Theory of the Frankfurt School can best be understood as the result of a progressive disillusion with revolutionary

expectations. Eliminating the Hegelian-Marxist dialectic of consciousness, which they replace by a Freudian account of sublimation and repression, Horkheimer, Marcuse, and especially Adorno, who also gave a Nietzschean twist to the concept of reification, radicalize the Weberian-Marxist strand in Lukács' theory. Universalizing and totalizing reification to the point that it appears as an ontological feature of human civilisation, they almost end up indicting Reason as such. Indeed, to explain totalitarianism, Horkheimer and Adorno develop a negative philosophy of history which uncovers in the first protohistorical attempts to dominate nature the origin of the fatal unfolding of a diabolic logic of increasing reification that will find its culmination (but not its endpoint) in the death camps. In his *Theory of Communicative Action*, Jürgen Habermas (1981), the main representative of the second generation of critical theory, reformulates the theory of reification in terms of the paradigm of language. In this perspective, reification is no longer associated with rationalization as such, as was the case with Max Weber and the Frankfurt School, but reconceptualized in terms of the 'colonization of the life-world' by the subsystems of the economy and the administration. When the mechanisms of systemic integration (money and power) force back the forms of social integration from those domains that can only be integrated through language, a reification ensues that leads to a pathological deformation of the life-world.

Reinforcement: Neurochemical Substrates

1. The Operant–Respondent Distinction

The neurochemical mechanisms that mediate reinforced or operant behavior may differ in a fundamental way from those underlying reflexes or respondent behavior. This is because environmental stimuli appear to control the two classes of behavior in fundamentally different ways. In reflexes, whether conditioned or unconditioned, the controlling stimulus precedes the response and elicits it. In operant conditioning, the controlling stimulus follows the response and elevates its subsequent probability. When the controlling stimulus precedes the response, information flow in the brain is afferent to efferent, as in the conventional reflex arc. On the other hand, when the controlling stimulus follows the response, as in reinforced behavior, the underlying brain organization seems to require an unconventional circuitry in which efferents are activated before afferents. However, the mechanisms for reinforced behavior do not require circuits that directly link efferent to afferent elements. This is because operant behaviors do not directly activate the goal-detecting afferent systems. Rather, the correct response operates on the environment to produce the goal object and it is this environmental change that activates the goal-detecting systems. Thus, although the reinforcement mechanism does not require efferent-to-afferent circuitry, it must recognize efferent–afferent contingencies and must be operated selectively by them, i.e., it must cause behavioral reinforcement only when the neuronal substrates of the correct response and goal object, in that order, are activated sequentially.

2. Characterizing the Brain Reinforcement Mechanism

The problem of characterizing the brain reinforcement mechanism has two main parts: the first is to identify the neuronal substrate that performs the reinforcing function (reinforcing substrate) and the second is to identify the neuronal substrate that is modified by the reinforcement process (target substrate). Since any goal object can reinforce any behavior in an animal's repertoire, it seems likely that there is (a) convergence of goal-object input to the reinforcing substrate, and (b) divergence of reinforcing output from this sub-

strate to the target substrate. Here we briefly summarize the substantial published literature that has been devoted to the identification of the reinforcing substrate. Until very recently, little consideration has been given to the question of the target substrate, but it may be useful to review some initial findings and to consider the directions that research on this problem may take.

2.1 Neurochemical Specialization

The idea that reinforcing functions are specialized neurochemically has guided research in this field for more than 30 years. The hypothesis that certain dopamine and opioid peptide brain cells may serve as reinforcing neurons is supported most directly by evidence from brain self-stimulation and drug self-administration experiments.

2.2 Electrical Self-stimulation of the Brain

In self-stimulation experiments, animals work to deliver electrical stimulation to their own brains through permanently indwelling electrodes. In the absence of other sources of reward, the reinforcement for self-stimulation behavior must arise from the neuronal activity that is excited by the electrical stimulus. If so, it would be logical to assume that some of the neurons under the electrode tip actually are the reinforcing neurons that mediate the effects of natural reinforcers or at least are neurons that directly excite them.

High self-stimulation rates are observed when electrodes are implanted in regions containing dopamine (or opioid peptide) cell bodies or pathways. In particular, self-stimulation tightly overlaps the distribution of dopamine cells in the ventral tegmentum and substantia nigra. Self-stimulation closely follows the anteriorly projecting dopamine fibers through the hypothalamus, but it correlates somewhat less closely with the dopamine terminal fields in the forebrain. The involvement of norepinephrine neurons in self-stimulation is more controversial. Although many laboratories report self-stimulation from sites in the vicinity of the locus coeruleus, it has not been possible to establish convincingly that the noradrenergic neurons that make up this nucleus are responsible for the reinforcing effect. Mapping of opioid peptide sites for self-stimulation is consistent with the idea that certain beta-endorphin and dynorphin neurons are involved in self-stimulation, but these studies are still in an early stage. The dopamine-opioid peptide reinforcement hypothesis also is supported by pharmacologic experiments. Antagonists of dopamine and opioid peptides, such as haloperidol and naloxone respectively, should block chemical transmission of reinforcement messages. In support of the model, there are many

reports that these drugs selectively block self-stimulation.

Interestingly, the pharmacology of avoidance behavior (a prototypical example of negative reinforcement) closely overlaps that of self-stimulation (exemplifying positive reinforcement). In particular, avoidance and self-stimulation behaviors are selectively facilitated by dopamine agonists, such as amphetamine, and both are selectively inhibited by dopamine antagonists, such as chlorpromazine. Such evidence suggests that a common dopamine substrate may underlie both positive and negative reinforcement processes.

2.3 Intravenous Drug Self-administration

In self-administration experiments, behavior is reinforced by systemic or central injections of neurotransmitters or drugs. Although thousands of chemical substances are available, animals and humans avidly self-administer only a few. These self-administered substances may properly be termed pharmacologic reinforcers and it is interesting to ask why these chemicals are selectively associated with behavioral reinforcement. It is no coincidence that most powerful pharmacologic reinforcers have the ability to mimic or release the hypothesized natural reinforcement transmitters. Thus, many dopamine and opioid receptor activators are known to support self-administration behavior. In particular, selective agonists acting at μ and δ opioid receptors function as positive reinforcers, as do the naturally occurring opioid peptides, β -endorphin and dynorphin. Similarly, agonists acting at dopamine D_1 -like and D_2 -like receptors, such as apomorphine (D_1/D_2), piribedil (D_2), and SKF 82958 (D_1) are self-administered. The patterns of self-administration for many of these receptor agonists (particularly, D_1 and μ agonists) resemble the patterns observed when highly addictive stimulant drugs (e.g., cocaine and amphetamine) or opiate drugs (e.g., morphine and heroin) are self-administered. Hence it is reasonable to suppose that addiction to stimulant or opiate drugs may depend largely on their ability to activate or to enhance the activity of natural dopamine or opioid peptide reinforcement systems respectively. Finally, dopamine and opioid peptide antagonists, such as chlorpromazine and naloxone, not only appropriately block the reinforcing effects of agents that activate dopamine or endorphin receptors, but also appropriately block the reinforcing effects of stimulant and opiate drugs. Serotonergic agents generally are not self-administered but serotonin agonists and antagonists have been shown to alter self-administration of psychostimulants such as cocaine.

The self-administration method also has been used in attempts to identify the sites of action of stimulants and opiates. In some studies, animals are trained to self-inject cocaine or morphine directly into the brain

in an attempt to find preferred sites for reinforcing effects. In other studies, dopamine or opioid receptor antagonists are injected into different brain regions in attempts to block intravenous self-administration of drugs of abuse. Results from several laboratories suggest that important sites of action for both stimulant and opiate drugs are concentrated in the 'extended amygdala' including brain regions on an axis from the nucleus accumbens to the central amygdala. Reinforcing actions also are reported after direct injections of cocaine in the prefrontal cortex, morphine in the ventral tegmental area, and dynorphin in the hippocampus. Evidently, target sites for the reinforcing actions of drugs are widely distributed in the brain.

A closer analysis of brain transmitter involvement in reinforcement has been accomplished using *in vivo* microdialysis to monitor neurotransmitter levels in various brain areas during drug self-administration. Each cocaine self-injection caused a large increase in dopamine levels in the nucleus accumbens and these dopamine levels usually fell substantially to a 'trigger' concentration before the animal delivered the next self-injection. The addition of heroin to the cocaine solution caused synergistic increases in nucleus accumbens dopamine levels that are consistent with the higher abuse potential of such 'speed ball' combinations.

3. Methodological Considerations

Although these anatomical and pharmacological findings are generally consistent with the idea that reinforcing functions are performed by specialized systems of dopamine and opioid peptide neurons, some important problems remain. Administration of pure substances in the self-administration experiments strictly controls the chemical nature of the reinforcing injections but because the distribution of injected transmitters to active sites cannot exactly duplicate that of naturally released transmitters, the ensuing pattern of receptor activation could be artifactual or misleading. On the other hand, while electrical activation of transmitter pathways during self-stimulation presumably releases the reinforcing chemical messenger in a relatively natural distribution at appropriate postsynaptic sites, the electrical stimulus also must cause the simultaneous release of many irrelevant transmitters and neurohormones, including some that are still unknown. Thus, in self-stimulation, identification of which cells and which transmitters are relevant to the reinforcement process is largely a matter of inference. Solutions based on mapping studies demonstrate self-stimulation in anatomically coherent systems and those based on pharmacological studies implicate specific neurotransmitters. However, the anatomical mapping data from most self-stimulation experiments are insufficiently detailed. At

the same time, many of the pharmacological reports can be criticized because they often fail to distinguish specific drug effects on reinforcement from nonspecific effects on motor performance or attention. In addition, some self-stimulation findings seem to contradict the dopamine theory of reinforcement. For example, lesions of the nigrostriatal bundle do not permanently eliminate substantia nigra self-stimulation and, if only motorically simple responses are required, hypothalamic self-stimulation survives extirpation of all forebrain dopamine terminals.

4. The Dopamine-opioid Peptide Theory of Reinforcement

Despite such difficulties, the dopamine-opioid peptide theory of reinforcement currently enjoys a widespread acceptance. First, many investigators are impressed by the powerful and reliable reinforcing actions that highly localized electrical brain stimulation and specific chemicals can produce. Second, investigators are impressed by the consistent picture of dopamine-opioid peptide involvement in reinforcement processes that has emerged from the self-stimulation and self-administration data. Other neurochemical systems, in addition to dopamine and opioid peptides, also are likely to participate in reinforcement functions. For example, brain cannabinoid and nicotine receptors are probably involved in the reinforcing actions of marijuana and nicotine respectively. As additional receptors are identified as candidates for reinforcing actions, questions arise regarding their primacy and specific roles in reinforcement. Evidence now exists, for example, that several transmitter systems (e.g., cannabinoid, nicotine) have receptors localized on dopaminergic neurons that in turn may represent the final common pathway for reward. Another indication of a final common pathway utilizing dopamine is that agents that directly stimulate dopamine systems (e.g., amphetamine or cocaine) are more robustly self-administered than are agents that indirectly stimulate dopamine neurons (e.g., marijuana or nicotine).

Although a final common dopamine reward pathway remains a possibility, the crucial importance of reinforcement for survival makes it more likely that redundant neurotransmitter systems are involved. Most research on reinforcement has focused on the familiar transmitter systems mentioned above but complete understanding of reinforcement neurochemistry must await the likely discovery of novel transmitters. For example, several hundred G-protein coupled receptors have been cloned but their endogenous transmitters have not yet been identified. Some of these 'orphan' receptors may well play a role in reinforcement and their endogenous ligands (when elucidated) will serve as novel reinforcement transmitters. Such discoveries will lead to a more subtle and comprehensive understanding of reinforcement.

5. Identification of the Target Substrate

As noted, little theoretical or experimental effort has been devoted to the identification of the substrate that is modified by the reinforcement process. What are the neuronal targets of the reinforcing neurons? Because it is operant behavior that is reinforced, it is plausible to assume that behavioral substrates are major targets. It is commonly believed that operant conditioning involves the strengthening or reorganization of complex (but yet to be identified) neuronal circuits, which presumably form the substrates of reinforceable responses. According to this conventional view, the whole response is the unit of reinforcement. Where in the rat's brain, for example, would one find the circuit for a lever-press response? How might this circuitry be reorganized when lever pressing is reinforced? These anatomical and physiological considerations, as well as difficulties at the behavioral level associated with response definition, have led some scientists to question the idea that elaborate neuronal circuits are the functional units for reinforcement. According to B. F. Skinner, a more useful conceptual scheme recognizes the ultimately continuous nature of operant behavior. In this scheme, behavior is construed—not as a series of discrete acts—but rather as a continuous flow of activity and interaction with the environment, which arises from the largely spontaneous activation of infinitesimal behavioral elements. It is these elements, or 'behavioral atoms,' and not whole responses, that are the units strengthened by reinforcement. If so, and if atoms of behavior can be represented by the activity of individual neurons, then it could be argued that it is the behavior of individual neurons, and not of neuronal circuits, that is directly modified by reinforcing signals.

The cellular reinforcement hypothesis is currently under test in our laboratories by use of a novel '*in vitro* reinforcement' paradigm. This method employs training procedures closely analogous to those of behavioral operant conditioning to answer the question: Can the activity of relatively isolated brain cells in hippocampal slices be reinforced by local micro-pressure injections of dopamine or other reward-related transmitters or drugs? It was found that the bursting responses of individual pyramidal neurons in the CA I layer were in fact progressively increased by burst-contingent applications of dopaminergic and cannabinoid receptor agonists. The bursting responses of CA3 units were similarly increased by opioid receptor agonists. The same microinjections, administered independently of cellular activity, failed to facilitate and frequently suppressed cellular bursting. This observation, and the fact that glutamate (an excitatory transmitter that is not associated with the behaviorally-reinforcing effects of drugs) failed to increase bursting, indicated that general stimulation of cellular activity is an unlikely explanation of the facilitatory action of the burst-contingent injections.

Reinforcement delays exceeding 200 ms largely eliminated the reinforcing action of dopaminergic agonists. These findings support the conclusion that the behaviorally-reinforcing effects of dopaminergic, opioid, and cannabinoid drugs can be modeled *in vitro* at the cellular level.

Reinforcement, Principle of

Reinforcement refers to an increase in the probability of a behavior when the behavior results in a positive consequence. That behavior is determined by its consequences is one of the most important principles within behavior therapy (see *Behavior Therapy: Psychological Perspectives*) for understanding the origins, maintenance, and change of clinically-relevant activities. 'Reinforcement' can denote (a) a principle of learning or behavior regulation; (b) a procedure designed to modify the frequency of an approved

behavior (the verbal form 'to reinforce' referring to the contingent delivery of a positive stimulus); or (c) the consequence itself (also 'a reinforcer'). The term connotes 'strengthening' and what is strengthened is the likelihood of a behavior reoccurring in a specific context.

There is circularity in such a statement, as a stimulus event is judged to be a positive reinforcement to the extent that it actually increases the likelihood of the behavior that produced it. Thus, reinforcement is not quite the same as reward, since a reinforcer is defined in terms of what 'works' or functions to strengthen behavior, whereas a reward is identified by what an individual expresses a desire for, or enjoys. In practice, however, one selects reinforcements on the basis of prior experience, observation, and intuition that the planned consequence will be desired or enjoyable. When an organism will engage in a behavior that produces a consequence (food, praise, stimulation, or even apparently negative outcomes such as fatigue or annoying someone else) it is referred to as positive reinforcement; when an organism works actively to reduce or eliminate events currently in existence (such as cold, teacher demands, loneliness, boring activities), it is known as negative reinforcement.

Any previously neutral stimulus that signals the onset or further probability of a reinforcer comes to have reinforcing properties of its own, and is described as a secondary or conditioned reinforcer. Socially, money is the classic example. In applied contexts, a stimulus that has no value other than a designated rate of exchange with something desired is called a token reinforcement—often these are symbols such as poker chips or points that can later be exchanged for privileges.

1. History of the Concept

Reinforcement is closely linked to evolutionary principles, in that it represents adaptive functioning with obvious survival implications, and applies to all species capable of benefitting from experience. Its origin as a formal principle of modern psychology derives from Thorndike's (1927) Law of Effect: the occurrence of a 'satisfying' event 'stamps in' the behavior that was instrumental in producing it. Hull's (1943) influential learning theory proposed that the increase is in the strength of the association between a prior stimulus (cue or context) and the response, with the mechanism underlying reinforcement being the reduction in a basic biological drive. However, many stimuli can serve as reinforcers when they have only incentive value (such as a sweet but non-nutritive substance).

Much past research has been devoted to the question of whether reinforcement is necessary for learning to occur; the present consensus is that it is not. The question, however, may be a spurious one, since it is difficult to imagine a behavior that has no conse-

quences, and the positive nature of the outcome might be as simple as reducing constraints on the individual, or predicting future pleasures.

In the classical conditioning paradigm (see *Classical Conditioning and Clinical Psychology*), Pavlov also used the term to refer to the 'unconditioned stimulus' (UCS: the stimulus that evokes the reflexive response). When this stimulus is regularly paired with (predicted by) a neutral stimulus, the latter comes to evoke a somewhat similar response. The UCS is thus considered reinforcement, since its occurrence increases the tendency to emit a response in the presence of a previously neutral stimulus. Of considerable theoretical and practical importance is the phenomenon that when the UCS is removed and the previously neutral stimulus presented repeatedly, the conditioned response eventually ceases to occur. This phenomenon, as well as the procedure of removing the UCS, is known as extinction. It has an exact parallel in instrumental conditioning: if the overt behavior no longer produces the positive outcome, its probability decreases. This process is not simply the opposite of reinforcement; it is not unlearning or forgetting, but learning to do something else.

Although central to both conventional instrumental and classical learning situations, the concept of reinforcement has acquired much of its practical, applied implication from Skinner's (1969) paradigm of operant conditioning (see *Operant Conditioning and Clinical Psychology*). The typical laboratory procedure is for a specific 'operant' response, such as the pressing of a lever or push button, to result in the automatic delivery of a small amount of food for a hungry animal. The operants studied have been discrete, simple responses that can be repeated easily by the subject. A vast body of experimental research has demonstrated that the form, intensity, and temporal pattern (rate) of responding is a function of the rule specifying the relationship between the operant response, its consequence, and the context in which the consequence occurs (referred to as the 'three-term contingency').

2. Contingency Principles

The effectiveness of this procedure for developing or maintaining a specified operant is influenced by the immediacy and predictability with which the reinforcement is delivered. Although it will slow the acquisition of new responses, the reinforcement need not be delivered after every response, an arrangement called a 'partial schedule of reinforcement.' The most common are ratio schedules, in which reinforcement is delivered after a specified number of responses; and interval schedules, in which reinforcement is delivered to the first response occurring after a predetermined period of time has elapsed. In the laboratory, these

different schedules of reinforcement produce characteristic patterns of response rate. Analogies are often made with workplace contingencies; for example, if one is paid on a piecework basis it is a ratio schedule, whereas being paid every month is an interval schedule of reinforcement. Reinforcement can also be delivered after a variable number of responses or periods of time—gambling on a slot machine represents a variable ratio schedule.

Of greater importance for application is that partial schedules of reinforcement result in a behavior being highly resistant to extinction, such that the subject will persist in the behavior for long periods of time, even when the reinforcement has been withdrawn (extinction). In clinical situations one might think that a behavior is maladaptive as it is apparently not being reinforced and should therefore extinguish. If the individual's history of reinforcement were known, however, it would be recognized that this behavior may have been reinforced sporadically in the past.

The precise form of any behavior can be determined by differential reinforcement, in which the criteria for exactly what response will result in reinforcement are carefully specified. By changing or narrowing these criteria gradually, a behavior can be 'shaped' into a specified configuration. Similarly, it is quite common in practice to reinforce differentially decreases in an undesirable behavior, or reinforce differentially alternative, more appropriate behaviors.

3. Limitations in Generalizing from the Laboratory

Despite the substantial body of knowledge derived from studies of animal behavior, the analogy between the operant laboratory and real life has limitations. Laboratory contingencies are contrived—unlike foraging in the wild, there is no intrinsic relationship between a lever press and obtaining food. There are many comparable artificial contingencies operating in everyday life, particularly work settings, in which a person is reinforced with money, food, or favors, for activities desired by the individual controlling these reinforcers. But more commonly our activities are intrinsically as well as socially rewarding, for instance, reading a book is reinforced by enjoyment of the story as well as by teacher approval, or climbing a mountain may be reinforced by a sense of accomplishment in addition to the admiration of friends.

It has long been debated that if an activity which is usually reinforced intrinsically is placed under an artificial external contingency (such as a monetary payment), this will later interfere with the intrinsic reward, such that once the artificial reward is withdrawn, the frequency of the behavior will drop below its previously (intrinsically) reinforced rate (see Carton and Nowicki 1998 for a discussion). There is also

considerable overlap in practice between the concept of reinforcement and that of feedback—providing people with information regarding their task performance. Feedback too can impair performance, regardless of whether it provides information about success or failure, by directing attention to self rather than the task at hand.

Another major difference between reinforcement studied in the laboratory and the principles affecting human social behavior is that the verbal specification of a contingency can function much like an actual contingency. Thus, for example, people can be promised a reward for an activity and this will change their behavior. Skinner referred to this as ‘rule governed behavior,’ whereas more cognitively oriented theorists prefer to talk of expectancies. Bandura (1977), for example, argued that performance on a task depends partly on the expectation that a certain reward will be forthcoming (outcome expectancy). Another way an individual can learn about a potential contingency between a behavior and a reinforcer is to observe someone else being reinforced for an activity; this is known as vicarious reinforcement.

4. Motivation and Individual Differences

Most general behavior theories argue there is a link between reinforcement and emotion, for example, Staats’ (1996) A-R-D model, which proposes that stimuli serving as reinforcers (R) have simultaneous attitudinal (A) value (can elicit emotion) and discriminative stimulus (D) functions (can serve as a cue for approach). As active approach behavior and reward systems are linked in terms of neural processes, there are plausible biological mechanism for personality differences in the degree to which a given individual is responsive to positive outcomes. Relative sensitivity to reward over punishment may also be a characteristic of individuals exhibiting certain clinical syndromes, such as Attention Deficit Hyperactivity Disorder (ADHD), conduct disorder, and recent onset schizophrenia. There are also individual differences in preference for a small but immediate reinforcer as opposed to a larger, but more delayed reinforcer, a pattern that is generally considered to be maladaptive and detrimental to individual success. Humans are more influenced by reinforcers they have chosen than those arbitrarily selected by someone else. When environmental conditions deprive an organism of the opportunity to perform a particular behavior that would be engaged in a free choice situation, it will perform other activities in order to gain access to that behavior, a phenomenon sometimes referred to as the Premack (1965) principle.

Where reinforcement is artificial, such as a socially determined prize for a job well done, humans learn from prior experience the standard of performance

that deserves to be rewarded. Even young children are unlikely to appreciate a reward given for performance that is below their own standard. Thus, although self-reinforcement is often included as a treatment component for enhancing self-control, it is unlikely to be influential over and above the intrinsic satisfaction of accomplishing one’s own goals. Furthermore, if the outcomes achieved after much effortful behavior are less positive than expected, people tend to reevaluate the outcome in an upward direction (Lawrence and Festinger 1962).

5. Reinforcement as Behavioral Regulation

Much of current reinforcement theory in the operant tradition is concerned not with understanding the motivational features of reinforcement, but with predicting the effect on the distribution of available activities of different conditions of reinforcement. Neobehavioral theories that relate reinforcement to motivation (e.g., need reduction), have given way to economic-type theories that consider the sum total of potential behaviors in a situation as well as the sum total of reinforcements. One of the most important observations underlying this approach is that if there is more than one operant being reinforced (concurrent operant schedules), animals will distribute their responses more or less in proportion to the amount of reinforcement available to each one. This is known as Herrnstein’s matching law (see Noll 1995 for a discussion).

In answer to the apparent anomalies discussed in Section 3, reinforcement is depicted as a homeostatic principle, referring to how an organism must adjust its actions to meet the demands of the environment. An organism will normally distribute its activities so as to minimize the demands (e.g., effortfulness of the response) and maximize opportunities, and this optimum—when there is unconstrained choice—is known as the behavioral ‘bliss point.’ Once reinforcement is seen in this light, it gives credence to applied approaches in which there is an emphasis on enhancing choices and opportunities for individuals in otherwise deprived environments, or those with limited responses in their repertoire.

Theories emphasizing behavioral regulation propose that contingencies serve to constrain the organism’s free flow of behavior. Given the wide range of behavioral choices available to individuals in natural situations, it is logical that removing a reinforcement for one behavior will not be successful in reducing this behavior unless another, more socially desirable, behavior is able to be reinforced. Clinical research has repeatedly demonstrated the value of reinforcing more appropriate alternatives. Since the systems or economic model emphasizes that increases in one behavior must inevitably be accompanied by decreases in

others, extinguishing undesirable behavior and reinforcing appropriate responses may be two sides of the same coin.

6. Conclusions

While context/behavior/outcome contingencies are essential elements in the shaping and development of new skills, the reinforcing event itself has complex influences on human behavior and often serves as a cue initiating other activities. The effects of reinforcement are relative—related to the levels of reinforcement for other possible behaviors—which has important implications for designing environments that will support socially desirable activities. That there are motivational and emotional properties of reinforcement should not be underestimated, such as experiencing success, the relief of reduction in anxiety, or the satisfaction of a craving. There are also cognitive properties, with the history of availability being judged by the individual and influencing expectancies regarding the relative outcomes of different actions. Past experience with certain types of contingencies and deprivation experiences influence the way an individual will respond to a given reinforcement contingency. The relatively simple idea that all behavior has a function—achieves some outcome for an organism—and that function regulates or controls the behavior, is a critical insight for analyzing behaviors that one wishes to change. However, the reverse of this principle—that we can artificially manipulate behavior by managing its consequences—has proved more complex than it appears, partly perhaps because humans at least, resist the experience that they are being deliberately controlled.

Relapse Prevention Training

Many psychological and psychiatric problems are characterized by a temporal pattern in which symptoms are either chronic or vary in severity over a long period of time, with oscillations between remissions and return of symptoms. Substance-related disorders such as alcohol dependence are often relatively enduring, and mood disorders typically follow the second pattern of alternating symptom presence and remission. The empirical demonstration of the efficacy of psychotherapeutic interventions requires substantiation of the long-term benefits of therapies for such disorders (see *Psychological Treatments, Empirically Supported*). Accordingly, there has been a growth of interest in the development of therapeutic approaches that are designed to minimize relapse (or, conversely, maximize the maintenance of therapeutic gains) over extended periods of time. Relapse prevention refers to a set of procedures that designed to obtain long-lasting benefits. Marlatt and Gordon (1985) published the seminal work in the area of relapse prevention, in which they described a set of relapse prevention strategies for excessive alcohol consumption and other addictive disorders. This approach applies a cognitive-behavioral perspective to the problem of relapse and involves the employment of a specific set of treatment techniques. Other researchers have focused on relapse prevention for a diverse range of problems, adapting the original approach accordingly. Empirical support for the approach has been mixed, but there are some encouraging findings in relation to some specific problems. Methodological issues in the research place limitations on the conclusions that can be reached at this stage.

1. Conceptual Basis of Relapse Prevention

The term Relapse Prevention (RP) has been associated with a particular set of techniques as described by Marlatt and Gordon (1985). It can be argued that any approach which has as its clear goal the minimization of relapse (or enhancement of maintenance) might be construed as RP. Few approaches other than Marlatt and Gordon's RP, however, have been embedded in a

coherent theoretical framework that is intended to be generalizable across a variety of psychological or psychiatric problems. Cognitive and behavioral theories provide both the framework for the development of RP techniques and the conceptual basis for understanding why a particular person relapses and how best the problem might be ameliorated (see *Behavior Therapy: Psychological Perspectives; Cognitive Therapy*). Specifically, problem behaviors are viewed as arising from the influence of both learning principles (classical and operant conditioning) and cognitive appraisal processes (attributions, predictions, and other judgments). For example, a person's alcohol consumption is regarded as being (a) elicited by environmental cues (presence of stimuli associated with drinking such as a glass, bottle, certain companions, time of day) and (b) reinforced by its consequences (stress reduction or mood enhancement). Apart from environmental cues, a considerable amount of attention is given the role of cognitive factors in RP. Cognitive factors may include, amongst others, causal attributions or outcome expectations. Marlatt and Gordon's RP approach draws heavily upon the concept of self-efficacy (Bandura 1977) in its theoretical foundation (see *Self-efficacy*). Thus, methods which enhance a person's confidence that they will be able to perform the necessary behaviors and the belief that their performance will lead to an effective outcome, are thought to be the ones which are most likely to prevent relapse. A good deal of the research literature on predictors of relapse has focused on self-efficacy. For example, low self-efficacy about the performance of particular behaviors has been found to be predictive of relapse across several problem areas such as alcohol use, obesity, depression, and smoking. The underlying philosophy of RP emphasizes the notion that the maintenance period is an opportunity for the practice of newly acquired self-control strategies. Any 'lapses' that occur are viewed as being useful to provide information about the ways in which people identify, contribute to the occurrence of, or respond to, high risk situations. A 'lapse' may involve a return to the problem behavior on a single, specific occasion (or a small number of occasions), but a 'relapse' involves a repeated accumulation of lapses that approximate the level of severity of the original problem. From this standpoint, 'lapses' are seen as providing positive experience from which to draw important information that might assist in preventing future lapses, and, by implication, future relapse.

2. Relapse Prevention Strategies

In principle, RP procedures may be implemented at one of three different points in time, either as: (a) an integral part of the initial treatment program; (b) a discrete set of sessions that occur towards the end of treatment; or (c) a set of sessions that are spaced across

a period of time after the end of initial treatment. In the case of the latter approach, sessions may sometimes be more properly regarded as 'booster sessions,' especially if the predominant approach involves a continuation of the basic components of the original treatment or the use of prompts for the person to employ the techniques used in the original treatment. Most commonly, Marlatt and Gordon's RP is viewed as an integrated treatment which focuses on the concept of prevention of 'lapses' from the outset, and continues this emphasis beyond the normal period of treatment into a 'maintenance phase.' In practice, studies of the efficacy of RP differ in the precise details of the timing of the delivery of the specific components. These components include (but are not limited to) the identification of high-risk situations, preparation for any high-risk situations that have been identified, explicit rehearsal of coping skills, relapse-crisis debriefing, education (e.g., about the effects of drugs), and lifestyle modification.

The identification of high-risk situations represents an essential component of the RP approach. For example, it might be found that resumption of alcohol consumption occurs when the person has had a clash of opinion with a colleague or manager at work. A list of idiosyncratic high-risk situations can be obtained, based either on knowledge of the person's previous history or on the responses to self-report inventories of typical situations in which the person is asked to indicate (a) how often these situations occur, and (b) how difficult it is to engage in the desired behavior or not engage in the undesired behavior when such a situation arises. In the case of cigarette smoking, typical high-risk situations could be (a) having a cup of coffee; (b) sitting down to study at the desk; or (c) seeing someone else smoke. Learning to recognize that a high-risk situation is occurring or is imminent is a crucial part of the RP approach. People are taught to recognize the importance of 'apparently irrelevant behaviors,' exemplified by the gambler who chooses to drive home from work via a more scenic route (justified by the better view) when the route just happens to pass the casino. On the other hand, other high-risk situations may be more obvious, even to the individual, such as the person who travels business class by plane and is, therefore, likely to be offered free alcoholic drinks. RP is also connected with the concept of the 'abstinence violation effect.' This effect is thought to underlie the occurrence of a relapse in a person who has merely lapsed by breaking a pre-planned limit on daily alcohol or cigarette consumption. It is argued that once a person has broken the limit, they may fail to exert any further control over their behavior. RP decreases this emphasis on 'rule violation' by focusing on self-control and deriving useful information from the occurrence of any lapses.

RP involves teaching people not only to identify such situations as risky, but also to prepare themselves for reducing the likelihood of a lapse. Simulations of

high-risk situations can be used to provide opportunities to practice behavioral responses under supervision of the therapist. Many relapses are thought to occur following the occurrence of negative emotional states such as anger, depressive mood, and anxiety. Thus, RP involves the identification of such emotion-behavior linkages and the use of cognitive-behavioral strategies for the management of these negative states. Other lapses may be triggered by interpersonal conflict and may necessitate a heavier therapeutic focus on helping people to develop better communication and interpersonal problem-solving skills. In the case of addictive behaviors, there may be social pressure to engage in smoking, drinking or other drug taking. Preparation for dealing with such social pressure through assertiveness training may be incorporated into the treatment. Lifestyle modification is also employed in order to increase the frequency of engagement in pleasant, relaxing activities that may also be incompatible with the addictive behaviors.

3. Efficacy of RP

RP has been the subject of a number of experimental evaluations since it was first proposed as a treatment for alcohol and other addictive problems. Wilson (1992) reviewed the existing RP literature in the areas of alcohol problems, smoking, and obesity. Carroll (1996) also published a review of RP to a wide range of problems. Twenty-six studies, on substance use only (covering the years 1978 to 1995), were the subject of a meta-analysis conducted by Irvin et al. (1999). Even before considering the results of the empirical literature, the point needs to be made that there is surprisingly little research published on RP despite its presence as a concept in the treatment-outcome literature for about two decades. The drawing of firm conclusions is hampered by this relatively small body of literature, especially given the diverse types of psychological problems to which RP has been applied and the variety of procedural modifications that have been made in the published studies. A second cause for concern is the relatively short length of follow-up periods, especially given the explicit focus on relapse as an empirical issue. While it is likely that maintenance diminishes as time increases, and this appears to be the case (Irvin et al. 1999), it is not clear what type and level of resources need to be put into RP-based therapeutic endeavors to bring about meaningful results in the public health sense. With these, and other limitations in mind, the following tentative conclusions can be drawn.

The earliest controlled studies of RP were conducted on alcohol problems and it continues to be the main focus of attention for RP researchers. Varying degrees of success have been reported for RP in these studies. A number of methodological explanations may be offered for some failures to find differences between RP

and control groups in some studies, including low statistical power, ceiling effects associated with the success of the initial intervention, the brevity of the follow-up, and the sharing of common elements in the treatments. Irvin et al. (1999) conclude that, amongst the substance use disorders, the strongest positive effects for RP have been found for problem drinking, although even within this group of studies, the outcome variable that is associated with the best response is psychosocial adjustment rather than drinking behavior *per se*. Like problem drinking, relapse rates following smoking cessation programs are notoriously high. While some success has been achieved using booster sessions, these effects frequently are lost after the eventual termination of the booster sessions. Studies of relapse prevention strategies for smoking cessation have also yielded inconsistent results. In their meta-analysis, Irvin et al. (1999) draw attention to the relatively poor outcomes with RP in the area of smoking cessation. It should be noted that a few studies have been conducted on RP for illegal drug use. Cocaine use has been the subject of a small amount of research. As with smoking, evaluations of RP for these addictions have not been noted for their successful outcomes. Irvin et al. (1999) also conclude that the effects for these problems are weaker than those for alcohol problems.

The maintenance of weight loss following cognitive-behavioral treatment was the subject of a series of studies reported by Perri and co-workers in the 1980s (see Perri et al. 1992). In this research, behavior therapy plus relapse prevention training and contact after treatment produced the largest effects. Despite the sometimes positive outcome of longer-term treatment for obesity using adaptations of RP approaches, it is clear that the overall gains associated with treatments for obesity are often modest and that many people regain the weight loss during an initial treatment period.

Other psychological problems for which an attempt has been made to develop and evaluate RP approaches include depression (Wilson 1992) and sexual offending (Laws 1989). Although it is well established that relapse following an episode of depression is as high as 50 percent over a two-year period, there has been little systematic exploration of specific, psychologically informed RP methods for this problem. It is possible that focus on RP for some types of problems such as depression is misdirected because the major impact on maintenance may be derived from the potency of the initial cognitive-behavioral intervention.

4. Methodological Issues

There are several methodological problems in the study of RP and its effectiveness. RP clearly is concerned with long-term maintenance, but the relatively brief length of follow-up periods in many studies

places some limitations on the conclusions that can be drawn. The RP approach contains a number of specific components, but these components are not necessarily employed in all studies and it is not clear which components are necessary for the best outcome. In many studies, RP procedures have been mixed into a broader treatment, making it difficult to separate the effects of RP from those of other components. With some problems, such as depression, it would be preferable for research on RP to be conducted using samples of people who are at high risk for a subsequent episode rather than for all people who complete an initial intervention. In some studies, especially when the RP is being delivered following the completion of an initial broad-based treatment approach (e.g., cognitive-behavior therapy for depression or anxiety), there is a need to separate initial treatment responders from nonresponders. There is little point in examining the impact of a post-treatment RP on nonresponders to an initial treatment program because they have yet to demonstrate responsiveness to treatment. These methodological issues pose particularly difficult problems for which the solutions are generally costly and time consuming to implement.

5. Conclusion

Despite nearly two decades of research on RP, the research produced has been quite meager and many questions remain to be addressed or resolved. The studies of RP for any given problem are so few in number that it is difficult to draw any firm conclusions at this stage. Scattered through the literature, there is some encouraging support for RP in relation to alcohol-related problems, but strong conclusions are limited due to methodological shortcomings and the relative scarcity of studies. There is a need for a large-scale evaluation of RP with addictive disorders. There has also been some progress on the development of techniques for other problems such as obesity, depression, sexual offending, and health problems.

The field of RP research may benefit from greater attention to improving our understanding of the specific ways in which RP affects basic psychological processes (i.e., investigations of the mechanism of change). Further research is also needed on both general and problem-specific predictors of relapse for particular types of symptoms so that the RP approaches can be tailored more specifically to suit the features of specific disorders. The timing of the implementation of RP procedures also needs to be considered in relation to knowledge about the temporal patterns of symptom presence and remission that are characteristic of different disorders. Continued efforts to refine and develop novel variation on RP approaches to chronic mental health and physical problems should remain a high priority for research.

Relative Clauses

A relative clause (RC) can be defined as a subordinate clause which ‘limits the potential reference’ of a noun phrase (NP) in its containing clause, by describing a situation in which the referent of the NP participates. In the following examples, the RCs are enclosed in square brackets:

- (1) (a) The woman [who we met yesterday] owns the local supermarket.
- (b) We saw a lizard [which had a bright blue tongue].
- (c) The developer sent an update to every user [who registered the program].

The phrase ‘limits the potential reference’ needs some further discussion. In (a), the subject of the sentence is a definite NP which is presumed to refer to a single individual, who is being said to own the supermarket. The RC provides a substantial portion of the information needed to identify that individual (that we met this person yesterday), the ‘head’ noun *woman* providing the rest (that the person is an adult female). In (b) on the other hand there is no presumption of unique identification, but the content of the relative clause, ‘having a bright blue tongue,’ must be true of the object NP, so is limiting its potential reference. Example (c) is the most complex. Here, the NP that the

RC is delimiting doesn't refer to any specific individual, but we can still say that it is delimiting the reference of the NP, because the quantifier *every* indicates that if an entity satisfies the conditions indicated by the RC and the noun *user* (is a potential referent of the NP), then the developer sent that entity an update (see *Quantifiers, in Linguistics*).

A problem for defining RCs is provided by so-called 'Nonrestrictive relatives' (NRCs) such as this:

- (2) Lois was introduced to Clark, [who said that he had read all her books].

Here the bracketed clause is not really limiting the reference of the NP of *Clark*, since this is a proper name and presumed to identify an individual on its own. In some languages, such as English, NRCs show significant differences from ordinary RCs, while in others, such as Japanese, they don't (Kuno 1973, p. 233, Andrews 1985, pp. 28–9). It is not entirely clear whether NRCs should be regarded as a kind of RC or as a closely related construction.

1. Essential Structure

Since an RC delimits the reference of an NP by specifying the role taken by the referent of the NP in a situation, it needs to contain an internal position corresponding to the role of that NP, which can be called the NP_{rel} position. Many but not all contemporary syntactic theories postulate that the NP_{rel} position is occupied by an NP, which may be unpronounced, or moved from the normal location for an NP with that semantic role. In the RC (1a), for example, the NP_{rel} would be described as having the direct object role, and identified as the word *who* at the beginning of the RC, preposed from its usual post-verbal location.

From the viewpoint of formal semantics (see *Montague Grammar*), one can propose that RCs have the logical form of λ -abstracts on a variable in the clause, occupying the NP_{rel} position. For example, the logical form of *who we met yesterday* would be along the lines of:

$(\lambda_x) (\text{we met } x \text{ yesterday}).$

Such an expression is taken to denote the set of all entities such that if x refers to that entity, the sentence 'we met x yesterday' is true. If RCs are defined as clauses with this logical form, then NRCs can be treated comfortably as a type of RC.

2. Typology

The typology of RCs across languages can be organized in terms of two major parameters involving the position of the relative clause, and the treatment of

position of NP_{rel} within it, a variety of minor parameters involving other aspects of the form of RCs, and the extremely important topic of Accessibility, which will be deferred to the section on theoretical significance below.

2.1 Major Parameters

The first major parameter is the relationship of the RC to the NP whose reference it delimits. There appear to be five possibilities, falling into two major groups:

- (3) (a) The clause forms a constituent with the NP it modifies:
- (i) positioned after the head N of that NP,
 - (ii) positioned before the head N of that NP, and
 - (iii) appearing in an NP with no head N (alternatively formulated by saying that the head appears internally to the RC).
- (b) The clause doesn't form a constituent with the modified NP, but is a separate constituent:
- (i) at the front of the clause containing that NP, and
 - (ii) at the end of the clause containing that NP.

Types 3(a)(i) and 3(b)(i) can be illustrated clearly from English; all the examples above are 3(a)(i), while 3(b)(i) is illustrated by so-called 'extraposed' relatives like this:

- (4) A person was standing on the corner [who had a cockatoo on his shoulder].

Japanese provides perhaps the best-known examples of 3(a)(ii), which is widely found in verb-final languages, and sometimes in verb-medial languages such as Chinese

- (5) (a) Japanese (Andrews 1985, p. 27):
 Kore wa [ano hito ga kai-ta]
 this THEME that person NOM write-PAST
 hon desu.
 book is
 This is a/the book which that person has written.
- (b) Chinese (Li and Thomson 1981, p. 116):
 [Zhāngsān mǎi de] qìchē hěn guì.
 Zhangsan buy NOM car very expensive
 The car that Zhangsan bought was very expensive.

Example 3(c)(iii) is more exotic, but is commonly found in Native American languages. 6(a) is an example from Ancash Quechua (Cole 1987 p. 279), while 6(b) below is the corresponding 3(a)(ii) construction, also available in Ancash:

- (6) (a) [Nuna bestya-ta ranti-shqa-n]
 man horse-ACC buy-PERFECT-3
 alli bestya-m ka-rqo-n.
 good horse-EVID be-PAST-3

- (b) [Nuna ranti-shqa-n] bestya
man buy-PERFECT-3 horse (NOM)
alli bestya-m ka-rqo-n.
good horse-EVID be-PAST-3

The horse the man bought was a good horse.

In 6(a), *bestya-ta* 'horse' is playing the same basic function as the head N in an English RC, or in the 6(b) example, but both its position and its accusative case-marking are those appropriate to its function as NP_{rel}. Such constructions are often called 'head internal' RCs.

Finally, type 3(b)(i) is especially characteristic of (Indo Aryan) South Asian languages such as Hindi and Marathi (Srivastav 1991), although it is also found elsewhere, such as in Aboriginal Australia (Hale 1976):

- (7) (a) [Jo laRkii khaRii hai] vo lambii hai.
REL girl standing is DEM tall is
The girl who is standing is tall.

- (b) [Nyuntulu-rlu kutja-npa wawirri
you-ERG RC-you(SUBJ) kangaroo
pantu-rnu], ngatyulu-rlu
spear-PAST, I-ERG

kapi-rna purra-mi.
FUT-I(SUBJ) cook-NONPAST

I will cook the kangaroo that you speared.

These structures are often called 'correlative clauses,' and one can question whether they should be seen as a type of RC or a closely related construction.

Srivastav, for example, argues that they are in fact quantifying expressions which include reference delimitation in their function, rather than mere reference delimiters.

The second major parameter of variation in RCs lies in the treatment of NP_{rel}. There are three important and partially independent parameters of variation:

- (8) (a) Reduction of NP_{rel}:
(i) no reduction (NP_{rel} remains a full NP),
(ii) pronominalization (NP_{rel} is expressed as a pronoun), and
(iii) omission (NP_{rel} is not expressed).
(b) Marking of NP_{rel}:
(i) no special marking (NP_{rel} looks like an ordinary NP of a form that also appears in main clauses), or
(ii) a special 'relative' form is used for pronoun or determine of NP_{rel}.
(c) Change of position of NP_{rel}:
(i) remain *in situ*, or
(ii) move (usually to the front).

In both the internally headed RC of 6(a) and the correlatives of (7), NP_{rel} is unreduced. In standard English, NP_{rel} is either deleted or expressed as a special pronoun, which is furthermore moved to the front, perhaps accompanied by some surrounding material

- (9) (a) The people [we talked with *e*] were interesting.
(deletion from position marked with *e*)
(b) The people [who(m) we talked with *e*] were interesting.

(movement of relative pronoun *who(m)* from *e*-position), and

- (c) the people [with whom we talked *e*] were interesting.

(movement of relative pronoun together with containing PP).

In modern Hebrew (Borer 1984, p. 220), NP_{rel} can be omitted or reduced to an ordinary pronoun, which can either remain *in situ* or move to the front:

- (10) (a) Ra?iti ?et ha-yeled she- rina ?ohevet (?oto).
saw-I ACC the-boy that Rina loves (him)

- (b) Ra?iti ?et ha-yeled (she-) ?oto rina
saw-I ACC the-boy that him Rina

?ohevet.

loves

I saw the boy that Rina loves.

Pronominal NP_{rel} that remain *in situ* are often called 'resumptive pronouns.'

2.2 Minor Parameters

These are numerous; only two will be discussed here, clause introductory particles, and nominalization.

There may or may not be a clause introductory particle, which can appear instead of or in addition to a preposed NP_{rel}. In Modern Hebrew as illustrated in (10) above, the introductory particle is either *she*- (cliticized onto the next word) or *?asher*, and it is optional if NP_{rel} is preposed. In modern English, there is an RC-introducing word *that* which is optional, but can't co-occur with proposed NP_{rel}:

- (11) (a) The person (that) I saw was tall.
(b) The person who I saw was tall.
(c) *The person who that I saw was tall.
(d) *The person that who I saw was tall.

A somewhat more subtle form of variation is in clause-reduction. In the examples we have seen so far, the RCs are full-fledged finite clauses, but it is possible for them to become reduced. In Turkish, for example, when NP_{rel} is neither the subject nor contained in the subject (this is an approximation; see Underhill 1972 for further discussion), the subject of the relative clause is put into the genitive case, and the verb of the relative clause takes a nominalizing affix followed by cross-referencing as is normally applied to possessed nouns. The relative clause of 12(a) thus bears a considerable resemblance to the possessed noun phrase of 12(b):

- (12) (a) [oğlan-in git-tiğ-i] mektep
boy-GEN go-NOM-3SG school
The school that the boy goes to

- (b) Ahmed-in şapka-si
Ahmed-GEN hat-3SG
Ahmed's hat.

Lehmann (1986) observes that such reduction is especially characteristic of structures of type 3(a)(ii) (RC preceding head with NP), and is apparently absent for correlatives (type 3(b)(i)).

Many further potential features of relative clauses are discussed in typological surveys such as Downing (1978), Keenan (1985), Andrews (1985), and Lehmann (1986), and in the papers in Peranteau et al. (1972).

3. Theoretical Significance

The theoretical significance of RCs has derived largely from the study of 'accessibility,' the possibilities for the role of 'underlying position' of NP_{rel} within the RC. Historically, this seems to have been divided into two largely independent investigations. Ross (1967) (following on from earlier work by Chomsky) studied systematically what might be called the 'long distance' aspect of the function of NP_{rel}, the capacity of NP_{rel} to be located in a subordinate clause structure within the relative clause itself. Later, Keenan and Comrie (1977) investigated the question of what kinds of functions NP_{rel} can bear in a monoclausal RC.

The long-distance aspect of accessibility revolves around the ability of NP_{rel} to occur, and be moved, specially marked, or deleted in a wide range of environments, including from arbitrarily deep sub-clauses of the RC (NP_{rel} position marked with *e*):

- (13) (a) the book (that) Mary bought *e*,
 (b) the book (that) Mary thinks Jane discussed *e*,
 (c) the person (that/who) Mary thinks Jane spoke with *e*,
 (d) the book that Mary thinks that Susan says that Sam borrowed *e*.

This carries implications about the kind of grammatical theory required to describe languages; simple phrase-structure rules in particular are clearly not adequate, some kind of augmentation being required (in early generative grammar, it was assumed that grammatical transformations were required; subsequently, a wide range of alternatives was found).

Most important is the fact that in spite of the long distance possibilities for NP_{rel}, its positioning is, nonetheless, limited by principles which tend to be similar across languages. In most languages that allow movement or deletion out of subordinate clauses, for example, this cannot happen from clauses inside NPs (the complex NP constraint):

- (14) *the book that Mary believes the claim that Jane discussed *e*.

These constraints have been especially important for linguistic theory because:

- (15) (a) They apply to more than just relativization, but rather a wide range of apparent deletion and movement phenomena.
 (b) They appear in similar forms in many different languages (in both Irish and Hebrew, for example, the Complex NP constraint is observed when NP_{rel} is moved or deleted, but not when it is expressed as a resumptive pronoun).

- (c) It is not clear how they could be learned on the basis of direct evidence of the kind presumably available to children learning their native language.

They therefore raise fundamental questions about universal grammar and what it is that makes human languages learnable by children (see *Movement Theory and Constraints in Syntax*).

One of the more striking discoveries is that long-distance relationships appear to be composed of shorter ones; this was first proposed on theoretical grounds by Chomsky (1973), direct empirical evidence appearing in McCloskey (1977), where it was shown that in Modern Irish, clause introductory particles assumed a special form if they were in an RC, and contained that RC's NP_{rel} (McCloskey 1977, p.17):

- (16) (a) Meas mé gur thuig mé an t-úrscéal.
 thought I that understood I the novel
 I thought I understood the novel.
 (b) an t-úrscéal a mheas mé a
 the novel REL thought I REL
 thuig mé
 understood I
 the novel I thought I understood.

In 16(a) we see the normal form *gur* of the particle introducing a complement of the verb *think*, but in 16(b), when the object of this complement is a (deleted) NP_{rel}, the form *a* is used instead. Similar 'intermediate position' effects were discovered in other languages and collected in Zaenen (1983).

The other aspect of accessibility is the function of NP_{rel} in monoclausal RCs. Keenan and Comrie (1977) proposed that there was an accessibility hierarchy:

- (17) Accessibility hierarchy
 SU > DO > IO > OBL > GEN > OCOMP

such that any RC strategy would apply to NP_{rel} whose functions were a continuous segment of the hierarchy, and languages could always relativize subjects. In Modern Hebrew, for example, SU (subject) and DO (direct object) can be relativized by the deletion strategy, while pronouns (*in situ* or moved) can only be used when NP_{rel} is DO or below.

The validity of the hierarchy corroborates the universal significance of the grammatical relation concepts used in formulating it (see *Grammatical Relations*), and raises significant issues about their nature. For example, Fox (1987) observed that, in spoken discourse, it was relatively rare for transitive subjects to be NP_{rel} (10 percent), most NP_{rel} being either objects (45 percent) or intransitive subjects (45 percent). The high frequency of relativizing objects seems discrepant with a tendency for relativization to be restricted to subjects.

A solution is afforded by a reinterpretation of grammatical relations, in which the traditional 'subject' concept is split into one concept, associated with the semantic role of 'Agent,' and another with the semantic role of 'Topic.' This idea goes back to early work by Schachter (1997), in which relative clauses in

Tagalog constitute some of the evidence, and has been incorporated into many contemporary syntactic frameworks (see Manning 1996, Van Valin and LaPolla 1997 for recent discussion). Fox's observations then indicate that the grammatical relation at the top of the accessibility hierarchy should not be identified with the traditional concept of subject, but with the topic-oriented subject of this more recent work.

Relativism: Cognitive

Cognitive (or epistemological) relativism is the view that every belief is bound to some individual, group, place, or time—whence there are no objective, cross-cultural, and universal truths. According to it, what is true for us may be false for them. Hence, all beliefs would be equivalent. Whence there would be no point in searching for objective truths. Consequently, there would be no such thing as objective advancement of knowledge. Under cover of the search for truth there would only be struggle for power. Therefore, the task of the relativist would be to unmask ('deconstruct') scientific discourse and expose the powers lurking behind it. How this task can be accomplished without finding out what is really, truly the case, is not being explained.

1. Relations to Skepticism, Constructivism, and Postmodernism

1.1 Relativism is an Aspect of Skepticism

Cognitive relativism is an aspect of systematic (as opposed to methodological) skepticism. This is the view that truth is unattainable, whence 'anything goes.' It is part of anthropological relativism, and a frequent concomitant of axiological and moral relativism ('All value systems and moral codes are equivalent'). Relativism opposes absolutism, the view that all verities are both universal and timeless, hence uncontroversial. It also opposes scientific realism, which holds that there are universal truths, such as 'Agency and structure are mutually dependent.' But realism contends that, unlike mathematical theorems, propositions about matters of fact may be only approximately true, yet corrigible in the light of further discussion and new evidence. Thus, scientific realism is antidogmatic and moderate, whereas relativism is neither. In small doses, skepticism whets the appetite for research; in large doses, it extinguishes such appetite.

1.2 Constructivism Entails Relativism

Constructivism can be cognitive or ontological. The former holds that concepts and hypotheses are human constructions rather than either innate ideas or the product of revelation, perception, or intuition. On-

tological constructivism claims that the knower makes the world. Cognitive psychology has confirmed the hypothesis that all concepts and hypotheses are constructed rather than given. By contrast, ontological constructivism strains credibility. Moreover, it is destructive, because it dispenses with any tests aiming at checking whether a hypothesis matches the facts it refers to. In particular, it denies the difference between reality and appearance, which may be deceiving: it bans recurrent questions of the forms ‘What is really the case?’ and ‘Which of the two hypotheses is the truer?’

Whether ontological or epistemological, constructivism comes in two varieties: individualist and social. Whereas according to the former the individual is the source of everything, according to the latter the social group, in particular the scientific community, constructs whatever it studies, even natural things such as stars. Whether individualist or collectivist, ontological constructivism implies cognitive relativism. However, cognitive relativism can be held, and is usually held, independently of ontological constructivism. After all, it is logically possible to admit the reality of the external world while claiming that it is impossible to know it objectively, hence intersubjectively. Therefore, relativism must be evaluated separately from constructivism.

1.3 Relativism is a Component of Postmodernism

What is usually called ‘postmodernism’ in social studies and in philosophy is neither a worldview nor a method: it just boils down to the rejection of the ideals of rationality and objectivity. Cognitive relativism fits in with postmodernism because it denies the superiority of rigorous reasoning over ‘weak thought,’ as well as the possibility and desirability of attaining objective knowledge. It is unfazed by hard social statistics, or even by the findings of natural science. It ignores the difference between ‘I feel cold’ and ‘The room temperature is below the freezing point,’ and *a fortiori* between ‘That government is generally perceived as corrupt,’ and ‘The audits found that the government officials are regularly bribed.’

2. The Alleged Accomplishments of Cognitive Relativism

2.1 Relativistic Epistemology

Cognitive relativism is suggested by the multiplicity of simultaneous or successive rival views about many a domain of facts. Actually, such variety only goes to prove that scientific research does not guarantee instant, complete, and definitive truth, let alone instant worldwide diffusion. Experience shows abundantly that we often obtain approximately true data and

hypotheses, which can usually be improved upon. For instance, water was first regarded as simple and continuous, later as constituted by HO molecules, and nowadays as made up of H₂O molecules—and moreover as a mixture of light and heavy water. Scientific realism accounts for such successive approximations to the exact objective truth.

The denial of the possibility of objective truth has several consequences. One is that it discourages the very search for truth. Another is that it renders the idea of error unintelligible since, by definition, error is discrepancy from truth. A third consequence of relativism is that it regards all controversies as unending unless stopped by nonscientific means, such as authority or negotiation—which invites censorship. A fourth is that, by placing magical thinking on the same footing with critical thinking, it debases a key accomplishment of modernity. By the same token, it deprives people of a key tool to diagnose deceit and resist arbitrary authority.

2.2 Relativistic Sociology of Knowledge

Constructivist–relativist sociologists of science have been known to claim to study the sociology of peptides, rather than that of peptide-research laboratories. Moreover, they contend that scientific research is a kind of struggle for power, not truth. They miss the two main generally acknowledged motivations of basic scientists, namely curiosity and peer recognition. This explains why they have not helped explain the occurrence of any of the scientific breakthroughs in recent decades, such as the birth of tectonic plate geology, molecular biology, the neurobiological study of the mind, or socioeconomics. Understanding the search for truth requires realizing that this is what scientific research is all about.

Worse yet, although the constructivist–relativists talk much about power, they overlook the main loci of social power: politics, business, and organized religion. This explains why they have not studied such important facts as the campaigns against evolutionary biology; the budget cuts in pure mathematics, sociology, and the humanities under conservative governments; the persistent overlooking of naturalist (materialist) philosophies in the philosophy curricula; or the current toleration of charlatanism in the faculties of arts alongside the continuing demand for rigor in the faculties of science, engineering, medicine, and law.

2.3 Relativistic Pedagogy

If there is no objective truth, but only opinion, the teacher’s mission is not to teach but to promote the confrontation of rival views. In this view, the teacher is not a master craftsman but a moderator, and the student is not an apprentice but a discussant. This is in

fact how many university classrooms have functioned in the US and in Europe since the mid-1960s: not as learning centers but as debating clubs. Such transformation has had two effects, one positive and the other negative. The former consists in a lessening of the dogmatism, authoritarianism, and stodginess of traditional education. However, this liberation has also deprived students of the motivation and discipline required to learn difficult ideas and procedures—among them the art of informed rational discussion. Consequently, the graduates of relativistic pedagogy have few skills to sell. The most they can hope for is a university post where they can turn students away from serious learning.

3. Intellectual and Social Roots

Skepticism has waxed and waned in different periods since antiquity. It is likely that it prospers in times of social crisis, when the established order of things is challenged, and a number of individuals lose their old faith but are not yet ready to embrace any new belief system. In this connection, it has been claimed that relativism is a perverse effect of egalitarianism and liberalism. However, the Enlightenment and its heirs endorsed reason and science, which they regarded as universal. Their targets were despotism and religious dogma. Much the same holds for the Renaissance skeptics, such as Francisco Sanches and the early modern skeptics, such as Bayle, Montaigne, and Hume. But this does not hold for the ancient skeptics, such as Sextus Empiricus, who only criticized the ignorance and petulance of the professors of their time.

The postmodern skeptics, from the constructivist-relativists to the academic feminists and the 'deep ecologists,' are of a different color. Unlike the skeptics of old, they seldom argue cogently: typically, they just pile assertion upon assertion. Some of them attack reason and science out of horror of the nuclear bomb and other misuses of science. Others seem just alienated from the more rigorous, demanding, and rewarding disciplines. Some are suspicious of science because they confuse it with positivism. Others, because they mistake physical relativity (dependence of the values of certain physical magnitudes upon the reference frame) for cognitive relativism. Still others invoke either the Marxist thesis that ideas are produced by social classes, or the subjectivism inherent in phenomenology and hermeneutics.

The current vogue of cognitive relativism is further congruent with two contemporary social and intellectual currents and attitudes: individualism and uncritical nonconformism. The radical individualists, such as the members of the so-called 'me-generation,' claim that their own views are not inferior to any others. And the emotional non-conformists do not use social science to diagnose or cure social ills: they just revolt against all the powers that be—political, econ-

omic, and cultural. They mistrust or even reject the entire culture that comes with the social order they reject. In particular, they reject mathematics, science, and technology—some, for regarding them as tools of 'late capitalism.'

4. Conclusion

Cognitive relativism, like skepticism in general, has a grain of truth, namely, the thesis that all propositions about matters of fact are in principle fallible. But, to be realistic and fertile, fallibilism must be combined with meliorism, or the thesis that error can be corrected. What counts as truth in science and technology, even as partial truth, is universalizable. If a view is only acceptable to some people, then it is not scientific but aesthetic or ideological. Beauty may be in the eye of the beholder: truth is not. Unless this be admitted, it becomes impossible to distinguish science from pseudoscience and ideology, to tell science-based technology from quackery, and humanity from tribe. Worse yet, relativism undermines democracy and the rule of law, because both require rational debate and agreement about the truth or falsity of certain claims, such as, for example, whether the family is in decline, and whether 'wars on crime' work. In short, relativism paralyzes.

Relativism: Philosophical Aspects

1. Definition

Relativism is the view that cognitive, moral, or aesthetic norms are dependent on the social or conceptual systems that underpin them and consequently a neutral standpoint is not available to us. Relativists claim that standards of truth, rationality, and ethical right and wrong vary greatly between cultures and historical epochs and that there are no universal criteria for adjudicating between them. Relativism hence stands in opposition to universalism and absolutism. Although the first expression of relativism as a philosophical thesis is found in ancient Greece, it was only in the second half of the twentieth century that relativism became a prominent feature of various intellectual fields, including philosophy, social sciences, and literary theory. In recent years, post-modernism, in particular, has become identified with relativism.

2. Motivations

The appeal of relativism arises out of certain features of our experiences of the world as well as a number of intellectual currents.

2.1 The Indexicality of our Judgements

Many of our judgements and assertions refer to events that happen at a particular time, place, and are experienced by a particular individual. Such assertions seem to be true only at the time, place, or context of their utterance. For instance, the sentence 'It's raining today' is true at the time of writing it but may be false when uttered at a different time or place. This feature of our judgements has led some to argue that the truth of all our judgements depends on, and in that sense is relative to, their time and place, and context.

This argument for relativism, despite its popularity, is not very convincing. Sentences containing indexical

expressions such as 'this,' 'here,' 'now,' 'I,' etc., are abbreviations of statements or sentences containing references to specific objects, dates, geographic locations, and named persons. The content of an indexical statement can be made explicit in such a way that its truth or falsity would arise from specifiable events occurring at a particular time, place, or context. For instance, 'It's raining here today' is equivalent to 'There is rain in Dublin on September 12, at 5:45 local time, 1999' and that sentence is true or false irrespective of when or where or by whom it was uttered.

2.2 Perspectivalism

The perspectivalism of all our reports and experiences, the impossibility of having a view from nowhere, has been used to support relativism. All our judgements, beliefs, or assertions, it is claimed, are made from a point of view, a perspective. A God's eye view or a view from nowhere is not available to us. Perspectivalism goes beyond the mere indexicality of our judgements in that even a nonindexical judgement, for instance, 'there are nine planets in the Solar system,' is a statement made from a human perspective as we cannot step out of our skin, so to speak, and experience reality as it is. In addition, relativists assume, explicitly or implicitly, that different perspectives could not converge and therefore what is true or right from one perspective may not be so from a different one and consequently the truth of a judgement is relative to a perspective or point of view we have or we adopt.

2.3 Cultural Diversity

Increasing awareness of the extent of diversity of beliefs, practices, and customs of different cultures and different historical epochs has cast doubt on the universality and objectivity of our judgements. Most significantly, the reports by anthropologists about the thinking habits of remote peoples have led to the suggestion that all normative judgements, whether cognitive or ethical, may have only a local validity. Opponents of relativism argue that the extent and scope of diversity between different cultures and individuals is often exaggerated. Beyond the apparent dissimilarities, they argue, there are many core similarities which unify all human cultures and systems of beliefs. Relativists, on the other hand, believe that Western ethnocentrism and the intellectual legacy of the Enlightenment prevent us from appreciating or even seeing the uniqueness of different cultures and modes of thought.

2.4 The Disappearance of Old Certainties

The disappearance of old certainties, both in the religious and scientific arena, has been instrumental in the popularity of relativism in recent years. The collapse of a religiously motivated cosmology which

fixed the position of individual human beings within a larger and immutable framework and provided firm foundations for their ethical outlook helped to bolster a climate that was conducive to relativistic outlooks.

In science, the discovery of the possibility of non-Euclidean geometries followed by the scientific developments at the beginning of the twentieth century eroded the confidence placed in classical geometry and physics. Einstein's theory of relativity cast doubt on Newtonian physics and deprived it from the unassailable status it had enjoyed. The new theories in the area of quantum mechanics and particle physics, Heisenberg's Principle of Uncertainty in particular, often misrepresented and misunderstood, added to the belief that universal, absolute laws are rarer than it was once imagined.

2.5 Influence of Early Philosophers

In addition to the above intellectual and socio-historical influences, contemporary relativism is heir to the legacies left by earlier philosophers. The earliest documented source of relativism in the Western intellectual tradition is Plato's account of the Sophist philosopher Protagoras and his famous dictum, 'Man is the measure of all things; of the things that are, that they are; and of the things that are not, that they are not' (Plato 1961). As in twentieth century, the relativistic tendencies in ancient Greece were fostered by the increasing contact between the Greeks and other people; the realization that other societies may arrange their social and ethical beliefs and customs in radically different ways had a great impact on Greek thinkers. Relativism was subsumed under scepticism by the Pyrrhonian sceptics who in turn influenced Michel De Montaigne (1533–92) one of the most important figures at the outset of modern philosophy. Giambattista Vico (1668–1744) and Johann Gottfried von Herder (1744–1803) paved the way for historicism, which in turn has shaped twentieth century relativism. Contemporary relativists are influenced directly by the perspectivism of Friedrich Nietzsche (1844–1900) and the historicism of Wilhelm Dilthey (1833–1911).

According to Nietzsche, all claims of knowledge are representations of reality only from a certain standpoint. Reports of so-called 'facts' are statements of interpretation which could always be supplemented or replaced by other interpretations. Language is not a means of describing what there is, Nietzsche claims, rather it imposes its own interpretation on our thinking. Thus, the very idea of truth and reality is called into question by Nietzsche. Whether Nietzsche's perspectivism should be equated with relativism is open to debate. However, his writings have become a source of inspiration for postmodernist and relativist thinkers.

Dilthey also has influenced a relativistic understanding of social and historical conditions in con-

temporary hermeneutics and social theory through his argument that each nation can be seen as a self-contained unit with its own conception of reality and system of values. Different historical periods, Dilthey maintains, produce different norms and values, each of which is taken to be unconditional or universal. We cannot gain a correct understanding of social and intellectual conditions if we do not understand or take into account the inevitable historicity of all thought.

3. Varieties of Relativism

Relativism takes many shapes and forms. One way to distinguish between different types of relativism is to consider the questions:

(a) What is it that is being relativized?

and

(b) What is it being relativized to?

A reply to the latter question allows us to distinguish between subjective relativism (or subjectivism) on the one hand and social (or historical) relativism on the other. Subjectivists or subjective relativists argue that truth and falsity of all judgements and the right and wrong of actions are relative to the beliefs and opinions of the individual thinkers and actors. The view entails that the truth and falsity of our judgements come down only to what we believe or like. This type of relativism, although quite popular, is too naive and unsophisticated to be worthy of serious philosophical consideration. Subjective relativism rules out the possibility of disagreement and the very distinction between correct and incorrect judgements, for it turns all our judgements, as long as we believe in them, into correct or true ones.

Social (historical) relativism is the claim that the truth and falsity of all judgements and the right or wrong of actions are relative to their social, historical, and cultural contexts. According to this view, we are indeed in a position to distinguish between true and false beliefs and right and wrong actions and judgements, but only within the parameters of socially given norms and beliefs.

The most influential form of social relativism in twentieth century is known as 'cultural relativism.' Cultural relativism was inspired by the work of social anthropologists who conducted their fieldwork among tribal people. Ethnographic evidence seems to suggest that various groups of people hold systems of belief which according to Western standards are false, irrational, and even self-contradictory. The Nuer's belief that twins are birds or the Azande belief in witchcraft and oracles are some of the frequently cited examples.

Anthropologists distinguish between the methodological and the normative components of cultural relativism. The methodological principle enjoins the practicing anthropologist to refrain from taking judgmental positions on the people under study in

order to attain a greater degree of objectivity. The normative consequence of cultural relativism is respect for other cultures and value systems—which can manifest itself as an adherence to multiculturalism and avoidance of ‘ethnocentrism’ in contemporary Western societies.

One important stimulus for the adoption of cultural relativism has come from the study of languages of non-Western people. The work of Benjamin Whorf—known as ‘linguistic relativity’—is the locus classicus of this approach. Whorf’s study of American Indian languages, such as that of the Hopi, led him to claim that ‘we dissect nature along lines laid down by our native languages. The categories and types that we isolate from the world of phenomena we do not find there because they stare every observer in the face; on the contrary, the world is presented in a kaleidoscopic flux of impressions which has to be organised by our minds—and this means largely by the linguistic systems in our minds. We cut nature up, organise it into concepts, and ascribe significance as we do, largely because we are parties to an agreement to organise in this way—an agreement that holds throughout our speech community and is codified in the patterns of our language’ (Whorf 1956). According to Whorf, the Hopi articulate and hence perceive the world in terms of events rather than objects, and see time not in terms of duration as English speakers do, but as relations between events. Whorf’s principle of relativity states that ‘all observers are not led by the same physical evidence to the same picture of the universe, unless their linguistic backgrounds are similar, or can in some way be calibrated’ (p. 214). We see and hear and otherwise experience very largely as we do because the language habits of our community predispose certain choices of interpretation. In this sense, the worlds in which different societies live, he argues, are distinct worlds and not the same world with different labels attached to them.

Further ethnographic and linguistic studies have not supported Whorf’s hypothesis of linguistic relativism. Nonetheless his views have had great impact on the resurgence of interest in relativism in recent decades.

The attempt to answer the question ‘what is it that is being relativized?’ gives us a different set of subdivisions of relativism. Depending on whether cognitive or ethical norms are being relativized, philosophers distinguish between cognitive and moral relativism.

3.1 Cognitive Relativism

Cognitive relativism is the view that what is true or false, rational or valid can vary from society to society and culture to culture and we have no transcultural or ahistorical criterion for adjudicating between conflicting cognitive norms. Some main subdivisions of

cognitive relativism are relativism about truth, relativism about rationality and logic, and conceptual relativism.

3.1.1 Relativism about truth. Relativism about truth is the claim that what is true for one individual, or one social group, may not be true for another and that every effort to adjudicate between context-dependent standards of truth and falsity is bound to be futile. The truth of an assertion, so the claim goes, is relative to the beliefs, attitudes, and other psychological idiosyncrasies of the individuals, or more generally and commonly to the conceptual, or cultural, background of the persons uttering them.

Relativism about truth is the core of all relativistic positions since other subdivisions of cognitive relativism, and even moral relativism, are reducible to it. For instance, relativism about rationality can be expressed in terms of whether there are true (universal) standards of rationality. Relativism about logic may be restated as the question whether logical truths are relative to specific cultures or cognitive schemes or whether they are in any sense universal. Ethical relativism can be seen as the claim that the truth of ethical judgements is relative to the context or the culture in which these particular judgements are being made. In this sense relativism about truth is the most general and strongest form of relativism and the target of most criticisms of relativism (see Sect. 5).

3.1.2 Relativism about rationality. The relativist about rationality argues that various societies or cultures have different standards and criteria of rationality and we are not in a position to evaluate, or choose, between these divergent standards. For instance, Peter Winch has argued that since standards of rationality in different societies do not always coincide, we should use only contextually and internally given criteria of rationality in our assessment of the systems of belief of an alien culture. Winch, who based his arguments on Evans-Pritchard’s account of Azande’s beliefs in witchcraft and magic and who was greatly influenced by the work of the philosopher Ludwig Wittgenstein, argues that we can only use contextually and internally given criteria of reasoning and validity in our assessment of the systems of belief of other cultures, and hence we cannot impute irrationality or illogicality to the Azande. It does not make sense to speak of a universal standard of rationality because rationality means conforming to internal norms given by the language and society, i.e., the form of life in which the language is being used.

In more recent years, the discussion of the Azande material, coupled with a strongly relativistic interpretation of Wittgenstein’s views have led Barry Barnes and David Bloor to argue that not only standards of

rationality but also laws of logic, often seen as the necessary conditions for rational thought, are defined by and hence are relative to their social context. According to them the very distinction between valid and invalid modes of argument is relative to the practices prevalent in a given linguistic community or society and cannot in any sense be seen as universal. Bloor argues that there are no culture-transcendent rules of validity and inference. Different societies may have incompatible, but internally coherent, systems of logic and the norms of logical reasoning are relative to a background of cultural conditioning. According to Bloor, 'The Azande have the same psychology as us but radically different institutions. If we relate logic to the psychology of reasoning we shall be inclined to say that they have the same logic; if we relate logic more closely to the institutional framework of thought then we shall incline to the view that the two cultures have different logics' (Bloor 1976, pp. 129–130).

3.1.3 Conceptual relativism. Conceptual relativism is motivated by philosophical considerations about the relationship between human thought and the world rather than mere observation of cultural and historical differences, and for that reason it is both quite distinct from and much more sophisticated than other varieties of cognitive relativism. The roots of conceptual relativism rest with Immanuel Kant's (1724–1804) distinction between the data of our sense experiences and the principles of organization or categories we use to organize them. Kant believed that all thinkers necessarily apply the same categories or conceptual schemes to the undifferentiated flow of their experiences. However, once the distinction between a conceptual scheme and the content of that scheme was introduced, then it was easy to accept that there may be more than one system or scheme of organization and the idea of conceptual relativism was born.

One of the most influential versions of conceptual relativism in twentieth century was proposed by W. V. O. Quine (1908–2000). According to Quine, to be able to talk about the world and to cope with our stream of sensory experience, we must impose upon the world a conceptual or linguistic scheme or theory. However, it is possible to envisage a plurality of conceptual or theoretical frameworks all of which explain and predict our experiences of the world equally well. There are no determinate facts to enable us to choose between these different frameworks, hence what Quine has called 'ontological relativity' ensues.

The influence of Quine's views is widespread. Philosophers working in differing areas have explicitly, or implicitly, made use of his arguments to support their relativistic positions. We can see the impact of Quine's ontological relativism on the writings of Nelson Goodman and Hilary Putnam who have proposed very sophisticated forms of conceptual

relativism. Putnam, for instance, has denied that there is a fact of the matter as to even what counts as an object outside the standards set by a conceptual scheme. One and the same situation, according to Putnam can be described 'as involving entirely different numbers and kinds of objects' (1992, p.120). Different conceptual schemes will contain bits that are 'true' (or 'right') and bits that will turn out to be 'wrong' by the standards appropriate to the scheme itself—but we do not have an account of truth which would be external to, and independent of, all conceptual schemes.

It is important to note that most conceptual relativists, Quine and Putnam in particular, wish to distance themselves from cultural relativism which they think is fundamentally incoherent (see Sect. 5). Their brand of relativism is based on their theories of meaning and truth rather than the purported differences between cultural traditions.

Conceptual relativism has also influenced the philosophers of science, Thomas Kuhn and Paul Feyerabend, who have emphasized the role of different modes of reasoning at various periods in the history of science and have argued that scientific theories belonging to these divergent styles of reasoning are incommensurable. Kuhn has claimed that scientists working with different paradigms live in different worlds, Feyerabend has argued that a change of universal principles brings about a change of the entire world. Speaking in this manner we no longer assume that there is an objective world that remains unaffected by our epistemic activities, except when moving within the confines of a particular point of view. Kuhn's thesis of incommensurability rested on his assumption that scientific theories cannot be compared or assessed independently of the paradigms in which they are embedded. For Kuhn, each paradigm acts as a unique and untranslatable language or conceptual framework and since rival paradigms do not have access to a common criterion for adjudication, they cannot be compared and hence remain self-contained and beyond the critical reach of other paradigms. According to this understanding, incommensurability implies that evaluation of different conceptual schemes, cultures, or ways of life is impossible.

Subsequent to the first publication of *The Structure of Scientific Revolutions* in 1962, Kuhn, unlike Feyerabend, attempted to distance himself from relativism but his views remain an important source of inspiration for relativistically inclined thinkers in many fields.

3.2 Moral Relativism

Moral inquiry is concerned with how life should be lived and how human beings should behave towards each other and their world. Moral relativism is the claim that there exist diverse, incompatible moral

systems and there are no overarching criteria to decide between them. Moral relativists start from the premise that moral values are grounded on societal conventions, historical conditions, metaphysical beliefs, etc., which vary from one society or social grouping to another and argue that there are no neutral standards available to us for adjudicating between such competing claims. The truth or falsity, the appropriateness or inappropriateness of ethical beliefs, are relative to their sociohistorical backgrounds and moral beliefs cannot be assessed independently of their social framework.

Moral relativism is usually subdivided into descriptive and ethical (or meta-ethical) relativism. Descriptive relativism purports to be an empirical doctrine based on observation of diversity in moral judgements and moral values in different societies and at different times. There is widespread disagreement among individuals and cultures on issues ranging from capital punishment to abortion, from human rights to animal rights, and so on. Descriptive relativists go so far as accepting that there may be broad similarities in the core beliefs of different societies, for instance, injunctions against the killing of innocents, but argue that such shared values are given very different and even incompatible interpretations by different cultures.

Ethical relativists claim that descriptive relativism entails that all ethical judgements are relative to the culture or context in which they are made and that there is no unique criterion for adjudicating between them. Of course moral diversity is compatible with the possibility that there are right and wrong answers to ethical questions. But this would depend on having a dependable path towards the discovery of ethical truths or the establishment of a universal framework for arbitrating between incompatible moral claims. Ethical relativists deny this possibility because they claim that any rational decision making procedure will have deeply seated normative historical and cultural presuppositions embedded in it. Reason and rationality are themselves evaluative concepts, constrained in turn by cultural and historical influences and hence are incapable of leading us to a set of neutral universally applicable standards of evaluation. Thus, ethical relativists deny the possibility of convergence between conflicting ethical frameworks.

Ethical relativism can be embraced independently of cognitive relativism. Ethical relativists may agree that convergence between diverse world views and theoretical frameworks is possible in the natural sciences but deny that this is the case in the realm of ethics. According to this view, moral precepts and judgements are not part of and do not pertain to the natural furniture of the universe. They are man-made and would not exist independently of human actions, beliefs, and customs, hence, there exists a fundamental difference between scientific investigations and moral enquiry.

Ethical relativism is often associated with tolerance and open-mindedness. It is sometimes argued that ethical relativism is itself a normative doctrine insofar as it prohibits interference with the ways of life and moral practices of other cultures. But this degree of tolerance can also lead to moral indifference and even nihilism. A relativist does not have the certitude to condemn genocide, torture, child abuse, etc., so long as it is argued that such actions are part of the fabric of the social life of some cultures and peoples. Furthermore, if ethical relativism is true then even tolerance and noninterference could not be seen as a universal ethical value and could not be recommended to those who do not already embrace it.

4. New Developments

Relativism has gained support from two recent philosophical developments. A new variety of relativism has been introduced through the work of the neo-pragmatist philosophers, the most prominent among whom is Richard Rorty. Although Rorty denies the charge of relativism he does believe that truth, rationality, and objectivity are all defined only in terms of the practices of a community. Furthermore, he argues that no external questions can be asked about the relationship between the practices of a community and a reality that exists independently of it. 'Objective truth,' then, for Rorty, is simply the best idea we currently have about how to explain things. The argument supports relativism insofar as it identifies truth with (best) views current in a society at a given time.

The work of postmodernist cultural and literary theorists has been hugely influential in establishing relativism as one of the strongest intellectual currencies of recent times. Jacques Derrida's proposed deconstruction of Western ideas of logic, truth, and rationality has been seen as a harbinger of a new intellectual era free of the logocentrism and phallogocentrism of Western rational intellectual traditions. Derrida, like Rorty, has denied that he is a relativist but his own and his fellow postmodernists' writings lend themselves easily to relativistic interpretations.

5. Arguments Against Relativism

Relativism has been challenged on several grounds.

5.1 The Self-refutation Argument

The most common criticism leveled against relativism is the charge of inconsistency. The argument goes back to Plato and the main claim is that relativism, at least in its stronger form of relativism about truth, is either

inconsistent or incoherent because of the dubious status of the claim that 'truth is relative.' It is suggested that if 'truth is relative' is itself true unconditionally, then there is at least one truth which is not relative, and hence relativism is not true. If, on the other hand, 'truth is relative' is true only relative to the relativist's framework, then the claim is devoid of significance. To avoid inconsistency a relativist should accept that 'truth is relative' is itself only relatively true, i.e. true only for people who suggest it, but then she or he would not be in a position to try and convince a non-relativist of the veracity of the claim. The relativist is condemned to silence.

5.2 *Argument from Translation*

A new type of criticism of relativism has surfaced in recent years directed at the intelligibility of the claim that one and the same statements may be true for one linguistic community and false for another. Donald Davidson, one of the main advocates of this position, argues that all types of relativism rely on the assumption that there can be radically divergent conceptual schemes or systems of belief. In order to ascertain that a system of belief or cognitive scheme diverges from ours in a significant manner, he argues, we first need to identify such a scheme. In order to identify something as a belief we must be able to interpret it (or translate the sentence expressing that belief into our language). But, to translate a sentence or to assign meaning to it, we will have to regard that sentence, or the belief system underpinning it, as true or in agreement with us. A correct understanding of the beliefs and other propositional attitudes of a person, Davidson maintains, leads to the conclusion that most of her beliefs must be true. If this argument is right, then relativism cannot even get started, because arguments for relativism are built on the premise that there are, or can be, fundamental cultural and conceptual differences between human beings. If this assumption is untenable, then so is relativism.

5.3 *Evolutionary Arguments*

The origins of this approach can be traced to Quine and his infamous dictum that natural selection guarantees that organisms would know many truths and abide by the laws of logic and rational cognitive procedures or become extinct. The philosopher of mind, Daniel Dennett, following Quine, has argued that natural selections guarantee that most of an organism's beliefs will be true and most of its strategies rational. 'True' and 'rational' have to be interpreted univocally, therefore we have empirical grounds for rejecting the possibility of relativism about truth and rationality.

Relativism has survived 2,000 years of attempts to bury it. Its perennial appeal and periodic fashionability are due to its ability to capture and express an essential insight, be it in an exaggerated fashion, about the human condition. The insight that we live in a world of pluralities and do not have access to univocal answers to our diverse problems.

Relativism, Pluralism, and Skepticism (Philosophical Perspective): Cultural Concerns

Few terms in our critical language are as ambiguous as pluralism and relativism. Under diverse definitions, their relationship could be said to range all the way from twins to deadly enemies. Both have been accused by some monists as furthering rank skepticism or nihilism. Meanwhile, defenders have vigorously denied that either term necessarily entails utter skepticism, or Pyrrhonism, or what Bernard Williams has called vulgar relativism. This article pursues pluralism as the best escape route from naive dogmatism and naive (hyperskeptical) relativism. (For a useful, though somewhat superficial, history of skepticism, especially in the Renaissance, see Popkin 1979.)

Almost every serious critic would agree that some extreme forms of either term can lapse into the kind of skepticism or nihilism that threatens genuine intellectual inquiry or achievement. Genuine inquiry is doomed if no claim to ‘truth’ has any validity except for the claimer, and no one thus has any real reason to listen to the arguments of anyone else. Fortunately, more and more postmodernists, some of whom for a while edged towards such utter skepticism, have attended to diverse cogent attacks on the ‘vulgar’ or ‘total’ forms of doubt. They have acknowledged that all arguments for total nihilism are paradoxically self-destructive; no one can offer a coherent defense of utter skepticism without violating that defense by claiming to offer, unskeptically, this one coherent defense. What is more, the would-be utter skeptics usually reveal many other deep commitments that contradict their skeptical claims. Meanwhile, many have argued that the term relativism need not be identified with nihilism (Pepper 1942, Williams 1972, Shweder 1989, Goodman 1978, Rorty 1989, Krausz 1989).

Cultural relativism—‘though truths exist, they are always relative to some cultural placement’—has been

much more successful in resisting attacks from defenders of hard truth of various stripes. Its defenders have ranged over a vast diversity of arguments. Some have moved dangerously close to utter skepticism by implying, but never stating, that whatever any given culture claims is true must be true, even if it entails mass genocide or the ritual torture and murder of the innocent. At the opposite extreme, some have labeled our ‘scientific,’ ‘rational,’ ‘antisuperstitious,’ ‘intellectual’ culture as inherently, self-evidently superior to all the naive, primitive, ‘believers’ in claims that violate scientific convictions. As Shweder describes the way too many rationalists, including professed cultural relativists, have viewed the world:

Nature is mindless, objective, and visible. It is empty of such unseen, unobservable, meta-physical things as god, sin, obligation, value, morality, and so on. If such things exist at all, they exist only as reality-positives in the mind. And if they exist only in the mind, they are not objective and thus ought not be (sic) allowed to be constraining. If human beings feel constrained by such things, it is only because, not yet realizing their essential nature (self-determination), they do not distinguish between truth and poetry, confusing, quite irrationally, external reality with what exists nowhere else but in their minds (Shweder 1989, p. 121).

Even when we follow Shweder and rightly reject such extremes and decide that truths do exist, though in multiple forms, we are still faced with the complex problem of how to deal with that multiplicity. For cultural pluralists who refuse to dodge the problem, the best possible method is to search for common ground that underlies surface differences. (Sometimes they—we—stumble upon another route, after the probing: ‘By studying my opponent carefully I have learned that I was wrong and he/she was right; now my pluralism includes memory of my previous error.’) When for example we discover that every culture, including the most rationalistic versions of our own, exhibits some form of embrace of an unprovable ‘transcendent’ ‘world’ or ‘reality’ or God, we no longer have good reason to consider religious commitments absurd: they are shared by all cultures. Again to quote Shweder 1989:

In that (our) post-Nietzschean world God is not dead; only positivism and monotheism are dead. Polytheism is alive and well. Its doctrine is the relativistic idea of multiple objective worlds [including the world of scientific rationalists], and its commandment is participation in the never-ending process of overcoming partial views (pp. 132–3).

1. Plurality of Thought-modes

Once we embrace that form of cultural pluralism, value-terms like ‘dead’ and ‘partial’ turn our problem in the direction of philosophical inquiry: how to deal with plurality not just of culture systems but of

thought systems, including value judgments. Even those 'rationalist' philosophers who are totally anti-relativist, antiskeptical, exhibit a plurality of conflicting thought-modes. Too many have faced that conflict with either passionate commitment to 'the one true system' (such as the positivism that most of us, including most professional philosophers, by now question) or the philosophical skepticism that Richard Rorty and Stanley Fish and many others have at times edged toward (even while claiming not to).

What has been too often ignored by those who justifiably attack the first of these paths, dogmatic monism, is the problem of how we are to deal with that plurality of 'contexts' or 'belief systems,' or 'structures of thought' or 'thought-modes' to which all of our assertions are 'related.' Every thinker has to admit that all thinking takes place in a conceptual context in which all assertions are interrelated, interdependent for their full understanding; even claims to factuality have different meanings in different thought-modes. Yet only careless extremists can deny that some 'contexts' are better than others: truer, or 'fuller,' or less vulnerable to refutation.

The pluralistic problem can thus be summarized like this: a devoted, honest Nazi who asserts that the commitment to the one superior race with its superior values justifies genocide, employing as evidence some 'facts' about past misbehavior of Jews and amazing achievements of Aryans like Beethoven, is asserting facts that though in one sense are context relevant, cannot be claimed by an anti-Nazi to be just plain nonfactual. But how, then, can one assert, as we all would, that the entire context of such Nazi thinking is just plain wrong, without falling into dogmatic assertions that are finally totally dependent on an equally unprovable cultural context? How finally do we avoid a form of relativism that grants the Nazis equal intellectual status?

2. Truth Exists—in Multiple Forms

The only possible answer is to develop some form of 'systems pluralism' that allows for distinctions among a plurality of defensible systems and a plurality of inferior, less defensible systems. While there is a genuine plurality of 'truths,' genuine truths that are of equal validity and systems that are universally true in the sense of being irrefutable, no one of them is universally true in the sense of being easily either translatable to other 'systems' or immune to seeming refutation from other 'truths.' But that collection of irrefutable context-systems or thought-modes does not mean that other systems or modes cannot be shown to be inferior. The Nazi illustration reveals that one particular belief system can be finally rejected, first because it will be condemned by every other major mode of thought, and second because its disastrous consequences are revealed by history, as they finally

were to Heidegger when he faced the consequences of his early Fascist thinking.

The history of philosophy, like the history of various cultural relativisms, can be seen as an implicit demonstration both that genuine truth exists, in a variety of defensible forms, and that the diverse forms are never easily intertranslated in intelligible form. Indeed, in most versions, 'believers' believe that they can, in using their own version of truth, refute the other versions (see Russell 1948, as an example of careless refutation of all modes but his own).

The clearest support for a plurality of legitimate thought-modes (along with a larger plurality of illegitimate ones) is found in the ways in which the major, great, surviving philosophies conflict, at least on the surface, and yet reveal immense capacity both to seem to refute other systems and to genuinely resist refutation from the others. In a short discussion, it will be impossible to demonstrate this case fully (for extended treatment, see Booth 1979, Garver and Buchanan 2000, Booth 2000, McKeon 1951).

3. McKeon, the Greatest Pluralist

To me by far the most penetrating of the many efforts to face plurality is that of the much-neglected Richard McKeon. As McKeon probed major thinkers throughout history, he more and more aggressively asserted that there are a small number of absolutely irrefutable (yet seemingly conflicting) thought modes, while there are many totally refutable modes and many other half-defensible but truncated modes. Having pursued every major thinker to the depths, he developed the notion of what his best defender, Walter Watson, has called 'reciprocal priority'—what might be called 'reciprocal irrefutability' (see Watson 1993, the best single introduction to reciprocal seeming refutation and actual nonrefutation; it is based on the lifetime work of Richard McKeon).

McKeon's classification of defensible modes became increasingly complex throughout his life, and it cannot be summarized here, as is evident in his final, most complicated chart, which was not published until after his death (see Fig. 1).

Such complexities may well obscure the validity of his basic project, which was to reveal how first-class philosophers, irrefutable philosophers, have approached multiple truths with valid thought-modes that differ in many conflicting ways, especially in four major matters: (a) what is the proper subject matter, or definition of subject matter ('Modes of fact') of what we should think about; (b) what 'unprovable' first principles, or notions of the 'modes of being,' should one proceed from, taken as unquestionable; (c) what methods are the proper methods ('modes of thinking') for solving all problems; and (d) what is the point of it all, what are the true goals of human thinking. In my view his philosophical multiplicities could well serve as

Figure 1

McKeon's final classification of defensible modes (Printed posthumously in *Selected Writings of Richard McKeon*, Vol 1, 1998, p. 218, University of Chicago Press)

a rescuer of those who fear that cultural relativism will inherently destroy such terms as truth or objectivity or reality.

3.1 Definition of the Subject Matter: 'Things,' 'Thoughts,' 'Words,' 'Actions'

3.1.1 Things. The most famous of the classical philosophers agreed that what we should pursue is reality, 'what really is,' substance, being, actuality: whether air, water, fire, atoms, or ideas. Plato always operates with a strong conviction that there are some general truths, or principles, or ideas awaiting our clumsy efforts to discover them. His definition of the subject matter (the world, the universe, the nature of things, the One) is always implicitly a world in which Truth, Goodness, and Beauty are interrelated, harmonizable: a One that can, in theory, finally harmonize it all, even though no one thinker can capture it. Many modern cosmologists begin with a surprisingly simi-

lar pursuit of a supreme truth that is 'really there'—nature and its laws: this or that final theory will explain it all. For all of these, we should begin with some picture of the real, and then move from it to whatever questions arise about the rest of life.

3.1.2 Thoughts. Again and again, as McKeon traces brilliantly, philosophers have concluded that you cannot really begin there, with Being, struggling with ontological questions, because the picture of real reality always depends on how we think about it, and that leads to a take-over by one or another form of epistemology. Follow Kant and begin your thinking by thinking about thought, not about things or substance.

3.1.3 Words. That shift from subject matter to mind has again and again broken down as philosophers concluded that how we think depends on the

language we think with, so we should begin not with thought but with language. Especially in the twentieth century, more and more thinkers took their beginnings in language. For just about everybody thought had to begin with language. So-called analytical philosophy took over, as it had done for some 'skeptics' and 'relativists' throughout the ages, for a while, and later the deconstructionists produced a seeming revolution by claiming that language itself has no real substance.

3.1.4 Actions. Finally, the linguistic revolution has repeatedly been revolted against, by those who see action as the proper subject, the place to begin. Pragmatism in various forms has been seen as the true subject of true thinkers; inevitably they work back up from language to questions about abstract reality, ontology, epistemology, and linguistic analysis, but they always place action—with success and failure of action—at the top of the definition of subject.

3.2 Principles about 'Reality'

3.2.1 Comprehensive whole. Many philosophers, like Plato and some modern cosmologists, put as top priority a conception that there is some whole, some totality, some supreme collection or unity of all truths. Reality consists of that comprehensive unity or totality.

3.2.2 Multiple problems produced by the incomprehensible whole. Others like Aristotle while still in one sense pursuing the whole, see the philosopher's basic principle as to 'pursue truth about this or that particular aspect, or problem,' concentrating on solving the problems. Many such pluralists see no hoped-for 'top' but a collection of diverse subjects and problems; there may be a 'one' uniting them, but for us the world is multiple, created by and consisting of many causes and possible solutions.

3.2.3 Least, parts: 'atoms,' 'sensations,' etc. In contrast, philosophers like David Hume and many modern scientists put as the 'top' of their reality a kind of bottom: elements or particles or epistemological certainties from which they can reason upward to larger truths. Like some particle physicists, they hope to discover, by probing the depths, truths never even dreamed of by those who pursue the 'heights,' and those truths—whether about our most minute sensations or the most minute physical particles, will be totally irrefutable from the other perspectives.

3.2.4 Operational, pragmatic problems: truth is what works. Finally, philosophers who, like Cicero and other rhetoricians, put as top priority the successful operation of the practical world, beginning with questions of just what our pragmatic goals are, can build from their pursuit truths about life that may conflict irrefutably with many of the truths that the other three pursuers have proclaimed.

To say all this does not mean that the four choices of first principles will not reveal, down the line, agreed-upon truths. Many of the undeniable truths that each mode uncovers will be considered undeniable by each of the others. For example, it is always wrong, in principle, in all of the defensible systems, to violate the moral principles that you think your system has revealed, and many of them overlap those revealed in other systems. It is always wrong, in all systems, to deliberately, dishonestly, fabricate evidence to support your system. And there are many other overlapping moral principles, such as the relation of Cicero's 'Civility' to Aristotle's 'Ethics' and Plato's 'goodness' and Hume's moral standards, and the moral commands issued by John Stuart Mill's utilitarianism.

3.3 Methods

Major thinkers have always disagreed about just what methods are effective in yielding proof. Depending in part on their first principles and their definitions of the subject matter, they have ranged from the absolutely deductive synthesizers to the absolutely inductive analysers, with some pragmatists and linguists urging some middle ground of cooperative thinking and testing, not induction or deduction but what could be called co-duction. Plato always falls back on dialectic, even when exploring rhetoric and logic. Aristotle insists on a plurality of methods to meet a plurality of subjects and problems. Consider the contrast between that and the method of Hume, or of other thinkers who begin with the assumption that the true method of inquiry is to work analytically with the indivisible parts of the universe, not some ideological whole, and then to reason analytically 'upward' from those elementary parts. Whether or not such methods lead ultimately to this or that ontology or metaphysics, it is the right way to work.

Thus, without troubling too much about whether one will ultimately find a total view of everything, analytical reductionists know that they are dealing with reality, tough hard reality of the multiple parts. The more defensible among them generally have accorded a place for diverse methods, but some partial or flawed thought-modes have tried to reduce it all to one grand method, as modern scientists too often reduce everything to empirical demonstration of only one of Aristotle's four causes: the efficient, or mechanistic, or 'horizontal' bump-and-grind reality.

3.4 Goals

The diversity of goals is to a large degree implicit in all these other varieties. The goal of thought is to improve truth, for the sake of truth. No, the goal of thought is to improve conditions in the world, for the sake of what Plato called goodness. No, the goal of thought is to pursue beauty, proper kinds of eros, religious ecstasy, some transcendent escape from shitty reality, salvation.

For the monist or dogmatist, the goal is to demonstrate that there is only one right view of principles, subject choice, methods, and goals. For the pluralist who rejects vulgar relativism or skepticism, the goal is both to pursue some one or another of the major, irrefutable modes or, even better, to pursue what is the common ground among the defensible modes, thus demonstrating their defensibility.

The suggestion, in this cursory summary of just one brand of philosophical pluralism, is that all thinkers in all subjects—philosophical, religious, anthropological, political, literary—could reduce pointless debates about truth and objectivity if they thought harder about just which definitions, principles, methods, and goals they are depending on.

4. The Plurality of Pluralisms

One unavoidable problem for anyone who chooses the pluralist route is the immense complexity of modes and the rivalry of pluralisms in dealing with the modes. The rivalries often lead many of us pluralists to retreat, as we sometimes observed McKeon doing, to some version of 3.2.4, a loose-jointed ‘operationalist,’ ‘rhetorical,’ or ‘practical’ (pragmatic) corner of the chart, with an emphasis on how to improve the world by improving thought about it. But even as we do so we have to recognize that other thinkers, in contrasting modes, will be discovering truths that we ignore.

We thus end with a plurality of pluralisms, some more defensible than others, just as cultural relativists end with a plurality, some more defensible than others. All of the pluralisms are ‘relativistic,’ in the sense that within each system every claim, even a claim of fact, is relatable and to some degree dependent on the total thought-mode. Conclusions within a given mode are testable within that mode, and will often even prove to be testable and acceptable within other modes. But no one system is totally refutable by any other system, even when all other systems agree that one system is flawed.

Thus, serious explorers of the issues ‘relevant’ here have two main choices, whenever they find that no one controversy seems resolvable: retreat to the study of some one cultural system or thought-mode, ignoring the others, or pursue the mission of finding common ground among the conflicting systems. Only this second choice can avoid dogmatism, on the one hand,

and on the other skepticism, reductionism, and nihilism, both directions producing absurd destruction of meaningful inquiry.

Reliability: Measurement

Whenever an aspect of human behavior is measured, the question always arises: how good is the measurement process? In the behavioral sciences, conceptual and statistical models for answering that question are generally divided into two major categories: reliability and validity. As a first approximation, one may think of validity as concerned with whether the right construct is being measured. Reliability as concerned with the issue of how well we are measuring whatever it is that is being measured (regardless of whether or not it is the right quantity to measure). When choosing a measurement method, one must consider both of these issues; the total error of measurement comes from both the unreliability and invalidity of a measure. While this article primarily concentrates on reliability, it also discusses the measurement process as a whole, and the relationship between reliability and validity issues.

As with many terms, the scientific and psychometric uses of the word 'reliability' derive from, but are different than, the everyday use of the term. In everyday life, a car would be considered reliable if it started every time. If the word were used in the technical sense, one would also say that a car was reliable if it never started; it would only be unreliable if it sometimes started, and sometimes did not. The technical term, in other words, is more concerned with consistency of behavior, regardless of where the behavior is on a scale. The main question is whether one gets the same answer every time a measurement of an individual is made. Whether that measurement is then useful is a question of validity; a measurement procedure could be perfectly reliable but useless.

Reliability theory generally begins with a conceptual framework, which is then translated more formally into a statistical model. Most reliability theory is concerned with a particular type of measurement instrument, multiple-item tests, and some theory is applied in an even more limited setting of items that are scored dichotomously as true or false. The three most commonly used models are (a) classical test theory, based on factor analysis; (b) generalizability theory, based on analysis of variance (ANOVA); and

(c) item response theory, based on 'latent trait models.' Other statistical methods are usually needed for dealing with measurements that are either not tests, such as observations of behavior, or are not multiple-item tests. While much of measurement theory (and terminology) originally derived from consideration of ability tests, the theory applies equally well to many other areas of behavior, such as personality assessment.

1. Classical Test Theory

Classical test theory (CTT) is based on the assumption that a single underlying dimension (a trait or skill) is being measured, and that every person has a single true score, T , on that dimension. The underlying dimension or test domain may be more or less 'pure'; for example one might think of skill in (a) doing multiplication of 3-digit numbers, (b) solving algebra word problems, or (c) solving college mathematics problems. The important consideration is that all items on the test are measuring this skill or trait, and that the skill or trait is well defined. Each person's observed test score, X , is assumed to be determined by his or her true score T plus some error of measurement, e , which would either raise or lower the observed score relative to the person's true score. The basic equation of classical test theory is therefore:

$$X = T + e \quad (1)$$

in which the quantities are as defined above, and the errors are assumed to have a mean of zero and to be uncorrelated with (unrelated to) T .

What exactly does T represent? Conceptually, the definition requires a bit of imagination, and tolerance for ambiguity: imagine a person being tested over and over again, using different sets of items selected from the collection of all items designed to measure the underlying construct. (A test may consist of any number of items, including the special case of a single item, such as an essay.) The average of all these scores (more technically, the expected value) is the person's true score T .

The first major consequence of this model is that the variation among observed test scores (σ_x^2) is the sum of the variation in true scores (σ_T^2) and the variation in the errors of measurement (σ_e^2); that is,

$$\sigma_x^2 = \sigma_T^2 + \sigma_e^2 \quad (2)$$

The optimal case is when the error for each person is zero; then there is no variation in errors, so $\sigma_e^2 = 0$. Consideration of this equation leads to the definition of reliability as the proportion of total variance in

scores that is attributable to true variation rather than error variation; that is,

$$\text{Reliability} = \sigma_T^2 / (\sigma_T^2 + \sigma_e^2) = \sigma_T^2 / \sigma_X^2 \quad (3)$$

For example, if the true score variance were 8, and the error variance 2, then the total variance would be 10, and the reliability would be $8/10 = 0.8$. One useful interpretation of this number is that it is the square of the correlation between true scores (T) and observed scores (X).

Among the interesting implications of the CTT model is that a test can be made more reliable by making it longer; adding items increases the true score variance at a faster rate than the error variance. One aspect of test design is determining how long a test must be to have a reliability great enough for the intended uses of the test.

Another implication of the model is that the reliability of a test is not a single number, but depends on how individuals were sampled to take the test. If a broad range of people are sampled, so that the true score variance is large, then the reliability will be greater than if people with a more limited range of true scores are sampled. (This is because the error variance would be the same in each case.) For example, if a test were given to all high school seniors, it would have a higher reliability estimate than if it were only given to seniors who planned to attend a highly selective college or university.

1.1 Estimation of Reliability

Unfortunately, since true score and error variation are not directly observable, the definitional equation (3) above cannot be applied directly. However, this conceptualization and the accompanying statistical model lead to several possible methods for estimating reliability. First, one could randomly divide any multiple-item test into two halves, and see how the scores on one half related to scores on the other half. If a test were perfectly reliable, then each person would get the same score on both halves of the test. Of course, the correlation is never perfect; the observed correlation allows the calculation of an estimate of the reliability of the whole test. Other methods use the correlation among the items to estimate reliability. These methods, including Cronbach's alpha (developed from an idea of Louis Guttman), are based on the same conceptual and statistical principles as the split-half coefficient.

Because each person is measured at one time point, any variability due to changes in that person across time is ignored by these methods. Here is where the definition of true score becomes critical. One can think of 'true' changes in true score (due to learning or

forgetting in between testing times); one can also think of more temporary changes, due to illness, noise or distractions in the testing room, and so on. In addition, some characteristics are expected to be variable over time; these include measures of mood. In personality psychology the more labile characteristics are called *states*, while the more stable characteristics are called *traits*. In classical test theory, the temporary effects are included in errors of measurement, while changes in traits are generally not. In spite of this conceptual uncertainty, this suggests another commonly used strategy for assessing reliability: Give the same test to a group of people at two different times, and see whether their scores are closely related. For obvious reasons this is called test-retest reliability. Of course, one assumes that the first measurement does not affect the second measurement, which may or may not be the case, and which must be considered. To minimize the effects of 'true' changes in true scores over time, the time period between testings must be kept relatively short.

A related method uses two or more forms of a test, with each form being constructed in an identical manner, so that the forms will be as nearly alike as possible. If in fact they have the same means, variances, and reliabilities, then they are said to be *parallel tests*. If we administer two such forms to the same group of people (e.g., on two consecutive days), the correlation between scores on the forms is called a parallel test estimate of the reliability.

In addition to measuring the overall performance of the test, we are also interested in how well we have estimated the score of each individual. The *standard error* of the test score is such a number; if small, then the score is a more accurate estimate of ability than if the standard error is large. As an example, suppose a person has a score of 120 on an IQ test, and the test has a standard error of 5 points. Then we can construct a 95 percent *confidence interval* around the estimate by adding and subtracting two standard errors (10 points, in this case); here the interval is from 110 to 130. This means, roughly speaking that there is a 95 percent chance that the interval will contain the person's true score.

Besides considering the reliability of the test as a whole, one must also consider how good each item is in the test. The most commonly used method to assess this in CTT is the item-total correlation, which measures how well the item discriminates among people of varying skill or ability levels. To calculate this, one correlates scores on the total test (usually with the particular item omitted) with scores on the item (with 0 used for an incorrect response and 1 for a correct response). In other words, an item is good if people who score high on the test tend to get the item right more often than do people who score at lower levels on the test. An item would be considered bad if people with low scores on the test were just as likely to get the item right as people with high scores on the test.

In the test construction process, items that have low item-total correlation are generally omitted or re-written.

Another common item statistic is the proportion of test-takers that get the item right; this is usually called the *difficulty* of the item (though *facility* would be more appropriate). While it is commonly reported, it is of little relevance for reliability; item difficulties are more important when trying to tailor a test for different ability levels, or to compare the characteristics of tests that are supposed to be equivalent (parallel, in technical terms).

1.2 Weaknesses of Classical Test Theory

CTT has several weaknesses that have led to the development of other models for test scores. First, the concept of reliability is dependent on the group used to develop the test. If the group has a wide range of skill or abilities, then the reliability will be higher than if the group has a narrow range of skill or abilities. Thus reliability is not invariant with respect to the sample of test-takers, and is therefore not a characteristic of the test itself; in addition, neither are the common measures of item discrimination (such as the item-total correlation) or item difficulty (percent getting the item correct). As if this were not bad enough, the usual assumption that the standard error is the same for test-takers at all ability levels is usually incorrect. (In some extensions of CTT, this assumption is dropped, but these extensions are not well-known or widely used.) CTT also does not adequately account for observed test score distributions that have floor and ceiling effects, where a large proportion of test-takers score at either the low or high end of the test score range.

CTT has difficulties in handling some typical test development problems, horizontal and vertical *equating*. The problem of *horizontal equating* arises when one wishes to develop another test with the same properties as (or at least with a known relationship to) an existing test. For example, students who take college admissions tests such as the ACT or SAT should get the same score regardless of which version of the test they take. *Vertical equating* involves developing a series of tests that measure a wide range of ability or skill. For example, while we could develop completely independent tests of arithmetic for each elementary school grade, we might instead want to link them to have one continuous scale of mathematical skill for grades 1 through 6. While vertical and horizontal equating is not impossible within CTT, they are much more straightforward with item response theory (IRT).

These problems of CTT are partly due to some fuzziness in the theory (the population to be sampled is usually not considered in any detail in the theory). But they are also due to the failure of most data

collection to be carried out on a random sample from any population, let alone a population considered appropriate for the test being investigated. In practice, convenience samples are used; these generally fit some criteria that the investigator specifies, but are otherwise taken as they are available to the researcher. Finally, CTT as originally conceptualized was never intended to address some of the practical testing problems described above.

2. Generalizability Theory

While classical test theory provided a framework that has proved useful in a number of situations, psychometricians realized many of its limitations even as they were developing the theory. Most importantly, they realized that a wide variety of factors could influence observed test scores, including how the items were generated, tests were administered, and items were scored (especially if they were free responses scored by raters). In classical test theory, these factors were all included in the (one and only) error term in the statistical model. To include these factors in their statistical models, psychometricians developed what is known as generalizability theory (GT), which included more than one source of error in test scores.

GT is based on the statistical methods of analysis of variance. Factors thought to have a major influence on test scores are included in a design, and the analysis allows the researcher to determine how much influence each factor has on variation in test scores. GT allows the computation of different estimates of reliability, depending on which factors are considered important for a particular use of the test.

As an example, consider a test of writing, in which each student writes three brief essays, each of which is scored by two raters. GT allows the estimation of how much variation in test scores is due to variation in essay topics, and how much is due to variation in raters.

Like classical test theory, GT is primarily concerned with the behavior of the test as a whole, rather than the performance of components, such as subscores or items. For further details on GT, see *Generalizability Theory*. The classic source on GT is the book by Cronbach et al. (1972). Shavelson et al. (1989) provides a less technical overview.

3. Item Response Theory

Since 1980 there has been a steady rise in the use of item response theory, or IRT, to solve some of the problems that CTT could not adequately deal with. IRT, like CTT, is based on an assumption that a single underlying dimension is being measured. But the basic conceptual idea behind IRT is the relationship be-

tween the score (usually right/wrong) on an item and the underlying dimension, whereas CTT is based on the relationship between total test score and the underlying dimension. This relationship represented by an item characteristic curve, or ICC, shows how the probability of getting the item right (for dichotomous items) changes with the underlying trait. As the probability cannot be below zero or greater than one, the ICC generally has an elongated S shape. In three-parameter models, the items may differ in whether the curve starts at zero for people of very low ability (no guessing) or above zero (if guessing correct is likely); how fast the curve rises (discrimination); and whether the curve is to the left (easy), in the middle, or to the right (hard). In two-parameter models, only discrimination and difficulty are used; guessing is fixed at zero. And for one-parameter (Rasch) models, only difficulty is used; guessing is fixed at zero and discrimination at one for all items.

IRT models solve many problems that were difficult for CTT, including the ability to construct a different test for each test-taker, so that students at all levels of ability can be assessed with items appropriate to their status. Such 'adaptive tests,' generally administered by computers, are becoming standard in many large-scale testing situations in some countries, including the Graduate Record Examination (GRE) and licensing examinations in many fields.

In IRT, the traditional concept of reliability has no place. Instead, the emphasis is on the more basic concept of standard error of measurement; that is, how accurately has a test-taker's true score been estimated? For a fixed test given to a group of examinees, the test characteristic curve shows the standard error for each level of ability. Unlike the simplifying assumption of CTT, the standard error can vary with ability. For example, if a test is relatively easy, the standard error will be smaller for students of low ability levels, because the test is better matched to their ability; higher ability students will not be well-measured by an easy test.

4. Reliability in Criterion-referenced Measurement

In some measurement situations the primary interest is in determining whether or not a person meets a predetermined standard or criterion. These judgments are sometimes made for individuals (e.g., is my student Karol reading at grade level?), and at other times for groups (e.g., what proportion of eighth-graders are reading at or above grade level?) In everyday life, drivers' license test provides a familiar example of a criterion-referenced test. In education, the theory of criterion-referenced measurement was developed to provide suitable technical scaffolding for making such judgments.

Again using the concept of consistency as a basis for conceptualization, reliability of criterion-referenced measures is concerned with issues such as whether an individual would have received the same classification if tested by different raters, on a different form of the test, or on different days. It is clear that the consistency will depend on how close the individual's true score is to the cut-point determining mastery. If a person is well above or below the cut-point, decisions will tend to be more consistent than for people near the cut-point. In the extreme, if a person's true score is exactly at the cut-point, then that person will pass half the time and fail the other half, no matter how well the test is constructed.

Because of the 'yes/no' nature of scoring, criterion-referenced test theory is somewhat different than the usual classical test theory, but only because some different statistical methods are appropriate for this type of data. Criterion-referenced measurement is also more obviously concerned with decisions made on the basis of a test; other test theory models are only implicitly concerned with such decisions. For more information about criterion-referenced measurement, see Hambleton et al. (1978), Harris et al. (1974), and Popham (1978).

5. Issues for Observational Measures

While many characteristics can be assessed through tests and questionnaires, others are better assessed through observation of behavior. Behavior can be assessed through direct observation, or it can be recorded for later coding into categories. The recording can be more or less direct, ranging from video and audio devices to the memory of observers about past behavior (where the recording is in the mind of the observer).

Behavioral observations tend to take place in 'real world' settings, and generally (but not always) under uncontrolled conditions. Unlike tests, where those taking them know and expect that their behavior will be observed, in natural settings one can imagine a range of possibilities for reactivity to the act of being observed. The more unobtrusive the observation, the more confidence one has in the quality of the measurement (though this generally would be classified as affecting validity, rather than reliability). The classic reference on unobtrusive measurement is Webb et al. (1966).

Some issues tend to arise much more frequently in the case of observational measures than with tests and questionnaires. One such issue is the decision of whether to consider a characteristic being assessed as categorical or continuous. For example, one might want to say that a person is either depressed or not, rather than being given a rating on a (nearly) continuous scale from not at all depressed all the way

through to extremely depressed. In such a case, the underlying trait is categorical, and different statistical methods are required. The most commonly applied method in this case is latent class analysis, which has been used in settings as diverse as determining stage of development of children, psychiatric diagnosis, and medical diagnosis.

One also tends to see different types of observed measures with observational data. Sometimes a variable has unordered categories, as would be the case if one classified a student in a class as sitting quietly, sitting but making noise, or being out of his or her seat. Other times a variable may be a count or a rate, such as the number of times a student is out of his or her seat, or the number of such times divided by the amount of time during which he or she was observed.

Typically there are multiple observers of behavior, or multiple coders of recorded behavior, or both. (This can, of course, occur for certain types of tests, not just in behavioral observations. Essay tests are a common example, because multiple raters are often used. Similarly, portfolio assessments of students' work are often based on the judgment of multiple raters.)

These considerations present additional problems that affect the reliability of observational measures. While consistency remains the primary concern, and the reliability (and validity) of behavioral observations depends on many of the same factors as for tests, additional factors for observational methods include length of the period of observation, the conditions under which observations are made (including irrelevant stimuli), and the observers, raters, and coders used.

As one might infer from the discussion of generalizability theory (GT), observational measures usually have more than one possible source of error, unlike what is assumed in classical test theory. In addition to inter-observer agreement problems, observers can make their observations at different times, in different settings, and under different conditions; all of these contribute to the error of measurement. GT allows researchers to estimate how much variability in the observations is due to each of these potential sources of error.

These differences from typical test data have additional implications for the statistical theory and data analysis methods generally used with observational data. When data come from observers, the issue of reliability is primarily a matter of whether two or more observers would come to the same conclusion (or, if a rating, the degree to which they agree), and whether the conclusion depends on when and for how long the observation occurs. For variables that fall into categories, one apparently simple method is to calculate the proportion of instances in which two raters or observers agree with each other about the category into which a particular observation should be placed. Unfortunately, the simplicity is only apparent, because for behaviors that are either rare or very common, a

high percentage of agreement can occur by chance. For example, if a student is classified as out of seat on 10 percent of occasions by each observer (and in seat the other 90 percent), then the observers would agree 82 percent of the time even if they were responding independently of the actual behavior. Therefore, such measures are typically corrected for chance agreement. Additional complications arise when there are three or more observers, and when observers do not rate or observe for the same period of time.

Details on statistical methods suitable for analyzing observational data are found in Suen and Ary (1989).

6. *Relationship of Reliability to Validity*

In classical test theory, one cannot have a validity of a test that is higher than the square root of the reliability. This has led some to conclude that reliability is more important than validity of a measure, because a test cannot be valid if it is not reliable. While a test cannot be valid if its reliability is zero or extremely low, it is possible for one test to have a higher validity coefficient than another, even though the first is less reliable. Suppose that two tests (or other measures) are not actually measuring the same true score, because they are measuring different traits. Then the one with a lower reliability can have a higher validity if the trait it measures is more closely related to the outcome that the tests are meant to predict. For example, a paper-and-pencil test of rock-climbing skill might have greater reliability than a performance test done on a climbing wall in a gym, but the latter might still have greater validity as a predictor of performance might in an actual rock-climbing situation.

The (invalid) conclusion about the relationship of reliability and validity has often caused a strain between quantitative researchers and qualitative researchers. Qualitative researchers often use measurement procedures that have lower reliability than the procedures devised by quantitative researchers, but the qualitative researchers prefer these less-reliable measures because they are measuring what they want to measure. It is quite possible that in many cases they are right, and their less reliable measures have greater validity than certain measures that are more reliable.

7. *Suggestions for Further Reading*

Martin and Bateson (1986) is a short introductory work on measuring behavior. The two most popular undergraduate texts on measurement are those of Anastasi (1988) and Cronbach (1990). At a higher level are texts by Crocker and Algina (1986) and Allen and Yen (1979), and the general reference work edited by Linn (1989). McDonald (1999) is a very new text that provides a unified treatment of many issues in test theory. At a very advanced level, the classic text on

both CTT and IRT is Lord and Novick (1968). A more modern text on IRT is Hambleton and Swaminathan (1984); a simpler version is Hambleton et al. (1991).

D. Rindskopf

Religion and Economic Life

Investigation of the relation between religion and economic life has long been a central concern of sociological reflection, but the topic has been largely defined through debates on the relationship of religion

and capitalism, the latter being the specific and dominant expression of economic life in modernity. The work of Karl Marx on the origins and world historical significance of capitalism, and of Max Weber on the Protestant ethic and the ‘spirit of capitalism’ and the economic ethics of the world religions, inevitably overshadow the discussion of both the history and the contemporary forms of the ambiguous and changing relation between religion and economic life. These classical discussions do not, however, exhaust the topic, which can be divided as follows. In Sect. 1, precapitalist configurations of religion and economic life are reviewed both as regards the sociological, or socioeconomic, study of Western history and, very briefly, the anthropological study of primarily non-Western cultures. In Sect. 2, the emergence of modern capitalism is considered in relation to political economy, Marx and Marxism, and Weber’s account of the elective affinities between religion and economic life. Following this, in Sect. 3, some contrasting reflective religious responses to nineteenth and twentieth century capitalism are outlined. In Sect. 4, contemporary capitalism, now unfettered by ideological confrontation with socialism, is represented as the driving force informing globalization, commodification, and managerialism, and as possessing such comprehensive power as to provoke and sustain a wide range of contrasting religious responses. In the concluding section, possible futures and research options are considered in relation to the capacity of economic life to destroy and recreate ‘nature,’ to reforge the parameters of human self-understanding, and to virtualize the condition of humankind. Economic life would seem increasingly to have become ‘life’ itself.

1. Precapitalist Configurations of Religion and Economic Life

The relation of religion to economic life is a function of the totality of any given society and its cultures; besides this, the way in which the interfusion of intrinsic, use, and exchange values may be understood depends on the theoretical assumptions of the inquirer. The most relevant founding fathers of sociology, Marx, Weber, and Simmel, sought to develop grand theory. In general terms, sociologists of religion have devised and reinforced relatively homogenous accounts of the modernization process and attendant phenomena of secularization, and they have used particular economic theories in order to inform and justify their approaches. By contrast, under the influence of Marcel Mauss’ account of the gift and using exchange theory (Gregory 1994), anthropologists have generally paid more attention than sociologists to specific human ecologies and reciprocal community economies as originating in ‘stone age economics’ (Sahlins 1974). Some anthropologists have corre-

spondingly defended distinctive and reciprocal human ecologies and cultures against the ravages of economic modernization in ways inadmissible to orthodox sociologists.

Archeological and textual records indicate that ancient Egypt, Assyria, Babylon, and Israel all had contextually relevant, practical financial institutions, but there is little or no trace of analytical effort. The history of Western economic thought is normally traced back to the primarily agrarian world of the fourth and fifth century BC which knew the small trading firm and had a well-defined merchant class. The representative unit of the economy was the household and commodities were exchanged in free markets. In the Graeco-Roman world early 'economic' reflection was based on the '*nomos*' or law and rule of the household '*oikos*,' and the practical wisdom of household management (*oekonomikos*) was the source from which early economic conceptions were derived. In the setting of the city-state (*polis*), the universal existence of slavery ensured that labor was relatively fixed and immobile. Religion and economic life as part of the cultural superstructure were conditioned by the dependence of ancient Greek and Roman life upon a slave economy; correspondingly, manual labor was regarded as menial. Later, the Classical tradition provided some of the core values of Western culture for two millennia.

Central to Greek thought were the good life and reflection on the nature of virtue: seen thus, economic activity amounted to a mere external factor. Plato and Aristotle were, however, aware of such concepts as the distinction between use value and exchange value, the role of money, and the division of labor. In *The Republic*, the latter corresponded with the human types of ruler, soldier, and worker, and each class pursued its proper, specialized goals. The ideal rulers, the philosopher kings, would ostensibly be free from vulgarity of wealth. Aristotle, as did Plato, assumed the existence of slavery, but he envisaged a wider participation of citizens and reflected upon the distinction between use and exchange value, favoring value based upon use. The arts of commerce and the practice of usury were condemned, above all the latter, which makes gain out of money itself and not from the natural object. Money was to be understood as a medium of exchange, a unit of account, and a store of value; but in itself money was barren, and usury the oppressive exploitation of misfortune. The classical Christian doctrine of the Trinity, couched in terms of the 'economy' of God's self-revelation of his 'essential' being, employed a metaphor with an enduring importance. Later, the evolving theology of the atonement repeatedly exploited certain economic metaphors, not least in the conceptuality of payment of debt and redemption from sin.

Little new was added to Greek economics by Roman thought. The denigration of manual labor was continued by such writers as Cato and Cicero. Pragmatic

management of ever larger estates (*latifundia*) and slaves was required, but the system based upon slavery was first questioned in principle by early Christianity. As with other aspects of life in the Roman Empire (for example, military service), the early Christian Church introduced subversive ideas which underwent rapid accommodation. While debates took place in the early church concerned (e.g.) alms-giving, according to Schumpeter there was little substantial interest in what was to become the dismal science of economics, for 'the Christian Church did not aim at social reform in any sense other than that of moral reform of individual behavior,' nor, moreover, 'did the Church attempt a frontal attack on the existing social system or on any of its more important institutions.' Indeed, 'It never promised economic paradise or, for that matter, any paradise this side of the grave' (Schumpeter 1954, p. 72). This is a view endorsed by Michael Mann, who argues that 'Christianity was a form of ideological power Only by becoming a Christian could one live a truly meaningful life' and that its 'power resides originally in the fit between the Christian message and the motivations and needs of the converted' (Mann 1986, p. 302). The question as to the 'fit' or affinity, elective or otherwise, between the impact of individual Christian belief and spirituality upon individual motivation and economic life has remained a matter of central importance above all in the thought of Max Weber. In a more uncompromising way, Marxist analysis implied that the religious ideology that emerged in the theological debates of the patristic theologians of the first four centuries in the West was but a reflex of the material base; this, however, does less than adequate justice to the complexity of the factors involved.

After the fading of the eschatological expectation of the earliest Christian communities and abandonment of the primitive communism, monasticism did, initially and in principle, preserve the radical exemplar of the economic ethic of the Synoptic Gospels (Troeltsch 1931). The religious orders that emerged from the practice of the Desert Fathers provided both the basis for the continuity of a religious culture and an economic model compatible in key respects with the warrior culture of feudalism. Monastic communities and the religious orders came to be centers of rational economic organization in ways that prefigure the business corporation. Monastic organization created wealth which, in turn, led to inner contradictions tackled by attempts at institutional reform—and which later became the target of acquisitive envy during the Protestant Reformation.

At the high point of scholastic theology and in the context of feudalism, a crucial debate took place which connects the early economic ideas of Aristotle (and of his wide philosophical concerns) with the early modern loosening of the constraints upon economic activity that facilitated the growth of international trade, and the justification of such expansion in

mercantilism. In the Middle Ages, Europe was characterized by a relatively stable agrarian, largely subsistence economy with slow urban growth. Central to urban productive activity was the guild, a form of association which ensured corporate monopolies, the protection of members, standards of quality, and price stability. The presence of the Church in relation to all social institutions ensured an unparalleled degree of cultural interfusion between religion and economic life. Social status and social function implied definite religious duties in a divinely ordered governance that extended throughout the body politic. Nineteenth-century guild socialism attempted to recover something of this integration of meaning into 'menial' work.

St Thomas Aquinas, the leading theologian of scholasticism, defended the just price and the prohibition of usury, the core principles of the attempted control by the Church of economic life. Estimating the just price based on moderate gain was a difficult task: the merchant was justified in trading at a price which ensured the life of his household in its accustomed style. Following Aristotle's account of money as barren, St Thomas condemned usury, the lending of money at interest, arguing that given the true role of money solely as a medium of exchange, it did not exist in the way that a rented house continued to exist when occupied by a tenant. St Thomas' counter-realist account of money applied more to the ethics of the personal loan rather than to large-scale financial transactions. During the course of the fourteenth and fifteenth centuries the increasing complexity of major financial transactions made it increasingly difficult to fit new practices within the constraints of Church law and this was reflected in modifications of St Thomas' rigorist views.

The prohibition of usury was circumvented through the creation of an international system identified with the Jews that was capable of supporting the accumulation of the major loans required for effective warfare. A similar role was also undertaken for a limited period by the Templars. The pariah status of Jews and their indispensable role in facilitating financial transactions and more widely in commerce came to reinforce negative attitudes which provided a long-enduring basis for anti-Semitism (Stern 1977, Chap. 18). The role of such Jewish thinkers as Marx and Sombart in the theorization of capitalism in the nineteenth century and beyond reinforced the impression that Jews and modern capitalism were intimately and fatefully inter-related (Paul Morris in Roberts 1995, Chap. 5). Freudian psychoanalytic accounts of the power of money as supreme 'reality principle' have continued the decoding of economic life. Present-day Islam continues the formal prohibition of the practice of usury, but Islamic banking and investment systems have nonetheless devised ways and means of adapting this restraint to the global economic system (Choudhury and Malik 1992).

In the early modern period, the growth of international trade, the breakdown of comprehensive ideological unity within Christendom following the Reformation, and the destruction of stable communities unified by shared religious values were factors associated with the rise of mercantilism. During the course of the sixteenth, seventeenth, and eighteenth centuries, economic analysis gradually gained increasing autonomy, throwing off the remaining constraints of scholasticism. Mercantilism and then physiocrat economic theory developed as distinct schools, which reflected the conditions of their countries of origin, England and France, where trading and rent of land represented prime sources of value, respectively.

2. *The Emergence of Modern Capitalism and its Critique*

The advent of early industrialization and the development of the factory system brought about unprecedented social disruption, breaking many ancestral ties: this process required both explanation and legitimation. In the *locus classicus* of political economy, *The Wealth of Nations* (1776), Adam Smith articulated a world view informed by the image of the pin factory in which virtue is equated with profit; his analysis of the rational division of labor and its necessary place in the making of profit grounded in the accumulation of surplus value of labor provided the justification for the removal of remaining constraints. The quasi-providential 'Invisible Hand' purportedly provided a spontaneous connection between individual wealth creation and the common good of society. Political economy attained a high status among an ascendent entrepreneurial class as it emancipated economic practice and provided the means for the elimination of embedded social, ethical, and cultural inhibitions, including those traditionally endorsed by religion in pre-industrial agrarian societies.

Marx regarded the intellectual destruction of religion by the eighteenth century Enlightenment as the axiom underpinning the true emancipation of humankind through subsequent social, political, and economic critique: there was, therefore, in principle no basis for any mutual reflective encounter between religion and economic life. Seen in full historical perspective, the theory of alienation adumbrated in the posthumously published *Paris Manuscripts* of 1844, the theory of society as composed of material basis and ideological superstructure in the *German Ideology*, the quasi-Hegelian ontology of capitalism expounded in the *Grundrisse* of 1857–8, the 'fetishism of commodities' in volume I of *Das Kapital*, and the later explorations in *Theories of Value* were all components in a theoretical scheme to which an adequate theological response has never been forthcoming. The representation of the proletariat in the

Communist Manifesto as the class excluded from all classes crystallized the fears of churches already confronted with their loss of influence over a growing urban working class and its anti-clericalism.

The uprooting of agrarian workers from an ancestral status sanctioned by divine order and their regimentation into a disciplined, wage-earning working class differentiated by a new division of labor created rather a dilemma for the churches. On the one hand, the Anglican clergyman Thomas Malthus endorsed population regulation in accordance with economic needs. On the other, the living conditions of the working class were an affront to those sensitive to the historic Christian teaching on wealth and poverty. Such figures as the Scot, Thomas Chalmers, English Christian socialists, and continental religious socialists struggled to find ways to redefine the role of religion under industrialized conditions. An unchurched, brutalized proletariat also, however, represented an inner threat to the role of Christian elites, clerical and intellectual across Europe. In the English religious establishment, serious critical engagement with 'scientific socialism,' or, moreover, with political economy was minimal. Methodism was exceptional in that it successfully harnessed religion and industrial work in ways which, according to the Halévy thesis, spared England a revolution.

Max Weber was fully aware of the threat which Marx's thought and Marxist socialism created for Liberal Protestant European bourgeois culture and society. According to Weber, the *mentalité* associated with the capitalist mode of production had historical connections and elective affinities with 'this-worldly' Protestant asceticism. It is therefore customary (but not undisputed) to link the nascent 'spirit of capitalism' with the much disputed 'Protestant ethic,' above all within the Reformed Christian tradition. Weber explored the affinities between the single-minded pursuit of God and an equally focused desire for profit, but he also applied his analysis to the major world religions, classically, for example, to the religion of India (D. Gellner in Roberts 1995, Chap. 1). Marx and Weber agreed on the centrality of acquisitiveness to the bourgeois mind: political economy both explained and justified the alienative emancipation of single-minded acquisitiveness from contextually embedded human needs. Weber used the Latin scholastic ascription of God as supreme good when he analyses this distinctive mind-set and hinted at its wider implications:

In fact the *summum bonum* of this ethic, the earning of more and more money, combined with strict avoidance of all spontaneous enjoyment of life, is above all completely devoid of any eudaemonistic, not to say hedonistic, admixture. It is thought of so purely as an end in itself, that from the point of view of the happiness of, or utility to, the single individual, it appears entirely transcendental and absolutely irrational. Man is dominated by the making of money, by acquisition as

the ultimate purpose of his life. Economic acquisition is no longer subordinated to man as the means for the satisfaction of his material needs (Weber 1930/1976, p. 53).

In *Religion and the Rise of Capitalism*, R. H. Tawney applied Weber's insights to seventeenth-century England, and provided an indirect critique of the *laissez-faire* liberal capitalism which underwent economic and social crisis during the period between the First and Second World Wars. Later, further British explorations of the processual metaphor of the 'rise' of capitalism were extended by V.A. Demant to its 'decline' and its 'persistence' by R.H. Preston. Christian thinkers such as the Anglican William Temple relied upon the emerging Keynesian standpoint in advocating 'middle axioms' as the basis for socio-ethical intervention. Following the Second World War, the Keynesian program of partly state-managed mixed economy (and declining) capitalism underpinned the ideology and implementation of the 'welfare state' for 30 years until the 'triumph of capitalism' associated with the Reagan-Thatcher era. The re-assertion of neo-classical economics (Friedman 1962) and the ideology of the New Right (Green 1987) stripped away both tacit belief in the 'hidden hand' and all ascetic hesitance with regard to hedonism (Roberts 1992). Mainline religions in Anglo-American Western countries were split between localized variants of the 'option for the poor' and outright endorsement of the 'enterprise culture.' Those who advocated the option for the poor were depicted as naive and ill-informed practitioners of the 'kindness that kills.' Conversely, New Right ideologues proclaimed the virtues of greed, the adequacy of the 'trickle down' theory of welfare, and the necessity of a docile, 'flexible' labor force willing to undergo repeated social deracination.

3. *Reflective Religious Critiques of the Relation of Religion and Economic Life*

The most significant mainline religious response to industrialization and to the growth of capitalism and Marxist socialism is to be found in Roman Catholic social teaching. After lengthy consultation provoked by the changing socioeconomic conditions of the nineteenth century, the papal encyclical *Rerum Novarum* was published in 1891. Aware of the fate of the Catholic Church in revolutionary France (and then later of the Orthodox Church in Soviet Russia), papal teaching represented the historic struggle between capital and labor as conflict between the competing rights and obligations of owners and of workers, in relation to which the Church was to exercise a moderating role. Both parties were to recognize the mutuality of their rights and obligations, and to relativize these through acknowledgment of the

Beatific Vision as the sole and legitimate goal of humankind, thus hopefully resisting the Weberian slippage (under conditions of secularization) from the spiritual worship of God to the practical service of Mammon. For a century the Church developed this doctrine through a series of encyclicals culminating in Pope John-Paul II's *Laborem exercens* (*On Human Work*) (1981). Following the collapse of Marxist socialist states in 1989/90 the changing nature of capitalism was recognized in the encyclical *Centesimus Annus* (1991). The latter contains a cultural rather than a politico-legal analysis and critique of both socialism and capitalism in which the integrity of the human agent is asserted against the contradictions of a destructive, secularizing modernity in need of comprehensive re-evangelization.

Direct intellectual contact between Christians and Marxist socialists did not take place on a significant scale until after the Second Vatican Council (1962–5) and took the form of Christian–Marxist dialogue during the following decade, but even this discussion of the nature of ‘true humanism’ would seem to have had minimal long-term influence. At the same time ‘political theology’ embodying a synthesis between Protestant theology and various strands of revisionist Marxism also developed in Germany. Insights from political theology were transplanted to Central and Latin America, where, after the Second Vatican Council and the Medellín Bishops’ Conference of 1968, ‘liberation theology’ emerged in the context of rapid industrialization and urbanization, a situation similar in important respects to the conditions the young Marx and Engels had observed in the Rhineland in the 1830s. This theology drew critical perspectives from Marxist analysis of society but side-stepped the atheistic aspects of Marxism, as was to be emphasized in the critical response of the Sacred Congregation in Rome. In Central and Latin America liberation theology’s stress upon the ‘option for the poor’ has tended to exacerbate a divergence between Roman Catholicism and Pentecostal Protestantism, where the latter has performed a role analogous to that of Methodism during the European industrial revolution (Martin 1990, pp. 27ff.). The most radical theological critique of capitalism through the representation of the imbalanced distribution of wealth in the global economy was a confessional issue (Duchrow 1987).

The Roman Catholic apologist and critic of liberation theology Michael Novak has written of a ‘magic capitalism.’ Humankind has to abandon the naive and infantile ‘dream’ (the ‘false consciousness’) of socialism, and to recognize the universal necessity of alienation at the heart of a vital economic reality. Every individual must pass through a rite of passage in which each encounters the ‘empty shrine’ of ‘democratic capitalism’: this is the contemporary ‘dark night of the soul’ (Novak 1982/1991, p. 53). Humankind may then draw upon spirituality, theology, and religious values (above all, those taken from Christianity

and Judaism) for the individual strength to survive and compete. Others, like Peter Berger, deny that capitalism has such mythicizing power (Berger 1987). Other accounts of religion and economic life are to be found in Protestant Christian theologies of ‘God’ the Economist. (Meeks 1989).

Recently, the globally influential ‘Third Way’ politics of the center left advocated by such prominent figures as President William Clinton, the British ‘New Labour’ Prime Minister Tony Blair, and the British sociologist Anthony Giddens has been accompanied by a revival in Christian socialism and continuing campaigns to remoralize the individual. This post-Keynesian and postcommunist active capitalism seeks to combine the ideology of entrepreneurial zeal with managerialism and relentless sociocultural ‘modernization.’ The ‘Third Way’ contributes to the increasing salience of the religious factor in economic life, albeit with paradoxical consequences.

4. *Contemporary Capitalism: Globalization, Commodification and Managerialism*

Contemporary capitalism has both diversified into a plurality of capitalisms, each with its contextually relevant elective cultural affinities between religion and economic life, and has consolidated itself through globalization into an infinitely complex singularity. The representation of globalization as a new paradigm for the sociological interpretation of religion (Robertson 1992) has encouraged investigation of the struggle both between and within religions for power and influence in the context of the asymmetrically distributed economic opportunities and outcomes in an ever more competitive core–periphery world system (Beyer 1995). Moreover, the problematic interface between the global and the local has become the focal point of social identity formation (Castells 1996, Vol. II, Chap. 1). Commodification, the ascription of exchange and monetary value to all aspects of the world and human life, has advanced inexorably with the result that the economic function is central, and natural or intrinsic values become ever more marginal and are reduced to mere market values. Global managerialism (Entemann 1994), mediatized marketing techniques, and the application of ‘neo-Fordist’ organization to mind-work (Drucker 1993) have accelerated the uniformitarian ‘production’ of human beings through rational ‘quality’ education and training. These are now processes replicated within some influential strands of both mainline religion and alternative spiritualities.

Information technology has increased the velocity of circulation of all forms of ‘capital’ to the point that space–time compression is having pervasive cultural consequences in new ‘economies of signs and space’ (Lash and Urry 1994). For those at the heart of a

core-periphery economic system, capitalism has become 'soft' and infused with transformative cultural power (Thrift 1997). Under these conditions, religious language and theological vocabulary have become resources for the expression of economico-cultural power. Thus, terms like 'omnipresence,' 'omnipotence,' 'omniscience,' and 'instantaneity' formerly attributed to the 'God' who subsisted at the core of Western consciousness are perhaps the only adequate conceptual categories for such transmutations. Spiritual practices are now recruited into management training in order to assist through the provision of peak experiences the strongest possible integration of individual motivation with corporate goals (Roberts in Roberts 1995, Chap. 9). The religious field may be remapped in relation to these ongoing transformations of economic life. The application of rational-choice theory to religious behavior, a syncretic global marketplace of New Age 'self-religions' and spiritual body practices, the managerialization and marketization of mainline Christianity, Christian fundamentalist 'prosperity theology,' neo-pagan 'nature religion,' and ecological piety are all indications that religion and economic life are in active and sometimes mutually contradictory synergies. Consequently, there is no one 'spirit of capitalism' in advanced modernity—but a multiplicity of affinities and collusions in context marked by growing differentiation between 'religion' and 'spirituality.'

5. Conclusion: Future Prospect—Research Options

In the modern world, the last *residua* of hunter-gatherer societies and subsistence agriculture struggle with globalized economic power: the modern and the postmodern conditions sometimes co-exist in close, yet problematic contiguity (Harvey 1989). From being marginal to the order of things, conscious economic rationality is now for many 'life' itself. 'Economic life' tends to absorb, transmute, and meld 'reality' into seamless economies of virtualized simulacra, a globalized *maya*, outside of which there would appear to be no fulcrum for a critical ideology or politics of resistance (Baudrillard 1981). In a world in which the virtual exerts hegemony over the residual real the cosmos is silent; yet ambiguous opportunities abound, not least for women seeking freedom from both biological and social construction, as cyborg, prosthetic, and virtual cultures are created and colonized. After the so-called 'End of History,' leading sociologists of religion such as Steven Bruce and Bryan Wilson continue to represent religion as subject to terminal attrition by an inevitable process of secularization. Regarded thus, religion can no longer be a resource for the culturally significant critique of total human submission to the dictates of 'economic life.'

Little would seem left for the researcher into the relation of religion and economic life other than to report on the final stages of religious decline.

Given the comprehensive economization of human life and the deteriorating global condition, the putatively normative pursuit of socio-scientific research on the assumption that it is value free and objectively disengaged is ethically untenable. Moreover, the comprehensive absorption by 'economic life' of the physical and biological basis of culture and society—and even of 'nature' itself—is ecologically unsustainable. Under conditions of totalizing inclusion in which the integrity of the ecosystem is reduced to a sociological and economic construction, deviant, marginal, and engaged research is essential. It is perhaps through an interdisciplinary and ecologically informed anthropology and in 'new economics' that the tools will be found with which to develop research into religion(s) and spiritual practices that may provide a vital but neglected resource for a sustainable human ecology and world survival.

Religion and Gender

According to Social Sciences religions are social and cultural features, resulting of specific historical constructions. Religious beliefs and symbols as well as church organizations are the result of social processes in which social agents are inscribed. Every religious action is limited and directed by the social situation of religious agents, official leaders, or simple believers. Practices, representations, symbols, and discourses of religious field are accomplished by socially placed believers. Even when they express their faith supposed to be absolutely private, social relations take place. Classical approaches of religions deal with the question of how social class influence religious believers and behaviors. Nevertheless, the ways gender and race influence beliefs and religious institutions have rarely been taken in account.

In the context of feminist critique to the female exclusion of the possibilities of formulating knowledge, the efforts to alter the ways of thinking are an integral part of the historical struggle of women. In the seventeenth century, Sor Juana Inés de la Cruz, a Mexican Catholic nun, invoked the right of women to participate in knowledge in the same manner as men. The development of feminist studies, especially from the 1970s on, led to the formulation of sophisticated feminist criticism of the traditional and modern forms of Western thinking. Thus, practically all areas of

knowledge have been questioned by feminist theoreticians who developed alternative proposals to hegemonic forms of knowledge.

Women have also brought the field of religious studies into question. Feminist theories and methodologies have been applied to the field of religion especially by using the category of gender or social relations with respect to sex, showing how a significant part of traditional studies in this area treat religious agents without distinction of gender and race. This generalization can be found in the use of homogenizing categories of a complex reality. Observe the categories entitled 'clergy,' 'laity,' 'hierarchy,' etc.; they are employed without any reference to the sex or race of their components. The consequences for analysis have been shown by empirical research attesting to the manner in which the field of religion is molded not only by class, but also by gender and race. The approach in terms of gender, therefore, questions the pretentious neutrality of the social sciences in their aim to examine religions.

Among the main critical concerns of these issues is the uncertainty that the sexism inherent in historical religions can be overcome. In the opinion of a few of those who study the issue, these religions are inevitably androcentric. These scholars propose the creation of alternative religious spaces where women can produce new forms of relating with the sacred, which is also thought of in an innovative way. Other scholars believe that the problem of historical religions is that men appropriated them. It is necessary to recuperate the original traditions and foundations for women to find their place in these religions.

Another area of criticism is religious organizations, churches, and others in which women as a whole are excluded. From Judaism to Taoism (Sharma 1987, Gross 1996), religious organizational forms are analyzed as social institutions that guide and control women's lives and bodies. Special reference is made to three aspects that exclude the female population in these institutions: the sphere of decision-making and power, symbology and the predominance of a monotheism in which the divinity is male, and the formulation of theological and moral discourse.

1. Feminist Criticism of the Classics of the Sociology of Religion

The specific field of sociology of religion has also been submitted to the scrutiny of feminist critique. Scholars point to sexism in the analysis of religion found in the work of classical authors in this area, such as Durkheim and Weber (Erickson 1995, Bologh 1990). The first author places a rigid division between the sacred and the profane to explain social life and religion. The power generated by rites and beliefs establishes this separation. Men, holy beings *par*

excellence and having been gifted with a soul, are the protagonists of beliefs and rites whereby new relationships and society itself are created. Women, lacking a soul, are relegated to the sphere of the profane, repetitive day-to-day life and the absence of creative capacity. Only power and violence are able to keep these two spheres separate. In modern, secularized societies, rites and beliefs are meant to help keep the ideal world of men separate from the world of women by force.

Weber's sociology of religion also bases itself on dichotomy: religions founded on both rational and ascetic ethics combat magical and ecstatic religions that incorporate eroticism. The first religions are aimed at action in the world and allow one to attain the greatness of a hero, a charismatic leader or a prophet. The second religions lead to love and only serve to 'comfort the warrior,' and are negative in relation to action in the world. Men are associated with the religions of active asceticism and rationality and are responsible for progress since they have been equipped with heroism. Social order is founded on the empire of reason and greatness, at the cost of the repression of the sentiment, eroticism and magic attributed to women.

The two classical authors defend the dominant social order in relation to the subordinated positioning of women, thus legitimizing the dominance of the male elite both in society and in religion sustained by the female population and the masses. After them, other sociologists addressing the religions institutionalized in churches rarely realize that the nature and functions of religious power are based on the sexual division of the work. The separation of the cleric from the layperson is, at once, a separation of men and women in which the power is attributed exclusively to men. One of the problems with the sociology of social and religious organizations is, as feminist sociologists demonstrate, the abstract treatment of the categories used as supposedly neuter in terms of gender, which prevents the perception of fundamental elements of reality. Even if certain studies include considerations on women, they are generally descriptive and exclude any analysis or explanation of male dominance.

2. *Feminist Contributions to an Understanding of Religion*

Feminist critics envision creative, new directions for classical and current studies of the social studies of religion, challenging their pretentious neutrality and objectivity. For example, Gross (1996) proposes the necessity of academic objectivity and, at the same time, empathy with respect to the subject matter. Empathy would be the most appropriate methodology to deal with polemic themes arousing intense emotions. It allows one to understand the believer's

point of view and creates an important point of contact between academic religious studies and religious practices from a perspective of personal faith. The effect of religious studies therefore is that which radically refutes absolutism.

In the field of theology, scholars bring traditional representations of divinities into question, in an attempt to overthrow the monotheistic, male conception of the Christian God, for example. According to a significant group of feminists, Christian women theologians reject the traditional understanding of 'human nature,' which quarters women into the specific area of maternity by destiny and not by choice. This rejection of the biological resource to explain social and religious order of the sexes leads women to radically criticize the current hierarchical organization of ecclesial institutions, especially the Catholic Church. An affirmation of an individual autonomy that is not opposed to the construction of collective ideas but rather supports them further leads women to claim recognition as moral agents capable of making ethical choices in all fields of life, including those related to the control of sexuality and the capacity to conceive new human beings.

An analysis of the consequences of exclusions that fall on women in the area of religion shows that they are not limited to the fact that women are prevented from being included in the decision-making process in churches and the formulation of authorized knowledge. These consequences also extend to the symbolic field, since they keep women within a closed circle of impurity. The impossibility of presiding over rituals considered fundamental to the development of faith and the delimitation of distinct physical spaces according to sex, with secondary importance being attributed to women, among other examples, add to the religious image of the female population as sinners and polluters of the sacred. In the case of Catholicism, this happens in a radical way. In order for a man to re-establish the relationship of a community of believers with its God, it is not only necessary that he be a man, but also that he be celibate, i.e., that he not touch any women.

Another area in which there are significant feminist contributions is the history of religion. By interrogating existing historiography and the silence with regard to female proaction, and by confronting the difficulty of sources, women scholars have been seeking to write a different history in which facts, figures, and processes are shaped by the social relations established between the sexes. Catholic religious nuns rigorously trained not to have a 'personal or collective history' have been the subject matter of historical and sociological study.

In all fields of religious study, feminist scholars affirm that the fundamental issue is to understand the way in which symbolic activities—beliefs, rites, and religious discourse—that seem to escape sexual differentiation, similar to the ordering of the internal

power structure of religious institutions, truly conform to such differentiation. Feminists are therefore concerned with showing how religions are presented in social and historical reality to be molded and interwoven with gender relations.

3. *Womens' Investment in Religion*

Feminists commonly affirm that religions historically have been spaces for guidance and control of the behavior, thoughts, practices, and representations of women. Nevertheless, many scholars believe that religious space is contradictory and ambiguous for allowing women to have certain gains in concrete historical situations. For this reason, women invest in religion to find possibilities for development and autonomy to counteract the institutional investment in control. Religions can function as mobilizing forces, allowing women to resist disciplining religious and social power.

Feminist scholars of religious history asked historiographical sources demonstrating religious women's protagonism in different religions and diverse societies and historical periods. For instance, some Buddhist traditions became attractive for women because of the large number of famous female practitioners and teachers found in their ranks. In Taoism we can find important women alchemists, monks with their own monasteries and accomplishing high roles as shamanistic mediums. In Christianity, women monks were the chiefs of mixed monasteries, with male and female monks, in medieval Europe. They managed high levels of ecclesiastical power.

Research on nineteenth century Europe and Latin America shows that under certain circumstances religions historically have become unique social spaces for the female population. These spaces further act as a refuge and create conditions for women to escape male control, including by opening up the possibility of not marrying in order to dedicate themselves to spiritual life in convents and similar places. Recent studies have reported alterations in the religious field that are partially favorable to women. This is the case of Christian Ecclesiastical Base Communities, which offered many women from poorer communities the possibility of removing themselves from the domestic environment and unbalancing sex relations as well as an important learning in exercising leadership (Drogus 1997). These communitarian spaces enabled the assimilation of feminist concepts allowing women to criticize the Catholic ecclesiastical institution as male-dominated and patriarchal. It is interesting that apparently opposite fields of discourse—feminism and Christianity—were blended to empower women. New religions were also dealt with in this manner, with research showing their ambiguities in relation to the gains they offered the female population.

Another strategy women use in their favor is the reinterpretation of sacred texts. Like many Christian theologians who developed new readings of the Bible, Islamic female scholars reinterpreted the Koran, showing that male domination of the female population, as well as the idea that women were created for men have no basis on the sacred books. Equally they deny women of being guilty, based on the proposition of the guilty figure of Eve. Buddhist scholars affirm the equalitarian original character of Buddhism. They argue that Buddha taught women as well as men and had both as his followers.

Hence, women's investment in religion can be explained not only by the social control exerted over them through religion, but also by their taking advantage of their religious participation.

4. *Future Directions of Research*

The affirmation of religious experience as a gendered experience has led specialists in religious studies and theologians of various religions to reflect with ever-increasing depth on the different ways in which men and women deal with their religious beliefs and practices. In this vein, many fields have lent themselves to feminist research in order to understand and explain women's relationship with religion and their place in historical religions. One of the most useful fields seems to be that which analyzes the effects of the contemporary re-arrangements occurring in religion both in the West and the East on the lives of women and, as a consequence, men. Another area of research, in terms of claiming sexual and reproductive rights, is that which aims to discover the ways in which different religions appropriate the female body and seek to control its sexuality and reproductive capacity. One area open to empirical research still remains: the conditions for women to produce new religious practices, discourse, and symbols and the effects on religions and the entirety of believers, whether men or women.

In sum, the growth of empirical data prepared taking gender as theoretical tool should offer new clues for understanding and explaining the reality of religions in societies of the third millennium.

Religion and Health

There are two distinct ways in which religion may be related to health. Religions—complicated systems of symbols, beliefs, practices, and the social institutions associated with them—may be classed with the psychosocial factors with apparent influence on health status. In this view, religiousness may be a protective or preventive factor in reducing mortality or morbidity. A second view reverses this causal order, in that religious beliefs and practices are often turned to by individuals and families faced with serious illness, or at the end of life, and religiousness can be affected by changes in aging or health status.

1. Religion as a Factor Affecting Health

The earliest examples of practices designed to promote the public health are to be found, among primitive peoples, inextricably mingled with the ritual of religion.

These are the opening words of C-E. A. Winslow in the entry for 'Public Health' in the original 1935 *Encyclopedia of the Social Sciences*. Winslow, professor of public health at the Yale School of Medicine, known for his studies of the decline in infectious disease mortality, draws attention to early quarantine efforts in ancient Persia and among the Biblical Hebrews as effective public health practices, motivated and given form by religious beliefs. The burial of the dead, the separation of lepers from the community, or the ritualistic preparation of meat for consumption are but a few of the early examples of practices carried out for religious reasons that had unintended public health consequences. In general, this characteristic of being unintended is typical of the work discussed under this heading—religious practices or beliefs seen to have associations with health are not undertaken for the purpose of improving individual or community health, but rather, are ends in themselves.

The social scientific origins of both theoretical and empirical work on religion and health can be found in Emile Durkheim's (1951) *Suicide*. Durkheim demonstrated, with the use of European national and regional statistical records, that suicide rates varied dramatically and predictably with certain social characteristics, among them the rates of Protestants, Catholics, and Jews in a population. His demonstration that suicide rates were lower among regions with larger Catholic and Jewish populations led him to denote types of suicides (*anomic* and *egoistic*) in modern

societies. Suicides were prevented in religious and other social groups that regulate or constrain the behavior of individual members, and also provide them with integrative and socially supportive relationships.

Despite this foundation in late nineteenth century classical sociological thought, research on religion was largely absent from social scientific work in health until the latter half of the twentieth century. When such work did appear, it was limited to studies of small, peripheral subpopulations, or to suicide as the only cause of death. Beginning in the 1960s, studies finding lower rates of mortality and morbidity (particularly hypertension) for clergy, members of religious orders, and certain sectarian groups including Seventh-Day Adventists, Mormons, and Amish, appeared in US medical and public health literature (Jarvis and Northcott 1987). Work on religiousness and suicide rates has also appeared steadily, with generally consistent support for Durkheim's original findings (Pescosolido and Georgianna 1989). More generalizable findings came in 1979, when the well-known Alameda County (California, USA) analysis of social networks and mortality appeared (Berkman and Syme 1979), quickly followed by similar findings from large population studies in Tecumseh County, Michigan (USA), and Evans County, Georgia (USA). In each of these longitudinal studies, social ties, including ties to religious congregations, were associated with lower mortality risks.

These studies were important for many reasons. Until this time, the social environment, long a member of the agent–host–environment triad in multifactorial models of disease causation, had primarily been thought of as having negative influence on health. Social environments were considered sources of stress; social conditions were frequently operationalized as poverty, urban crowding, time-pressured working conditions, or the stress of modern life. The social network studies opened for consideration the possibility that the social environment also provided positive or protective factors in health. The first social network studies were also important because they included some measure of affiliation with a religious group or attendance at religious services.

In the 1980s and 1990s, studies focusing specifically on religion as a mortality risk factor appeared, primarily from the US and Israel, most showing a moderately large and significant protective effect, even after adjustments for possible selection factors, confounders, and mediators (Kark et al. 1996). For example, Hummer et al. (1999) found that frequent attendance at religious services reduced mortality risk such that seven years was added to life expectancy at age 20. These findings were different from the earlier studies of homogeneous religious groups or clergy, in that they represented the general population, with its natural heterogeneity in religious behaviors and beliefs. Like the social network studies, they were

longitudinal, and thus were able to adjust for the health status of respondents at the start of the study. Data from prospective observational studies with well-designed health status assessment at baseline is critical, particularly when measurement of the religion variable is limited to the indicator of attendance at religious services. The potential selection effects of healthier members of the population attending religious services more frequently, and being at simultaneously lower risk of mortality, are obvious. Additional important selectivity variables included in these analyses include age, sex, socioeconomic status, education, ethnicity, and marital status, as religious participation is generally higher for women, married couples, blacks, older people, and those with higher education and income.

However, a chief criticism of the studies in this emerging field is that most contain only one or two indicators of religiousness, inadequate conceptualization and measurement for such a highly complex set of practices, beliefs, and institutions. Most frequently, attendance at religious services has been the only available measure. When some measure of private religious feelings or practices has been included and compared, attendance is usually the measure with the largest protective effects. Better measurement of the independent variable is clearly necessary before a larger understanding of explanatory mechanisms can be gained. At the present stage of research, however, several mechanisms through which religiousness might affect mortality have been described.

1.1 Reduction of Behavioral Risk Factors

The health economist Victor Fuchs observed in the early 1970s that religious teachings regulate and constrain human behaviors in numerous ways that have known health consequences (Fuchs 1974 pp. 52–5). He noted the enormous differences in infant, child, adolescent, and adult mortality rates in the two adjacent states of Utah and Nevada. Population density, climate, health care, income, and education levels in the two states were rather similar; any advantage went to Nevada. Yet death rates in Nevada for males aged 40–49 were 54 percent higher, and for females 69 percent higher than in Utah. When the causes of death were limited to cirrhosis of the liver and cancer of the respiratory system, Fuchs found that the corresponding figures were 111 percent and 296 percent. He attributed the dramatic differences to the ‘different lifestyles’ of the residents of the two states, Utah being primarily inhabited by Mormons who do not drink alcohol or smoke tobacco and ‘in general lead stable, quiet lives’ with high marriage and fertility rates and low divorce rates. Even within the Mormon church, levels of adherence to church doctrine have been shown to be associated with reductions in smoking and alcohol-related deaths (Gardner and Lyon 1982).

Most religious groups, however, do not have specific, doctrinal beliefs regarding these behavioral health risk factors, and yet rates for cigarette smoking (Koenig et al. 1998a) and substance use (Kendler et al. 1997) are significantly lower among those who attend religious services regularly, even in studies of religiously heterogeneous populations. A US national study of high school seniors found that the more frequent attenders, and those who thought religion was important in their lives, had lower rates of smoking, alcohol and marijuana use, carrying weapons, getting into fights, and driving while drinking. They also had higher rates of positive health practices such as seat belt use, and eating fruits, vegetables, and breakfast (Wallace and Forman 1998).

Religious involvement among adolescents that lowers many behavioral health risks is especially important because it represents a lowering of lifetime risks for behaviors such as smoking, which are most likely to begin in adolescence. Moreover, an analysis of data from the Alameda County study shows that religious attenders who do smoke are more likely than nonattenders to quit smoking during the course of a follow-up study, and hence further reduce their mortality risk (Strawbridge et al. 1997). Thus one of the mechanisms through which religion influences health consists of the constraints placed on behaviors that are sensation-seeking, self-stimulating, and increase risk to the self and others. The reduction in lifestyle risk factors results in lowered rates of lifestyle-related causes of death, and in at least one study a temporal pattern of religious practices preceding risk reduction behaviors has been established.

1.2 Enhancement of Social Support Networks

A second mechanism by which the effects of religious involvement may operate is through the expansion and maintenance of social support networks. The study of religion and health is in some ways derivative of the study of social networks and health, and indeed the latter studies provided the earliest modern findings, in Alameda County and elsewhere, as noted above. This mechanism represents the parallel strain in the Durkheimian theoretical tradition, that religious institutions provide both regulation for the behavior of members, as well as integration, or feelings of belonging in a social group. Religious congregants report larger social networks of both friends and relatives, and also more social support from them, compared with nonattenders (Ellison and George 1994). There are several reasons why religious congregations would serve as centers of effective social support for members of all ages, but particularly for the elderly. Congregations offer a mix of strong and weak ties, and can thus offer a broad range of emotional and instrumental supports.

Congregations of all major faiths share values and beliefs about the importance of helping others who are less fortunate and also provide organizational structure for mounting such efforts. Religious institutions provide both support and opportunities to support others, and reciprocal or bidirectional social support may be the most beneficial. Finally, as a corollary of this, members of religious groups who have served others in the past, and who have seen others receiving help, have reason to anticipate support in the future in the event of need.

Population studies of religiousness and health outcomes, particularly mortality, have generally included some assessment of these two explanatory mechanisms (e.g., Hummer et al. 1999, Strawbridge et al. 1997). Usual findings have been that: (a) religious involvement, particularly public participation in services, is associated both with better health practices and with higher levels of social support, and (b) these known behavioral and psychosocial risk factors explain some proportion (but not all) of the effect of religiousness on later health outcomes. In studies of healthy populations, then, religion (conventionally operationalized as attendance at religious services) appears to be related to a lower risk of mortality after adjustment for known confounders and selectivity variables, and the effect is partly explained by existing explanatory mechanisms and partly independent of them. This is just an emerging field, however; the number of extant studies is relatively few, the measurement of the religion variable is undeveloped, the research has been largely done in the US in regional samples with Judeo-Christian beliefs, and other explanatory mechanisms should be tested.

2. *Illness and the Search for Meaning*

The first part of this article has been concerned the unintended health consequences of religious practices, or measurable changes in health that result from religious practices undertaken for religious and not health-related purposes. Equally important for a social scientific study of religion and health, however, are religious beliefs and practices that are engaged in as a direct result of illness. Religious groups can offer both spiritual and tangible support to the sick, including prayers and comforting rituals, but also meals, visitation, childcare, and even financial help. A US survey of the use of unconventional medicine found that 25 percent of their national sample reported that they had used prayer as a treatment for illness in the past 12 months; only exercise, with 26 percent, was used more often (Eisenberg et al. 1993).

Research on the effects of religious coping (including but not limited to prayer) has frequently taken indicators of mental health and well-being as outcomes; studies of recent widowers, parents who had

lost a child, women with hip fractures, or elderly men with multiple chronic illnesses have shown lower rates of depression among those with religious beliefs or participation compared with those who have none. For example, hospitalized patients diagnosed with major depressive illness were found to have a shorter time to recovery from depression if they felt themselves to be more intrinsically religious (Koenig et al. 1998b). In another study, heart patients who felt that they received strength and comfort from their religious beliefs had a lower risk of death during the six months following surgery than those who did not (Oxman et al. 1995). At the same time, not all forms or styles of religious coping may be benign, for example, when the cause of an illness is attributed to moral failure; research is just beginning on maladaptive religious coping (Pargament 1997).

Classical sociological theories of religion again anticipate these functions of religion in health. Weber's concept of 'theodicy' provides a historical model of the articulation of the problems of individuals with religious language. Religious individuals can draw on the experiences of fellow believers or the stories of their faith tradition to put their own lives into a larger context, to learn lessons from others who have faced similar circumstances, to reduce fear, or to gain hope for the future. Religious ritual practices for mourning or for healing can assist individuals in making transitions to new life stages in which adaptation to loss is required. Religious coping strategies appear prominently in the coping repertoires of aged individuals faced with their own serious illness, or the illness or death of a loved one, situations over which the individual has little direct control, and which may lack clear explanations or challenge beliefs that the world is just (Pargament 1997). In contrast with the population studies described above, in which attendance at worship services was most predictive of later health outcomes, studies of religious coping frequently find that subjective religious beliefs or nonorganizational forms of religious practice (e.g., private prayer) play an important role.

Religious beliefs and practices are especially prominent in the care for and concerns of individuals at the end of life. The modern hospice, begun in England in the 1960s, was modeled after medieval Christian institutions that cared for the dying, and the spiritual concerns of patients are still a central aspect of the new field of palliative medicine. There is also some evidence that the observance of religious holidays may alter the timing of death for elderly individuals; multiple studies in both Jewish and Christian populations have observed short delays before death that permit the celebration of a last sacred ritual (Idler and Kasl 1992).

Despite a background in the Durkheimian and Weberian traditions of the sociology of religion, the field of research in religion and health remained mostly unexplored through the century, but has begun grow-

ing quite rapidly in the 1990s, especially in the US, where levels of interest in religion are generally higher than in Europe. One may anticipate further growth in this field, as the measurement and conceptualization of the relevant domains of religiousness and spirituality improve, and as the population ages and the prevalence of chronic illness increases.

Religion and Politics: United States

Contrasted with other developed Western societies, high levels of religious affiliation and practice persist in the United States. Although the USA has maintained a constitutional separation of church and state, its citizens' religious beliefs and practices have often had political consequences. This article reviews theoretical and empirical literature about the mechanisms that link religion to American politics.

1. Definitions of Central Concepts

According to Durkheim, 'religion' is a form of collective memory for a society that projects order, stability, and predictability in social interactions on to the Divine will. Leege argues that 'People (who) share a sacred community...develop the self-confidence to act in concert. Religion specifies what action to take, and religious beliefs (and religious institutions) create the obligation to act' (Leege and Kellstedt 1993, p. 10). For the adherent, the political consequences of religious beliefs are that if life is not genuine unless lived in a religious way, so politics is not just unless its policies measure up to God's law.

Culture and religion have a deep symbiotic relationship. 'Culture' is a template—in Geertz's term 'a set of control mechanisms' (Geertz 1973, p. 49) for social relationships. When undergirded by religious values, culture establishes a moral order (Wuthnow 1987). Culture performs three central functions for a society: (a) it offers identity, (b) it prescribes norms for behavior, and (c) it maintains boundaries on relationships (Wildavsky 1987).

'Politics' refers to collective action. Politics resolves conflicts over social goals and the means for attaining them through collectively binding decisions (Easton

1953, Lasswell 1958). 'Power,' the ability to get others to do one's bidding (Dahl 1956), is the central relationship in politics. Culture and religion are important to politics because they help to legitimate social hierarchies, set goals, and specify boundaries on political institutions.

In democratic societies, religious institutions are normally located in the civil society. 'Civil society' is that collection of cultural norms, social and economic institutions that compose a way of life but cannot legitimately employ the means of coercion. They range from freely chosen activities (voluntary associations, market transactions) to activities resulting from one's station in society (class obligations). Since 'church' is in civil society and the 'state' potentially possesses the legitimate monopoly over the means of coercion (Max Weber, in Gerth and Mills 1946), Americans often stress the need for constitutional separation. A theocracy merging the two would be dangerous, but a public square devoid of humane religious standards for justice would lack transcendent perspectives and meaning (de Tocqueville 1958).

2. Role of Religion in American Social and Political Life

Max Weber (in Gerth and Mills 1946) argued that to understand a nation's religious world views, one should ask what its people are saved from and saved for. The American social system and its mythology reinforced a deep sense of equality and enterprise; one could become whatever one wanted through individual initiative. But how could some legitimately rule or become wealthy in a nation without a natural aristocracy? After all, the USA was settled heavily by those who had run foul of the law, escaped from conscription, would not submit to ecclesiastical order, or wanted nothing of the poorhouse. Creating a nation of such people, Legee et al. (in press) argue, would be a recipe for anarchy. However, a founding myth joining the Pilgrim covenant of popular sovereignty under God to the righteous life of Puritans would provide a legitimating moral order. Out of the welter of humanity, one could know whom to trust in economic relations or whom to invest with political power by their public righteousness. Evidence of religious commitment afforded social standing. From Thomas Jefferson to William Jefferson Clinton the test of religious commitment has been a test of fitness to rule.

Beyond its cultural function, religion persisted for three reasons, and each gave it a political character. First, contrary to the lazy monopoly that most European churches exercised (see Finke and Stark (1992) for a discussion of this thesis), American churches had to compete for adherents. In addition to dispensing the sacraments, churches developed a wide range of ministries, programs, and social services to

attract and hold the loyalties of their members. Political interests evolved from efforts to maintain and extend such programs. Second, as economic development created an ever more complex society, and individualism became the dominant social philosophy, people needed an institution to provide meaning in everyday life. The church became that solace and gathering place for 'people like us' (see Fowler 1989). Yet urbanization and mass communication thrust people with very different cultural and religious values into proximity with each other (see Engels, in Benson (1979, p. 205) for a realization of how this process undercut a Marxian interpretation of historical stages). Often people felt compelled to seek state action to protect or extend their parochial values (see Hertzke (1993) for two illustrations of cultural populism in recent American politics). Third, a transformationist impulse ran deeply through American piety. Calvinism, the dominant cultural form of American religion, had specified that righteousness would be evident in diligent work, the acquisition of wealth, and charity for the less fortunate (Weber 1946). Nevertheless, righteousness was difficult in an unjust society. Society needed to be transformed from time to time to be a fitting vessel for God's people. The Declaration of Independence, abolition of slavery, Civil War, prohibition, social work and welfare reform, labor rights, anticommunism, the Civil Rights movement, and current antiabortion politics—all were argued in the name of God. The myths of the righteous citizen and 'the city on a hill' not only fueled progressive reforms throughout American political history but also legitimated less-than-righteous foreign policies.

Finally, theorists argue that religion is relevant to American politics because of the permeability of its political structures. Its systems of federalism, division of powers, checks and balances, multitudes of interest groups, etc., all invite citizens to find the appropriate venue for success with their policy or issue (summarized in Wald 1997). For example, if religious groups cannot get an anti-abortion amendment out of Capitol Hill, and if the White House abandons them, they can turn to Supreme Court appointments, or they can argue for a shift in most abortion decisions at the state level (e.g., *Webster vs. Reproductive Health Services* 1989), where it is easier to mobilize a successful coalition locally. Most political careers in the USA depend on support at the micro level, and that is also where organized religion has its strength.

3. Mechanisms that Enhance or Diminish the Linkage between Religion and Politics

Much research in this field has addressed the political consequences of different ways of being religious (see Stark and Glock (1968) and Lenski (1963) for pioneering work on the dimensions of religiosity, and Legee and Kellstedt (1993) for more recent methodological

work on American National Election Studies datasets). The most persistent theme is that the creedal dimension, i.e., what people believe, has powerful effects on politics. Through a complex model, Glock and Stark (1966) showed that the more orthodox the Christian beliefs, the more likely an American is anti-Semitic. The findings remained controversial, however, because of the measures for orthodoxy: The items tap beliefs common to the evangelical Protestant tradition but overlook beliefs that derive from sacramental/incarnational Christianity.

To avoid over-reliance on the beliefs dimension, many scholars, following the lead of Kellstedt (Leege and Kellstedt 1993, pp. 273–304) have developed indices from ‘minimal’ Christian beliefs/practices across several dimensions. Regarding the partisan and ideological consequences of religion, they conclude that the higher the level of religiosity, the greater the Republican loyalty and degree of conservatism—regardless of denomination (Green et al. 1996, especially Chaps. 14 and 15). Leege (1996), however, has shown that among Catholics generational and gender differences override the effects of either beliefs alone or multiple-measure indices of religiosity. Further, higher levels of religiosity among African-American Christians and among Jews are typically associated with some aspects of political liberalism and Democratic loyalty (see recent studies in Smidt and Penning (1997)). Scholars recognize a large unfinished agenda on the measurement of beliefs and practices, especially in the over-reporting of church attendance.

In some respects, greater progress is shown in the political consequences of religion as a group phenomenon. Churches and religious traditions are often reference groups, waxing and waning in salience for their adherents. They develop interests, seek either to protect their values from threat or to evangelize their values, or become the target of persecution. The last is particularly important to political mobilization. Converse’s (1966) study of Catholics in the 1960 election showed that Protestant Democrats not only left their party’s Catholic nominee, but that Catholic Republicans crossed over to Kennedy, and all Catholics were more highly mobilized. Those most likely to show the mobilization effects and to be drawn to Catholic Kennedy were not those who attended mass regularly but those who identified most closely with being Catholic. Social identification trumped social cohesion, i.e., regular interaction with fellow group members (see Turner in Tajfel (1982) for this distinction). Further, reinforcing group loyalties enhanced the attraction of Kennedy, e.g., Irish urban Catholics were drawn more to him than Polish nonurban Catholics. Thus, religious effects partake also of other cultural group identifications.

Nevertheless, frequency of interaction with fellow religionists can have profound political effects. In carefully controlled studies, group norms about political values and candidate selection are shown to be

propagated through behavioral contagion among church attenders (Wald et al. 1988). Where fellow church members are also informal discussion partners, political views are most likely to be reinforced and turned into political actions (Gilbert 1993, Huckfeldt et al. 1993). Even if religious congregations are composed of like-minded people, Jelen (1991) has argued, religiously based political mobilization is unlikely to occur until a negative outgroup, an external enemy, is identified.

Many leaders, both religious and political, attempt to define political agendas, issues, and choices in ways that will mobilize or demobilize religious adherents. This may or may not have political consequences. Earlier, Hadden (1969) warned that liberal activists among the Protestant clergy involved in civil rights and antiwar efforts were driving a wedge between their churches and their congregants. Quinley (1974) argued that the division was not universal, but that there was something of a two-party system emerging among the clergy: Liberals committed to social change addressed largely justice and peace issues, whereas conservatives addressed those moral issues having to do with sexuality, reproduction, family life, and national moral decline; still, the latter were less overtly involved in politics. An important study of the politics of clergy from eight Protestant denominations (excluding the Catholic churches such as Anglican, Lutheran, and Roman Catholic) shows that the two-party division is very evident, the gap in political involvement has closed, and the values of the clergy can be traced directly to theological differences (Guth et al. 1997).

Do the laity follow the beat of these ordained drummers? That is a more complex matter. Most studies are limited to comparing the values and actions of clergy samples with the values and actions of laity samples from their denominations. Already, we observed that most of the action in American religion and politics is local; therefore, an appropriate design for assessing clerical cue-giving effects would use the parish or congregation as the unit of analysis. While the possibilities of controlled studies can be seen (e.g., Roozen et al. (1984), Leege et al. (1984–9), Jelen (1991), Olson (2000)), they are still largely at a typological development stage and offer samples of such small sizes that generalizations are difficult.

Promising hypotheses include the following: (a) the more consummatory the loyalty to a local church, the more influence its pastor has over the religious and political life of its people; (b) the deeper the theological understanding of each member, the more likely that moral values shared by clergy and congregants will guide political choices; (c) the greater the sense of oppression, threat, or status loss felt by church members in modern society—where the subjects of concern are the norms by which we should live—the more the receptivity to cues from religious leaders; (d) the smaller and more homogeneous or selective the religious body, the more dominant its leader’s political

views; (e) the greater the legitimacy of corporate political involvement by the church, the more influential its leadership on a course of political action; (f) the more the issue concerns activities that individuals or families can influence (e.g., consequences of sexuality) rather than the product of impersonal economic forces (e.g. plant closings), the more religious leaders can define the political agenda; and (g) the greater the individual's intrinsic level of interest in politics, the more he/she will hear political cues when given by a religious leader. Impediments to political leadership by clergy abound: (a) separation of church and state illegitimizes the more overt political actions by religious groups; (b) religious groups specialize in salvation, not public policy; (c) religious groups can lose tax exemptions and other privileges when they become too political; (d) within the pluralistic civil society, the church is only one of many groups competing for loyalty and influence; and (e) within the democratic political process, compromise is more characteristic than success on issues defined by churches as zero-sum.

Beyond the local level, churches engage vigorously in politics. Noting a leadership vacuum in many Republican county and state party organizations, Religious Right groups such as the Christian Coalition were able to consolidate dominance over about half of the state party central committees (Rozell and Wilcox 1997). On the policy advocacy front, Wuthnow (1988) has noted a great increase in the number of religious interest groups that are arranged across denominational divides. A number of scholars (see Hertzke (1988) as representative) have examined the organization and tactics of denominational and ecumenical interest groups in Washington. Although their official lobbies are small, they use the full range of inside-the-Beltway tactics. Given the decentralization of policy-making, the larger church bodies or coalitions have similar lobbies at the state level. Outside the Beltway, church interest groups seek to mobilize home district pressure through direct mail and fund-raising, letter writing and contacting, candidate ratings and thinly disguised endorsements, get-out-the-vote drives, and media dramaturgy.

A few studies have shown the impact of the public officials' own religious beliefs and practices on their policy preferences and actions. The most comprehensive of these (Benson and Williams 1982) shows that substantial segments of both political conservatives and political liberals act from religious predispositions. The former affirm an individualism-preserving religion and politics (emphasis on the ways laws create order and protect individuals from their own worst impulses), whereas the latter embrace a community-building religion and politics (emphasis on social transformation, justice, and peace). This study inspired later work by Legee and Welch (1989) where the same types were found in mass samples of Catholic laity, and by Guth et al.'s (1997) clergy study.

Thus, religiously inspired public officials, clergy, and laity appear to have in common certain foundational religious beliefs that divide them from each other both theologically and politically. At the same time it is important to note that (a) a substantial proportion of public officials are only nominally religious, and (b) representational roles (read: the imperative to be re-elected) constrain translating religious beliefs into public policy.

Finally, political elites in the USA need religious groups if they are to achieve their goals of election/re-election. Religious group membership provides a useful basis for political market segmentation. Strategic politicians can mobilize religious group members by advocating policy interests, stressing group affinities (e.g., Kennedy as a modern Catholic, Reagan as an apostate Irish Catholic), or symbolically pillorying the 'enemies' of a religious group. Effective as mobilization is, demobilization of a religious group which composes part of a rival party's majority coalition has the same impact on chances of victory. This is done by stressing how the rival party has deserted the religious group's values (Legee et al. (in press) apply social attribution theory to understand this strategy). Over time, crystallized party images come to include the policy positions of religious groups and even the group itself. For example, the public associated evangelicals and fundamentalists with the Republican Party as early as 1964 and 1980, but they became central to the party image from 1988 to 1996.

Decisions to rely on churches for political mobilization are well advised. Using a resource theory of political participation, Verba et al. (1995) show that churches nurture skills that easily transfer to the political sector. Thus, minorities such as African-Americans associated with black churches participate more than a socioeconomic model would predict, while many Latinos associated with Catholic parishes not developing such skills participate less. Wald (1997) argues that the following skills are germane to politics derive from church participation in the USA: (a) social skills in listening, mediating, and leading; (b) awareness of public issues from a moral perspective; (c) encouragement to join other civic and community betterment activities; (d) a conviction that there is a sacred character to social obligations that transcends self-interest; and (e) the self-esteem that derives from practice with public assignments.

Empirical evidence, then, sustains the argument that religion has measurable effects on American politics, at the same time that certain styles of influence attempts are circumscribed. Basic problems of conceptualization and measurement, underspecified models, endogeneity, failure to anchor puzzles in strong social theory, and inappropriate samples continue to characterize this developing field of inquiry.

D. C. Leege

Religion and Science

The intersection of religion and sciences has been both more complex and less conflictive than is frequently depicted by those who cite the trial of Galileo, the dispute over the theological implications of Charles Darwin's theory of natural selection, and the Scopes Trial as evidence of the historical incompatibility of religious beliefs and scientific endeavor. This article will first examine the conflict thesis, then survey the history of the relations between religion and science in the Western tradition from the fifth century BC to the

end of the twentieth century with special reference to Christianity.

1. *The Historiography of Religion and Sciences*

The thesis that Christianity has been historically hostile to science was popularized by two influential works that appeared in the late nineteenth century: John William Draper's (1811–1882) *History of the Conflict Between Religion and Science* (1874) and Andrew Dickson White's (1832–1918) *A History of the Warfare of Science with Theology in Christendom* (1896). White, the first president of Cornell University, argued that Christianity had a long history of opposing scientific progress in the interest of dogmatic theology. Wedding a triumphalist view of science to a dismissive view of theology, his thesis struck a responsive chord in American thought, which was at the turn of the century increasingly committed both to a secular outlook and to recognizing the central role that the sciences played in modern society. The Draper–White thesis became enormously influential in America both among academics and in the popular mind. It came to dominate the historical interpretation of the relations of religion to science during much of the twentieth century. Reflecting a positivist outlook, it viewed science as continually progressing and overcoming the entrenched antagonism of religious opinions, which invariably retreated before its advance.

Some historians regarded the Draper–White thesis as oversimplifying and distorting a complicated relationship. Thus, Burt, in *The Metaphysical Foundations of Modern Physical Science* (1932), suggested that, far from being hindered by religion, science was in fact indebted to theological ideas. Alfred North Whitehead, in *Science and the Modern World* (1926), rejected the view that in controversies between science and religion, religion was wrong, and ... science was always right. The true facts of the case are very much more complex, and refuse to be summarized in these simple terms. A number of important studies, by Robert K. Merton, Herbert Butterfield, and Alexandre Koyré, among others, also challenged the conflict thesis.

A smaller number of historians of science went even further to argue that specific components of Christian theology were responsible for the scientific revolution. Reijer Hooykaas contended that Calvinism's accommodationist understanding of Scripture and its voluntaristic theology encouraged scientific endeavor. Similarly Stanley Jaki, in *Science and Creation* (1974), maintained that Christian theism, the doctrine of Creation, and the belief that the universe is governed by a rational and benevolent deity were necessary preconditions of the development of modern science.

In the last three decades of the twentieth century several scholars have provided a more systematic

reevaluation of the conflict thesis. Two major contributions to the literature came from Lindberg and Numbers (1986) and Brooke (1991). In the introduction to their composite volume, Lindberg and Numbers argued for an historical picture that recognized 'a complex and diverse interaction that defies reduction to simple "conflict" or "harmony"' to replace the largely polemical one drawn by Draper and White. Brooke objected to imparting essentialist understandings to words like 'science' and 'religion,' which had many different meanings over time and could not be reduced to simple static concepts. 'Natural philosophy,' for example, denoted something very different in the seventeenth century from 'science' in the twentieth. The growing acknowledgment that in their relations religion and the sciences have exhibited a multiplicity of attitudes, reflecting local conditions and particular historical circumstances, led Brooke to suggest that a 'complexity thesis' is a more accurate model than the familiar conflict thesis. The views of Brooke, and Lindberg and Numbers have gained increasing acceptance among professional historians of science.

2. *Greece and Rome*

Western science as an explanatory enterprise began with the Greeks. It was in the sixth century BC that the Pre-Socratic philosophers like Thales (fl. 585 BC), Anaxagoras (c. 500–428 BC), and Anaximander (c. 610–546 BC) challenged the mythopoeic picture of the natural world. Most Pre-Socratics understood the world in nonmythological terms, viewing it as the product of natural forces. In the late fifth century BC they experienced some popular opposition in Athens. In c. 437–436 BC Anaxagoras was prosecuted on a charge of impiety and his books publicly burned.

By the end of the fifth century BC natural philosophy (physical science) had come to be recognized by the Greeks as offering the most suitable means of understanding the world of nature and religious issues and hereafter were to play a limited role in either hindering or encouraging scientific endeavor in the classical world. This does not mean that religious ideas were of no account in formulating world views for the Greeks or for the Romans, who took over the philosophical and scientific culture of the Greeks. The Epicureans explicitly repudiated a religious view of the universe while for the Stoics, science (especially cosmology) and religious thought were related intimately. Moreover, the Greek view of the world was predominantly an organicist or vitalist one. Philosophical naturalism, which was espoused by the Pre-Socratic philosophers, the sophists, Aristotle (384–322 BC), and the Epicureans, always remained a minority opinion in Graeco–Roman thought. In general the Greeks conceived of nature as a divinity. Plato (c. 427–347 BC) believed that a world soul (psyche)

animated the universe, in which the sun, the moon, the stars, and the planets were gods. A vitalist world picture, stripped of its pagan elements, was transmitted by the Romans to Western Europeans, who continued to hold it well into the Middle Ages.

3. Late Antiquity and the Middle Ages

Christianity, founded by Jesus of Nazareth (c. 4 BC to 29 AD), spread rapidly throughout the Roman Empire owing to its extensive missionary activity. In the second century AD Christian apologists (theologians who defended their faith philosophically against pagan critics) began the process of harmonizing Christian revelation with Graeco-Roman philosophy. Apologists like Justin Martyr (c. 100–165), Tertullian (c. 160–220), and Irenaeus (c. 130–200) were intellectuals who had received their education in classical culture and were influenced strongly by it. Their opinion of natural philosophy, which was a component of Greek philosophy and inseparable from it, was ambiguous. While they often denounced it for its pagan religious or anti-Christian elements, they employed its methods, thought forms, and vocabulary—and drew on it when it was useful in the rational defense of Christianity. These church Fathers hellenized Christianity by taking over elements of classical culture and incorporating them into the Christian world view. Tertullian, for example, who asked, ‘What indeed has Athens to do with Jerusalem? What harmony is there between the Academy and the church?’ is sometimes cited as an example of early Christian anti-intellectualism. Yet he often borrowed from Greek natural science and medicine to buttress his theological arguments. Not all Christian apologists accepted Greek science, however. A few, like Tatian (second century), who were influenced by ascetic ideals or concerns about potential demonic influences, were either guarded in their acceptance or hostile in their approach to Greek pagan natural philosophy.

The most influential of the church Fathers was Augustine of Hippo in North Africa (354–430). Augustine shared the reservations of some of the Fathers about the value of natural philosophy but he recognized its utility. Like other Fathers he rejected *curiositas*, the desire to pursue knowledge for the sake of knowing, which he regarded as a characteristic feature of pagan learning. But Augustine believed that the study of natural philosophy was legitimated when it served higher purposes, such as aiding in the understanding of Scripture or lending support to Christian theology. By becoming the handmaiden of Christian theology natural philosophy was assured a place in the emerging Christian culture, one that was to last through the Middle Ages and well into the early-modern period.

The early Middle Ages (c. 500–1000) was a period of disintegration that followed the collapse of the Roman

Empire in the West under repeated attacks and occupation by Germanic barbarians. As towns became villages, public services ceased to exist, and roads became impassable, the cultural continuity with the classical world was nearly severed. Educational institutions disappeared and learning remained alive only in Christian monasteries. A few distinguished figures stand out from the intellectual gloom of the period for their interest in natural philosophy, much of it derived from Neoplatonic sources. They include Cassiodorus (c. 485–580), Isidore, bishop of Seville (c. 560–636), the Venerable Bede (c. 673–735), and John Scotus Erigena (c. 810–877). These men could do little more than preserve as much as possible of the accumulated classical heritage, including natural philosophy, but they did so as clerics, within a monastic framework, and with the confidence that scientific knowledge, as a handmaiden to theology (*philosophia ancilla theologiae*), was worthy of being transmitted to future generations.

The eleventh and twelfth centuries experienced the revival of trade between Western Europe and the eastern Mediterranean, together with the concomitant renewal of urban life, the growth of manufacturing, and the beginning of the gradual transformation of Europe from a rural to an urban economy. Cathedral schools sprang up in cities and gradually replaced monastic schools. In the twelfth century natural philosophers avidly studied Plato’s *Timaeus* and attempted to harmonize its cosmology with the Creation account in Genesis. The Arabs had preserved Greek learning, and works by Greek authors on natural philosophy were translated into Latin from Arabic, thus making available much new scientific material. The most important were the extant works of Aristotle, which by the thirteenth century had been translated in their entirety, replacing the influence of Plato and creating a major intellectual transformation of Western European universities. Muslim contributions (for example, in optics) were significant as well.

There was much in Aristotle’s writings that was useful to European Christians and that could be harmonized with Christian theology. But there were also areas of potential conflict, such as Aristotle’s belief that the world is eternal, that the soul is not immortal, and that the universe can be accounted for by naturalistic and even deterministic explanations apart from divine providence. These and other incompatible doctrines caused the teaching of Aristotle’s natural philosophy to be banned from the University of Paris (site of the preeminent theological faculty in Europe) in 1210 and 1215, but by 1255 his writings had gained official sanction and they came to be widely studied. A number of distinguished scholars, including Roger Bacon (1213–1291), Albert the Great (1200–1280), and his student Thomas Aquinas (c. 1224–1274), attempted to create a synthesis of Aristotelian philosophy and Christian theology that would rec-

oncile the Christian faith and classical reason. The existence of a more radical faction at Paris, headed by Siger of Brabant (c. 1240–1284), led the bishop of Paris, Etienne Tempier, to condemn, at the request of traditional theologians, 13 philosophical propositions espoused by Siger. In 1277 he increased the number of propositions condemned to 219. The condemnations represented a conservative backlash that placed limits on speculation in natural philosophy. In the long run, however, they provided arts masters at Paris with incentives to explore other scientific options that lay outside Aristotelian natural philosophy, particularly by way of ‘thought experiments’ that entertained hypothetical possibilities, such as the existence of other worlds or of a vacuum. In fact, freedom of scientific speculation was relatively broad in late medieval universities, which were supported by the church.

4. The Copernican Revolution and Galileo

When joined with Aristotelian physics, the geocentric theory of the solar system, as refined by Ptolemy of Alexandria (second century AD), was almost universally accepted in the West and taken to be compatible with their theologies by Jews, Muslims, and Christians until the seventeenth century. The first major challenge to the Ptolemaic theory came with the publication of Nicolaus Copernicus’s (1473–1543) *De revolutionibus orbium coelestium* (*On the Revolutions of the Heavenly Bodies*), which appeared after the author’s death in 1543. Copernicus advocated a heliocentric model of the solar system. How he came to espouse it is unknown but he might never have published it had it not been for the encouragement of a young Lutheran astronomer, Georg Rheticus (1514–1574) of Wittenberg. Although they initially rejected its heliocentric cosmology, Lutherans at the University of Wittenberg, including the Protestant reformer Philip Melancthon (1497–1560), were attracted to the mathematical convenience of the new theory. Elsewhere, however, European natural philosophers rejected it for a variety of reasons, many of which were scientific rather than theological. In the year 1600 there were probably no more than 10 Copernicans in all Europe.

One scientist who was quick to embrace the new theory was Galileo Galilei (1564–1642), a young professor of mathematics at the University of Padua. Although secretly a Copernican by 1597, Galileo did not publicize his views until 1613, when in *Letters on Sunspots* he declared his acceptance of the heliocentric system. It was, however, his *Letter to the Grand Duchess Christina* (1615), in which Galileo argued that Scripture did not intend to impart scientific truth but accommodated itself to popular language in describing the natural world, that provoked the Catholic Church’s response. Although a layman, Galileo had undertaken to interpret the Bible. In the following

year (1616) he appeared before the Congregation of the Holy Office (the Inquisition). Cardinal Bellarmine stated his willingness to accept the Copernican theory if it could be proven (which it could not be at the time); otherwise Scripture ought to be read literally as teaching geocentricity. The Church declared the theory ‘false and contrary to Holy Scripture’ and recommended that *De revolutionibus* be ‘suspended until corrected.’ Galileo was warned not to teach or defend heliocentrism except as a hypothesis until it could be proven. In 1632, after maintaining silence for 16 years, Galileo published his *Dialogue on the Two Principal World Systems*, an ostensibly even-handed debate between proponents of the Ptolemaic and Copernican theories in which the arguments for the Ptolemaic theory were made to look feeble. Galileo was summoned to Rome, where he stood trial in 1633. Compelled to abjure his belief that the earth moved, he was confined to a country estate near Florence, where he continued writing until his death in 1642.

The traditional picture of Galileo as a martyr to intellectual freedom and a victim of the Catholic Church’s hostility to science is little more than a caricature. The trial of Galileo must be understood against the backdrop of his own times. A vain and ambitious man, he did not suffer fools gladly and he had a penchant for making enemies in high places. Among those he alienated was Pope Urban VIII (1623–1644), who had earlier encouraged Galileo’s researches on the motion of the earth, but came to believe that Galileo had betrayed him in deliberately violating an injunction not to teach Copernicanism. Moreover, strong reaction against Copernicanism (and Galileo’s espousal of it) came from the Aristotelians of the scientific establishment, some of whom were determined to entangle Galileo with the Church. In particular, Galileo aroused the ire of a loosely-organized movement of traditional scientists called the *Liga*, which succeeded in introducing theological issues into scientific discourse and attacked Galileo for his views.

In contrast with the relative freedom of intellectual debate that natural philosophers in European universities had enjoyed in the late Middle Ages, the Protestant Reformation had made the Catholic Church more cautious. In the question of whether Scripture ought to be read as teaching a geocentric universe, the Church was anxious to prove its good faith in interpreting Scripture literally in the face of Protestant attacks on its allegorizing tendencies in biblical exegesis. Aristotelianism became, in its Thomistic form, a rigid dogma and the papal court became, after the Council of Trent (1545–1563), more authoritarian. The Inquisition and the Index of Prohibited Books, introduced into Italy by forces of the Counter Reformation, were employed against Galileo. The prosecution of Galileo represents not the *cause célèbre* in the alleged warfare of science with theology, but a dispute that involved multiple issues, including

powerful personalities and vested professional and ecclesiastical interests, which complicated Galileo's championing of a revolutionary change in astronomical models.

5. *The Mechanical Philosophy and Natural Theology*

By the mid-seventeenth century, the Copernican theory had come to be accepted widely throughout Europe, owing largely to Galileo's promotion of heliocentrism. The seventeenth century saw, too, the formulation of a mechanical model of the universe, which attempted to account for all natural phenomena in terms of matter and motion without reference to action at a distance. The mechanical philosophy had its roots in corpuscular materialism, which explained physical phenomena by the interaction of tiny particles of matter called atoms. While elements of the model had been adopted by several of the leading figures of the scientific revolution, its most influential advocates were René Descartes (1596–1650) and Pierre Gassendi (1592–1655), who sought to devise a new philosophy that would replace Aristotelianism. While Descartes and Gassendi grounded their mechanical philosophies in theological considerations, critics feared that their views would lead to materialism, as they did in the case of Thomas Hobbes (1588–1679), or to deism, as they did in the case of Voltaire (1694–1778).

The mechanical philosophy received its greatest synthesis at the hands of Isaac Newton (1642–1727) in his *Principia Mathematica Naturalis Philosophiae* (*Mathematical Principles of Natural Philosophy* (1687)). By his discovery of the principle of universal gravitation, Newton succeeded in harmonizing celestial and terrestrial mechanics, bringing for the first time the whole of nature into a precise rational interpretation. Newton's picture of a universe governed by uniform laws that could be described without recourse to primary causes resulted in the widespread belief that nature was self-governing and aided the 'natural religion' of deism and its idea of a 'watchmaker' God. It is ironic that Newton, himself a Christian (although an Arian), inadvertently laid the groundwork for the rationalism of the eighteenth-century Enlightenment. On the basis of his synthesis of the mechanical philosophy David Hume (1711–1776) developed a materialistic philosophy in England, while in France philosophers like Julien Offray de La Mettrie (1709–1751) and Baron d'Holbach (1723–1789) embraced atheistic materialism.

The popularity of the mechanical philosophy led in the latter half of the seventeenth century to the creation of a natural theology that continued into the nineteenth century. Natural theology describes the existence and attributes of God by means of knowledge derived from natural reason rather than from special revelation. There were several grounds for its attrac-

tion: the wonders of scientific discoveries, many of which could be seen for the first time with the invention of the microscope; the desire to secure an adequate foundation for a theology of divine providence that would confront the perceived dangers of materialistic atheism; and the enormous influence of Newton's mechanical picture of the world. The argument from design became the cornerstone of a natural theology, in which God was described as a craftsman, a geometer, or an architect. Not all exponents of natural theology were deists; many theists, especially those who were repelled by religious enthusiasm, were involved in the enterprise of demonstrating the majesty of the Creator from the intricacies embedded in his creation. In William Paley's (1743–1805) influential *Natural Theology, or Evidences of the Existence and Attributes of the Deity* (1802) natural theology reached its apex.

6. *Geology and Darwinian Evolution*

The influence of the Enlightenment, with its exaltation of reason and rejection of special revelation, can be observed in the developments that were occurring in science, particularly in the increasing tendency to seek naturalistic explanations and to divorce science altogether from theological considerations. In the seventeenth and eighteenth centuries theories of the earth had sought to weave together geology and theology in what was termed 'physico-theology.' Many of these theories calculated the age of the earth by using biblical chronologies in a way that could be harmonized with physical principles. Invariably they postulated a young earth. While most attributed organic fossils to the Noachian Flood, by the eighteenth century it was becoming increasingly difficult to explain the global distribution of fossils by a single event (the Deluge) that had taken place a few thousand years ago. The French naturalist Georges Louis Leclerc, Comte de Buffon (1707–1788), a deist, proposed a much older earth (publicly of 75,000 years and privately perhaps as old as three million years) and suggested that each of the six biblical days of Creation might correspond to an immense length of time. Georges Cuvier (1769–1832), a devout Protestant, demonstrated the existence of fossil mammals unlike any in his own day and without any apparent intermediate forms. He argued that a series of geologic catastrophes had eliminated species in past ages. Cuvier's catastrophes were not global and in his case did not derive from his religious convictions. But they were later read as such and were appropriated in English natural theology to support catastrophism, which became a popular form of physico-theology that attributed geological changes to great catastrophes of the past, the most recent being the biblical Flood.

The Scottish geologist Charles Lyell (1797–1875) rejected altogether providential interventions in geologic history. In his *Principles of Geology* (3 vols. 1830–1833) he succeeded in severing geology from theology. Lyell rejected diluvialism (catastrophism) for what became known as uniformitarianism: the theory that geological changes on the earth's surface have occurred slowly over long periods of time and that in explaining change we refer to processes that we currently observe. Previous proponents of diluvialism, like William Buckland (1784–1856) of Oxford and Adam Sedgwick (1785–1873) of Cambridge, quickly abandoned catastrophism and adopted the new geology, which Christians harmonized with the Genesis account of Creation in a relatively painless fashion. A group of laymen, who called themselves Mosaic or Scriptural geologists, continued to take their geology from Genesis but they were marginalized since nearly all professional geologists abandoned the Noachian Flood as an organizing idea in accounting for changes in the earth's history.

Charles Darwin (1809–82) had, as a young man, been influenced by Paley's natural theology. During his voyage aboard the H.M.S. *Beagle*, however, he read Lyell's work and began to think that slow changes had produced the geological phenomena that he observed. His theory of evolution by natural selection, published in *Origin of Species* (1859), made use of Lyell's theories that the earth was very old and the fossil record imperfect. Evolutionary ideas had preceded Darwin. Originating in the Enlightenment, they had already been proposed in the eighteenth century by Charles's grandfather, Erasmus Darwin (1731–1802), and by Jean-Baptiste Lamarck (1744–1829), the latter proposing the theory that acquired characteristics were inherited. By the mid-nineteenth century the belief that transmutationism (evolution) represented a divine plan was widespread. In advancing natural selection as a mechanism for evolution, Darwin argued that in the 'struggle for existence' those individuals with even a slight advantage would survive and pass their advantage on to their offspring. Herbert Spencer (1820–1903) referred to it as the principle of the 'survival of the fittest.'

Darwin's theory met with a mixed response that cut across conventional professional and religious boundaries. Some scientists initially rejected it, while a number of clergymen accepted it. Conservative anti-Darwinists, including several leading naturalists like Louis Agassiz of Harvard (1807–1873), geologists like Canadian William Dawson (1820–1899) of McGill, and theologians like Charles Hodge (1797–1878) of Princeton Seminary rejected it, fearing the break with final causes. A second group of Christians accepted evolutionary theory as compatible with a biblical faith. They included the Scot James McCosh (1811–1894), president of Princeton University, and the American botanist Asa Gray (1810–1888) of Harvard. A third group came to believe that evolution had

rendered supernatural religion untenable and opted (most often) for some form of philosophical materialism.

By the 1870s, however, most scientists and a large body of the educated public had accepted some form of evolution (though not necessarily natural selection). Full acceptance of Darwin's views on human nature, as set forth in his *Descent of Man* (1871), was more difficult for Christians. Darwin maintained that moral values were rationalizations of social instincts that had developed by natural selection, thus asserting a full-blown materialism. Alfred Russell Wallace (1823–1913), the codiscoverer of the theory of evolution by natural selection, rejected materialism, maintaining that the creation of the human mind required non-material forces.

In the 1920s evolution was one of several theological issues that divided the major Protestant denominations of North America in the modernist–fundamentalist controversy. While many Protestants (as well as some Roman Catholics and Jews) had come to believe in an old earth and to harmonize belief in evolution with a nonliteral interpretation of the Genesis account of Creation, conservatives emphasized in their rejection the atheistic and materialistic dangers inherent in a naturalistic theory of human origins. But the Scopes trial, held in Dayton, TN in 1925, symbolized the inability of biblical literalists to withstand the force of Darwinism, which was taken for granted by the intellectual elites of Europe and America. Anti-evolutionism was pilloried in the American press as a rearguard reaction to scientific progress and it was associated with nativism and rural and uneducated religious fundamentalism. Although biblical catastrophism was revived in the 1920s, it enjoyed favor only in conservative and sectarian Protestant circles in North America before it exploded into the popular creationist movement (called 'Flood Geology') in the 1960s.

7. Twentieth-Century Physics and Cosmology

While religious issues had been increasingly excluded from scientific discourse in geology and natural history (the study of natural objects, plants, minerals, and animals) in the nineteenth century, they had continued to be discussed in natural philosophy. From about 1895 modern physics began to deal with issues that went beyond those of classical physics, including quantum mechanics and special and general relativity. Several discoveries in modern physics challenged the determinism of the Newtonian mechanical model. Foremost was the indeterminacy principle of Werner Heisenberg (1901–1976), which demonstrated that one could not know perfectly both the position and momentum of a subatomic particle. Heisenberg's principle gave rise to much discussion of its wider

philosophical and theological implications, particularly relating to the possibility of intelligent design of the universe and human free will.

In cosmology too discoveries were made that suggested theological implications. Edwin Hubble's (1889–1953) discovery that the universe was expanding at a tremendous rate led the Roman Catholic priest and physicist Georges Lemaître (1894–1966) to propose what became known as the big-bang theory: that the universe had begun as a dense 'primeval atom' that had exploded in the distant past. It was challenged by the steady-state theory, developed in England and championed by Fred Hoyle (1915–), according to which the universe is eternal but matter is being continuously created in space. In the late 1960s, several observational discoveries led to the almost universal acceptance of the big-bang theory, which was argued by some researchers, like Paul Davies (1946–) and Frank Tipler (1947–), to strengthen belief in God's creation of the universe.

Another cosmological theory that engendered a good deal of theological discussion was the Anthropic Principle (a term coined by Brandon Carter in 1974), which asserts that the emergence of human beings in the universe is not an accidental by product of purposeless cosmic evolution. According to this theory the universe was so finely tuned during its earliest moments that if any one of several physical parameters had been slightly different it would have been unsuitable for the survival of human life. Hence, it is argued that the inhabited universe is anthropocentric, having been designed for human beings. The Anthropic Principle reintroduced into cosmological speculation at the end of the twentieth century issues that were long thought to have been laid to rest, including questions of teleology, intelligent design, and divine providence.

8. Conclusion

By the 1940s the modern synthesis of genetics and Darwin's theory of natural selection, which accounted for random variation by genetic mutation, made it possible for biological scientists to adopt a fully naturalistic position in both method and metaphysics. Naturalistic evolution, it was alleged, was able offer a complete explanation for the origin and development of the universe and for all forms of life, as well as for social factors like language, religion, and ethics. While scientists like George Gaylord Simpson (1902–1984) considered materialism to be the only philosophical position capable of scientific support, it was far from universally accepted within the scientific community. The last decade of the twentieth century, moreover, saw a resurgence of interest in the relationship of religion to the sciences. This interest arose from a variety of sources both within and outside the scientific community, including those of Christian and other

theistic traditions (who most often asserted the complementarity of religion and the sciences), process philosophers, proponents of New Age and pantheistic spiritualism, and non-Western religious traditions. Perhaps it reflected the widespread recognition that, for all its achievements, science does not provide ultimate answers to questions regarding the meaning of the universe or of life itself.

Religion and Youth

Religion has traditionally been an important aspect of personal and social identity. Socially, it provides a 'language'—a set of beliefs, values, and practices—which form an ultimate framework of meaning and order, binding people into one community rather than another. Individually, religion locates a person within a social context, conferring a sense of belonging, a way to understand the self in relation to the world, and a purpose to life. Western society is changing rapidly, however, bringing new uncertainties to the social context of identity formation (Giddens 1991). The last 30 years have seen economic restructuring, expansion of educational provision, new developments in communication and information technology, increased social and geographical mobility, changes in personal relationship and family norms, challenges to gender roles, and the generation of new attitudes and accepted ways of being. This raises the question as to what part religion plays in the formation of young people's identity today?

1. Who are the 'Young People'?

Before considering the relationship between religion and youth identity, it is important to note that the category 'young people' and the concept of 'youth' are problematic. There is no consensus on an upper age for 'young people' and surveys are reported using different age bands for the youngest groups. 'Youth' signifies a period of transition between childhood dependency and full adult responsibility but significant transitional markers, such as the school leaving age and access to employment and financial independence, vary between countries. There can also be age disparities within societies regarding different types of adult responsibility such as marriage and voting rights. Indeed, 'youth' is increasingly being separated from age altogether and becoming a valued personal quality to be retained throughout life. Furthermore, the experience of youth varies greatly according to gender, ethnicity, class, etc. Bearing these conceptual problems in mind, the picture of youth presented here is necessarily a generalized one and the discussion focuses on Christianity which remains the dominant religious tradition in the West (60 percent of

Europeans and 76 percent of North Americans claim a Christian identity, Brierley 1997).

2. Young People's Religious Beliefs and Practices

The data on young people's religious beliefs and practices are complex and sometimes contradictory. Throughout the industrial West young people are less likely than older people to actively engage with institutional religion (Halman and de Moor 1993, Clark et al. 1995). This may reflect a stage in the life cycle, but the evidence suggests long-term change as well.

Table 1 illustrates declining religiosity among youth in Europe on a number of traditional variables and Table 2 indicates how religiosity varies among young people cross-nationally.

From Tables 1 and 2 it can be seen that while Church association is declining, private prayer and belief in God remains quite high. Belief in the soul and life after death is also apparent. Half of European youth and 79 percent of young people in the United States (Inglehart et al. 1998, Vol. 151) describe themselves as 'a religious person.' More locally, there is evidence to suggest that young people take an interest in supernatural phenomenon, nontraditional beliefs, and 'folk' religion. Table 2 indicates the extent of

Table 1

a RC = Roman Catholic; P = Protestant; M = Mixed Protestant and Roman Catholic.

belief in reincarnation. In England and Wales approximately one-third of young teenagers believe in their horoscopes, ghosts, and the possibility of contacting the dead (Francis and Kay 1995, p. 152).

It is also important to recognize that while established mainline church membership is declining, there is some growth among smaller nonestablished churches, especially those which adopt an evangelical and charismatic form of spirituality. In this context the nature of belief and practice tends to be more emotive and personal. For example, young people are more likely to think of God as an intimate friend than as a righteous judge or creator. Various non-Christian new religious movements also attract a minority of youth, although these groups have not counteracted the overall drift away from the Church (Bruce 1996, p. 188).

Young people therefore retain a degree of private belief and practice which could offer an ultimate basis for identity formation. However, Table 2 indicates this is not necessarily the case. While many young people believe in God, God and religion are not very important for a large number of them. Gender studies further reveal that religion is less important to men and boys than it is to women and girls. Women in paid employment, however, tend to be more like men in their religiosity, so as more young women expect to

have working careers, this gender difference is likely to decrease in favor of the perceived irrelevance of religion. What then is the significance of religion for young people's identity?

3. *Young People's Religion and Identity*

The data suggest three broad patterns of relationship between religion and identity among young people in modern Western society.

3.1 *Secular Identity*

Some young people reject religion altogether (according to the 1981 European Values Survey, 27 percent of people under 35 claim to be atheists, Harding et al. 1986, p. 48), but a large number have remnants of traditional belief, echos of an early but incomplete socialization into the Christian framework of their culture. These young people tend not to be hostile to Christianity and may even 'believe' to some extent, but generally they are ignorant and indifferent to its teachings. Christian plausibility has been undermined by increasing contact with the competing truth

claims of other faiths and philosophies, and by the perception that science offers more convincing explanations of life than does religion. Consequently, Christianity has little, if any, significance for these young people's self-understanding. For the most part, they orient their lives according to a utilitarian rational world view gaining their identity through material consumption and through immediate intimate relationships with family and friends. Links between religion and self-understanding are only salient on special occasions (such as the celebration of a birth or a marriage), or at times of crisis (such as during illness or death) when an implicit Christian identity is unearthed. Even then the significance of religion is fleeting. Its main function is to provide a culturally acceptable background for the renegotiation of an essentially secular identity which is largely achieved through the gathered family and friends. Committed religious belief or understanding is unnecessary in this context.

3.2 *Spiritual Identity*

Some young people are more active in their approach to religion and identity. They are aware of a wide range of religious symbols from a number of traditions and approach them as a cultural resource which can be subjectively used in a reflexive process of identity formation. Religious symbols provide a means of self-exploration, a source of empowerment and personal growth, around which a sense of self can be constructed. Without recognizing an external authority, these young people are free to decontextualize, reinterpret, and juxtapose apparently contradictory symbols without any sense of conflict. Religious truth and certainty is judged according to subjective experience and utility—if it feels right, or meets an individual's needs, then it is 'true.' This type of religiosity requires little commitment to any particular tradition and the individual can easily move from one set of beliefs and practices to another.

Religion of this type is heavily bound up with the commercial world, especially as presented in New Age philosophies. It generally appeals to older youth in their late twenties rather than to teenagers who cannot afford the more expensive esoteric practices on offer. Where younger age groups do take an interest in these nontraditional forms of religion, it often overlaps with entertainment, is not taken seriously, and competes with other leisure pursuits. As such it does not form an ultimate basis of identity.

3.3 *Religious Identity*

The remaining young people choose to belong to a particular religious group or church and find their

identity within a community of believers. This may be accomplished through a conversion experience to a new religious tradition, or it may be a reaffirmation of the religious tradition of childhood (sometimes this is conflated with broader issues of ethnic identity by way of 'cultural transition' or 'cultural defence', see Bruce 1996). Either way, the emphasis is on a conscious, autonomous decision to be a part of the group. Consequently, religious identity tends to be strong and salient.

In this respect, the churches which attract young people are often evangelical and charismatic, and are well suited to fostering religious identity. The conservative theology, strong social networks, and high degree of commitment these churches usually require encourages a dominant sense of group belonging around religious themes. A charismatic orientation to the group adds a further dimension in terms of religious experience which helps to authenticate the young person's beliefs, and allows for self-expression and a sense of intimacy with God and other believers. In this context a strong sense of religious identity is established.

4 *Summary*

In conclusion, over the last 30 years established institutional Christianity has generally become less influential in the formation of young people's identity. However, the rate of Church decline is beginning to slow down and religious ideas have not disappeared from society. Consequently, Christianity, independently or as part of a heterodox collection of beliefs and practices, does continue to inform youth identity to a certain extent. It remains to be seen whether the latter two patterns will overturn the general trend towards a secular identity among Western youth in the future.

Religion: Culture Contact

1. A Model of Encounter

In many studies of culture contact there is a perceived dichotomy between the acceptance and the rejection of Christianity. This model of religious change, often advanced by those who have a stake in defending religious boundaries, stems from false assumptions about the nature of the religious encounter. Its premise is of an essential or textual Christianity confronting an essential or ideal traditional (or folk) religion—the religion of the invader confronting the religion of the autochthon. But, Christianity has never been propagated as a monolithic entity encountering a homogeneous local society. A more appropriate model involves a number of modes interaction. First, there was the encounter of a variety of mission Christianities, often mediated by local agents, with a traditional religion which was open, dynamic, and plural in nature. And, this religious encounter cannot be divorced from its political and socioeconomic context. It needs to be situated within a second set of conjunctions between the forces of capitalist imperialism and local institutions. Moreover, those encountering Christianity never adopted it wholesale. Specific ethnic groups, classes, and social categories appropriated particular ideas and practices and new forms of popular or vernacular religion, both traditional and Christian emerged out of processes of gleaning, borrowing, and recoding. This article considers these various modes of interaction with specific reference to Africa but with a Latin American aside.

2. Scholarly and Popular Misconceptions about the Encounter of Religions

2.1 Syncretism

In order to arrive at the above model of religious encounter it is first necessary to deal with a number of scholarly and popular misconceptions about the process. First, there is the issue of syncretism. This is a contentious term, often used to denote inauthenticity, or the pollution of a notionally pure tradition by symbols and meanings taken from alien traditions (Shaw and Stewart 1994). In African studies, missiologists and theologians have used syncretism as ‘a term of disapprobation denoting the confused mixing of religions’ to explain the rise of movements of Christian Independency, such as Zionism in Southern Africa and Aladura in West Africa. In Latin American studies, syncretism has far less of a pejorative connotation. Here scholarship on culture contact has been coloured by the optimism born in the heyday of the American melting pot ideology and portrayed African derived cults such as Vodun or Santera as a celebration of indigenous agency in the face of colonialism and other forms of alien domination (Shaw and Stewart 1994; see also Rostas and Droogers 1993). Recently, anthropologists and social historians have discredited the idea of essential, untainted traditions, exploring instead the processes by which they have been invented or imagined. Where the study of syncretism has most value is when it is understood as a form of cultural politics in which religious practitioners engage in heated polemic about religious hybridity while seeking to claim the moral highground of authenticity.

2.2 African Traditional/Folk Religion

A second set of misconceptions surround the nature of African traditional religion which has been portrayed consistently as ahistorical in contrast to the dynamic religions of the book, Christianity and Islam. If missionaries prior to the twentieth century admitted Africans had a religion at all, most, but not all, saw it as no more than primitive superstition blocking the advance of Western civilization. While early twentieth century anthropologists such as Edward Evans-Pritchard and Meyer Fortes were better informed about African traditional religion they viewed it no less ahistorically. Critical of missionaries whom they argued were destroying ancient and intricate mechanisms of social cohesion, they wrote detailed studies on the function of traditional religion in maintaining the organic stability of African societies. Some of the next generation of missionaries such as Bruno Gutmann or Mabel Shaw (see below), inspired by this functionalist anthropology came to appreciate the supposed communality of African traditional religion and sought to engineer these values in an ‘adapted’ Christianity.

Historical models of African religion also found their way into scholarship beyond social anthropology. Scholars of comparative religion sought to respect all religious traditions and make points of connection between them. Thus, eminent comparative religionists described African traditional religion completely in experiential terms (Parrinder 1954). Leading African theologians have also asserted an historical model of African religion. Mbiti has contended that African religion has no future tense and possesses no founders, prophets, or converts. Africans shared the same underlying philosophy but each 'tribe' had its own religion into which its members were born. While celebrating this integration of religion and society, Mbiti argues that the boundedness of African traditional religion means that it is incapable of adapting to the increasing scale of interaction that colonialism has engendered, and will inevitably decline (Mbiti 1969).

The rise of African history as a discipline from the late 1950s onwards confronted ahistorical notions of African traditional religion. Particularly important has been the emergence of oral history. Some African religions such as the Mbona cult in southern Malawi have shrines maintained by priesthoods who retain extensive traditions referring back to founding figures and cycles of revival, cleansing and prophecy (Schoffeleers 1992). Moreover, the notion of the boundedness of African religious and social identity has been challenged by research on ethnicity. Many of the 'tribal' identities claimed by contemporary Africans are in fact colonial and postcolonial creations. Hence, the concept precolonial Kikuyu or Shona religion makes no historical sense.

African historians have now replaced the old model African religions as a total organic collectivity with a more dynamic and complex one. African cults symbolized and articulated social and economic relationships and thus their adherents were involved in a range of religious interactions that began at the level of family and faction but could extend across their polity and beyond. Guilds of men propitiating hunting spirits united disparate groups of hunters throughout a region. Cults of the land, sometimes operating across a number of polities, enforced ecological rules concerning clearing, planting and reaping. And cults of alien or a-social spirits established the rules of communication between traders and the communities with whom they interacted (Ranger 1987). This more open and pluralist model of African traditional religion helps explain its resilience and adaptivity through the twentieth century.

2.3 Missionaries and Local Agents in Africa (and Latin America)

Neither was African traditional religion 'crushed' by a destructive monolithic mission Christianity acting as

the handmaid of colonialism. Such a wholly negative view of missionaries not only overlooks the contribution of local agents to the foundation of the African church but it also ignores the variety of mission Christianities and complex relationships they had with colonial states and African societies. Missionaries were influenced by different theologies and they were as diverse as the historical contexts and social sources from which their movements arose.

The contrast between the earliest Catholic mission enterprises and those of the first nonconformist missionaries could not be greater. The first wave of Catholic missionaries to sixteenth century Congo were controlled and sponsored by the Portuguese state. Mission took the form of a single religious enterprise conceived of in terms of territory. Co-opting state machinery in a union of faith and politics, Portuguese Catholics sought to create Christian kingdoms through the conversion of elite (Gray 1990). The early nineteenth century nonconformist missions were an extension of the culture of voluntary association and private enterprise that underpinned industrialization. Nonconformists like the London Missionary Society (LMS) in southern Africa were not especially interested in converting kings and aristocrats but rather turning ordinary Africans into sober and industrious Christians (Hastings 1994).

Missionaries also differed on the meaning of conversion. High Church Anglicans from the UMCA, German Lutherans, and Catholics believed that salvation was received through the sacraments and the liturgy, and sought to Christianize entire communities. By contrast, those Protestants influenced by revivalism placed a greater emphasis on salvation acquired in an intense and personal way. Their emphasis on moral conduct and lifestyle led to greater separation of the convert from their former community. While many missionaries were ethnocentric and culturally arrogant others did make a sincere and concerted attempt to come to terms with African culture and religion. As early as 1855 Bishop Colenso of Natal wrote a cogent argument for toleration of polygamy in his *Remarks on the Proper Treatment of Polygamy*. By the twentieth century a whole spectrum of missionary responses to their local settings had emerged. There were imaginative attempts at the translation of Christian ideas into an African idiom. Mabel Shaw of the LMS made extensive use of image of God/Jesus as 'Chief' and the idea of the Christian community as a 'tribe' in her work amongst the Bemba. Another approach was the Christianization of traditional rituals so that they might find force in a Christian community. The most common example of this was the adaptation of traditional rituals of initiation. Here the endeavors to Christianize the traditional rite of passage by UMCA Bishop to Tanzania, Vincent Lucas of Msasi, have been well documented (Ranger 1972).

Indeed, while many missionaries to Africa have been criticized for their cultural imperialism, others

may be taken to task for their conservatism. The German missionary and anthropologist, Bruno Gutmann, believed that the growth of African personality and morality was connected to the essential forms of community life: clan, neighborhood, and age grade. Thus, he developed an 'indirect rule' approach to mission, highly attractive to the Tanzanian colonial state, which sought to create Christian communities through traditional institutions and leadership (Kaplan 1995). When the radical black American educationalist W. E. B. du Bois visited West Africa in 1923, he criticized the fashionable 'emphasis on the preservation of traditional culture.' This du Bois thought, formed part of a white man's plot to maintain the African as a willing but useful servant of the imperial cause.

Perhaps unexpectedly, the last great new wave of mission Christianity, following earlier Catholic and nonconformist waves, has been the most adversarial towards traditional culture and religion. This is the Pentecostal movement that arose in America and northern Europe, 1900–10, and collided with Africa and Latin America almost immediately after its inception, and in subsequent surges throughout this century (Maxwell 1999a, Freston 1995). In part a reaction against the liberalism and modernism of established church theology, Pentecostalism actively believed in the supernatural. But while taking African and Latin American belief systems seriously Pentecostalism nevertheless demonized them (Maxwell 1999b, Lehmann 1996). Traditional spirits, whether good or bad in local cosmological terms, were collapsed into the category of the demonic. Thus, Pentecostals have been characterized by their aggressive stance towards traditional practices, and the destruction of charms and fetishes as polluted objects. Yet, even this Pentecostal attack on things 'traditional' can be interpreted as a form of Africanization: a perpetuation of a tradition of cyclical societal cleansing.

Finally, those scholars who continue to insist on the alien nature of African Christianity fail to grasp the role of local agents in the Christianizing of the continent. Pioneer missionaries were responsible for vast tracts of territory. Few and far between, their priorities were first translation work and then the construction of mission infrastructure. Many simply struggled to survive disease and learn the local language. The work of conversion was left to local agents, freed slaves, and converts from already missionized areas. Because overstretched missionaries were unable to monitor their activities these Catholic catechists and Protestant evangelists had much room for creativity. There were also movements of Christians happening completely independently of missionaries such as the Christian refugees who fled the expansion of the Zulu Kingdom in the 1830s and carried Christianity with them into Lake Malawi region. Another example was labor gangs, such as

groups of Pedi in the Transvaal, South Africa in the 1840s–1860s, who encountered Christianity in their work place and spread it through the process of labor migration. Often missionaries would arrive in a village to find Africans already there teaching the faith.

3. A Latin American Comparison

Latin America did encounter a monolithic mission Christianity. For over three hundred years the subjects of Spanish and Portuguese empires were exposed to state-sponsored Catholicism. Yet, from the very beginning of these Iberian empires there was a debate within Catholicism about the nature of traditional belief. While Spanish imperialists exterminated Indian peoples on the pretext that they were idolaters or devil worshippers Bartholomé de Las Casas described their pagan practices as their own way of approaching the Christian God. Las Casas, a sixteenth century Dominican, also argued for a clearer separation of the church from the imperial project, while the Franciscans and later the Jesuits established local regimes which while patriarchal did offer more humane conditions than their secular coevals.

Latin American Catholicism could also embody regional and national identities. The cult of the dark faced Virgin of Guadalupe, which dates from the mid-sixteenth century, offered a range of protective and curative functions. The Virgin appeared on the banners of those who sought independence from Spain in the early nineteenth century (led by village priests) and was subsequently made universal patron for the whole of Mexico (Brading 1991). Official Catholicism, initially opposed to nationalist movements, took a generation to come to an accommodation with the new nations before becoming embroiled in a century of warfare between conservatives and anticlerical liberals or radicals.

The strength of the sacred canopy of Catholicism varied across the continent. Some of the Amazonian peoples remained 'unreached' until the arrival of twentieth-century Catholic and Protestant missionaries. In other instances the Catholic overlay remained thin. The Maya of Guatemala, who resisted for centuries, retain numerous traditional beliefs, praying to the ancestors as well as the saints, visiting the shaman alongside the priest. In Brazil, Catholicism is often cross-referenced with belief in African Gods imported along with African slaves. In contrast to the literature on African religion, scholarship on Latin America more often equates 'folk' or 'traditional' religion, not with non-Christian religion, but with a 'syncretistic' mix of Catholicism and surrounding religions.

The degree to which Latin American Catholicism drew from other religions rather than retaining a more distinctive identity is explained by combination of two

factors: first, its close relation to the institutions of the state; second, the absence of alternative and competing Christianities. Catholicism was the established religion. Even at local level the church was often a major landowner and the priest involved in local politics. Catholic ideology legitimated social relations of production on the *hacienda*. The local level Catholic representative was usually not a catechist but a foreign priest. In the absence of other Christianities and a strongly independent Catholic dynamic Latin Americans were far more selective in their response to Catholicism and that selectivity came to be accepted by the authorities. Thus, for instance, Ecuadorian Quichua used the cult of the Saints and different visions of the virgin to reach those extrahuman forces they believed dominated them. Prayers, ritual drinking, dancing, and the wearing of lavish costumes took place to influence God's intermediaries. The same process of selection, of course, occurred within African Christianity, but in an atmosphere of Christian pluralism, African Christian identities took on a sharper definition.

Latin American Catholicism, in its different forms, remained monopolistic until the late nineteenth century when liberal elites opened doors to north Atlantic Protestantism and migration. The first wave of missionaries were predominantly older Protestant denominations such as Methodists and Baptists, offering welfare and education, but throughout the twentieth century Pentecostal and conservative evangelical waves came to dominate. The opening up of the religious field was accompanied by the break-up of Catholic sociopolitical hegemony. Agrarian reforms, anticlerical regimes, the rise of the mega-city and the partial liberalization of Catholicism made alternative religious adherence possible.

The persistence of pre-Christian cults is supplemented by their re-invention by middle class intellectuals in search of an authentic religion. One such group is the Association of Concheros in Central Mexico who have fused Catholicism with a blend of notional religious traditions from peoples such as the Aztecs and Chichimecas (Rostas 1993). In the African context such invented religious traditions are not so much sources of spirituality as markers for ethnicities.

Doubtless, if Spain and Portugal had retained and expanded their mercantile empires in Africa then African Catholicism may well have more closely resembled the early Latin American type. But Spain and, to a lesser extent Portugal, did not figure highly in the 'Scramble(s)' and the accompanying Catholic impulse was generally of a non-Iberian variety, involving a plurality of Catholic missionary orders working in competition with Protestantism. Given the open and plural nature of African traditional religion, the varieties of mission Christianity and the contribution of local agents, the African encounter took a profoundly different form from the Latin American one.

4. *Resilience and Innovation in African Traditional/Folk Religion*

Throughout the nineteenth century traditional religion innovated in response to the array of changes that accompanied the slow penetration of first, mercantile, and later capitalist, relations into the African interior. The increasing scale of social interactions that these changes brought led local intellectuals to innovate to make sense of this new world breaking in. In some cases they developed the idea of the High God with a macrocosmic reach to match Africans' expanding horizons. In other contexts, cults of possession became more widespread linking people together over wide regions through their shared affliction by the same amoral spirit. In many places the colonial occupations of the 1870s–1890s coincided with and precipitated ecological crises. In what appeared to many as a millennial moment, great prophetic figures, such as the Shona Chaminuka medium, arose to interpret colonialism and capitalist imperialism in a way that offered their followers conceptual control over what was happening. Thus, the great transformations were not an alien imposition but part of an unfolding local narrative.

In a similar manner, the new religion of Christianity was understood in terms of the old categories of traditional religion. Some missionaries were seen as witchcraft eradicators, whose presence inaugurated movements destroying charms and fetishes (Maxwell 1999b). Other missionary pioneers, with their bags of simple medical cures were seen as traditional healers (Hastings 1994). Others still were welcomed as sources of revelation about the High God.

While specific forms of traditional religion, such as hunting guilds, declined under colonialism, other forms of traditional religion moved to the center of the stage. African religious leaders, such as the famous Kinjikitile in Tanganyika, offered their cults as means of uniting acephalous societies against German occupation. And during the era of decolonization, religious leaders once again helped coordinate resistance against colonial states. In Zimbabwe's war of liberation Shona spirit mediums moved popular understanding of myth and taboo to enable stranger/guerrillas to be legitimated in local terms as hunters and warriors (Lan 1985). Although the labor migration led to decline of some cults of the land, in other instances traditional religion became more ecologically orientated helping Africans to become peasants and articulating their objection to state intervention in their agriculture.

5. *The Foundation of Vernacular Christianities in Africa and Latin America*

Nevertheless, Christianity has made tremendous headway in Africa and Latin America. In Africa great movements of Christianity in Buganda, the Ivory

Coast, Igboland, and Manicaland occurred during the Scramble(s) and in the first decades of the twentieth century. But these grassroots initiatives often happened in a haphazard and unplanned manner far from missionary influence or control, and through this indigenous agency local or vernacular Christianities were founded.

Besides the significant contribution of African agents, vernacular Christianities had two other key defining features. The first was the seizing of the landscape by symbolically sensitive missionaries and African Christians. Mountains, rocks, caves, trees, and pools, which often had traditional religious associations, were resacralized in Christian fashion. Catholics turned them into shrines and grottos—places of pilgrimage. The Anglicans made holy ground through creation of cemeteries.

The second key feature of these vernacular Christianities was the adoption of Christian symbols and powers and Christian literacy because they had utility in helping Africans prosper and relate to the colonial economy. While traditional religion could become more ecological in orientation to help Africans become peasants, Christianity could equally fulfill that role. Catholic prayers, invocations, and rituals were perceived as efficacious in protecting crops and providing soil fertility. American Methodism with its strong emphasis on discipline, an intense personal experience, and gospel of the plough provided the perfect ideology for peasant entrepreneurs (Ranger 1987).

Christian approaches to healing were also important. Pentecostal and revivalist emphasis on the satanic causes of illness resonated with traditional personifications of evil and disease. Likewise, divine healing through the laying-on of hands resembled the practices of traditional healers, though, of course, Pentecostals claimed a different source of empowerment. Miraculous cures through veneration of the saints provided a Catholic counterpart to Pentecostal spiritual healing. St Thérèse of Lisieux was perceived as particularly powerful in Africa. Seminaries of African priests were placed under her protection and she was appointed 'regent' of at least one African country. Finally, African Christian movements were often animated by a grass roots adoption of literacy. For these Africans, literacy, schooling, and church were synonymous in representing progress (Ranger 1987).

Specific social categories were often responsible for the localization of Christianity. In the nineteenth century Africa, kings and chiefs often converted to extend their ideological legitimation and to benefit from the technological and diplomatic advice missionaries had to offer. But these traditional leaders were slow to change their ideas and practices. In both continents younger men and women often converted and changed the very culture these male gerontocrats wished to preserve. The conventional language of Christians: 'coming forward,' 'setting themselves

apart,' and declaring for a 'completely changed life' took on a new meaning when merged with Christianity's individualist conscience (Fields 1985). It offered younger men, returning from the workplace, legitimate reasons for ignoring the burdensome demands of traditional commensality, the Latin American *fiesta* (Earle 1992), or African fertility and harvest rituals. Likewise, it enabled more individualist peasants to separate themselves from the 'wasteful' and time consuming demands of their kin, and in the Latin American context, fictive kin: God children (Goldin and Metz 1991). Faith in Christ gave women recourse to another male authority other than that of the household head, and directly undermined elder male notions of patriarchy by demonizing the ancestor spirits which legitimated it. Likewise, the prayer band and the fellowship meeting offered a vital source of solidarity for women otherwise divided by exogamy, polygamy, and fear of witchcraft accusation, and an engine of resocialization for the wayward male. Pentecostalism offered its own unique source of empowerment. Gifts of prophecy, tongues, healing, and exorcism turned a marginal woman or man into someone of consequence (Gill 1990). Catholicism was frequently an intensely feminine religion. Its Marian emphasis offered women a double-edged model of liberation and resignation.

Material benefits also accompanied conversion. The church offered networks of contacts and solidarity to labor migrants entering the cities, mines, or farms, and it created new alliances of Christian kin within the village. Although Pentecostalism's doctrine of male headship legitimated gender inequalities, its emphasis on industry, sobriety, and sexual propriety diminished aspects of male sex roles that are harmful to women (Gill 1990). Throughout the townships, shantytowns, and villages of Africa and Latin America the puritan ethics advanced by Pentecostals, other non-conformists, and groups like the Watch Tower have pulled families and small communities out of cycles of poverty, or at least stopped them from slipping over the edge.

Where Christianity has not eroded African traditional religion, it has nevertheless often changed it. Christian ideas and practices have found their way into non-Christian religions. Contemporary African genealogies tracing the origins of significant territorial spirits may include references to Hebrew patriarchs such as Noah or Abraham as useful embellishments (Bourdillon 1988). And traditional concepts of God have likewise been sharpened by Judaeo-Christian ideas about the divine.

None of the above should for one moment suggest that missionaries have not been important. It is rather that their importance came in ways they did not expect. Missionary teachings on domesticity shifted gender relations and created new social classes out of missionized elites. And work on languages such as the creation of vernacular alphabets and grammars has

had an immense impact. Not only has it created written languages where none previously existed, but these in turn have helped create new ethnic identities in both continents. In Latin America, the influence of one organization in particular, the Wycliffe Bible Translators, cannot be underestimated. In Africa, literacy and schooling enabled Africans to form their own cultural movements and provided access to political ideas other than those peddled by colonialists.

6. Christianity in Contemporary Africa and Latin America

The process of culture contact of course continues. Despite the fact that the center of Christendom no longer lies in the post-Christian West but in the South, the Western impulse to mission has not abated. It has, however, changed in nature. First, the majority of contemporary missionaries are North American in origin, reflecting the rise of the US as the new imperial power. Second, these missionaries are usually evangelical, charismatic, or Pentecostal and believe that conversion entails an individualized born-again experience. Finally, this new strand of born-again Christianity has a strong affinity with the electronic media.

The arrival of this new type of conservative Protestantism, which exploded across Latin America in the 1960s, and across Africa a decade and a half later, raises the inevitable question of whether it is just another American cultural export (Gifford 1998). While America is the major cultural and missionary dynamo for the born-again movement there are other epicenters in Southern and West Africa and Brazil, each contributing their own 'prophets' and media packages to increase the heterogeneity of the movement. But more importantly, the born-again movement has always been conducive to indigenization. Its lack of tradition, its scorn of formal theological education, its reliance on lay initiative and management, its family and neighborhood cell structure, and its acceptance of the supernatural make it particularly responsive to local agendas. While its stress on releasing converts from the demands of kin, both alive and dead, and its emphasis on building nuclear families may smack of western individualism, these tendencies are useful to African (and Latin American) peasants facing the decline or break-up of the communal system and migrant workers coming to terms with the rise of the mega-city (Martin 1990).

Finally, culture flows do not just move from the West to the South, they are multidirectional. While African and Latin American diaspora have for centuries transported their religions to the West, contemporary Latin American and African Christianities impact on Europe and America in ever more profound ways. In the 1970s and 1980s Latin American

liberation theologians shook up Western theological establishments, while the spirituality of Latin American base communities inspired many Westerners working for justice and peace. Today, mission partnerships bring African Anglicans to British parishes and returning missionaries import Christian song and liturgy from the South into their home churches. Added to this is the growing appeal of African Pentecostal and charismatic leaders in Western preaching and healing circuits. Some of these leaders' churches also finance their own mission initiatives. The arrival of African missionaries in London's Oxford Street, or Brazilians in Portugal, brings mission Christianity full circle.

Religion: Definition and Explanation

This article sets out the main forms explanations of religion take by reference to their scope and the extent to which they preserve or subvert the self-understanding of religious believers. At the maximum level of scope explanations of religion amount to comprehensive theories of religion. Typically, such theories also seek to subvert the way in which religious individuals understand their own beliefs and actions. The need for comprehensive theories of religion is shown to arise out of the methodological demands of social and behavioral science itself. Theories of religion need to demarcate their subject matter and hence depend on and give rise to definitions of religion. The article sets out the differences between the main styles of definition of religion (substantive, functionalist, experiential, and family resemblance) and explores the possibilities of finding common ground between them.

1. Explaining Religion

1.1 The Nature of Explanation

Explanations are answers to requests for understanding. To explain something may be to: (a) make it known in detail; (b) render it intelligible; or (c) account for it. Disciplines such as the anthropology of religion may explain a religious phenomenon by citing further facts about it, thus explaining it in sense (a). Or they may explain a religious phenomenon by setting out its connections with other, more familiar or easily understood social facts, thus explaining it in sense (b). These forms of explanation need not overturn, but may merely supplement, the motives and reasons the religious themselves acknowledge as behind their beliefs and behavior. However, the social and behavioral scientist may seek to account for a religious phenomenon (type (c) explanation) by giving its cause and in the citing of that cause may set aside the self-understanding of religious actors. For example, the anthropologist may seek to account for ecstatic religious experiences in terms of the social status, particularly social power, such experiences give to their possessors (Lewis 1989). If this factor is a sufficient explanation, then the agents' belief that they are genuinely possessed by gods or spirits is an illusion.

1.2 Radical Explanations in the Science of Religion

It is characteristic of the social sciences in the nineteenth and twentieth centuries that they have gone beyond seeking to explain particular religious phenomena. They have produced explanatory theories seeking to account for the existence of religion as such. Such theories hold that the tendency of human beings to engage in religion cannot be taken as a given; there is something problematic in such engagement. For example, an evolutionary theorist may see religious phenomena as 'survivals,' that is dysfunctional judged against the circumstances of modern society and thus as a remnant of a once adaptive means of organizing social life (Tylor 1903). A psychological theorist may see a striking correlation between religious symbolism and psychic needs, suggesting that religion is motivated by persistent and universal wish-fulfillment (Freud 1927/1978).

The explanations of religion thus produced are radical, comprehensive, and external. They embody the 'hermeneutics of suspicion' (Ricoeur 1970). Religious consciousness is treated as a form of false consciousness. Religious symbolism is a code. Ostensibly it speaks of gods and spirits. In reality its components refer to aspects of the human, social world. A psychological, sociological or anthropological theory of religion enables us to reinterpret and decode religious symbols by correlating them with

mundane forces and facts hidden from the conscious mind of the religious actor.

1.3 Methodological Skepticism

The assumption that religious thought and action cannot be taken at face value but must be explained from the ground up is in part a product of the philosophical skepticism about the gods and the limits of human knowledge engendered by the Enlightenment. Some argue that such skepticism, or naturalism, is required by any sound methodology for the human sciences (Preus 1987). The only explanatory factors the human sciences can know of and thus recognize are mundane ones. They can only produce explanations of religion that deal in natural causes. Hence, they must adopt an attitude of suspicion toward religion's own 'memory' of humankind's contact with supramundane realities, and reinterpret religious symbols accordingly.

1.4 The Cultural-Symbolic Paradigm

The arguments for methodological skepticism are crucial in supporting radical, comprehensive theories of religion in the social and behavioral sciences. Without methodological skepticism, the production of such theories is not mandatory for those unconvinced of the Enlightenment's case against religion. The case against methodological skepticism can be made from within a contrasting approach to the explanation of human, social phenomena: the cultural-symbolic (Byrne 1997). This has its ancestry in the stress on *Verstehen* as the appropriate and unique stance to take toward the human world advocated by German social theorists in the idealist tradition, such as Dilthey. On a cultural-symbolic approach, there is something that marks out the human world as different from the natural. Its objects—human beliefs, actions and institutions—are endowed with meaning independent of any sense social scientists impute to them by their theories. The meaning they have is a result of the fact that they are informed by concepts. A human act, for example, has the sense it has by virtue of it being done for a reason and being directed to an end. That sense is dependent on agent's own beliefs and concepts. A standard way of explaining a human act is to bring out the reason/end the agent had in performing it. Such an explanation will fail unless it uncovers the agent's reason/end. Human action is thus informed by concepts. We explain human acts by bringing out their background in the agent's beliefs and intentions and by making those beliefs and intentions intelligible by reference to the rule-governed forms of social life in which they are embedded. Crudely put: to explain religious phenomena in this way is to account for them in terms of how the world appears to religious actors themselves and in terms of

the forms of individual and social meaning these actors create in the institutions which they fashion (Winch 1958).

The cultural-symbolic approach preaches methodological agnosticism. Religious actors' beliefs relate to suprahuman and supramundane realities. These beliefs need neither be endorsed nor denied by the social scientist in bringing out their sense or relying on their explanatory power. Both their sense and explanatory power relies on the beliefs making action and thought intelligible in terms of how the world appears to these agents. Whether the world is as it appears to these agents is irrelevant. By the same token, the question of whether the referring expressions used in reporting religious actors' beliefs really do refer is irrelevant. It is enough that actors intend to refer to gods and like things by these expressions. Since methodological agnosticism in the explanation of religion is not committed to the truth of actors' beliefs or to the real existence of things corresponding to the referring expressions in reports of those beliefs, it is a thoroughly naturalistic approach to the interpretation of religion (Clarke and Byrne 1993).

The cultural-symbolic approach can admit that there are forms of religious life which function ideologically or are the product of illusion. Investigation may show that individual religious phenomena exhibit forms of human meaning-making which fail of a minimal rationality and are corrupt. In such cases the hermeneutics of suspicion may be appropriately applied (MacIntyre 1971).

2. Defining Religion

2.1 The Purposes of Definitions of Religion

The social scientific study of religion needs a definition of religion in order to demarcate the subject matter of its inquiries. Theories of religion require definitions of religion at this initial stage for a parallel reason. Definitions may also serve the purposes of theories of religion by suggesting an initial interpretation of religion on which the theory may build. A complete theory of religion will also give rise to a definition of religion by way of summing up what it has concluded about the essential nature or origins of religion. Definitions of religion offered at the first stage are operational ones; definitions of religion offered at the end of theorizing can be styled 'theoretical.'

2.2 Types of Definition

Religion may be defined in terms of the typical content of its beliefs. Substantive definitions are illustrated by Tylor's definition of religion as 'belief in spiritual beings' (Tylor 1903). Religion may also be defined by reference to the role religion plays in personal and social life or the structure of religious thought and

action. Such structural–functionalist definitions are illustrated by Durkheim’s definition of religion in terms of a symbols system enforcing a distinction between sacred and profane reality and uniting members of society into a common moral community (Durkheim 1912/1967). Experiential definitions demarcate religion by reference to a putative common, or core, experience religious actors participate in, as illustrated by Müller’s claim that religion consists in the ability to experience the infinite in the finite (Müller 1893). These three modes of defining religion are united in seeking necessary and sufficient conditions for the classification of an institution as religious. Family resemblance (or polythetic) definitions reject this search. Their advocates maintain that the things we call ‘religions’ form a loose class. There is no attribute or set of attributes which unites them all: there is merely a network of overlapping similarities (Southwold 1978).

2.3 Issues Dividing Definitions of Religion

Family resemblance definitions are divided from the rest about the degree of unity to be expected among the class of things the Western academy has chosen to call ‘religions.’ The remaining styles of definition illustrate the conflicting pull of issues of scope and clarity. A substantive definition of religion gives the concept of religion clear boundaries and increases its utility in the demarcation of social phenomena. However, the cost of that clarity is to restrict the scope of the class thus created, threatening thereby to rule out by definition the possibility of nontheistic religion. A structural–functionalist definition gives the concept of religion broad scope, defending the thought that religion can be seen as a universal human phenomenon, but at the cost, its critics will charge, of making the concept too vague.

A means of harmonizing the two dominant approaches (substantive and structural–functionalist) may be found in a moral definition of religion. A religion is a symbolic system (with associated beliefs and practices) which articulates the thought that there is a source of moral order behind the world, that is the thought that the realms of value and fact are ultimately united. There are important social and personal needs met by religion so defined and its symbols have a typical content. They must purport to refer to transcendent realities which function as the ground of the natural order and the source or guarantors of morality. These realities are typically, though not inevitably, modeled on human agents (Byrne 1999).

Religion: Evolution and Development

Both evolution and development are ways of looking at the history of religion. Development implies some kind of directional change in the history of a particular religion, whereas evolution implies comparable directional changes in a number of religious traditions. Since histories usually describe directional change of some sort, the idea of religious development merges into the much larger field of the history of religions. Therefore this article will focus on religious evolution.

1. The Term ‘Religious Evolution’

The idea of religious evolution, like the idea of social evolution, has been much criticized in the twentieth century, although neither idea has been entirely abandoned. If the notion of religious evolution is to be salvaged it must be dissociated from several preconceptions of its nineteenth century proponents. These preconceptions include the idea that all religions must be fitted into a single (unilineal) pattern, that progression through a fixed series of stages is inevitable,

and that more advanced stages are 'higher' (ethically and spiritually better) than earlier ones (Comte 1830–1842, Tylor 1871, Spencer 1876–1997, Marett 1914, etc.). It is the notion of inevitable progress that has been rejected by twentieth century writers; the idea that religious change correlates with social change in comparable ways across traditions can still be defended as 'religious evolution.' Contrary to common belief, it is to the writings of Max Weber (1920–1921, 1921–1922/1978) that a defensible conception of religious evolution owes the most.

2. The Protestant Ethic

Weber began his study of religion with his famous *The Protestant Ethic and the Spirit of Capitalism* (1904–1905/1930). At first glance, it might seem that this book is simply a developmental history focusing on a dramatic change within a single religious tradition. However, it is clear from the place of the Protestant ethic argument in *Economy and Society* (1921–1922/1978) and in the *Gesammelte Aufsätze zur Religionssoziologie* (1920–1921) that Weber believed that ascetic Protestantism was an indispensable catalyst for the emergence of a new form of society, which he called modern capitalism. Never before the Reformation in the West was the hold of agrarian society, organized through patrimonial (including patrimonial bureaucratic) and feudal political forms, broken through. Once established, however, capitalism became a worldwide phenomenon, even though taking different forms in different civilizational areas. Thus Protestantism, though occurring in only one tradition, played, indirectly but crucially, a developmental role cross culturally, and thus can legitimately be considered an instance of religious evolution.

Since Weber's time there has been a search for functional equivalents of Protestantism in other traditions that prepared some societies better than others and some groups in some societies better than others for the transition to capitalism, or, perhaps better, to modernity (Bellah 1957, Eisenstadt 1968). Ernest Gellner made the interesting suggestion that there were elements in all the great traditions, Islam in particular, that might have led to a Protestant-like breakthrough, but that a combination of fortuitous circumstances in Western Europe made it possible for it to occur there (1988). This raises the interesting question of what gave the great religious traditions a rationalizing potentiality even if it was only fully realized in one case.

3. The Axial Age

In his comparative studies in the sociology of religion (1920–1921) and in the sociology of religion section of *Economy and Society* (1921–1922/1978) Weber

pointed out that in each of the world religions, sometime in the first millennium BC, there emerged prophets or saviors who radically rationalized previous forms of what he tended to call magical religion. In each case the emergent figure (Confucius, the Buddha, the Hebrew prophets, Socrates, Jesus) preached a systematic form of ethical conduct quite different from the diffuse ritual and sacramental practices that preceded them. By calling these new symbolic forms 'rationalized' Weber was pointing to the fact that they were more coherent, more cognitively and ethically universalizing, more potentially self-critical (reflexive), and more disengaged from the existing society than what preceded them.

Weber's friend, Karl Jaspers, spoke of this period as the Axial Age (1948), and S. N. Eisenstadt has contributed significantly to the further study of what he calls Axial civilizations (1986 and elsewhere). Following Weber one can characterize each of the Axial breakthroughs (first millennium BC China, India, Israel, Greece) as involving, to different degrees and in different ways, an element of world rejection (Weber 1920/1946). Religious renouncers (Dumont 1980) in each case called the empirical world into question and, by invoking a transcendental realm, provided a significant degree of tension between worldly interests and religious demands that enhanced the possibility of social change. Although Weber himself contributed to the stereotype of static traditional societies, in his studies of particular traditions he discerned significant possibilities of social transformation (Weber 1920–1921, 1921–1922/1978).

Subsequent scholars have pointed out the dynamic potentialities in all the great traditions. What scholars such as Gellner have emphasized is that a radically rationalized ethic of conduct, such as that found in Protestantism, was not in itself enough. As long as the existing military, political, and religious hierarchies of agrarian societies could contain these rationalizing potentialities within monastic orders or private conventicles, a new type of society could not emerge. What made Protestantism successful was not just its unique ethic but the possibility of gaining sufficient political influence (in Geneva, the Netherlands, England, and New England) to institutionalize that ethic in the major spheres of social life.

4. The Shape of Religious Evolution

If Weber had at least two stages of religious evolution, namely an Axial stage correlating with the emergence of historic agrarian societies, and a modern stage for which ascetic Protestantism was an indispensable precondition, did he have any more stages? In looking at his historical sociology as a whole it is clear that he did. The world religions were preceded by societies organized primarily in terms of kinship and neighborhood and in which religion was primarily magical, by

which Weber meant, one in which ritual means were used to attain utilitarian ends such as rain, good harvests, human fertility, etc. While such a three-stage typology is for many purposes adequate, it does seem possible to refine it further.

Bellah, in his essay *Religious Evolution* (1964), suggested a further differentiation of the early stages. He distinguished between a 'primitive,' now better, 'tribal,' phase, and an archaic phase. Myth and ritual characterize tribal religion—indeed they may be co-terminous with hominization itself—but they are myth and ritual of a particular type. The spiritual beings whose activities are narrated in the myths are not gods and are not worshipped. These half-human, half-animal, often ancestral, beings express in archetypal fashion the social and ecological life of the people. Ritual involves the reenactment of the primordial events such that mythical time becomes present, not the worship of distanced deities. Tribal religion is most characteristic of hunter-gatherers, but is also common in horticultural societies. With agriculture and the emergence of complex chiefdoms, and particularly with the early state, archaic religion comes into being. While in tribal societies every clan can be traced to an ancestral being, in archaic societies only the aristocratic lineages claim divine descent. A hierarchic pantheon of gods appears, quite different from the mythical beings of tribal religion. The gods require worship, and, significantly, sacrifice, in many cases human sacrifice, and a differentiated class of priests who supervise the worship. In archaic societies the ruler often claims descent from the highest god, even the claim to be a living god himself. In general, archaic religion is characterized by a fusion of political and religious hierarchy largely missing in tribal society. Examples of archaic societies, often identified as Bronze Age societies, would include third and second millennium BC Mesopotamia, Egypt, the Indus Valley, and North China, but also early first millennium AD Japan, and first millennium AD Meso-America and Peru.

It was in the midst of or on the peripheries of such archaic societies that the axial religions of the first millennium BC emerged. They took the hierarchical tendencies of archaic religion in a radically transcendental direction. All value was seen to reside in a realm beyond this world and thus this world and all the worldly hierarchies within it were relativized and potentially delegitimized. But in most cases the new Axial religions either remained marginal to the centers of power or, if they were recognized by the ruling center, they made compromises with it so that they largely legitimated that center rather than challenged it, thus allowing a quasi-archaic situation to continue. This is not to minimize, however, the importance of Axial religions in the elite education and culture of each of the great traditions. Also, the critical potential of the Axial religions was continually reasserted in the form of heresies, uprisings, and rebellions (Eisenstadt

1986, 1999), but these were normally either destroyed, marginalized or, if successful, coopted by the existing structures of power.

A simplified way of looking at the shape of religious evolution was proposed by Bellah (1964). He argued that whereas tribal and archaic religions were primarily this-worldly in orientation, which is what Weber, perhaps unwisely, meant by the word magical, the Axial religions were world-rejecting (and thus, for Weber, very importantly, magic rejecting), although they differed as to whether this rejection was to be worked out within the world (ethically), or as far as possible outside the world (mystically). It should be remembered that in its radical consistency Axial religion was never more than the religion of a minority; the majority continued to entertain beliefs and practices continuous with archaic or even tribal religion, which is what Weber meant by the return to the garden of magic (1920–1921).

With the Protestant Reformation, however, the belief in a radically transcendent God had dramatic this-worldly consequences: the consistent demands of an Axial ethic were to characterize every sphere of daily life. But in the subsequent development of modernity, though the this-worldly dimension remained dominant, its transcendental basis became transformed into immanentism, thus returning the modern world in a much different way to this-worldly immanentism of pre-Axial times. Weber clearly observed this transition, but viewed it almost entirely negatively. The modern world of rationalization would run on its own bureaucratic and economic energies without any transcendental sanction, would become an iron cage (1904–1905/1930). Charles Taylor has described the same transformation in less somber hues as 'the affirmation of ordinary life' and has stressed growing individuation (1989). In any case, though the world of the Protestant Reformation and the Western world since the eighteenth century (and, more recently, much of the rest of the world, as well) are clearly different, it is doubtful whether the Protestant phase needs to be designated as a separate 'early modern stage' as Bellah did in 1964, or whether it should be seen as merely the opening transition toward modern religion, the contours of which, though it has been developing for several centuries, are still far from clear.

The shape of religious evolution should not obscure its many irregularities, its lack of unilineal consistency. Regression was always a possibility: Axial Greek civilization did not emerge from the womb of archaic Minoan and Mycenaean societies, but only after the breakdown of those societies and the return to tribalism. Stages were sometimes skipped, especially on the peripheries of advanced societies: the Israelite Axial breakthrough began in a tribal confederation on the boundaries of archaic empires; Muhammad grew up in the tribal city of Mecca but founded an Axial civilization, to be sure under Jewish and Christian

influence. Not only was every religion from tribal to modern full of internal tensions and divisions but all of them were open to continuous external influence.

5. *The Causes of Religious Evolution*

To move beyond description and consider causation is always difficult in historical sociology; nevertheless, how one answers the question of causation, even tentatively, will determine how one understands the entire process. Religious evolution is certainly embedded in social evolution and cannot be understood apart from it. Long-term tendencies, such as the increasing division of labor, the increasing capacity of states to mobilize social power, the development of media such as money and writing, the differentiation of elites of various types as carriers of distinct cultural traditions, the tendency of pre-modern societies to oscillate between political centralization (patrimonialism) and decentralization (feudalism) all influenced and were influenced by religious beliefs and practices.

There has been a tendency among supporters of the idea of social evolution, Marxist and non-Marxist alike, to emphasize economic factors as causal, and religious developments as epiphenomenal. It has been common to believe that Max Weber reversed this understanding and held that religion was primary in social causation. A reading of Weber's entire work, which puts *The Protestant Ethic and the Spirit of Capitalism* in its proper perspective, makes it clear that such was not his belief. Rather, Weber argued for the relative independence of the religious dimension as a factor in social life, but one that always interacts with other factors, notably economic, political, and legal. S. N. Eisenstadt rephrases Weber by showing that it is not just a matter of emphasizing multi-causality: while never sufficient as a causal factor in itself, religion provides the indispensable element of *cultural codes*, not only for the institutionalization of new social forms but, when internalized in personality systems, for new forms of individual motivation as well (Eisenstadt 1999).

Religious elements have played a critical role in all the great social transitions. Terrence Deacon has even argued that the origin of language among the early hominids was probably facilitated by what he specifically calls ritual (1997). Some primates today can learn words, but only under the most intense pressure of human teaching. Deacon hypothesizes that the bodily and repetitive nature of ritual may have been a necessary precondition for the counterintuitive, from an early primate point of view, shift to symbolic representation that is the basis of language. In any case, Paleolithic evidence, difficult to interpret though it is, suggests that ritual played a central role in creating the social solidarity and respect for the

normative order of kinship relations that differentiate humans from other primates.

The transition to archaic society is associated almost everywhere with monumental temple architecture, large-scale sacrifice, and divine kingship. It would seem that the move from the basic egalitarianism of tribal society to the intensely hierarchical and centralized order of archaic societies was only possible with the institutionalization of new religious codes, in association with an unprecedented concentration of social power.

While causal linkages are far from clear, the first millennium BC did see a number of developments that might have prepared the ground for the rise of the Axial religions. These include the beginnings of a market economy, an increase in bureaucratic and military power, and increasing differentiations of social classes, all of which could have given rise to Weber's 'problems of meaning' (1921–1922/1978). But an indispensable precondition for these radical new religious developments was the existence of cultural elites at least to some degree independent of central political power. These include the Hebrew prophets, the Greek philosophers, the Chinese sages, and the Indian ascetics and mystics. It was among these groups that archaic symbol systems were radically reinterpreted in a transcendental ethical and spiritual direction.

The influence of the Protestant Reformation on the emergence of modern society has been the subject of a vast literature. A significant recent development, however, has been the recognition of the importance of a 'disciplinary revolution,' particularly associated with the Calvinist wing of the Reformation (Gorski 1993). The disciplinary revolution operated at a number of levels: a new code of systematic ethical action expected from believers, new institutions capable of enforcing the code, and new solidary organizations strong enough to influence political and economic developments. The transformation of these new codes under a variety of influences and pressures into such tendencies as utilitarianism, liberalism, Jacobinism, and socialism, and more recently, individualism and fundamentalism, has significantly affected the shape of and the tensions within modern society.

Thus, viewing the process as a whole, it appears that religious evolution is not only a subject of great interest in itself, but is a critical dimension of social evolution.

Religion: Family and Kinship

This article will consider how these institutions, with their associated ideas and practices, intersect with one another. Family and kinship are closely related concepts, which together incorporate a number of issues, such as marriage, reproduction, family roles—particularly mother, father, children, and grandparents—descent and alliance, inheritance and taboo. Religion refers to the sum of beliefs and practices, ideas and attitudes, movements and institutions, symbols and experiences by which individuals and groups give meaning and order to their world, often with

reference to a supernatural being or power. How has religion been involved in the social organization of kinship and the family, and how have issues surrounding kinship and the family affected religious beliefs, attitudes, and practices? In what ways have kinship arrangements and the family served the interests of religions? A range of different religions, family types, and kinship arrangements will be referred to, and contemporary debates about the relevance and ethics of the family, to which religious voices have contributed, will be discussed.

Most of those who have written about the institution of the family comment upon its resilience. Although a variety of family types have been in evidence in different historical periods and societies, families have always existed in order to create and strengthen alliances between groups and to provide a suitable location for reproduction and the nurture of children. A small family unit may incorporate a single parent and child, with larger units incorporating several generations of adults including siblings, and their children. In some societies the idea of family has referred to all those who live in a household, including pseudokin and servants. Kinship, though some have limited its definition to ties of blood, is generally held to refer to systems of both descent and alliance, and to both biological and social relationships. Anthropologists who have researched kinship have been interested, for example, in how certain groups have sought to maintain their blood-line through the generations, or have organized the family to pass down wealth through the male line, in how some groups have developed kinship arrangements to ensure rights over children through the control of women, and how others have used marriage as a means of creating powerful new kinship bonds. Such studies have often involved understanding how religious ideas or ritual practices have been used to reinforce or symbolize such arrangements. Arnold van Gennep, for example, in his famous study of rites of passage published in 1960 [1908], showed how a Turko-Mongolian group called the Bashkir used rituals to mark the important economic and social aspects of marriage. He described the extended visiting and eating rituals associated with the payment by the groom's family of the bride price, and showed how a lengthy game of hide and seek on the marriage day signified the loss of a daughter to one family and her gain by another.

Social scientists have also shown how religious ideas and practices have reinforced common conceptions of kinship and family life. Taking the example of the Christian Right in America in the 1980s, they have shown how religious groups were able to contribute to the formation of a popular family ideal. They have shown, however, that this ideal—of a nuclear family comprised of a heterosexual married couple with children—is not the traditional institution its supporters believed it to be so much as a postmodern

fantasy. 'The family is dead, long live our families,' a phrase used by Judith Stacey, a feminist sociologist, points to the redundancy of this popular ideal in the face of the complex reality of historical and living families in different social settings. How other religious groups have contributed, not only to reinforcing, but also to challenging ideas about the family, will be the subject of section 1.5.

1. The Role of Religion in the Organization of Kinship and the Family

1.1 Kinship and Inheritance

Religious ideas, myths, and practices have had a role in many societies in unholding social institutions, and many social scientists have sought to understand this. One example of this is the Indian caste system, which captured the attention of Max Weber and later anthropologists such as Louis Dumont. Weber held that there was a necessary relationship between caste and religion in India, that without caste there was no Hindu. He drew this conclusion because he saw that the religious rites and duties of Hindus were related to their social rank through a system of closed status groups or castes. These were different to tribes and guilds by virtue of their rules regarding marriage and eating. In particular, Weber noted the importance of the dominant group, the Brahmins, a priestly caste, around whom the entire system was organized. He recognized, however, that the modern caste system had grown to incorporate castes comprised of religious groups other than Hindus, and also suggested that it was severely shaken if not undermined by the challenge of modernism.

Later scholars considered aspects of the caste system in more detail. Dumont focused on hierarchy, examining the use of rules and practices concerning purity and pollution in distinguishing and ranking different castes. Others challenged his view, suggesting that those able to wield power in the system were not necessarily those who were most ritually pure. Most scholars have accepted some kind of relationship between religion and caste, however, acknowledging the role of scripture (especially the *Laws of Manu*), the function of the Brahmins in authorizing the system, the role of ritual in purification, and the part played by religious groups in both manipulating caste for advantage and challenging it.

Just as Indian kinship arrangements were legitimized by religious texts and commentators, so were those in other societies. What came to be understood as the Confucian family ideal—*hsiao*, the virtue governing family relationships—was first prescribed in the classical texts of ancient China such as the *Book of Changes* and the *Book of Rites*. Within Islam, the family was privileged above other social institutions in the *Qur'an* and in later Islamic legal writings.

That European Catholicism reinforced ideas of feudal kinship and the family has been shown by the sociologist Bryan Turner among others. Developing the historical materialist ideas of Friedrich Engels on the family, he stated that the teachings of the Catholic Church in the Middle Ages on sexuality were important for reinforcing the norms of monogamous marriage and the control of women's sexual behavior. These norms, along with laws concerning inheritance through the male line, enabled dominant feudal families to ensure the stable transmission of property from one generation to the next and to avoid the dilution of the estate's wealth through illegitimacy. The Church further served this system through its Religious Orders which were often a destination for those excluded from inheritance, such as younger sons and unwanted daughters.

Religious teachings have played a part in social control at many times and in many societies. Women have often been the focus for this because of the importance of their reproductive role. For example, within Islam, polyandry (a wife taking more than one husband at a time) is prohibited, whereas polygyny is accepted, with the proviso that a husband should be able to provide equally for all his wives (a maximum of four) and children. This may be explained biologically because a woman's reproductive capacity is limited by the gestation period of the embryo, whereas a man may father multiple children simultaneously, thus reproducing his blood-line several times over. Socially, it may be explained by the fact that polygyny was the norm in Arabia at the time of Muhammad. Prevailing social practice was endorsed by the *Qur'an*, and, since that time, some Muslim marriages have been polygamous, particularly in African countries where polygyny was prevalent before the arrival of Islam. Many voices, including religious ones, have spoken out against this practice, but its place in Islamic scripture is unalterable given that the *Qur'an* is Allah's revealed word.

1.2 Marriage

The teachings and rituals associated with marriage are indicative of the value attributed by religions to the family as a significant institution. The family is given legal privilege in Islam, and in Judaism, and Sikhism it is of central importance. In Christianity, the family competes with the Church for priority, and, in Buddhism, with monastic alternatives. The presence of the ascetic life—lived alone or in community—in many religions challenges the adequacy of the family as the best place for spiritual progress, liberation, or salvation. In two modern, global sectarian movements, the Church of the Latter Day Saints and the Unification Church, the family is not only prioritized socially, but is of central theological importance in defining the nature of both the cosmos and divine-human relationships.

The social meaning of marriage is the alliance between two individuals and often between the families or clans of which they are a part. To avoid incestuous relationships, all societies have rules about who may marry whom. In many countries marriage alliances are legitimized in law. Religious understandings of marriage differ, although they all build upon these basic social requirements. In Judaism and Islam, marriage is understood as a contract divinely sanctioned by God, while in Christianity it is a sacrament. In Hinduism, it marks the beginning of a stage of life. Rituals of marriage often symbolize the social and religious ideas embodied by tradition. For example, the exchange of rings, the use of a marriage canopy, the act of circumambulation—together around a fire or of one partner around the other—and the sharing of garlands or food are symbolic of the nature of the marriage relationship, the intention of the partners, and, in the Jewish case of the breaking of a glass, of the fragility of the institution.

Religions have gone beyond these definitions and symbols to reinforce prevalent social ideas about marriage in their teachings, as the case of polygyny in Islam showed. Cousin marriage too is endorsed by Shar'iah or Islamic law, and is also accepted in Australian traditional religions, in order to maintain close, stable relationships and to give sanction to the retention of property within the group. Hindus, though expected to marry within their caste, are prohibited from marrying someone with a common grandparent, thus ruling out close cousin marriages. Arranged marriages, where parents or guardians select marriage partners for sons and daughters, are not obligatory in Hinduism or Sikhism, but they have become a social norm recognized by the majority of Hindus and Sikhs if not always adhered to by them.

Sexual partnerships outside marriage, both heterosexual and homosexual, have frequently been the subject of religious injunctions, often constituting a taboo or ritual prohibition. The breaking of marriage bonds or divorce, similarly, has been an issue where religious teachings have contributed to social control. The use of the *talaq* or marriage repudiation in Islam and of the *get* or bill of divorce in Judaism, both practices which endorse the rights of the male party over the female, have caused consternation among activists campaigning either for equal rights or simply for fairness in situations of relationship breakdown. However, both of these religions have made some provision for the property rights of women during marriage and after divorce, or the death of their husbands, in Judaism through the *ketubah* or marriage contract, and Islam through the *mahr* or dowry provided by the husband. In contrast to these two religions which, owing to their contractual view of marriage, have endorsed divorce, Catholic Christianity has eschewed it, seeing it as the breaking of a sacrament. Christian denominations in the West in the twentieth century, in the face of the increasing divorce

rate, sought to reassert the value of marriage and to encourage reconciliation in the case of marriage breakdown. They were often divided on the question of whether second marriages should be sanctioned.

1.3 Roles and Relationships

The biological functions normally associated with the social unit of the family are reproduction, nurture of children, and preservation and control of fertile adults, particularly women. At different times and places, a variety of social arrangements have been in operation to facilitate these. Responsibilities for children, whether the provision of food and other resources, or of nurture, have been variously divided among men and women, parents and grandparents, though women have had a mothering role in most societies. Perhaps the most commonly recognized family roles have been those of mother, father, children, grandparents, siblings, and ancestors. Religious beliefs and practices have played an important part in endorsing such family roles and the duties associated with them. Roles have often been conferred through rituals, affirmed by religious teachings, and sometimes mirrored and authorized by mythic accounts of divine family roles.

The use of ritual in celebrating entry into different life-stages, conferring appropriate roles, and ensuring group membership, continuity, and loyalty has been the subject of anthropological debate. Functionalists, such as Durkheim and Malinowski, and later, Rappaport, stressed the importance of ritual for social integration, whereas Edmund Leach held the view that rituals reflected conflicting interpretations and often contained the seeds of social instability while legitimizing a particular power structure. This ambiguity was also acknowledged by Victor Turner who held that the symbolic complexity of rituals made space for competing interpretations, thus enabling solidarity to be achieved without compromise. These scholarly perspectives were significant for understanding many types of ritual, including those related to the family. For example, in his study of the Ndembu of Zambia, Turner described the various symbolic meanings of the milk tree, for girls at the time of initiation, for their mothers, and for the society of which they were a part. It symbolized breast milk and the mother-child relationship, the exclusion of men from women's experience, but also the separation of the growing daughter from her mother. Turner suggested that this tree constituted a dominant symbol which enabled the expression both of dissonant interests and of the solidarity of the group as a whole.

Religious rituals and symbols, then, may sometimes affirm divergent viewpoints about family roles and relationships for the social good. Religious teachings, however, are often less ambiguous, constituting normative statements about family life and the roles and duties of mothers, fathers, and children. Householder

life has been prescribed by religious and moral texts in many societies. A nineteenth century example of this may be found in the schoolbooks produced during the Meiji period in Japan when the imperial ideology of State Shinto was gaining its fullest expression. The emperor was held to be the supreme father or head of house, guiding his family, with each individual family being a branch of the same tree, following the same structure. This patriarchal ideal, which came to apply also to corporate families, was authorized by the Shinto myth of the sun goddess, Amaterasu-o-mikami, of whom the emperor was held to be a direct descendent.

A more recent example, which builds on earlier Confucian family ideals, may be witnessed in the teachings of the Unification Church, a movement which began in Korea in the 1950s and was popularized in the West in the 1970s. According to the *Divine Principle*, the movement's founder, Sun Myung Moon, and his wife are the true parents of the world. They seek to heal the broken family, bringing people together regardless of social or religious background. With God as the father of all creation, Jesus as the true spiritual father, and the holy spirit as the true spiritual mother, the movement mirrors this divine family in the human family, with God as the focal point, the male as head of the family, and the mother subject to her husband. With the essential fourth component, their children, they are expected to prepare, through active missionary service, for the second advent. The Unification Church is an example of a religious group for whom the family ideal is central in its theological, ethical, and social teachings, and for whom family relationships are the model for all other relationships.

1.4 The Significance of the Family for Religions

Having seen how religious ideas, practices, and institutions have contributed to forming and legitimizing kinship arrangements, marriage practices, and family roles and relationships, the significance of the family for the maintenance and continuity of religions will now be considered. As was seen in the case of the Unification Church, the family motif has, at times, been an organizing principle for ordering and giving meaning to both divine-human relationships and social life. Other late-modern religious movements, taking their inspiration from Christian rather than Confucian models, have likewise focused on the family as the central expression of community life. The Church of the Latter Day Saints, or Mormons, has seen the eternal family unit (including ancestors) as the primary institution for guiding the individual in his or her spiritual journey. Parents are believed to have duties, not only to care for children, but also to ensure their religious nurture and to confer priesthood upon them. As spiritual progress depends on membership of an eternal family, sex and procreation outside mar-

riage are prohibited, and an active interest is taken in family history and genealogy. The Church's theological and ethical view of the family has led to particular family patterns developing among its members, e.g., a low marital age, large families, support of elders within families, a low divorce rate, and conservative sexual values.

Some Christian denominations and sects depend upon commitment to the family to maintain the group and pass on its beliefs and practices from one generation to the next. In the nineteenth century, Protestant sects in the New World such as the Hutterites, the Mennonites, and the Amish ensured their continuity through the generations primarily by means of the social control of families, marriage within the sect, ethical conservatism, and the religious nurture of children within the family. For some peoples, religious transmission across the generations has been related to ethnicity, itself determined by kinship arrangements, intergroup marriage, and close family ties. Despite having differing myths of origin and notions of identity, Jews, Hindus, Sikhs, and Zoroastrians have been defined by their relationship to a land or a people, and have carried their religious ancestry as a mark of birth. The family has been important for these groups in preserving biological and social ties with others in the group and with ancestors, and in maintaining the group for the future. Current concerns in Jewish and Zoroastrian communities about out-marriage are an example of the importance of family continuity. Additionally, debates within all these groups about the validity of the conversion of outsiders are indicative of the stress they have placed upon ethnic exclusivity. Within Orthodox Judaism, for example, Jewish identity and culture are only transmittable by the mother. If a Jewish woman marries a non-Jew, their offspring may return in the future to the Orthodox Jewish fold; if a Jewish man marries a non-Jew, their offspring may not. This represents an end to the Jewish line. Liberal, Reform, and Conservative Jews have a range of views on this and on the subject of conversion to Judaism.

The family is a major bearer of religious tradition. A new generation of young people may be brought into the life of a faith community by parents and grandparents, thus ensuring the survival of the religion. However, this process of religious reproduction introduces mutation and adaptation. New generations and changing times often require the reinterpretation of traditions, and the introduction of innovation, even if this is within existing religious frameworks. Many scholars of religions have been keen to understand intergenerational religious change, and to examine the methods of religious socialization used within various religions at different times. It can be instructive, for example, to compare the way in which one religious tradition is transmitted differently by families in different locations through variants on the same story, the use of local languages and rituals, and the

involvement of different family members. Traditions surrounding the birth of Jesus in Christianity, for example, are celebrated and passed on in quite different ways by Christian families across the globe.

1.5 Contemporary Religious Views of the Family

Nineteen ninety four was the United Nations International Year of the Family, and the institution of the family and the values associated with it were high on the political agenda in many countries. There was little agreement, however, about these issues. In America and Europe, some supported the nuclear family ideal outlined earlier, of two married parents with several children; others hailed what they called the 'post-modern family,' which was variously constituted of one or more adults of either gender and sexual orientation in a parental role with children. Realistically, in global terms, family types were still more open, including joint and multigenerational families, war-torn and other divided families, families with foster children, and childless families. Religious institutions were often asked for their views on the nature of the family and family values. What were their views on divorce, broken families, remarriage, and the postmodern family? What about birth control within the family, including fertility treatment? Did they have a view on gay and lesbian parenting? What did they think was the effect of women working on the family unit, especially on the socialization of children? A variety of views were offered, some traditional, some liberal, depending on the religious institution or movement and the denomination or group within it. The Catholic Church, for example, under the leadership of Pope John Paul II, continued to articulate a conservative position on marriage, the nature of the family, and sexual ethics. However, in practice, many Catholics contravened Church teachings. Some Reform and Progressive Jewish and liberal Christian groups made provisions to accept cohabitation, second marriages, and gay and lesbian unions, stressing the need for mutual support and care within partnerships and family groupings rather than traditional prescriptions about the inviolability of marriage and sexual ethics.

From the 1970s, the major collective voice for change regarding the family within religious institutions worldwide was that of women. Informed by the research and critiques of feminists, religious women from all over the world called for family-friendly teachings and practices, and respect for women's gifts and roles. In many countries, religious women challenged the law on family issues. In India, feminists fought for women's right to work outside the family, women's property and inheritance rights, and campaigned against dowry and female infanticide, all issues influenced by traditional Hindu and Muslim norms regarding women's roles and expectations.

Women were also able to challenge traditional views of the family by forging new religious roles for themselves or founding alternative religious movements. In Africa, in some traditional religions and new independent churches, women, through the acquisition of spiritual power, were able to circumvent the normal social requirements of wife and mother. Susan Starr Sered, in her research on religions dominated by women, gave examples of independent women who had broken with tradition and established new religious families and communities. She also showed that it was not only contemporary Western spiritual feminists who cried, 'No Father in heaven,' but also Thai, Burmese, Japanese, Brazilian, and Korean women who turned equally to female and male spirits for answers to problems, often seeing them as extensions to their own human families.

Religion, History of

1. Historical Background to the Term 'History of Religion'

The Latin term *historia religionis* first appeared in the sixteenth century and was employed alongside related terms such as *historia ecclesiastica* to entitle chronicles of important events in church history, and the life histories of influential theologians and witnesses of the Christian faith. The term was also applied to accounts on the origin and development of Judaism and portrayals of foreign religions. In his *Historia Religionum* (1697), Gebhard Theodor Meier used the concept in the sense of a comparative study, aimed at portraying a history of the three monotheistic religions. Compared with the more descriptive treatises on religion, comparative *historiae religionis* drew on theological distinctions, such as that between God's chosen people and heathens, to the end of justifying the exclusive truth claims of Christianity. In his *Abris einer Geschichte der Religionspartheyen* (1755), the Protestant theologian and student of Christian Wolff, Sigmund Jacob Baumgarten (1706–1757), examined these different methods and aims of religious historiography, explicitly distinguishing between a *usus relativus* and a *usus polemicus*.

From the 1880s onwards we find the introduction of new compound terms of religious historiography which competed with *history of religion(s)*, *Religionsgeschichte* or *histoire des religions* and reflected a heightened interest in scientifically recording and interpreting religious phenomena. The appearance of the terms 'philosophy of religion', 'science of religion', 'religious studies,' and—later—'sociology of religion', 'psychology of religion,' and 'phenomenology of religion' demonstrated the increasing differentiation within the scholarship dedicated to scientifically interpreting religious culture. However, none of these new academic subjects succeeded in establishing itself as a dominant or authoritative discipline for investigating and interpreting religious systems of belief. Academic research into religion is characterized, rather, by a high plurality of divergent and competitive disciplines that have been institutionalized quite differently, mainly in the countries of Europe and in the USA. This rivalry between disciplines also applies to the historical inquiry into religions: besides professional historians, who sought to render their discipline the new leading human science of the nineteenth century,

other cultural scientists and theologians also participated in the historical study of religion and contributed significantly to its advances. As a result, most of the 'classical' works in nineteenth century religious historiography were not compiled by historians but by theologians (or former theologians), philosophers, ethnologists, philologists, sociologists, and professors in the nascent university disciplines, Sinology, Indology, and Egyptology.

In the course of these developments, the term 'history of religion' remained controversial. Friedrich Max Müller (1823–1900), who is regarded as the founder of the 'comparative science of religion' (*vergleichende Religionswissenschaft*), abandoned the term 'history of religion' in favor of the 'science of religion' in order to emphasize the scientific aims of an inquiry directed towards all historically given religious phenomena and traditions, and which strives to emancipate itself from the prejudiced approach of both theology and philosophy. Other researchers of religion, such as Cornelius Petrus Tiele (1830–1902), preferred the term 'comparative religion'. Nevertheless, common to all these different terms and their respective definitions of approach was the motivation to dispense with theologically orientated normative constructions in the study of religion. In Anglo-Saxon countries, this movement found its most important source of support from the so-called 'Lectures', an institution backed by the private endowments of wealthy patrons (in 1878 Friedrich Max Müller inaugurated the 'Hibbert lectures' and, in 1888, the first 'Gifford lectures' were given). The first professorship for the 'General History of Religion' was established in Geneva, in 1873; in 1877 the universities of Leiden and Amsterdam followed suit. In 1879 France's first chair in *Histoire des religions* was founded at the *Collège de France* and in 1886 the Graduate School of Sorbonne, *Ecole Pratique des Hautes Etudes*, instituted its *Section des sciences religieuses*. However, this appearance of several chairs in the 'history of religion' and 'religious studies' did not achieve the full emancipation repeatedly postulated by Christian theologians. In Germany, for instance, most religious-historical chairs were set up within evangelical-theological faculties; and even where this was not the case and provision made for institutional independence, as in The Netherlands, the majority of scholars appointed to such chairs were theologians.

2. History of Religious Historiography

The intellectual reflection on religion(s) can be traced back to scholars in Greek and Roman antiquity. Here we find the origination of several important topoi that continue to influence the study of religion (such as the critique of religion, theories on the origin of religion and its social function, the comparison between polytheism and monotheism). Notwithstanding this

degree of continuity, the ancient world's approach to the subject of religion cannot be termed 'historical'. Beyond the context of Graeco-Roman traditions, we can also find evidence of the examination of religious life in early Arabic, Persian, and South-East Asian scholarship. However, the influence of these traditions on European historiography of religion has been minimal. One central impetus for broadening Europe's religio-historical horizon was provided by the overseas conquests of the fifteenth and sixteenth centuries. What conquerors and travelers had to report on the foreign religious ideas and practices of the far-off lands they had visited led scholars to question the cultural self-evidence of Christianity, particularly after its confessional pluralization following the Reformation. In an attempt to intellectually overcome religious pluralism as well as the denominational conflicts within Christianity, E. Herbert of Cherbury (1581–1648) focused on a 'natural religion of reason' which he believed to be the true essence of all the different guises of positive religion. In doing so, this British deist introduced a distinction that would later be appropriated by Enlightenment theologians.

However, strictly speaking, it was the seventeenth century that gave birth to the historiography of religion proper. In the wake of the ecclesiastical schism and resultant religious wars, the Christian 'culture of unity' (Troeltsch) began to crumble and was soon replaced by an absolutist state which succeeded in politically neutralizing the vying religious parties by way of an absolute leader ruling over all religious parties. At the same time, the religious conflicts of the seventeenth century gave rise to the interest in a history of religion which was not conceived theologically, but had recourse to an impartial 'third' standpoint beyond confessional polemics. This was found in the 'historico-philological method' based on the principles formulated by Jean Mabillon (1632–1707) in his *De re diplomatica*, which was one of the first comprehensive treatises on methods of documentation and the study of hand-written manuscripts. The publication of this work in 1681 can be seen as the birth of textual criticism that played such a central role in the development of religious historiography. At about the same time, Richard Simon (1638–1712) applied literary-critical methods to the study of the Pentateuch in his *Histoire critique de l'Ancien Testament* (1678) and, in doing so, was one of the first to expose the religious history of the Judaeo-Christian tradition to the process of historicization. This rigorous distinction between the theological and historical historiography of religion also formed the guiding precept of Johann von Gro(e)ning's *Historie der heutigen Religionen* which appeared in Hamburg in 1702. In dismissing every form of *theologia polemica*, this author declared his commitment to a historical approach orientated towards the facts.

That the historian had not irrevocably displaced Christian apologetics, however, is evidenced by

Jacques-Bénigne Bossuet's (1627–1704) work *Discours sur l'Histoire universelle* (1681) which appeared in the same year as Mabillon's important treatise and adhered to an interpretation of world history stressing God's saving grace. In opposition to Bossuet, Montesquieu (1689–1755) banished the guiding hand of divine providence from history and declared mankind to be history's focal point. The human being, expounded Montesquieu in *Esprit des lois* (1748), is determined by lots of factors—climate, laws, customs, and traditions as well as religion—the combination of which gives rise to the particular intellectual characteristic of a nation and its underlying 'spirit'. The work of the Göttingen exegete Johann David Michaelis (1717–1791) illustrates how Montesquieu's point of departure could be used to widen the religio-historical perspective. According to his own statements, Michaelis sought to view the Old and New Testament 'through the eyes of Montesquieu'. To this end he reconstructed in his six-volume *magnum opus*, *Mosaïches Recht* (1770–1775), the structure and contents of the Mosaic codex from the climatic, economical, political, and socio-cultural preconditions of its natural environment, and thereby offered an interpretation of this codex in the spirit of Montesquieu and in reply to the demands of his day.

Alongside this *historico-philological* examination of religion, we also find the appearance of the *psychological* approach to religion, as represented by David Hume (1711–1776) in his treatise *The Natural History of Religion*, published in 1757. Hume was not primarily concerned with explaining religion historically, but rather with accounting for religious ideas and practices as phenomena of the human psyche under the dictates of irrational emotions such as fear and hope. Because Hume saw reason as having gradually overcome these irrational forces in the course of history, however, this Scottish philosopher had also furnished the historiography of religion with an evolutionist perspective that would then feature as a key concept in the second half of the nineteenth century.

With the conception of world history as a developmental process from lower to higher, that is to say, from uncivilized to rational forms of life, religion came to represent not an exception to, but a manifestation of these historical dynamics. The evaluation of religion's status within this process of advance was divided: either one adopted a religio-critical stance, and assumed that reason would eventually replace religion (Voltaire, 1694–1778), or one took up a more positive, religio-historical position, and integrated religion into historical progress. One leading exponent of the latter position was Charles de Brosses (1707–1777). In his study *Du culte des dieux fétiches* (published in 1760) he employed a comparison between ancient and contemporary African cult ritual to support his claim that fetishism—understood as the worship of arbitrarily chosen natural objects or living creatures—is to be identified as the original form of all

religions. However, in the course of mankind's historical advance this has been successively superseded by the worship of celestial bodies, by polytheism, and then finally by monotheistic religions, he contended.

In his *Grundriß der Geschichte aller Religionen* (1787), Christoph Meiners (1747–1810) also construed the history of religion as part of a general historical process of cultural advance. As a result of this pronounced tendency in the eighteenth century to assimilate the portrayal of religion into an all-encompassing cultural historiography, the traditional anchor of religious history in the theological field of church history began to corrode, causing a telling shift of emphasis. Johann Christoph Gatterer (1727–1799), for instance, dealt with church history within the framework of a universal history of religion. In a similar vein, Christian Wilhelm Flügge approached church history as an aspect of religious history that he conceived as a branch of the general cultural history of the human spirit.

Resistance against this linear and optimistic idea of historical progress had already begun to emerge in the eighteenth century. For Jean-Jacques Rousseau (1712–1778), scientific and technical progress amounted to a moral step backwards behind the original and good 'natural state.' Even religion, he argued, has not escaped this cultural decline, but degenerated from an honest 'affair of the heart' into an institutionally depraved ecclesiasticism no longer capable of integrating the community. Nonetheless, because Rousseau considered religious feeling to be the strongest social bond, in *Contrat Social* (1762) he spoke up for a religious 'occupation' of the values which hold together the political community, viz. the establishment of a 'civil religion.'

Similar ideas were to be voiced by Alexis de Tocqueville (1805–1859) almost a century later who, in his famous work *De la démocratie en Amérique* (1834/40), prognosticated that the politico-moral consensus within democratic societies would adopt the socially integrative role which religion had played in the social system of the Middle Ages. In eighteenth-century Germany, Johann Gottfried Herder (1744–1803) likewise objected to the belief in progress of Enlightenment thinkers, supporting the Romantic conception of history as a process of organic growth. In doing so, Herder influenced the organo-historical ideas of classical German historicism. This school of thought also rejected the Enlightenment's linear concept of history and belief in universal-historical progress, viewing history as the unfolding of individual cultural units.

The turn of the century into the 1900s was also a transitional period for European historical consciousness which had begun to move away from universal generality and attach greater importance to that which is particular and individual. This change of perspective not only enhanced the status of the historical religions, which had been neglected by the

concepts of historical progress of the eighteenth century, but also paved the way for the empirical research into the history of religion, especially the intensive analysis of ancient religious traditions.

Among others in Germany, Otto Jahn (1813–1869) and Karl Otfried Müller (1797–1840) devoted their scholarly activities to investigating ancient mythology. In his influential study *La cité antique* (1864), the French historian N. D. Fustel de Coulanges (1830–1889) examined the stabilizing function of religion for the Greek polis and Roman system of rule. Furthermore, this new interest in empirical research into religion led to what Edgar Quinet described in his work *Génie des religions* (1842) as an 'Oriental Renaissance': the first translations of India's holy scriptures had already begun to appear at the end of the eighteenth century.

In 1808, Friedrich Schlegel published his writings on the language and wisdom of India (*Über die Sprache und Weisheit der Inder*) whose conception of religious history diametrically opposed that of the Enlightenment. In India's ancient wisdom, Schlegel saw the realization of a unity between nature and spirit (Geist) which 'enlightened Europe' had forfeited and India itself submerged, and which he strove to reconstruct from the oldest of India's religio-historical sources. Drawing on Schlegel, Georg Friedrich Creuzer (1771–1858) and Joseph Görres (1776–1848) called into question the origins of antiquity's mythical tradition, claiming that Greek myths originally derive from the wisdom of Indian priests. With this Romantic enthusiasm for oriental languages and literature, the availability of translations of the latter and, not least, the advances in the field of 'historical and comparative linguistics since the turn of the nineteenth century,' the historiography of religion in the nineteenth century was afforded a wide range of new stimuli.

The endeavors of Franz Bopp (1791–1867) to distill a common Indo-European proto-language from a grammatical comparison between Sanskrit, Greek, Latin, Persian, and German, for instance, gave the comparative study of religions new impetus, temporarily pushing universal interpretations of history into the background. Aside from the work of Eugène Burnouf (1801–1852), a prominent figure in the historiography of Iranian religion, it was above all the services of his, and Bopp's student, Friedrich Max Müller, which rendered the philological approach beneficial to religious historiography.

Analogous to the Romantics' interest in the origins of religious history, Müller linguistically classified the Indo-European languages, particularly with reference to their respective names for God, to the end of reconstructing a primal religion common to all these peoples, which he saw as having once flourished in the advanced civilization of ancient India. Hermann Usener's (1834–1905) investigations into ancient religious history were also based on a combination of philologico-comparative studies and theoretical-

explanatory ambitions. With his programmatic work on an interdisciplinary ancient religious history—which his students Eduard Norden (1868–1941) and Ulrich von Wilamowitz-Moellendorf (1848–1931) advanced—Usener not only influenced the study of ancient religion, but also classical philology, art history and oriental studies, not least cultural theory until well into the twentieth century.

Besides the philological exploration of religious traditions, which chiefly focused on antiquity and the Orient, the second half of the nineteenth century also witnessed the proliferation of ‘ethnological’ research into contemporary, non-European religions which had not been taken into consideration by the romantically inspired religious historiography of such scholars as F. M. Müller. That these religions had become the focal point of attention within nineteenth-century religio-historiographical discourse was due to a revival of the evolutionist theory, aimed at assimilating the individual, historical, and divergent forms of religion into a universally applicable model of cultural advance.

In his major work *Primitive Culture* (1871), Edward Burnett Tylor (1832–1917) held the view that the religions of contemporary tribal societies represented the beginnings of religious history and therefore attached great importance to the investigation of such communities. However, Tylor’s claim that animism (the attribution of a living soul to plants, inanimate objects, and natural phenomena) constituted the primal form of religion was soon superseded by other theories on the origins of religion, the most influential of which was William Robertson Smith’s (1846–1894) totemism theory tracing religion back to the worship of ancestors symbolized by totemic emblems of plants and animals. Emile Durkheim’s (1858–1917) writings on the elementary forms of religious life (*Les formes élémentaires de la vie religieuse*, 1912) can be seen as the most prominent adaptation of Smith’s propositions. Religio-historical evolutionism proved to be an extremely resilient paradigm, providing the working hypothesis for James George Frazer’s (1854–1941) reconstruction of religious history on the basis of contemporary ethnological material in his famous twelve-volume opus *The Golden Bough* (1890–1915).

In the latter half of the nineteenth century, ethnological and philological investigations into the history of religion found enormous support within academia and aroused ever greater interest among the general public. This trend was evidenced in the UK by the positive response to lectures in this field of study (cf. Sect. 1) and the huge popularity of Ernest Renan’s (1823–1892) *La vie de Jésus* (1863) in France and David Friedrich Strauss’ (1808–1974) works *Das Leben Jesu* (1835/36) and *Der alte und der neue Glaube* (1872), as well as Hermann Oldenberg’s book *Buddha* (1890), in Germany. *Historical* scientists, by contrast, showed very little interest in religio-historical phenomena; the majority of professional historians adhered to a narrow politico-national approach to their subject in

which religio-historical questions remained peripheral.

The few exceptions, held in high esteem today, were then decisive outsiders, such as Jules Michelet (1798–1874), who in his 17 volumes on the history of France (*Histoire de France*, 1833–1867) drew attention to the religious folklore of the Middle Ages and, in doing so, became a predecessor of the *histoire des mentalités* (cf. Sect. 3), or Jacob Burckhardt (1818–1897) who in *Weltgeschichtliche Betrachtungen* (1868–73) and *Die Kultur der Renaissance in Italien* reflected on religion as a third historical ‘power’ (*Potenz*) alongside culture and politics.

The cultural-historical revival at the turn of the twentieth century effectively placed religion at the forefront of scholarly discourse throughout Europe and the USA. The rapid erosion of time-honored cultural traditions, the growing insight into the social costs of capitalist modernization, and the new disintegrative tendencies in many Western societies provoked heated debates on the relationship between the religious history of European countries (as well as that of the USA) and their individual formation processes as modern societies. In defiance of traditional disciplinary borders, the historical research into religion became a central medium for the self-reflection of Western societies. From a systematic perspective, three closely connected issues came to play a decisive role in this intensive exploration of religious history around 1900. These issues included: the participation of religious traditions in the genesis of modern occidental rationalism; the socially integrative potential of religion in functionally differentiated and politically fragmented societies; and the cultural relevance of differences between Christianity’s denominations on the one hand, and non-Christian religions, especially those of the East, on the other.

First and foremost, this discourse applied to Protestant theology which had largely viewed itself as a historico-cultural science of Christianity since the mid eighteenth century and, since the 1880s, became increasingly aware of the interrelations between the Christian religion and its non-Christian environment. Above all, it was the proponents of the so-called ‘History-of-Religions School’ (*Religionsgeschichtliche Schule*) within German Protestant theology who, in classical exegetic and religio-historical treatises, analyzed the interconnections between Jewish antiquity and the religious worlds of the ancient Orient, and the syncretistic character of Christianity. Although religio-historically minded scholars of the Old and New Testament, such as Hermann Gunkel (1862–1932) and Wilhelm Bousset (1865–1920), as well as the systematic theologian and cultural philosopher Ernst Troeltsch (1865–1923)—named the ‘systematist of the History-of-Religions School’—viewed ‘religion’ as a relatively autonomous cultural power *sui generis*, they nevertheless gave greater priority to investigating the interactions between religious and other spheres of

culture. Ernst Troeltsch's 'The Social Teaching of the Christian Churches' (*Die Soziallehren der christlichen Kirchen und Gruppen*, 1912) is regarded as the most important work of this religio-historical group. In this publication, Troeltsch embarked on a cultural-historical reconstruction of the formative influence of Christianity's denominational churches and sects on social ideas and the effects of social structures on the formation of religious ideas and communities. Appropriating the typological distinction between 'church' and 'sects', developed by his friend Max Weber (1864–1920), Troeltsch differentiated between 'ecclesiasticism', 'sectarianism,' and 'mysticism' as specific forms of religious socialization. With Weber, Troeltsch shared the ambition to demonstrate the significance of religious ideas and practices for the emergence of the modern world. In *Die Bedeutung des Protestantismus für die Entstehung der modernen Welt* (1906), he focused on Protestantism and Calvinism, in particular.

While Troeltsch transformed church history into the cultural and social history of Christianity, Weber expanded his pioneering study 'The Protestant Ethic and the Spirit of Capitalism' (*Die protestantische Ethik und der Geist des Kapitalismus*, 1904/05) into an extremely elaborate enterprise of categorically comparing the economic ethics of the world religions (*Die Wirtschaftsethik der Weltreligionen*, 1915). In 'The Protestant Ethic', Weber had inquired into the effects of a religiously shaped *habitus* in areas of life and culture far removed from those commonly associated with religion in the narrower sense of the term—above all, in the economic sphere. In his comparative analyses of the economic ethos of the world religions, however, he primarily concentrated on occidental rationalism and sought to grasp its particularity and formative power on cultural life. Today, scholars are more skeptical of the details of Weber's ideas. Nonetheless, it cannot be denied that the worldwide reception of his theories and derivations in the study of religion has scarcely been matched by any other oeuvre.

3. Overview of Recent Research

Since the 1960s, the renaissance of religious movements in many societies, the upward trend of 'fundamentalism' and Protestant sectarianism, the spread of charismatic Christianity, and the manifold processes of a rapidly changing religious landscape (conversions, new syncretism) have attracted the attention of historians and led to a critical revision of the 'secularization theory', which equated social modernization with a general decline in religion. Religion has been rediscovered as a relatively autonomous system of communication and symbolism which shapes the *habitus* of individuals or identity constructions of social groups, and exerts a positive or

negative influence on the development of societies. As a result, the old debates on the definition of religion and master narratives on modernization de-Christianization or secularization are being steadily replaced by micro-studies into the diverse religious milieus of the modern age. While religion has become a central topic in the historical discourse of all countries generally, several national-cultural particularities deserve mention.

In France, the work of Lucien Febvre (1878–1956) and Marc Bloch (1886–1944), together with the journal *Annales, Histoire, Sciences Sociales* (originally entitled *Annales d'histoire économique et sociale*) they founded in 1929, supplied the historiography of religion with an innovative approach which broke with the politico-historiographical tradition of the nineteenth century. Their objective was to uncover a temporal stratum of *longue durée* (Fernand Braudel, 1902–1985), that is to say, extensive periods of time which formatively shape not only political and socio-economical history, but also the concrete experiential world of the general population. Concepts stemming from *Annales*-historiography, such as 'structure' and '*longue durée*,' were then applied heuristically to the broader discussion of collective 'mentalities,' from which the historiography of religion profited in particular.

Although the term *histoire des mentalités* soon became a key concept of *Annales*-historiography, no agreement had been reached on the question as to what 'mentality' exactly means. These definitional problems notwithstanding, *histoire des mentalités* can be generally described as an historical discourse directed towards the collective consciousness of an epoch, i.e. its cognitive, ethical, and affective dispositions, which form the unquestioned cultural basis for the daily life of individuals and social groups, thus constituting their identity. In its application to the history of religion, this approach initiated a change in perspective away from the narrow argumentation of ecclesiastical historiography: religious history came to be seen as a history of religious consciousness whose carriers remain for the most part anonymous. Following this, historians of religion in France began to attach less importance to major events, personalities, and institutions, and focus on 'structural-historical' and, in particular, 'anthropological' lines of questioning.

Here their investigations have been concerned with historically varying attitudes to birth and childhood, mortality and death, corporeality and sexuality, nature and the environment, God and the Church, heaven and hell (cf. Ph. Ariès, M. Vovelle, J. Le Goff, J. Delumeau). To date, however, exponents of *histoire des mentalités* have scarcely researched the religious culture of more recent history, concentrating rather on the Middle Ages and early Modern Age, and—in co-operation with experts in ancient history such as J.-P. Vernant, M. Detienne and P. Vidal-Naquet since the

1970s—on the religious history of antiquity. Further drawbacks of applying this historical approach to religious historiography arise from its emphasis on the alleged durability of mental dispositions, its disregard of the processes of change within religious mentalities, and its neglect of the conflicts caused by differing religious backgrounds (resulting from the acculturation of foreign ideas and practices or due to inner-social differences).

In Germany, the 'socio-historical turn' of the 1960s and 1970s as well as the institutional separation of church history (pursued within theological faculties) and general history encouraged scholars to view religion and confession as nothing other than marginal factors in the history of the modern age. Since the 1970s, however, several attempts have been made to integrate religio-historical perspectives into social historiography (cf. W. Schieder, R. van Dülmen, R. von Thadden) and to open up historical research in church history and theology to the methodological debates of cultural and social scientists (cf. M. Greschat, K. Nowak, F. W. Graf). Numerous younger historians are now conducting research into a range of religious milieus, such as ecclesiastical organizations and festivities, theological controversies and quarrels over religious symbolism as well as the tense co-existence of Catholics, Protestants, and Jews. The collapse of East Germany, moreover, has generated a new sensibility for the political role of churches and their partly antagonistic, partly affirmative relationship to the 'political religions' of the twentieth century. And last, but by no means least, the holocaust initiated worldwide intensive research into the cultural climate of German Judaism and the conflict-ridden history that finally led to the destruction of the 'German-Jewish synthesis.'

In the UK, discussions continue to be determined by the weight of social anthropology (cf. B. Malinowski, A. R. Radcliffe-Brown). Here, from the outset—unlike in Germany—'society' and 'culture' were seen as one, and consideration given to the class-specific religion of the workforce and the processes of religious change in this country's urban centers (cf. H. McLeod). Particularly pioneering were the studies on the connection between religious radicalism and revolution (cf. Ch. Hill) and between Methodism and the emerging labor movement (cf. E. P. Thomson). Research into the processes of religio-theological differentiation in the Anglican churches has also drawn on the interpretative approach of *histoire des mentalités*.

In the USA, historians of religion since the 1980s have been strongly influenced by the 'interpretative' ethnology (stressing the concept of 'understanding' rather than that of 'explanation') and cultural anthropology of C. Geertz. Beyond the classical self-reflective discourse on the religion of native Americans, the faith of the Pilgrim Fathers, pluralism within Protestant denominationalism, the emergence of a specifically American Catholic self-understanding in the late

nineteenth century and a 'civil religion' (N. Bellah) capable of integrating religious pluralism, in the most recent American historiography of religion themes such as gender, race, language, and the religious forms of minority groups have played an important role. In addition, the ethnological debate on 'Writing Culture' (viz. the constructive character inherent in self-portrayal and the description of that which is foreign; cf. F. Clifford/G. E. Marcus), the comparative analysis of fundamentalist movements in the world religions (M. E. Marty), the interpretation of Latin America's religious developments (D. Martin) and the interrelation between law and religion (W. Fallers Sullivan) have featured as central concerns of recent research. Current North American religious historiography has also profited greatly from the application of economico-theoretical approaches (R. Stark, Bainbridge W S (1985), Stark R, Finke R (2000)).

4. Outlook

Religion has gained in importance worldwide and this situation has accordingly afforded the research into religion greater significance. At the forefront of this discourse we find the questions concerning the interrelatedness of religion and ethos, the political relevance of religion, the construction of religious identities of minority and the conflicts between members of different religions and confessions. The debates on migration, religious conversion and new syncretism have shown, however, that historians of religion find it difficult to precisely grasp the long-term changes of religious mentalities. The correlation of conflict-ridden modernization, on the one hand, and the renaissance of strictly binding religion on the other, promises to become an issue of particular concern in the future: for the rapidly advancing globalization of capitalism, together with its constraints on heterogeneity, will only fuel those religious movements intent on communicating a more fulfilled form of human life which transcends an existence solely defined by the utilitarianism of economic rationality.

Religion: Mobilization and Power

In what ways does religion mobilize believers? How are they empowered by their beliefs, and to what end? Religion, as a phenomenon, has always contributed to both social conflict and social cohesion. It has the

power to mobilize individuals, communities, and nations. Within religious institutions, power is as inevitable and ubiquitous as anywhere else. It can be the power of good, or morally ambiguous potency. Equally, it can come vested or masked as unction or inspiration. To speak of religion is always to speak of some kind of notion of power, whether it be attributed to divine, human, elemental, or cosmic sources. Relations of power are amongst the most significant aspects of any religion, especially when considering its context and cultural intercourse.

The study of power and mobilization in relation to religion must be rooted in theory, history, and praxis. For example, any consideration of church–state relations inevitably is concerned with control, legitimacy, and authority. It is impossible to conceive of a discussion concerning the origins of the Church of England that does not involve power–relations: those between the Pope and King Henry VIII; between the Reformers and Roman Catholicism; between competing powers at court; between competing ideological and political convictions on the nature of individual salvation and the centrality of the church; vernacular liturgies and scriptures, and their overall hermeneutical control and its centralization; between individual states and their subjects, and their right to any kind of religious choice, including that of dissent. The Church of England—‘by law established’—is a form and exercise of power in nearly every era of its history and at every level of society, from government to parish, from individual to state. To study the church is to study power, in periodic, dispositional, episodic, and latent forms.

Globally, religion operates as a form of power and mobilization almost everywhere. In the USA, although no religion is established (the Constitution separates the churches and State), the outcome of increasing pluralism and secularisation has seen, amongst other phenomena, the mobilization of the New Right, and the movement of Roman Catholicism from a private to ‘public’ denomination, both on a select range of moral issues. As a number of scholars (Haynes, Casanova, etc.), have shown, this is a form of counterpower: the secularization theories (so prevalent in the 1960s and 1970s) have had to capitulate to the rise of a new religious consciousness in industrialized nations. They see modernity not as the harbinger of secularization, but rather of privatization, a by-product of late capitalism. Religion has fought against being squeezed into the private and subjective realm by recovering and reconstituting a public role. It is now a potent force for mobilization on a range of public issues in the political and social spheres. The example of the USA shows that the forces of pluralism, industrialization, and secularization can be combated by religious power at many levels.

In the last quarter of the twentieth century, the competition and association of powers between religion and society (e.g., Bosnia), church, and state

(e.g., Ulster) has operated differently but no less dynamically in Europe. In Eastern Europe, religion (mostly Christianity and Islam) played an important role in the diffusion of the communist monopoly. The vociferous activity of some Muslims in Western Europe has questioned the limits of liberalism in politics and education; in Northern Ireland, religious polarization has attempted to hold out against political reconciliation; the conflicts in Bosnia suggest that the purity of religious and ethnic enclaves is prized above any peaceable settlement. Added to this, there is a discernible rise in new religions, sectarian movements, and a patchy but popular inculcation of 'ordinary' spiritual ideology, indicating that religion remains a perennial public force.

In Africa, the Middle East, South America, Central Asia, the Indian subcontinent and South East Asia, religion has found itself harnessed to many nationalist causes. The symbiosis has often been so intricate as to make the political power play indistinguishable from that of the religious: Lebanon, Israel, Sikh nationalism in India, and Buddhism in Burma are perhaps the most notable examples. The origins of Pakistan lie in religious conflict and differentiation, as does civil war in Rwanda. Equally, it is also important to note that the resurgence of religious identity threatens existing religious powers, especially those allied to the State. Islamic movements in Turkey, Algeria, and Egypt demonstrate that religious fundamentalism is a powerful and popular force for social mobilization. In South Africa, religion has played a vital role in securing peace and democracy following the end of Apartheid; the 'Truth and Reconciliation Commission' was birthed in Christian theology, and chaired by an Archbishop (Desmond Tutu).

1. Religion and Power

Sociologically, distinctions between authority and force, and between violence and resistance, will and desire often cluster around the study of power. In political science, power usually is configured in terms of the ability of its holders to carry out their will, exact compliance, exert force, and compel obedience. To touch on authority, as part of power, is to study of relations, rules, and regulations. To focus on force, as another arm of power, is to consider compulsion, threats, and violence. In any consideration of politics, religion, or society, the subject of power (and its legitimacy) is never far from the surface.

The concept of power in social sciences interfaced with any confessional theology has no unity of discourse. Social scientists assess the 'power of God' through its social and observable outcomes: constructions of reality, rhetoric, sociality, and activity. On the other hand, believers claim to know and experience this same power personally and communally, in ways that appear to be either inaccessible

to or immeasurable for social scientists. Part of the problem is this: 'power' is what we call 'something': it is primarily a noun, not a verb (Morris 1987).

Although the verb does exist in the sense that we may speak of empowering, the fact that it is mainly a noun has implications for the way in which 'power' is described and studied. All too commonly, power is run together with verbs that are deemed to be its associates. For example, from a sociological perspective, a theoretician like Dahl (1957) describes power by contrasting it with near-synonyms like 'influence,' so that power becomes like influence. This becomes more obvious in May's *Power and Innocence: A Search for the Sources of Violence*, in which the noun again assumes the characters of the nearest relevant verbs. For May, power is exploitative, manipulative, competitive, nutrient, or integrative (1976). Each of these types of power represents a different level of threat, force, or coercion, ranging from the mutually empowering (integrative) to the potentially violent (exploitative). Thus, 'power'—at least so far as religious believers are concerned—loses its reality in some sense here, precisely because the verbs are allowed to project on to a passive noun. Perhaps this is why deconstructors of power such as Foucault (1984) have looked at power and seen 'nothing'—only reciprocal relations. On the other hand, 'realists' such as Weber (1947) have seen the concept of power as a 'highly comprehensive' schema within sociology for the analysis of circumstances and situations.

Van der Leeuw's (1938) phenomenology of power also recognises that one cannot prove there is such a 'thing.' He suggests that sensitivity to power has been largely forgotten in 'modern' society, but in primitive society, power developed into religious monism, which reached its climax in monotheism. In contemporary society, power is not encountered in nature or personality, but in the dispersed forms of social organization. However, the essence of religion is power, driven towards monism, which has a tendency to conflate the psychological with the cosmological, the sociological with the theological: religion is a description of concepts of power and their use.

More recently, and from an anthropological viewpoint, Lewis (1996) has also argued that although religious power assumes many different forms (which may appear to be unrelated or mutually exclusive), it is an appropriate 'theme' through which to approach religion holistically. For Lewis, religious power is best understood as a negative force that opposes malign spiritual powers. Thus, the shaman assumes the charismatic role par excellence—being able to exorcise the evil and prepare the way for blessing. In effect, the shaman stands between negative and positive power as a broker, a fixed point of passage and determinacy that both creates and obviates power. Like Van der Leeuw, Lewis cannot 'see' power, except in the way that it is related to, and in the social and ritual structures that are based on its assumption.

Thus, and sociologically, the conceptions of power can be divided into two very broad categories. On the one hand, there are those which are asymmetrical, stressing conflict, will, resistance, and the like: social relations are assumed to be competitive, conflictual, and dialectical. A *Jihad* ('fighting against unbelievers') may be understood in this way (Peters 1996). On the other hand, there are conceptions that imply that all may make some gain through power. Here, power is a collective capacity or achievement, born not out of conflict, but communal welfare (Lukes 1978). As McGuire (1992), many forms of Christian nationalism offer 'social cohesion.'

Although it is helpful to be mindful of these two broad categories, it should be noted that they are somewhat inadequate in the analysis of religion. To an extent, all religious movements have elements of both categories within them. This must be because the religious-social system itself is one of exchange alongside being one of power, which therefore allows for conflictual and communal action together. Beyond this, however, there is no account of subliminal power, which is so critical for an understanding of religious behavior. Power is not just attached to structures and positional personality, but also to nonstructural interaction and roles. Parsons therefore eschews 'canonically correct' definitions of power: it actually covers more than it can define. It must take account of magnitude, distribution, scope, domain, and outcomes. Moreover, it must consider resources, skills, and motivations. In considering power and mobilization in religion, the investigator is always close to the analyses of causality, which in turn refers to power; its measurement, exercise, distribution, and impact.

Morriss (1987) suggests that careful attention to the etymology of power reveals its own diversity, prior to any linkage to verbs. Power is 'ability to do or effect something or anything ... energy, force, effect ... an active property, capacity of producing ... possession of control or command over others ... dominion, rule, legal ability, commission, faculty ... political or national strength.' That there is an overlap with verbs about power is clear: but that there is not complete synonymy is also clear. Morriss argues for a dispositional understanding of power. That is to say, power is seen as a relatively enduring capacity within any given object. Dispositional views of power are held in contrast (but not necessarily in opposition) to episodic ideas, that see occurrences or events as specific exercises of power. Morriss (1987) does point out that this power is not something that can be observed. Power is known only by its reification, which is ultimately an indirect but material way of inferring what power might be at work. This conclusion underlines his plea for power not to be studied in isolation: the subjects and objects of power require a methodological tolerance in the spheres of theory and evidence.

Clegg (1989) syncretizes the work of the previous

theorists discussed, and effectively constructs an 'open' theory of power based on the concept of circuits, nodal points, and agency: it has political, organizational, and theological resonance. Clegg begins his work with an overview of earlier theoreticians such as Hobbes and Machiavelli. This is followed by discussion and critiques of Dahl, Russell, Bachrach, Baratz, Weber, and Wrong, revolving around the 'two faces' of power, namely the relationship between 'intention' and 'structure,' and which enjoys supremacy in society. According to Clegg, these debates, naturally enough, were eclipsed by more substantial models. Lukes proposed a three-dimensional model of power by identifying the centrality of 'interests'; Habermas focused on ideal speech situations, ideology, and hegemony; Giddens on the relationship between agency and structure in terms of power. Each of these speaks to the religion-mobilization axis.

But Clegg moves beyond each of these explications, working in Parsons, Foucault, and Mann (among others) into an overall integration that respects the dispositional and facilitative approaches to power, besides stressing the vital role of strategic agency. As he states, 'a theory of power must examine how the field of force in which power is arranged has been fixed, coupled and constituted in such a way that, intentionally or not, certain "nodal points" of practice are privileged in this unstable and shifting terrain' (1989). This is a critical observation in the field of mobilization, religion, and power, for change is neither predictable or necessary, yet its occurrence is beyond question.

Any discussion about the true nature of power and where it lies will be at the heart of all religious belief. Liberation theology, feminist theology, and other new 'disciplines' within religion could be read by some as being mainly in terms of reconstituting the balance of power in ecclesiastical and social structures. The Nation of Islam has done the same within a North American context, although this is still developing. These theologies are effectively a form of revolution and resistance. The effect of the stress on power has led to more self-conscious questioning by some writers, who are beginning to question the nature of the power, that would generally be uncritically appealed to.

With respect to Clegg and Morriss, one of the difficulties of studying 'pure' power is that it is not one 'thing' to be observed. For example, a nationalist uprising in India may have a religious dimension functioning at many different levels: provision of identity, ideology, legitimization, coupled with notions of sacrifice, taboo, and salvation. Equally, an examination on the origins of Methodism would need to consider the power of mass meetings, the appeal of hymns, testimonies, and religious experience, not to mention the mobilization of displaced rural and agrarian populations in their search for meaning and community. Discerning power in such scenarios is a complex task.

Given the myriad of studies on power and attendant methods, the most practical way forward, especially given the multifarious nature of 'power' that occurs within religious movements, is to return to the agents or 'nodal points' of power identified by Clegg, and focus on their relationality. The advantage of Clegg's conceptualizing of power in terms of circuits, flow, and agency is that one can often identify the delimited 'field' of power (such as an organization), the directionality of power within the structure ('flow' or hegemony), and the specific nodal points of power such as a guru, infallible text or law, or episode (e.g., 'flashpoint'), as well as the latent forms of power embedded in culture, ethnic identity, and political situations.

This theory of circuits of power does not attempt to marry the 'nonrealist' tendencies of Foucault with the 'realist' or 'identification' trends of someone like Weber or Wright-Mills (although a focus on relations steers a middle course between realist and nonrealist accounts of power). Instead, it describes power in terms of circuits, which are organized through agencies. However, it does allow that the agencies cannot be seen as 'effortlessly rational or powerful,' since their 'carrying capacity is itself opened up for scrutiny in power terms.' This view of power is more contingent than monolithic. It has space for dispositional, facilitative, and episodic power within the same or overlapping frameworks. This has implications for the study of mobilization.

Dispositional power, as its description suggests, is the tendency or habit of an individual or group: in many religious movements, this is reflected in the 'grammar of power as a concept' that helps form the social and religious community, possibly even the State (its identity and constitution). Appeals to an 'almighty' God, or the 'monarche' of God, or to a 'Lord,' or to more specified concepts of omnipotence, have direct social and political consequences. Kings, Queens, dictators, and rulers in many faiths, past and present, have depended on such conflation. Any present sociopolitical governance can be a divine instrument and referent that is used in the furtherance of subjugation and legitimization.

Facilitative power describes the points of access through which power can be reached, reified, and exchanged. Episodic power can be used to describe the 'surges' or 'events' of power that may alter the shape, perceptions, or behavior of individuals and groups. Central to these three 'circuits' is organization, and many a religious movement is able to demonstrate systematic configuration in each field. For example, the ideology present in postmodern charismatic worship could be said to be dispositional; the charismatic leaders are facilitative; the 'invocation' of the Holy Spirit a 'cue' for episodic manifestations of power to be unleashed (Percy 1996, 1998).

Episodic power is less easy to identify as a factor within mobilization. Any seminal moment can turn an

ordinary crowd into a passionate army. A martyrdom, miracle, or the raising up of a messiah can provide a single moment from which power flows. The declaration of *Jihad*, the proclamation of a fast, or the threat of heresy to authority can do the same. The very genesis of religious mobilization can be traced back by believers to an event that revealed, defined, and motivated a new community to hold, channel, and disperse power in new and particular forms.

Charisma is also a factor within mobilization. One way of understanding the place of agencies in circuits is to see them as process of power-exchange, a mechanism where power is given up or received, or raw material transformed into a type of 'power.' In other words, John Wesley may have been a charismatic religious leader, but he also functioned within a charismatic situation, which he could not entirely control, although he might have directed.

An account for the resurrection of the charismatic religious leader in postmodernity lies, in part, in Weber's own writings (which in turn is indebted to Nietzsche's notion of 'will to power'). Weber differentiated between 'religion' and 'magic' in the way that he differentiated between ancient and modern. Religion was rational, organized, and functional. Magic was primitive, a legitimate form of domination, and placed power outside ordinary temporal spheres (1947). Within magic, there were prophets, magicians, and shamans. Weber saw the prophet as the most significant bearer of charisma, since their claims were based on personal revelations that ultimately developed a personal following (1965). Yet these distinctions are to be understood as fluid: priests and prophets practiced magic, and there was routinization in the prophetic as much as in the religious. As nearly every preacher knows, propaganda is the highest form of political authority: aims and objectives are seldom met by organization or negotiation, but rather by power and mobilization.

2. Summary: Power and Mobilization

Recent civil strife in Northern Ireland illustrates religion's capacity to promote both social cohesion (e.g., Corrymeela Community) and conflict (e.g., Ian Paisley's anti-Roman Catholic rhetoric). Behind this aspect of sociality lies a complex history of the struggle for power and factors in mobilization—both for war and peace. In terms of power, the divisions between Protestant and Catholic are simultaneously elementary and complex. The 'two traditions' do not just represent different religions, but rather different politics, histories, and ideologies. In terms of mobilization, the preservation and flourishing of Protestant and Catholic communities has often been cultivated through episodic and dispositional conflict, which has seen many casualties and fatalities. Power and mobilization are deeply intertwined through armed

hostility, marches of protest or ritual (Orange Day Parades), sectarian division, and political aspiration. Two 'civil religions' effectively have promoted civil division.

Yet the hopelessness of this situation, in which two forms of 'civil religion' (in terms of their power and mobilization) have failed to cancel each other out, has given rise to a third option: a peace process. Here, religion has been no less involved, although the forces for power and mobilization have recognized that a political solution should bring a degree of peaceable co-existence between competing religious-sectarian convictions. The emerging and fragile détente serves to remind that the goal for many who first engage in hostilities is actually to end conflict; whether they succeed or not, power and mobilization often end in some kind of settlement.

At the beginning of the twenty-first century, it still remains the case that some of the bloodiest conflicts known to humanity have been inspired by or utilized powerful religious symbols and ideas. Keeping the faith 'pure' and protecting the sacredness of the *Koran* has given rise to *Jihad* and *fatwah*. Promised lands and sacred sites continue to call communities and nations to arm, from Judaism to Hinduism, and from Ulster to Amritsar. Equally, faith and fear in the shadow of the Millennium remain a source of violence and violation, from Jonestown to Waco, from Aum Shinrikyo to the Manson murders, and from the Solar Temple and Cargo Cults through to Heaven's Gate. In the midst of this, 'established' religions continue to war in regions such as the Balkans, at great human cost. The history of power and mobilization in religion is, all too often, a litany of tragic events, a requiem for the human race.

Yet to see religion like this is only to view it from the dark side. Religion remains a vital force in much of the world. Millions if not billions of the world's population have a 'religious impulse'; this involves a quest for meaning 'that goes beyond the restricted empirical existence of the here and now' (Haynes 1998). Religion inspires; it binds together, creating communities of affinity and affectivity. It offers revival, revolution, and surprise; and then again respect for the past, remembrance and ritual. Gandhi, Pope John Paul II, and Martin Luther King have been instrumental in turning back tides of nationalism, communism, and racism (even though they have all used a reconfigured form of nationalism and religion to achieve political and social ends). Religion can be an irresistible force that can move the apparently unmoveable. For many, religion remains a viable form of liberation; some hope in the midst of despair.

In spite of the attempts of some sociologists of religion to retain substantial elements of a secularisation thesis (e.g., Wilson, Bruce), religion stands, in many parts of the world, as a protest against and an alternative to 'secular' life. Will American Christian fundamentalists, Egyptian and Algerian Islamists, or

Hindu nationalists someday become nonreligious? It seems unlikely: religion retains its power, and its capacity to mobilize, evangelize, and scandalize.

Any discussion of power and mobilization in religion must take account of the following dynamics. First, religious groups and communities will perceive themselves as vessels or bodies that somehow hold, manifest, or reify divine power in a particular way, distinguishing themselves from 'society,' or perhaps their enemies, or other groups deemed to pose a threat or competition. Second, the structure of the group or community will most likely 'mirror' a proposed divine order; there will invariably be a conflation between the offices of leadership and the concepts of deity. Leaders of religious communities are supposed to resemble their gods. Many social communities attempt to correspond to a higher order that has theistic resonance. And yet, no democracy is immune from theocratic comparison; no theocracy can escape the process of routinization, as well as a degree of secularization. Third, there will be some sort of theology of power that will account for how divine power is to be reified and passed on: this is a key determinant in mobilization. Here, leadership, sacred texts, rituals, symbols, or stories play a vital part in moving believers from passivity to passion, and then to power. Every form of transcendence, no matter how 'other,' is received individually and communally, and worked out in social and political spheres. Fourth, the power that is witnessed to will be antisocial or suprasocial, requiring believers to be mobilized for change and social transformation whenever they perceive their own sense of divine order to be under threat, or require a new order to be imposed. It is against this background that an Islamic nationalist uprising, or Catholic and Evangelical picketing of abortion clinics, or the work of reconciliation and peace in South Africa and Northern Ireland, are to be ultimately understood.

Religion: Morality and Social Control

In most societies at most times religion has been the key institution devoted to answering three of the fundamental questions human beings have posed, namely, 'How and why were the universe, life and humankind created?,' 'What moral rules should we follow in order to lead good lives?,' and 'What becomes of us after we die?.' Most of the great world religions

have answered the three questions together as part of a single coherent narrative. With some religions a just and righteous God was said to have created the world and its inhabitants, communicated moral decrees to them by revelation, and would after their deaths sit in judgment on them and assign them to paradise or to hell according to whether or not they had obeyed these precepts. Other religions held that the sum of an individual's good and bad deeds in this and previous lives would determine the nature of a reincarnation after their death according to the law of karma (Davies 1999). Clearly, beliefs and institutions of such fundamental significance are of great importance for social control. As Professor A G N Flew (1987, p. 71), the distinguished philosopher of religion, has noted:

Can we not understand the hopes of the warriors of Allah who expect if they die in Holy Wars to go straight to the arms of the black-eyed houris in paradise? Can we not understand the fears of the slum mother kept from the contraceptive clinic by her priest's warning of penalties for those who die in mortal sin? Of course we can: they both expect—and what could be more intelligible than this?—that, if they do certain things, then they will in consequence enjoy or suffer in the future certain rewards or punishments.

The nature of the social control thus exercised varies greatly from one society to another, as does the degree to which emphasis is placed (a) on social conformity as part of the natural order of things, (b) on establishing, monitoring, and controlling the nature and content of an individual's conscience, or (c) on claiming to be able to affect or at least to predict a person's fate after death.

Sometimes these forms of social control have simply reinforced other forms of power available to the secular rulers of a society, as when these rulers have also been the key religious authorities or the two groups have been closely allied. Likewise, resistance to the ruler might well be reinforced by religious dissent (Martin 1978) but with the caveat that the degree of social control that the dissenting group, whether the seventeenth century English upholders of the Cromwellian Commonwealth, the Roman Catholic exorcisers of a moral monopoly in Ireland (Inglis 1998), or the Sikhs of the Punjab, exerts over its members may be exceptionally high.

Religion can, of course, be an independent source of power and social control, sometimes exercised over matters that are of little interest to the secular authorities. The medieval Roman Catholic Church's forbidding of marriages between cousins up to the sixth degree or the refusal of the Greek Orthodox Church to permit a person to marry a fourth time after the deaths of three spouses were forms of social control that were at times a nuisance to the rulers of the relevant societies, who were concerned mainly with forming dynastic alliances and producing male heirs. They were part of a set of independent social controls

Table 1
Trends over time in England and Wales

	Reforming Britain 1860–1905	Respectable Britain 1905–60	Permissive Britain 1960–2000
Religious adherence and membership	Rising	Falling slowly and unevenly	Falling rapidly
Crimes of violence and dishonesty	Falling	Rising slowly and unevenly	Rising rapidly
Illegitimacy	Falling	Steady at a low level except in wartime	Rising rapidly
Drug and alcohol abuse	Falling unevenly	Falling to a low level	Rising

exercised through these churches' monopoly over the creation and dissolution of marriages, and hence over sexuality, reproduction, legitimacy, and inheritance, i.e., over crucial aspects of not only personal but also material and political life.

This form of social control may be seen as what Polanyi (1951) has termed deliberate or corporate order comparable to, say, a centrally planned economy, statute law, or the internal workings of a private bureaucracy. In each case there are, of course, divisions of interest, contested areas of authority, and competition between individuals and sectors using the exploitation and interpretation of rules to enhance power, but in principle there is a hierarchical system that may not be contested beyond a certain point. Rome has spoken, the matter is closed and the Brahmins alone can determine a caste's pedigree and thus influence its position in a hierarchy of purity of which they are the apex (Dumont 1970). Yet in all cases in traditional societies, most social control would have been local. Violence, theft, or sex with other men's wives would be kept in check by local opinion in one's village, *mir*, *mura*, *jati*, or kinship group rather than the direct use of priestly authority, the threat of divine wrath, or the dread of hellfire or of reincarnation as a scavenging dog. A mixture of respect for and fear of local chiefs, landowners, or state officials will also have played a part. Religion was just one part, though an important part, of local social control. Beneath the designed order lay a myriad local communities held together by an alternative form of order, the interactive order of face-to-face communities, the essence of *Gemeinschaft*.

Polanyi (1951) contrasts deliberate or planned order with spontaneous order which can be observed wherever stable arrangements evolve as a result of a large number of independent but interconnected decisions, as with the operation of markets through the price mechanism, systems of common law based on cumu-

lative precedence, or scientific progress through conjecture, experiment, refutation, and provisional confirmation. No one directs or designs these large, widely dispersed, flexible, and responsive instances of spontaneous order, yet they are much superior in their efficacy to most attempts to create a centrally controlled designed order. Their equivalent in religious terms and one with a crucial importance for social control may be seen in the flourishing of Protestant sects and denominations, and even of factions within the established churches in Britain during the nineteenth century, as the world's first urban, commercial, and industrial society was established and consolidated. This religious spontaneous order enabled Britain to shift from being a society of small, rural villages and towns based on local social controls to one of large, modern, urban conurbations while experiencing not crime and chaos but steadily declining rates of crime (Gattrell and Hadden 1980), illegitimacy (Hartley 1975), and drink and drug excesses (Wilson 1940). Britain was a more crime free and less deviant society in 1900 than it is today and than it had been 50 years before (Davies 1994).

Over time the pattern of crime and deviance in Britain follows a U-curve, falling markedly in the later half of the nineteenth century (Gattrell and Hadden 1980), reasonably stable in the first half of the twentieth, and rising very rapidly from the mid-1950s (Davies 1994). These changes are inversely shadowed by the growth and decline in church adherence in England and Wales, which grew rapidly in relation to population in the latter half of the nineteenth century and peaked in about 1904–5 (Brown 1992). There then followed an irregular decline with occasional periods of recovery until the late 1950s, after which there has been a steep and unreversed decline. There was a J-curve in piety which was an exact inverse of the U-curve in crime and deviance. No other variable fits this pattern with any such degree of exactitude. It is very

Table 2
Sunday School Enrollment

Year	Percentage of population aged less than 15 years enrolled in Sunday Schools
1818	12
1851	38
1891	52
1901	53
1911	51
1931	46
1961	20
1989	14

strong proof indeed of the effectiveness of spontaneous religious order as a means of social control. The relationship is summed up in Table 1 (Davies 1994, Hartley 1975, Lynn and Hampson 1977) showing the main trends between 1860 and 2000, trends that divide the period clearly into three phases 'Reforming Britain,' 'Respectable Britain,' and 'Permissive Britain' (Davies 1975).

Religious adherence and membership, although at all times involving a minority of the adult population, were a good index of the strength of the values of respectability, and thus of spontaneous self- and social control in British society. The incidence of deviant behavior clearly fell and then rose in Britain as this form of social control rooted in religion first became stronger and then later went into decline. The churches and chapels were the crucial institution promoting respectability in the nineteenth and early twentieth centuries, and membership and attendance were one way in which respectability could be acquired and proclaimed. Rising levels of membership and attendance gave those who were committed to their religion the confidence to promote and foster the virtues of self-control and respectability among the non-attending majority whose attachment to a church or denomination was at best nominal. To a substantial extent, though, they were receptive to the morality of respectability, and in particular they wanted it instilled in their children. The rise and the later fall of Sunday School enrollment and attendance shown in Table 2 (Gill 1992, Laqueur 1976, Martin 1967, Wilkinson 1978) is perhaps an even better measure of the changing importance over time of religion as a means of social control. It has been suggested reliably that between two-thirds and three-quarters of those enrolled were generally present in school on a Sunday (Gill 1992, p. 96).

The importance of popular Protestantism as a source of spontaneous social control and moral order in Britain during a time of massive internal migration to the new industrial and commercial towns and conurbations (Munson 1991) can be seen at work today in contemporary Latin America, a continent

currently undergoing a similar transformation (Martin 1990). Migrants leaving small, agricultural communities to work in the industrial and services sectors in societies as diverse as Chile and Guatemala have, like their British predecessors, sought to create for themselves through religion a spontaneous moral order, a social control based on respectability (Martin 1998, Martin 1990).

Protestantism has 'once again created a critical mass of persons for whom self-discipline, a work ethic and the values of domestic rectitude have become second nature' (Martin 1998, p. 28. See also Weber 1930). The truth has set them free from what otherwise would have been a morally degrading existence. Whether they will be able to sustain these virtues in the long run remains to be seen.

The importance of religion as an autonomous and potent means of social control has often been neglected by sociologists and political scientists, who are blinkered by their own obsession with economic and political power, and unable to appreciate the importance of religion. When they do turn their attention to religion as a means of social control, it is by choosing selectively examples such as the Inquisition, the Ayatollah Khomeini's regime in Iran, or human sacrifice by the Aztecs, which enable them to caricature religion-based social control as backward, oppressive, and irrational. On the contrary, social control rooted in religion is as varied as any other form of social control, and the distinctive spontaneous forms of social control that religion has provided in some countries during the difficult transition from a traditional to an urban and industrial society have been remarkable for their peaceable nature and civilizing influence.

Religion: Nationalism and Identity

Nationalism and religion share the ambiguous status of being the most potent and inspiring sources of collective identity, but also the most destructive forces for mobilizing large numbers of people and generating social conflict and change. The conventional view of their relationship is conflictual and evolutionary: the nation is opposed to the religious community, as nationalism is to religion, and national identities must, and will, in time supersede obsolete religious allegiances.

For ‘modernists’ like Ernest Gellner, Tom Nairn and John Breuilly, nationalism is a purely modern, secular ideology; it appears only when the age of tradition and religion gives way to that of modernity

and the nation-state. This was very much the view of Elie Kedourie, for whom nationalism was a doctrine invented in Europe at the beginning of the nineteenth century. As a secular ideology of collective Will and as a fruitless quest for unattainable perfection on earth, nationalism embodies a godless, antinomian chiliasm which ultimately can be traced back to medieval Christian millennial doctrines. Its effect is to subvert duly constituted authority and destroy the normal barriers between the public and private domains in the interests of a pure, acosmic brotherly love—in Africa and Asia, as well as in its European seedbeds. With equal regret and ire, but from the other end of the ideological spectrum, Marxists like Eric Hobsbawm can only see in nationalism, particularly of the ‘divisive’ post-1870 ethnolinguistic variety, a new set of ‘invented traditions’ in the hands of ruling capitalist elites and a despairing popular reaction, like fundamentalist religion, to the massive forces of social change and the failure to realize the project of socialist internationalism. Nationalism, in short, like religion, is increasingly a diversion and obstruction to the great globalizing ‘movement of history.’

This view has not gone unchallenged. Impressed by the evidence of ‘religious nationalisms’ in Asia, Africa, the Americas, and Europe, scholars like Mark Juergensmeyer have argued that ‘nationalism’ and ‘religion’ are often natural allies, and that religious movements like Shi’ism are seeking to reclaim the nation from the embrace of the secular state. For others such as Conor Cruise O’Brien, this affinity of religion and nationalism, or ‘holy nationalism,’ can be traced back to the Old Testament. It is also possible to argue that such well-known cases of secular nationalism as Jacobin France, Kemalist Turkey, Stalinist Russia, and Maoist China did not attack religion as such, and were in any cases transient phases of revolutionary politics which always sees the return of a society’s ‘central values.’ From the standpoint of collective identity, religion and nationalism can often be mutually reinforcing, and hence classic ‘weapons of the bourgeoisie,’ in Leninist parlance.

A third view sees in nationalism a species of religion in its own right, competing with traditional world or local religions for mass allegiance. Already in the 1960s, functionalists like David Apter had shown how nationalism performed the functions of a mass-mobilizing ‘political religion,’ a characterization recently developed by George Mosse in his penetrating studies of the liturgies of the civic religion of European, mainly German, nationalisms, and by Bruce Kapferer who, in an illuminating comparative study of Sri Lankan and Australian ideological politics, has demonstrated the ways in which a nationalist religion copes with problems of ontological insecurity and ethnic conflict. Benedict Anderson, too, though he fails to develop the point, sees nationalism more closely aligned to religion than political ideology, and the imagined community of the nation as emerging

out of, and against, the earlier world religious communities.

Each of these views has much to commend it, and can point to considerable supporting evidence. Equally, it is not difficult to find counterexamples. For every 'secular' nationalism drawing on ancient classical or pagan motifs and myths such as the Finnish Kalevala or the Homeric Iliad, we can find equally fervent religious nationalisms inspired by their respective religious ideals and appropriating their ethno-religious heritages, as the modern Hindu Indian movement has drawn on the Ramayana and Mexican nationalism on the cult of the Virgin of Gaudeloupe. The influence of traditional religions may prove equally ambivalent. If Buddhism underpins and is reinforced by Burman and Sinhalese national identities, the conflict between Protestant and Catholic Christianities only served to undermine the growing sense of German or Swiss national identities. As for Islam, it can buttress an all-Arab nationalism, but can equally undermine the Arab circle of allegiance in favor of the wider Muslim umma, or, in the hands of radical populist regimes like the Ba'ath Party, support the narrower circle of the Syrian or Iraqi nation-state.

This suggests that there can be no simple characterization of the relationship between the two modes of culture, identity, and belief. We have only to recall the contradictions that bedeviled the French revolution, often regarded as the first full-blown case of secular nationalism. From the very first oath sworn by the deputies on the tennis court in June 1789 to the last Jacobin journée, the *Fête de l'Être Suprême* in June 1794, classically-inspired secular and Christian religious motifs and rituals were combined, inspiring in the multitudes a powerful emotional blend of patriotic, fraternal political activism. Thus, as Simon Schama points out, at the *Fête de la Fédération* held on the Champs de Mars on July 14, 1790, Lafayette administered the oath to country and king and Talleyrand provided the mass and benediction, intoning: 'Sing and weep tears of joy, for on this day France has been made anew'; while over at Notre Dame, they performed a half sacred, half profane cantata entitled *Prise de la Bastille*, set to passages from the apocryphal, patriotic Book of Judith.

Similar religious motifs pervaded other nationalist celebrations; for example, the patriotic German festivals of the Wartburg in 1817 and at Hambach in 1834, described by Mosse, as well as the six-hundredth anniversary of the Swiss Confederation and the Oath of the Rütli, held in Schwyz and on the Rütli meadow in 1891. In the twentieth century, nationalist celebrations continued to employ religious imagery, most notably in the cult of 'fallen soldiers' and patriotic sacrifice, whether in the two world wars or the many more regional wars fought in the name of the nation, or the nation-to-be.

These considerations point to a more complex

interplay and layering of religious and national identities and experience. Much of the confusion surrounding this problem stems from divergent definitions of both 'religion' and 'nationalism.' The evolutionary modernist 'secular replacement' perspective employs a traditional definition of 'religion' in which our everyday world is believed to be controlled by a supraempirical order (and/or beings) which is the source of salvation—a theocentric and cosmic belief-system; while its definition of nationalism as the aspiration of a people and culture to be autonomous and united in its homeland emphasizes its secular, linear, and anthropocentric character. It is easy to see how, on this schema, nationalism and religion become opposed: the nation replaces the deity, the nationalist movement the church, and posterity the after-life. For the alternative view which sees nationalism and religion as 'natural allies,' or even conflated as 'holy nationalisms,' nationalisms can take as many forms as there are peoples and nations; similarly with religions. So nationalism and religion are really continuous and mutually reinforcing, or superimposed; nationalisms are expressions of belief, or 'faith-communities,' just as churches or religious communities are really 'nations.' As John Armstrong suggests, religious communities easily slide into ethnic groups, and vice versa. But this is, once again, to muddy the waters, and preclude the possibility of a more discriminating analysis. After all, are all nationalisms equally 'holy'? Does religion always reinforce national identities? Isn't the 'faith' of nationalists quite different to that of a traditional believer in a local or world religion? That, at least, is how it has often appeared to many participants who faced difficult choices about the claims of God and state, religion and nation, particularly where the religion was transterritorial, even universal in its claims. Hence also the vital differences between secularizing nationalisms like the republicans in France or the Westernizers in Tsarist Russia, and the religio-monarchical nationalists in France and the religious narodniks in Russia.

This is where the third, or 'political religion,' perspective may help. We do not have to subscribe to its belief in the substitution of 'religion' by 'nationalism,' but we can with profit employ its wider, Durkheimian approach to religion—as a system of beliefs and practices relative to sacred things—to understand how and why modern nationalisms, defined as ideological movements for the attainment and maintenance of autonomy, unity, and identity for populations deemed to constitute 'nations,' can fulfill many of the identity-creating functions of traditional religions. This makes nationalism both a competitor to, and an ally of, traditional religions, depending on historical and social circumstances.

In practice, this tension and symbiosis between 'religion,' so defined, and 'nationalism,' produces a series of familiar mass phenomena. These include:

(a) The politicization of religion, in which tra-

ditional religious motifs are transmuted into secular nationalist features. Thus prophets, saints, and religious lawgivers like Moses, Muhammad, and Confucius are metamorphosed into national heroes, religious revelations are turned into national shrines such as Yasna Gora and Guadeloupe, scriptures like the Bible and Bhagavad-Gita are re-read as national epics, and miracles like the eight-day lamp of Chanukah become national feats of the Maccabees. Even commemorations like the death of Hussein at Karbala, or the Exodus across the Red Sea, are re-enacted as nationalist festivals in Iran and Israel.

(b) The messianization of politics, whereby the nation-state is sanctified and exalted, and its leaders are endowed with religious charisma. This was how their followers came to regard nationalist leaders like Nkrumah, Nasser, Herzl, and Soekarno, investing them with superhuman qualities as messianic deliverers and saviors. But the messianization of politics and the sanctification of the nation-state does not stop with the leaders; it includes the sacralization of ethnohistory, such as the Gaelic history of Ireland, the Christian mission of Poland, and the Hinduization of ancient India; the belief in millennial destiny such as we find in the United States or communist Russia; and the 'invention of traditions' such as the rites and ceremonies of Bastille Day, Independence Day, the Rutli Oath, and Armistice Day at the British Cenotaph.

(c) Religious populism, or the exaltation, even deification, of the 'people,' the ordinary people, as opposed to the elites. This may include the quest for purification of the people and their culture, in the tradition of Herder's cultural populism, sought by so many Central and East European nationalists, or by Indian, Arab, and West African nationalists like Edward Blyden; the return to 'authentic' folk traditions and their elevation to national status, as with the Finnish regard for the Kalevala and the Estonian for the Kalevipoeg, the Gaelic revival in Ireland, and the Mexican and Peruvian return to pre-Columbian Indian culture; and the glorification of the simple or, common people,' a political tradition that can be traced back to St. Joan, through the narodniks and Mussourgsky's depiction of the Simpleton-Prophet in Boris Godunov and Levin's discovery of truth among the peasants in Tolstoy's *Anna Karenina*, to Peronism, Poujadism, and the modern Russian nationalists.

Each of these mass phenomena mixes sacred and secular elements, or more accurately, sanctifies the worldly in unexpected, yet, given the background, quite logical ways. On this reading, nationalism is, as Kedourie affirmed, a secular, this-worldly, ideological movement, with clear terrestrial and anthropocentric goals. It does not seek a world beyond this earth, nor does it posit an unseen world guiding and making sense of the world of our senses. At the same time, nationalisms draw, in varying degrees, on the religious background and tradition of the populations whom

they deem to constitute nations. This is not, or not usually, a case of manipulation of 'atavistic mass emotion,' as Kedourie claims, nor of a need to control and channel the unleashed energies of the newly mobilized and enfranchised masses, as Hobsbawm argues. It is quite simply that most nationalists are steeped in the religious traditions of their forbears, even where they have rejected them, and that to make sense of their new political message, they have no alternative but to couch it in language and images that are familiar and comforting to their audience. Rarely do nationalists seek to destroy an old, religious identity, in order to build up a totally new national one, although they may attack the guardians of religious tradition who refuse to reinterpret the tenets of the faith in a 'politically relevant,' i.e., nationalist, manner. Hence, of any nationalism we must ask, not whether it is 'religious' or 'secular,' but how and to what extent it mingles sacred and worldly elements, and with what consequences. Similarly, we should enquire not whether the nation in question is seen as an 'ethnic' or 'civic' unit, and a religious or secular community, but how and to what degree its national identity is infused with sacred motifs and religious images, and with what kind of effects.

It may be useful to grasp the complexity of this relationship by distinguishing three 'levels of analysis.' The first is phenomenal: it describes and analyzes the kind of nationalism that is in the public domain, the official version proposed by the elites. Thus, we may use a shorthand to describe French nationalism during the Revolution, or Turkish nationalism under Ataturk, as avowedly 'secular,' even irreligious. And we may range official nationalisms and their political symbolism along a continuum of religious to secular poles. Here, of course, we are using the traditional definition of 'religion' as a faith that looks beyond this world for salvation.

A second level of analysis seeks to determine the content of unofficial and more popular kinds of nationalism and national identity. Here we can expect to find considerable variations in the extent and kind of religious motifs and sacred imagery and symbolism in different national identities and nationalisms, and in different religious traditions. On the one hand, are cases where classical, secular myths and imagery predominate; this was the case in France and the United States during and after their Revolutions, and in Italy from the Risorgimento to fascism. On the other hand, we find examples where religious images and motifs pervade the sense of national identity; this was the case among the Greek peasantry in 1821, the Russian peasantry under Tsarism, or the Ethiopian peasantry under the Emperors, as it is in Pakistan and Sri Lanka to this day. In all these cases, the respective traditional religions had played a large part in molding the sense of ethnic identity prior to the modern epoch; and each of these traditional world religions contained a large repertoire of sacred elements—scriptures,

liturgies, symbols, rituals, scripts, ceremonies, and the like. Some religions, indeed, like Christianity and Judaism, as Adrian Hastings argues, have provided particularly fertile terrain for the reproduction and proliferation of vernacular nations based on the Biblical prototype of the ancient Jews in their land.

Moreover, even in more advanced industrial societies, sacred imagery and religious symbolism may persist and underpin a sense of national identity, even where the majority of the population are, by conventional measurements, no longer practicing believers. In the United States, for example, for all its official civic secularism, large numbers of citizens espouse religious forms, images and rituals of the American nation, and continue to envisage its destiny in providential terms. The same is true, though in quite different ways, in France and Israel, despite the avowed secularism of the majority of their populations; the historic rationale and destiny of the nation remains part of the sacred realm, and the various religious symbols, images and motifs have done their work of forging the *raison d'être* of the French and Israeli nations.

This brings us to the third level of analysis. It requires us to adopt a wider, Durkheimian approach to and definition of religion, and a different perspective on the significance of the nation. On this general level, the nation can be considered as a 'sacred communion' that unites the dead, the living, and the yet unborn. This is not just a matter of imagination, as Benedict Anderson claims; it is even more a matter of will and feeling. The nation is, in the first place, a willed and a felt community, a moral community of collective purpose whose members are bound by powerful sentiments arising from a sense of presumptive ancestral affinity. (Presumptive, because myths of origin rarely correspond to the historical record of origins, let alone actual biological descent.)

This points to the dual origin of the nation: on the one hand, as a community based on presumed ethnic origins and descent, tracing their genealogy back to a specific place, time, and ancestor; and on the other hand, as a union of all those espousing common moral purposes and assumptions, a community of destiny who trace their ideological and moral lineage to the sacred properties of beliefs and practices of a community of the faithful. The fusion of these two kinds of community over the *longue durée* creates the basis for the modern nation.

What are the sacred properties of the beliefs and practices of the faithful? And how are they transformed into the national 'religion of the people'? Four kinds of sacred property form the main 'pillars' of the nation: belief in the chosen people; attachments to a sacred territory; memories of the golden age; and rituals of commemoration of the glorious dead.

(a) By the concept of the chosen people, I mean not simply any community that exalts itself and carries ethnocentric sentiments of superiority and exclus-

iveness, such as we find throughout history. The meaning here is more specific. On the one hand, there is a broader sense in which elites of nations feel that they are entrusted with a sacred mission by the deity—to convert the heathen, protect the church, or defeat the infidel. By this divine trust and mission, they are sanctified and, by extension, their people become the elect; they derive their rationale as a community from this trust; and they feel exalted by the sense of their divine calling and the success of their leaders. It is not always clear what the effects of failure are, or indeed what constitutes failure; one has the sense that this kind of chosenness is flexible and capable of considerable reinterpretation.

So indeed is the second, more precise 'covenantal' meaning. Here chosenness is conditional and popular. The whole community is chosen by the deity for a specific purpose, but only for so long as it fulfills its task and mission. Failure to do so leads to the loss of its status as the elect. This is the essence of the 'covenant.' Its purpose is to sanctify the community and to separate its members from their profane surroundings. In the Old Testament model, the Israelites were set apart in order that they might fulfill God's commandments and hasten his universal salvation. They were to become a 'holy people' and a 'nation of priests.' In their footsteps followed Armenians and Orthodox Greeks, Amharic Ethiopians and Orthodox Russians, Afrikaners and Ulster-Scots, and many others in the monotheistic traditions.

The sense of ethnic election has been widespread in all ages and continents, particularly in the looser, missionary form. Its origins are obscure, and it takes many forms, from the conquering zeal of Muslim Arab nomads and Catalan or Hungarian knights to the Celtic-Christian monasticism of the Catholic Irish and the pioneering providential faith of Protestant settlers in America. In each case, chosenness crystallizes the emergent sense of community and confirms its sense of special destiny. As much as any rule of endogamy, it helps to keep the community intact and guard its borders. And, more than any birth rate or territory or conquest, it ensures the long-term survival and persistence of the ethnic community that espouses it. This is especially true of the stricter, more popular, covenantal forms of ethnic election.

The sense of chosenness has carried into the modern world, albeit often in more secular versions. De Gaulle's vision of France's cultural and political mission, the Great Society proclaimed by Johnson for the United States, even the 'New Britain' of Blair and New Labour, echo the missionary kind of election myth. Communist ideals, pared down to 'socialism in one country,' embodied the old myths more shrilly, as did various radical nationalisms in Asia and Africa, from the Meiji reformers in Japan to U Nu's Burma and Nkrumah's African Christianity in Ghana, drawing as they did on Islamic, Hindu, Buddhist, or Christian imagery, but ultimately attempting to fuse

the genealogy of ethnic community with the sacred properties of a moral union, into the sacred communion of the nation.

(b) The origins of ideas of sacred territory are equally obscure, but we may attempt a sociological reconstruction. Territory has been valued not only for security and, of course, as 'hearth and home,' but also as the arena in which the members of a community live, work, and die. And are buried. Reverence for, and protection of, the last resting places of our forefathers and foremothers is one of the main ways in which stretches of territory are invested with special feelings and meaning.

Allied to this is the special collective reverence felt for the tombs and the sites of miracles and exploits of holy men, sages and heroes or heroines. Pilgrimages to shrines like Yasna Gora, Jerusalem, Qom, or Mecca endow these locations with reiterated, and so more lasting, veneration and awe. By extension, any site where heroes or saints displayed the qualities and values central to the traditions of the community is invested with significance and helps to bind the community to its sacred land.

Once again, we are dealing with the confluence of two processes. On the one hand, the sacralization of territory, sketched above; on the other hand, the territorialization of memory. The latter implies two subprocesses: on the one hand, the naturalization of history, turning the community's history into an integral part of its environment and treating it as 'natural,' part of the landscape which it inhabits; on the other hand, the historicization of nature, transforming the community's habitat and landscape into an essential component of its historical development. The effect of these two subprocesses is to bind together community and land into what we may term an 'ethnoscape'—in which the *ethnie* (ethnic community) belongs to, and is an intrinsic part of its landscape, and the landscape belongs to, and becomes an integral part of, its community.

Once ethnoscaping develop, binding together *ethnies* and their poetic landscapes, it is a short step to attaching special sacred qualities to the land. The land is not only 'ours,' it is sanctified as the place of 'our' providential history and the chosen arena for the unfolding of the divine plan through the exploits of His, and our, saints, warriors, and sages. That, of course, is how the Old Testament concept transformed the 'promised' into the 'holy' land of Israel, and how the Swiss shepherds and herdsmen began to interpret the reasons for their remarkable victories over superior Habsburg oppressors, as if the purity of their Alpine mountain fastnesses reflected their simple virtues and steadfast faith in God. Today, ethnoscaping and sanctified nature have often become flashpoints of bitter conflict—in Ulster, Kosovo, the West Bank (Judea and Samaria), Amritsar, and Tamilnad.

(c) The concept of a golden age can only be grasped in the context of the broader 'ethno-history' of the

community. This is the set of traditional, often sacred, histories recounted by the members of the ethnic community, as opposed to the more dispassionate attempts by professional historians to reconstruct the history of the community. The line between ethno-history and ethnic mythology is often blurred, if we interpret 'myth' not as fiction, but simply as a widely-believed tale told about the heroic or sacred past to serve present needs and goals. This is particularly true of those periods and episodes which later generations of the community have come to remember as high or canonical epochs in the unfolding story of the community. These we may call the 'golden ages,' because the memory of these periods is invested with a specific nostalgia and reverence, because they come to serve as models or guides to future action.

There are various kinds of golden age—religious, political, economic, military, artistic—and there may be several in the shared memories of those ethno-histories that are rich in events and relics and are amply documented. Modern Greeks, for example, can look back to the golden age of Athens or to that of imperial Byzantium, Indians to the epoch of the classical post-Vedic states or of the Maurya or Gupta empires, and the English to the kingdom of Alfred and the Anglo-Saxons or to the Elisabethan age. Each of the ages forms part of a wider ethnohistory and its memory can act as the point of reference for a salvation drama of the nation. In such cases, the epoch in question becomes a model, an exemplification of 'our true nature' and a repository of 'our virtues,' spurring the community to emulation. Shared memories of golden ages create a sense of the extraordinary, exalt the community, and confer on their members a sense of collective dignity and the promise of national regeneration.

(d) Among the shrines of the sacred territory, the Tombs of Unknown Soldiers and the monuments to the fallen soldiers and individual warrior-heroes occupy a special place. These are the memorials to the glorious dead. In all ages, from the fallen at Thermopylae or Avarayr to the mass war graves of the two World Wars, the exploits and self-sacrifice of fallen patriot-soldiers and heroes have always evoked a special sombre reverence, and elicited a special determination not to forget their heroism and live up to their example.

In the modern age, the commemoration of the glorious dead has become central to the celebration of the nation. In this respect, the French Revolution with its cult of martyrs like Le Peletier, Bara, and Marat and its commemoration of famous patriots in the Pantheon, *Aux Grands Hommes*, *La Patrie Reconnaissante*, set the tone; while Napoleon's Arc de Triomphe collectivised the memory of the triumphant heroism of La Grande Armée. As George Mosse has documented so vividly, this idea became central to the emergent German nation, with its memorials to ancient heroes like Arminius and to modern heroes

like the Völkerschlachtendenkmal commemorating the fallen at the battle of Leipzig in 1813. In Britain, Lutyens' Cenotaph in Whitehall embodied the grief and pride of the nation; the annual Armistice Day ceremonies there and across the land, to the strains of Elgar and Chopin and the reveille bugle calls, evoke the terrible sacrifices in two World Wars and the collective resolve of the British in an atmosphere of sombre reverence.

There are few modern nations that do not have their memorials to the glorious dead, their ceremonies of commemoration, and their shrines, icons, and symbols of martyrdom and heroism. In this respect, as in the other sacred 'pillars,' nations and their artistic representations have taken over so much of the symbolism and emotion of earlier religious traditions, and infused their this-worldly beliefs in posterity and the judgement of history with earlier sacred longings for collective immortality.

In these ways, nations and their nationalisms have emerged on a religious foundation and are infused with many of their sacred motifs and properties—'religion' being understood here in its wider Durkheimian sense as a collective bond of obligation in respect of sacred things, continually rehearsed in ceremonies and rituals. At the same time, individual historical expressions of a nation's identity may cleave closer to this religious base, or depart from it to embrace a more secular ideal and formulation. However, even in these latter cases, the nation continues to draw upon some of the sacred properties of earlier beliefs and practices and so remains fundamentally a form of sacred communion, uniting its members in a moral and ideological community of intimate belonging and collective moral destiny.

Religion: Peace, War, and Violence

The relation of religion to peace, war, and violence (or nonviolence) is bound up in the various visions of right relationships and harmony within human beings and between collectivites, including nation-states and ultimately global society. Within Eastern traditions, for example, a Buddhist espousal of nonattachment and rejection of anger implies a peaceable attitude, and a Confucian or Taoist espousal of harmony implies reluctance to engage in depredation and offensive war. Within Hinduism a major strain, at least as interpreted by Gandhians, recommends a nonviolent approach and the kind of exemplary spiritual suasion embodied in *satyagraha*.

In all the Abrahamic traditions there is a positive evaluation of peace, so that 'Peace be with you' and 'Grant us thy peace' are written into the most sacred parts of the Christian liturgy, while *shalom* and *salaam* are peaceable greetings in Judaism and Islam respectively. The Hebrew Scriptures themselves are contradictory. There is a tradition of the trickster deploying deception, such as befits ethnic underdogs, and an ideology of legitimate subjugation. At the same time there is a moral reserve about the taking of blood and a positive evaluation of Israel's helplessness (and

dependence on God). This mutates into Isaiah's vision of universal peace and of the righteous rule of God so central to the teaching of Jesus.

In the teaching of Jesus there is a radical reversal of values which includes a rejection of the negative reciprocity embodied in 'an eye for an eye' and the feud. The Kingdom of God inaugurates a peaceful world empire of love in a harmonious universal city, New Jerusalem, which has its foundation in the self-offering of the Savior as he confronts the powers of violence and injustice. Versions of this approach characterize Christianity in the earliest centuries, resulting in conscientious objection to military action, reinforced by refusal to take an idolatrous oath and expectation of a divine foreclosure of human history.

1. Christianity and War After Constantine

However, with Constantine's embrace of Christianity as guarantee of victory, the 'City of God' has to be firmly distinguished from the 'City of Man,' though many Christians came to see the empire as the divinely ordained vehicle of the Christian religion and its triumph. Christianity was now the faith of the majority, including the power holders and senators, not the hope of a minority mostly without access to power. It was implicated in the dynamics of power, even though monks and small groups maintained a devotion to peaceable ideals. Among these small groups were evangelical sects like the Waldensians and dualistic heretics like the Cathars. The church itself iconographically still embodied its original tension with 'the world' of power and violence, set over against icons which celebrate the proximity of the powers that be to the mandates of the Almighty. The church also attempted to adjudicate disputes, and even restrict weaponry, more particularly in the feudal period. It sought to enforce a 'truce of God,' in part to further its own geopolitical ends in confronting the Holy Roman Emperor and reversing the advance of Islam.

The movements of the late Middle Ages, eventually erupting in the Reformation, disseminated the Christian repertoire of themes beyond effective ecclesiastical supervision. There were intimations of collective peaceability in the Lutheran and Calvinist reformations, though these were rapidly checked by the fusion of reformed faith with the autonomy of monarchs and with national sovereignty. There were similar intimations of peace within the natural law traditions of Catholicism. However, the espousal of peace was inevitably a minority option, for example, among Christian humanists such as the Swiss Conrad Grebel, and the anarchopacifist wing of the Radical Reformation, for example, among Anabaptists and Quakers. These minorities came to represent a sectarian encapsulation of Christian radicalism over a wide range

of issues, including corporal and capital punishment, which leaked into the wider society over the next two or three centuries. It was, for example, chiefly among such groups that supporters emerged for the nascent peace societies of the UK and the USA in the early nineteenth century.

2. Proposals for Universal Peace

Ideas of universal peace burgeoned from the fourteenth century on, partly on the model of an imperial Pax Romana, centered on this or that universal monarchy, but also based on projects for an international order. These latter picked up the Christian humanism of Erasmus in his *Complaint of Peace* (1517) and the notions of natural law articulated by Grotius in his *De jure belli ac pacis* (1625). One of the most complex of these projects was the Abbé Saint-Pierre's *Projet pour rendre la Paix perpetuelle* (1713). The last two great peace plans of this period were Kant's *Perpetual Peace* (1795) and Bentham's *Plan for a Universal and Perpetual Peace* (1789).

Here one needs to distinguish types of approach and indicate a partial secularization of the religious vision of peaceable social and international order. A notable secularization was embodied in Machiavelli's statement of Renaissance political realism in *The Prince*, while from rather different viewpoints, Kant fused rational with Christian motifs and Bentham appealed to criteria of human happiness. This mixture of contradictory religious and secular discourses developed into the liberal internationalism of the nineteenth century. According to this tradition, especially as developed in the USA and the UK, there was a potential harmony of interests through the reciprocities established by free trade.

A parallel fusion of religious and political discourses also occurred in the democratic socialist tradition, by contrast with the Marxist variant predominant on the European continent which consigned religion to a realm of fantastic hopes devoid of scientific understanding. For Marxist-inspired movements, as also for anarchosyndicalism, violence was a midwife of a new revolutionary order. Out of the currents of liberalism and socialism emerged hopes of universal human and/or working-class solidarity which were articulated in theories of the social sources of war and the structural alterations needed for peace. However, the wars of 1914–18 and 1939–45 suggested these hopes were chimerical and the theories at best flawed, though capitalism was still widely blamed for international disorder and imperialism.

Out of this iron period grew a new realism about the role of national interest in the genesis of war, which was articulated both in religious and in secular form. The major realist theologian was Reinhold Niebuhr in his *Moral Man and Immoral Society* (1934) and the major exponent of secular realism was the American

Hans Morgenthau. At the same time there also emerged fully fledged empirical enquiries into conflict, including 'peace research.'

3. *Forms of the Peace Sentiment*

Thus over the last two centuries or so the 'peace sentiment' has been part of overlapping causes of a humanitarian and internationalist kind, simultaneously fed by religious and enlightenment sources. There causes have conjoined the gospels to reason, commonsense, and the quest for human rights in a radical critique of war and militarism. The nineteenth century sociologist Herbert Spencer, for example, had roots both in rational and evangelical nonconformity, and identified the alliance of state, priest, and military as a major nexus of conflict. A leftward leaning liberalism attacked the nation state and established religion in the name of a pacific internationalism. This was often referred to as 'pacifism,' meaning it presumed the onus of proof was on the proposers of war and held that the interests of those who stood to gain, for example, the armaments manufacturers, ran contrary to the interests of the majority. Liberal internationalists were not strict 'pacifists' however, because there were times when one had to crusade for liberal principles and for liberation—including that other liberal principle, national liberation.

Other humane causes loosely associated with the peace sentiment were reforms of penal practice, above all corporal and capital punishment and a new attitude towards the animal world, which might include vegetarianism, with its objection to meat, machismo, and blood. To these causes might be conjoined a preference for wholesome food to nourish wholesome bodies and lifestyles. All of these had religious roots, even though one cause need not strictly imply another, so that cornflakes were an outcrop of Adventist teaching without requiring pacifism, whereas the Quaker production of chocolate was clearly linked to it by association. Humanitarians opposed all kinds of brutalization, including male violence in the home and the army. A feminization of the psyche occurred, bred in the Sunday School and in progressive education alongside movements for factory reform and the provision of life-enhancing leisure pursuits, preferably in the context of 'nature.'

The concept of individual conscience took off from religious prescriptions like personal conversion and witness and then mutated into a new sensitivity, including sensitivity towards the effects on other peoples of conquest, imperialism, and exploitation. Thus alongside the nationalistic fervor infiltrating and informing much mass religiosity there ran a counterpoint of moral and political conscientiousness. There were movements for democratic scrutiny of foreign policy and the sale of armaments, for the arbitration of international disputes, the enforcement of interna-

tional law, and eventually the League of Nations and the United Nations. Alongside these ran mostly nonviolent agitations for civil rights and/or national liberation such as those led by Ghandi, Martin Luther King, Nelson Mandela, and Archbishop Tutu.

Of course, given the schooling of populations in patriotic sentiment, dissenting attitudes and conscientiousness usually characterized only a minority in the churches and even more so among people at large. This was above all true in wartime, when dissent from all war or from the claimed objectives of a particular war, could be defined as cowardice or disobedience to lawful authority. Yet conscientious objection still made headway and, at least in the countries of the North Atlantic, Protestant world governments reluctantly accepted that national claims to loyalty were not absolute. This partial tolerance applied to the 'historic peace churches,' such as the Quakers and Mennonites, but also included sizeable groups within the larger Protestant denominations, and it just about extended to secular objections rooted in socialism or humanitarian ideals such as were promoted by Leo Tolstoy.

The social ecology of the 'peace sentiment' over the last quarter millennium is clear enough. It began in the transatlantic world through a combination of religious and rational liberal motifs—Manchester allied to Boston—above all among Protestants, and by degrees affected established churches and the Roman Catholic Church. Given that the Roman Catholic Church was rooted in more organic and communal forms of society, especially in Latin Europe, its defence of the rights of individual conscience was originally weaker. Yet its transnational character always included a sense of the law of nations as nourished by the traditional concept of a just war, such as due proportion of means to ends.

With the development of weapons of mass destruction most mainstream churches expressed reservations about the doctrine of deterrence as it related to the 'just war.' On the one hand there were religious groups allied to secular middle-class radicalism in campaigns against nuclear armament and colonial involvements such as Vietnam, and on the other hand there were specialist commissions into the contemporary nature of war and peacemaking. Thus the Church of England produced a report *The Church and the Bomb* (1982) and the Roman Catholic Church in the USA published an extended critique in 1983.

In summary one may say that there has always been a dialectic relation between the idea of an all-embracing empire (the Roman Pax, Chinese imperial civilization) and the vision of a transnational unity, such as the Islamic 'Ummah' or the Christian *Oekumene*. In times of religious establishment, whether imperial, monarchical, or national, the former will inevitably tend to colonize the latter, so that the wider vision is maintained underground in liturgy, iconography, and movements of protest. However, as

religious groups became separate from the state the visionary repertoire gains more purchase, and is increasingly reinforced by the interdependence of global society. The resources on which the search for peace may draw become increasingly international, so that the message of the gospels, of Isaiah, and Micah mingles with Eastern and especially Gandhian, notions of nonviolent protest and moral suasion. Indeed, as Western protest has drawn on Eastern resources, so have Eastern movements been cross-fertilized by Western ones, not only Christianity but the works of Tolstoy and Thoreau.

Religion, Phenomenology of

Phenomenology of religion is an academic approach to analyze religion predominantly within religious studies. It is documented in a series of monographs

and handbooks, but it is also defined by a 'scholarly method' that utilizes principles of phenomenological philosophy. For the purpose of this paper, we shall distinguish: (a) the descriptive phenomenology of religion which refers to the classification and systematization of religious phenomena and the creation of typologies which account for different types of religion; and (b) the analytical phenomenology of religion which, in addition to the goals of descriptive phenomenology, is based on some explicit understanding of the philosophical background and methods of phenomenology and hermeneutics developed in the tradition of Edmund Husserl, Wilhelm Dilthey, Martin Heidegger, and Paul Ricoeur.

1. Historical Development, Institutions, and Representatives

Whereas the notion of phenomenology had been proposed by philosophers also preoccupied with religion, such as J. H. Lambert (1721–71), I. Kant (1724–1804), and G. W. F. Hegel (1770–1831), the contemporary notion of phenomenology of religion refers to a specialized field within the academic study of religion. The origins of this field go back to the Belgian historian of religion P. D. Chantepie de La Saussaye (1848–1920). Referring to Hegel's work (which includes the *Phenomenology of Mind*), he divided the science of religion into the history of religion and the philosophy of religion. With respect to the latter, he wanted the phenomenology of religion to not only avoid dogmatics, but to systematically order the main groups of religious phenomena according to the feature of the historical material. The most decisive breakthrough in the field has been due to the work of the Dutch professor of religious history, Gerardus Van der Leeuw who, in 1924, suggested phenomenology of religion to be a special method for the history of religion. Since then, the phenomenology of religion has produced, on the one hand, a series of 'monumental' contributions which provide systematic overviews on a broad variety of religions, or, on the other hand, monographs on typically basic features of single religious phenomena. Therefore, topics of the studies include general issues, such as the distinction between the 'sacred,' and the 'profane,' the 'numinous' or the experience of power, and on the other hand comparative studies on more specific religious phenomena, such as prayer, piety, or religious ceremonies. In the 1950s, phenomenology of religion became increasingly established in the academic studies of the history of religions, so that it became institutionalized as a specialized branch within *Religionswissenschaft*, Comparative Religion or Religious Studies. Although one should not ignore Britain (James 1938) and France (the Rumanian scholar's Eliade's (1949) first important book has been published in French), the main centers of development have been The Netherlands,

Germany, Scandinavia, Italy, and North America (cf. Pettersson and Åkerberg 1981).

2. Approach and Method

Phenomenology of religion differs from theology as well as from other specialized disciplines preoccupied with religion (philosophy, sociology, psychology, etc.) by its history and its method. Historically, phenomenology of religion opposed positivist and evolutionist approaches to religion by integrating historical knowledge of the facts with phenomenological methods. Whereas the sociology of religion, which developed almost simultaneously, focused on the external, public aspects of religion, the phenomenology of religion turned towards the essential aspects and started systematically to classify religious phenomena.

2.1 Descriptive Phenomenology of Religion

Phenomenology of religion draws on the impressive amount of data collected by the history of religion, but also on data collected by sociology, anthropology or the psychology of religion. Therefore, it can be said to be empirical. The basic method of descriptive phenomenology is the comparison of religious phenomena. It assumes that religious phenomena are comparable across different cultures and religions, and that the comparison does not only yield generalizable features but allows us to grasp the general features of religion. In analyzing the empirical forms of historical religions, phenomenology of religion tries to abstract from specific religions, and to then develop ideal types of religious phenomena, such as 'sacrifice,' 'fetish' or 'mysticism,' 'prophecy,' 'priest,' or 'cult.' Therefore, it can be said to be systematical. In order to pursue this task, phenomenology is considered to provide the method for finding the common denominators covering the diversity of empirical data. Religious phenomena include manifestations of the sacred, such as sacred places, mountains, buildings, active realizations of the sacred, such as rituals, prayers, holy words, religious beliefs, such as revelation, redemption, transcendence, and experiences, such as vision, ecstasy, or miracles.

The data on these phenomena are not to be observed from an external point of view, as in most sciences of religion. On the contrary, phenomenology of religion is nonreductionistic in identifying the specifically religious features of religious data. This is the reason for turning to philosophical phenomenology that is expected to analyze the meaning of religion to the person. At the basis of phenomenology of religion lies the analysis of religious experience rather than religious ideas, the beliefs, or morals. The accentuation of the lived experience may be one of the most important contributions of phenomenology to the study of religion.

Basically, religion is the opposite of phenomena: religion posits what it believes to be as existant, whereas phenomenology brackets exactly this belief in order to investigate how it may be constituted by consciousness. Thinking of others, in religion (or parapsychology), gets close to telepathy (think of the dead), in phenomenology, the others are but constructions. Almost simultaneously, J. W. Hauer developed a phenomenology of religion mainly on the basis of data on illiterate cultures. Among the major contributors to phenomenology of religion one has to mention Allen, Bleeker, Bollnow, Hultkrantz, Kristensen, Lanszkowski, Pettazzoni, Wach, Waardenburg, Widengren, etc.

2.2 Phenomenological Methods

Whereas the descriptive and typological branch of the phenomenology of religion remains silent about the methods by which it arrives at results, the phenomenological branch is characterized by additional methodological considerations that are based in philosophical phenomenology.

From the perspective of phenomenological philosophy, experiences are the processes by which consciousness is constituted. As consciousness is always intentional, i.e., consciousness of something, experiences, too, are characterized by intentionality, i.e., the fact that they are related to something else. Also religious experience is experience of something. To give an example: as Chantepie de La Saussaye has already stressed, it is only the meaning of the act that allows us to distinguish between the sacrificial priest and the butcher.

In order to arrive at the meaning of religious experience, Husserl recommended to perform what he called '*epoché*': the bracketing or suspension of all our unexamined assumptions, preconceptions, and prejudices about the phenomena under consideration. In performing the *epoché*, analysts are expected to turn 'to the things themselves,' i.e., to the phenomena as they are experienced. That is to say that phenomena, such as visions, auditions, or miracles, are to be understood according to the ('religious') meanings they have about the experiencing consciousness and not according to, e.g., a neutral scientist's observations. As an additional method, religious phenomena, such as 'snake symbolism,' can be made subject to 'free variation': by mentally varying aspects of this symbol, one attempts to arrive at the essential features of the '*Wesensschau*.' On the basis of these methodological operations, descriptions of the phenomena are considered to yield typical structures, essential meanings or even the '*eidos*' of religious phenomenon.

Attempts to understand the essential meaning of religious phenomena, finally, presuppose hermeneutics, i.e., the method of understanding ('*Verstehen*')

the subjects of religious experience. According to Van der Leeuw (1948), understanding is achieved by empathy: the investigator tries almost to re-experience the religious phenomenon in order to describe these experiences. Understanding, moreover, includes reflecting the context of the interpreters, accounting for the interpretive framework, and explicating their pre-interpretations. To some representants of the phenomenology of religion, such as Eliade, hermeneutics has become a leading principle of their method that allows us to unveil the deeper structure of the experiences of mankind. On these grounds, religious studies have also been equated to a hermeneutic anthropology.

Basically, one can distinguish three related approaches: a descriptive school which is preoccupied with the systematization of religious phenomena; the typological school which tries to distinguish different types of religion, and the phenomenological school in the specific sense of the word that applies methods borrowed from philosophical phenomenology.

3. Criticism

From its beginnings there has been a series of critical objections against the phenomenology of religion.

(a) Especially the phenomenological approach of Eliade is the target of Wagner's (1986) criticism who objects that his concept of the *homo religiosus* is guided by a notion of 'natural religion.' He argues that it presupposes some unwarranted knowledge about the religious situation in what Eliade considers to be 'archaic cultures.'

(b) With respect to religion, phenomenology of religion takes a decidedly substantialist position (Luckmann 1983). Moreover, critics charge that this substantialism is based on nonempirical, extra-phenomenological, and theological assumptions and intentions enter into the analyses of such classic representants of phenomenology of religion such as Kristensen, Eliade, or Van der Leeuw.

(c) To many critiques, this is due to the fact that methods are rarely unveiled. Despite the reference to phenomenological methods, the basic presuppositions often seem arbitrary, and also theoretical reflections are criticized to fall short of the diligent collection and classification of data.

(d) Since phenomenology provides the basic methodology for phenomenology of religion, it is particularly consequential that phenomenology of religion lost contact with the developments in philosophical phenomenology from about the 1950s. As a result, phenomenology of religion rarely is considered of importance in the analysis of religion within the tradition of phenomenological philosophy (Guerrière 1990).

(e) The phenomenology of religion has been criticized for ignoring the social and cultural contexts of

religious phenomena. Moreover, as phenomenology in general has been criticized for its naive attitude towards language and cultural perspectivism, also the phenomenology of religion is subject to criticism as to the linguistic and cultural bias implicit in the analysis of 'phenomena' and 'symbols.' Thus, the results of free variations depend on the phenomenologists' cultural background (Allen 1987).

4. Recent Developments

As a reaction to these criticisms, there has developed what Waardenburg calls the new style of the phenomenology of religion (Waardenburg 1973–1974). According to Waardenburg, this new style of investigation shares a series of assumptions: (a) religious phenomena are characterised by a variety of meanings and intentionalities which are the result of different, often materially based perspectives on the world; (b) religions are coherent, but essentially open systems of signs and symbols, the elements of which are selected according to the corresponding relevance systems; (c) religious phenomena are considered to be human constructions which are subject to social processes (as, e.g., traditionalization, institutionalization, or canonization). At this point, the phenomenology of religion overlaps with positions which have been developed within those branches of the sociology of religion rooted in the phenomenology of Edmund Husserl and Alfred Schutz (Berger and Luckmann 1963). This 'phenomenologically orientated sociology' regards religious experiences as, first, based on the profane transcendences of everyday life, and second, subject to processes of the social construction of multiple realities. By focusing on the communicative processes by which this social construction is accomplished, this approach tries to bridge the gap between empirical research and methodological reflections on this research. Moreover, in admitting that linguistic and cultural background knowledge enters into the phenomenologist's background knowledge, several of the new approaches to the phenomenology of religion accept an orientation towards a 'reflexive phenomenology.'

Religion: Psychiatric Aspects

1. Terms

According to *Webster's New World Dictionary*, *psychiatry* is defined as 'the branch of medicine concerned with the study, treatment, and prevention of disorders

of the mind, including psychoses and neuroses, emotional maladjustments, etc.' (p. 1147). In contrast, *psychology* is defined as 'the science dealing with the mind and emotional processes' and 'the sum of the actions, traits, attitudes, thoughts, mental states, etc. of a person or group' (p. 1147). From these definitions, it is clear that the realms of both these fields have considerable overlap in the questions they address about human behavior, and in many cases, knowledge that is garnered in one field is frequently shared and absorbed into the ensuing theoretical development of the other discipline. Hence, for the purposes of this article, which addresses the theoretical underpinnings rather than the actual practices of each profession, the ideas from psychology and psychiatry will be used interchangeably, except where otherwise denoted as specific to their field.

2. The Question

The question about the need for relationship between psychiatry and religion has emerged as a predominantly twentieth-century concern. The movement to inter-relate the two disciplines evolved as participants who believed strongly in the importance of religion in people's lives were concerned by the lack of religious involvement in modern medicine's approach to healing. Many adherents to this movement to intertwine the two fields reject the dualism of body and soul, believing instead that mind and body are inter-related and true healing is best realized when a holistic bio-psycho-social-spiritual approach is utilized.

As such, in recent years a growing number of psychiatrists and other physicians, psychologists, clergy, theologians, and religious philosophers who have not been satisfied with mainstream traditional and institutionalized efforts at healing have sought to combine the best of modern psychiatric medicine with religion/spirituality to develop an alternate method of healing to relieve mental and emotional distress. These practitioners are joined by religiously committed persons who are seeking treatment. At the same time, a number of traditionalists, both psychiatrists and clergy, are critical of incorporating religion and psychiatry into a single treatment mode. They raise the question whether religion and psychiatry should both be considered in aiding individuals, advocating rather that the two remain separate in their approaches to problem solving and actual practice.

3. Defining the Problem

In his book *The Structure of Scientific Revolutions* (1970), Thomas Kuhn defines a paradigm as a nascent model for looking at the universe in a specific manner, and answering questions from within that particular framework's perspective. Furthermore, according to

Kuhn, for growth to occur in science and/or ideology, rather than working toward consensus between paradigms, the premise for philosophical development should be that growth comes from complementary coexistence between paradigms, as each domain converses with the other within its specific applications.

It is arguable that religion and science are two different paradigms for understanding the universe, and humanity's role within it. The difficult and sometimes troublesome relationship between these two fields emerges in part as a result of the two different paradigmatic approaches to answering the same basic questions about humankind. Such questions include, but are not limited to these: what are the fundamental components of human beings? What causes illness? What helps keep individuals healthy?

Furthermore, the more recent developments of specialized disciplines such as psychiatry and psychology in the nineteenth and twentieth centuries also raised alternate perspectives on answering the questions to humanity's interpersonal troubles—answers different from those raised in their antecedent jurisdictions of religion and philosophy (Rechberger 1998).

The question raised is: do these alternate paradigms have communal merit in helping individuals lead happier and healthier lives, or should the division between the two fields of mental health and religion remain distinctly separate?

4. History

Since the 1700s, the period known as the Enlightenment, religion and science have experienced increasing differentiation and tension. Prior to this point in history, religion and science were interchangeable ideologies. In fact, as Murphy (1997) states, 'In the Middle Ages, theology was not only a science but also the queen of the sciences' (p. 155, italics in the original). Indeed, under the church's rule, when sixteenth and seventeenth century scientists such as Giordano Bruno, Tycho Brahe, and Galileo Gallilei offered data for understanding the universe different from the understood Biblical theology of the day, they were declared heretics, punished, and a few were even executed. However, the mathematical evidence presented by scientists such as Copernicus and Galileo was repeatedly validated and supported despite dispute from the church. Hence, for many, science became the primary source of information about the universe and its inhabitants. Furthermore, due to the infamy surrounding the church's declaration of heresy upon scientists such as Bruno and Galileo, religion was at least somewhat discredited as a viable source of answers to humanity's problems (Rechberger 1998).

Nevertheless, it is impossible to discount the effect religion has had on humanity throughout history.

From the earliest times, religious beliefs and rituals have been a central component of the lives of humankind, frequently providing the structural framework from which societal, cultural, and moral norms developed. In the Western hemisphere, the primary religions of Judaism, Christianity, and Islam have as a core belief a universal God who acts as creator, sustainer, and protector. In the Eastern hemisphere, the predominant religions of Buddhism and Hinduism depict God as less actively involved in the day-to-day workings of humanity; nevertheless, almost all world religions have similar beliefs and practices in a supreme being or group of beings that are in some way interested in humanity's development. Furthermore, throughout most of known history, it was the religious leaders—whether priest or shaman—who were considered healers (a tradition which continues today in less Westernized cultures). Indeed, prior to the 1800s, what scant treatment there was for mental illness was provided by the church. Unfortunately, one of the negative outcomes of the overlapping domains of religion and medicine was evidenced in the development of concepts such as demon possession and illness as a result of, if not punishment for, an individual's misdeeds. These explanations were broadly accepted as disease etiology in most Western nations well into the nineteenth century.

In contrast, however, one of the potential benefits of having the same person exercising both religious and healing functions allows for the possibility of positive coordination and integration between the two domains. Reformers such as Philippe Pinel (1745–1826) in France began to see the mentally ill as sick rather than sinful or wicked. Another reformer, William Tuke (1732–1822), opened the York Retreat in England in 1792, and other pious Quakers were early leaders in the care and treatment of the mentally ill.

Beginning in the latter part of the eighteenth century medicine was developing as an independent science dealing with the maintenance of health and the prevention, alleviation, and cure of disease. This was a clear departure from the intertwining of religious practice and medical intervention that had existed from earliest human history. Until this time it was the church that regulated medical practice by the very fact that doctors needed license from the bishop to practice medicine (Foskett, 1996).

Despite this emerging demarcation between religion and medicine as separate disciplines, some religious leaders continued an interest in maintaining the overlapping interests of religion and medical practice. This was particularly notable in the United States during the mid-nineteenth century, during a *zeitgeist* that advanced an increasing emphasis on the mind-body relationship. A strong—albeit minority—view of the positive benefits of intermingling religious belief and medicine began to develop. Many wrote about it, including Mary Baker Eddy (1821–1910), the founder

of Christian Science, and Ellen G. White (1827–1915), one of the founders of the Seventh-day Adventist church.

Eddy wrote, ‘If we understood the control of mind over body, we should put no faith in material means. Science not only reveals the origin of all disease as mental, but it also declares that all disease is cured by divine mind’ (1875, p. 169). Nearly 100 years prior to psychiatry’s recognition of the influence of brain chemistry on disease, Ellen G. White wrote that ‘the mind affects health to a far greater degree than many realize and many diseases from which men suffer are the result of anxiety, remorse, guilt and mental depression’ (1905, p. 241). These religious writers preceded Herbert Benson and Bernie S. Siegel’s twentieth century emphasis on the mind–body connection.

5. The Emergence of Mental Health Disciplines

While the trend of separating science and religion was evidencing itself by the growing separation between medical practice and religious ideology, the emergence of psychology and psychiatry as new scientific disciplines also demonstrated a distinct separation from their religious and philosophical roots. Examining the writings of the earliest primogenitors within these newly emerging disciplines clearly reveals the tension between science and religion as they developed differing paradigms to resolve questions about what the components of ‘good’ mental health comprise.

In the United States, it was pre-Freudian William James (1842–1910) who was at the forefront development of the profession of psychology, along with his Harvard colleague Hugo Munsterberg. Interestingly, James (see article on *James, William* (1842–1910)) refused to treat physiology, psychology, and philosophy as distinct and separate disciplines. Furthermore, his endeavor to maintain a balanced position between these domains is clearly reflected in his 1902 book, *The Varieties of Religious Experience*, which addresses the questions related to religion as it interacts with mental health. As James wrote:

The problem I have set myself is a hard one: *first*, to defend ... ‘experience’ against ‘philosophy’ as being the real backbone of the world’s religious life ... and *second*, to make the hearer or reader believe what I myself invincibly do believe, that although all the special manifestations of religion may have been absurd (I mean its creeds and theories) yet the life of it as a whole is mankind’s most important function’ (1902, p. xix, italics in the original).

Although James acknowledged religion as a social and cultural phenomenon, he was interested primarily in the individual response of a person to religious experience. More specifically, he expressed fascination

with the conversion process, the moral and mystical elements of the religious life, and the interaction between religious belief and illness—particularly healthy vs. pathological mental health responses to religion. James (see article on *James, William* (1842–1910)) espoused a favorable view of religion, based on his perception that ‘healthy-minded’ individuals respond positively to religious beliefs and are the happier for it. Yet this positive view of religion in the scientific community would shortly be denounced by the writings of psychiatrist Sigmund Freud (1856–1939).

The field of psychiatry, although historically a part of medicine, was marginalized as a profession until the appearance of Freud’s writings (Alexander and Selesnick 1966). His ideas about the dynamic structure of personality and the benefits of psychoanalysis revolutionized the field of psychiatry. In his radical new perspectives about the inner processes of individuals, Freud assessed humanity’s desire for God and the function of religion in everyday life as evidence of psychopathology.

In his book *The Future of an Illusion*, Freud (see article on *Freud, Sigmund* (1856–1939)) opined that faith is based on the illusion that an idealized father (God) can replace the lost, real father who has proven fallible to the child and is no longer a comfort and source of security. Freud’s solution to his depiction of this ‘infantile’ response on the part of individuals to create a ‘mythological’ God was for them to develop a realistic view of the reality that there is no God: ‘Man cannot remain a child forever; he must venture at last into the hostile world. This may be called *‘education to reality’*’ (1934, p. 86, italics in the original).

Although the idea that God is a projected illusion did not originate with Freud, his declaration that religious belief is an infantile projective fantasy cast a long shadow over subsequent practitioners’ theories about the relationship between religious belief and mental health. This perspective contributed to many decades in which psychiatry generally viewed religious belief with skepticism and antipathy. What little credit Freud gave to religion for ‘restraining the asocial instincts’ of humankind (p. 65), he reiterated that it had not done so successfully. Instead, Freud advocated that humans should place their trust in the rigors of the scientific method, out of which discoveries of the truth about the nature of individuals and humanity’s relationship to the world around it would emerge.

This review of the origins of psychology and psychiatry illuminates the tension between the positivist assumption—that the scientific method and rigors of research would eventually answer all of humanity’s questions about physical and emotional well being—and the alternate view that religious belief is a constructive addition to solving mental health concerns. Although some theorists continued to typify any religious belief as evidence of naivete or pathology, others dissented from Freud’s strict atheism and

instead posited a more favorable view of religious beliefs in their psychological theories.

Examples of some of the psychologists and psychiatrists who integrated religion with their psychological theories would include such notables as Carl Jung (1875–1961), Erich Fromm (1900–80), and Viktor Frankl (1905–97). The broadest incorporation of the spiritual with the psychiatric is found in Jung, a Swiss psychiatrist and contemporary of Freud. His worldwide travels, interest in the occult, tribal religion, and other non-mainstream mystical beliefs heavily influenced his subsequent psychological theory. In stark contrast to Freud, Jung's liberal premise that all psychic products—including visions, dreams, and hallucinations—are 'facts' and should be considered as having the same basis in reality as other physical facts, opened wide the door to religious belief and behavior in psychic functioning that Freud (see article on *Freud, Sigmund* (1856–1939)) had firmly attempted to close. Furthermore, according to Jung, it is not the business of psychology or psychiatry to prove or disprove the existence of God: it can only address the psychic effects of the God image and its mythic antecedents on human behavior.

Psychoanalyst Erich Fromm recognized the value of religion in providing healthy feelings of stability and security for individuals. In his book *Psychoanalysis and Religion*, Fromm stated, 'Man is not free to choose between having or not having ideals but he is free to choose between different kinds of ideals, between being devoted to the worship of power and destruction and being devoted to reason and love' (1950, p. 25). Fromm further advocated a surrendering of one's individual goals and identity in favor of living selflessly in community with others, a not uncommon ideal of both Judaic and Christian rhetoric.

Finally, Viktor Frankl, the Holocaust survivor and psychiatrist who wrote *Man's Search for Meaning*, articulated in his book the premise that all humans are on an unmitigated quest for meaning—even in the midst of horror and despair. Frankl clearly credited his spiritual belief as sustaining his mental health throughout his imprisonment, and contrasted his experience to other prisoners who lost their faith and subsequently their will to live, succumbed to illness, and died. Of the three highlighted theorists who have acknowledged the positive merits of religious belief on mental health, Frankl's testimony is the most graphic and recent representation of the positive outcome of melding the two.

6. Theology

It is not only within the realm of science that the questions about the potential benefits of intertwining psychiatry and religious belief have been addressed. A number of theologians, religious philosophers, and clergy have also debated the merits of incorporating

religious beliefs into the best scientific practices in mental health.

One of the earliest proponents of such an idea was Anton Boisen (1876–1965), a Protestant clergyman who had once experienced a psychotic illness and subsequently had been institutionalized in a mental hospital. He reported that the hospitalization was a religious renewal experience for him, and he believed that it could be that way for some other patients if the psychiatric community were sufficiently sensitive to the meaning of these experiences.

Another theologian, Paul Tillich (1886–1965), proffered a broader anthropological and philosophical context within which psychiatry could exist and still address its own, more specific concerns. Similar to Jung's placing limits on psychiatry's role in evaluating religious belief, Tillich opined that statements of ultimate concern belong to a domain beyond which psychoanalysis and the scientific method can neither disprove nor verify. Furthermore, Tillich reiterated that when psychiatry makes either negative or positive judgments about the reality of religious ideas and symbols, it has moved out of the realm of science and into the realm of metaphysics.

Current philosopher of religion Paul Ricoeur (1913–) has countered the reductive view of religion espoused by Freud, and the influence Freud's views have had over much of psychiatry and the wider culture shaped by these theories. In contrast to Freud's view that religion is basically a public expression of obsessive compulsive neurosis, Ricoeur espouses belief that humans grow when confronted by sacred figures who challenge them to become more than they are.

Other contemporary writers include Karl Menninger (1893–1990), who has written *Whatever Became of Sin?*, addressing the atheistic stance of psychiatry and the cultural disregard for personal responsibility. Another, Paul Pruyser (1916–87), writes about the need for psychiatry, with its empirically-based findings, and religion with its faith basis, to be utilized separately rather than attempt their integration in understanding and treating mental illness.

7. Practices Which Have Attempted to Merge Religion and Psychology

The concern by some psychiatrists and theologians to interweave the religious with the psychological led to the development of new strains of practice in both disciplines. The most broadly defined psychiatric and religious blend emerged as 'transpersonal psychiatry,' the outgrowth of Jungian mysticism combined with tenets of Eastern religion (such as Buddhism, Hinduism, and Taoism). Proponents of transpersonal psychiatry use drug-free methods familiar in spiritual practices, i.e., meditation, as part of the ritual for maintaining optimal mental health.

A distinctly different approach to the integration of religion and mental health has been seen in the emergence of 'Christian Psychiatry' in the 1970s and 1980s. Led by theologically conservative psychiatrists, this approach was specifically tailored for Christian patients whose treatment mode, psychiatrists believed, could be enhanced by incorporating elements of their Christian faith in their treatment. 'Christian psychiatrists' based their treatment on Biblical principles, including Bible study and prayer.

Also within the theological realm, the development of Clinical Pastoral Education (CPE) emerged as clergy became educated about the nature of psychological problems. Originally developing with the work of Anton Boisen in 1925, CPE emphasizes ministering to the patient by utilizing both theological tenets and psychodynamic theory. CPE subsequently has become an important part of seminary training: a requirement of some, and an elective in even more, to best meet the needs of pastors and chaplains in hospitals and other settings.

8. *Psychiatry Addresses the Issue of Religion*

More than 50 years of writing on the positive interaction between religion and psychological health passed before the field of psychiatry officially re-examined its Freudian views on religious belief. In 1956, R. Finley Gale, Jr., the incoming president of the American Psychiatric Association, devoted his entire presidential address to the 'Conflict and Cooperation between Psychiatry and Religion.' In that speech, Gale called for the development of a committee on psychiatry and religion within the organization, and further suggested that mental health chaplains be invited to join and participate in that venture.

Although the next several decades indicated some gains in psychiatric acceptance of religion as non-pathological, diagnoses as late as those found in the 1987 *Diagnostic and Statistical Manual, Third Edition*, Revised indicated religious belief as a factor indicated in poorer mental health (Larson and Greenwold 1997). However, the 1990 adoption of the *Guidelines Regarding Possible Conflict between a Psychiatrist's Religious Commitments and Psychiatric Practice* indicated that 'patient religious beliefs were being professionally recognized as not only acceptable, but important treatment factors' (Larson and Greenwold 1997, p. 22).

These guidelines highlighted the usefulness of obtaining information about a patient's religious or ideological orientation and beliefs, as well as of addressing the procedure for handling any conflicts between the patient's and the psychiatrist's belief systems. Psychiatrists were reminded that they should not impose their own religious, anti-religious, or other ideological systems or beliefs on vulnerable patients. Furthermore, these guidelines indicated that inter-

pretations concerning a patient's beliefs should be made in a context of empathetic respect for their value and meaning to the patient.

9. *Reflections on the Popular View*

Despite the defamation of religion by the scientific community, demographic studies indicate that those who define themselves as religious/spiritual in the population at large have remained relatively consistent over the past several decades. The first Gallup poll, conducted in 1937, indicated that 73 percent of Americans were members of a church or synagogue. A 1997 Gallup poll (March 24–26, 1997) reported that 96 percent of Americans believe in God or a universal spirit, with 67 percent indicating membership in a church or synagogue. Further, 61 percent indicate religion is 'very important' in their own life (with an additional 27 percent stating it is 'fairly important'), with 43 percent attending religious services weekly or nearly every week.

In addition, one cannot overlook the host of religious-secular self-help support groups in mainstream culture today, particularly Alcoholics Anonymous (AA), the most therapeutically successful of them all. Alcoholics Anonymous (along with its subsequent offspring such as Narcotics Anonymous, etc.) is considered the most useful organization in the United States to assist persons suffering from alcohol abuse and chemical dependence. AA operates much like a religious community, complete with doctrine. The 12 steps proposed as necessary to overcome alcoholism reflect a creed that shapes AA, and has strong religious overtones. A similar group, the Samaritans, operates primarily in the United Kingdom. Its 23,500 volunteers make themselves available by telephone 24 hours a day, by personal visits, and by letters.

10. *Recent Academic Research Supports the Benefits of Religion*

Finally, recent research studies on the interaction between religion and mental health indicate more positive outcomes for believers receiving mental health treatment than for agnostics or atheists. Supporting the anecdotal success stories from Alcoholics Anonymous, a study by Desmond and Maddux (1981) demonstrated that 45 percent of participants in a religious treatment program for opioid dependence were still sober a year later, in stark contrast to the mere 5 percent who had participated in a nonreligious treatment program.

More recently, Koenig and Larson (1998) indicated that in the last 15 years, over 50 epidemiological studies have been published which demonstrate that 'religious persons experience not only greater well-

being and higher life satisfaction, but less anxiety and depression, lower rates of suicide, less alcoholism, less loneliness, and better adaptation to stress than do persons without spiritual resources' (p. 385). Furthermore, a substantive body of research on the acts of religious belief, such as prayer, has demonstrated positive impact on both physical and mental health.

In the preface to his 1993 book *Healing Words*, Larry Dossey, M.D., originally a skeptic, writes about finding 'over one hundred experiments exhibiting the criteria of "good science," many conducted under stringent laboratory conditions, over half of which showed that prayer brings about significant changes in a variety of living beings' (p. xv). Research indicated that patients who became prayer targets experienced altered blood pressure, slowed growth rates of cancerous cells, dissipation of tumors, an increased rate of healing for wounds, and even altered probability for heart attacks.

Finally, in terms of practical and economic outcomes, research indicates that the spiritually committed are less likely to develop serious illness, spend less time in the hospital, and do better upon discharge than those patients who are nonbelievers or aspiritual (Koenig and Larson 1998).

11. Implications for Psychiatry Today

When research indicates that participation in religious activities correlates with a patient's strengthened immune system, a reduced risk (by 60 percent) of arteriosclerotic heart disease and pulmonary emphysema, an increased (between seven and fourteen years) life span (Koenig and Sloan 2000), as well as a decreased likelihood of depression, anxiety, and persistent mental illness, the link between religious belief and improved health both physically and mentally becomes noteworthy. However, some concern remains about the potential negatives of physicians and mental health practitioners encouraging religious belief in their patients.

Richard P. Sloan, Ph.D., director of the Behavioral Medicine program at Columbia Presbyterian Medical Center in New York, opines that when 'physicians depart from their medical expertise and enter the religious realm, there's an element of coercion because patients don't want to offend or disappoint their doctors' (Koenig and Sloan 2000, p. 159). Sloan believes that melding the two realms puts a physician 'in a terrible bind. If he believes that there is strong evidence associating religion with better health outcomes... he would be derelict in his duty as a physician if he didn't advocate religion' (p. 156). He further associates this advocating of religion to prescribing antibiotics: a physician doesn't ask whether the patient is in favor of taking them, but merely prescribes them as being the best course of treatment.

Sloan's concerns about the potential dangers from intertwining religious ideology and mental health are worth taking into account. History has clearly demonstrated problematic responses to the mingling of religion and science, and an uncritical absorption of religious ideology into psychiatric theory would be foolhardy. However, given the recent research that indicates the positive benefits of religious belief in better mental health outcomes, ignoring those data would be very poor science. It would seem that the best approach would acknowledge the inherent tension between the two paradigms of science and religion, with growth in both fields occurring as the result of conversant dialogue between the two, much as Kuhn (1970) advocated in his treatise on scientific revolution.

12. Future Considerations

Given the recent scientific evidence for positive outcomes for religious belief, combined with the statistics about religious believers in the population at large, a move toward educating psychiatrists about the interaction between religious belief and mental health practice appeared necessary. Hence, in 1995 the Accreditation Council for Graduate Medical Education (ACGME) responded with a requirement to include religion and spiritual factors in the human development curriculum. To assist program directors in meeting this requirement, a *Model Curriculum for Psychiatric Residency Training Programs* was developed by David B. Larson, Francis G. Lu, J. Swyers, and Elizabeth Bowman, among others. This model curriculum provided definitions, bibliography, and teaching options to fit individual programs.

Practical considerations aside, the intermingling of religion and science can remind psychiatry that it does not practice in a vacuum or without social, ethical, and public philosophical influences. Religion confronts psychiatry with decisions regarding the proper stance of a secular, therapeutic discipline on determining components of mental health. Because it serves a wide spectrum of humanity, psychiatry should not wed itself to a specific religious or cosmological creed. It should, however, consider a public philosophy that provides 'a broad, intellectual understanding of both its proper focus as well as how it should relate to the wider aspects of social and cultural action' (Browning et al. 1990, p. 20). Such an academic stance allows psychiatrists to take their patients' experiences and beliefs seriously and in a respectful manner.

Psychiatry is on its most solid ground when it is investigating the psychological meaning and motivation of the religious beliefs of any patient. To reiterate the concerns of James and Jung, what psychiatrists must not comment upon is whether there is an ultimate truth justification for religious faith, for 'God' is, logically speaking, an axiom and not an empirically testable scientific hypothesis. Rather, acknowledging

the commensurate questions of the two paradigms (What are the fundamental components of human beings? What causes illness? What helps keep individuals healthy?) and allowing each field to share knowledge with the other as a means of improving practice in both disciplines, appears to be the most prudent course. Complementary coexistence, while maintaining studied attention to the polarizing tendencies of both religion and science, is the most likely path to providing optimal care for patients.

Religion, Psychology of

The psychology of religion was a central part of psychology at its inception as an independent empirical discipline at the end of the nineteenth century. Psychology is also one of the family of human sciences that has made an important contribution to the study of religion. Paloutzian (1996) provides an accessible introduction. This article will look first at some key historical figures, then at contemporary research contributions, and finally at critical current issues.

1. History

Early work on the psychology of religion included quantitative methods, such as the questionnaire research of Edwin Starbuck on types of conversion. However, the most durable masterpiece of the early period was undoubtedly the qualitative research of William James. The psychology of religion continued to be a vigorous part of the discipline of psychology through the first quarter of the twentieth century, and the most widely read summation of that period was J. B. Pratt's, *The Religious Consciousness* (see Wulff 1997).

From about 1925, there followed a fallow period in the psychology of religion, in part reflecting the behaviorist direction taken by the discipline generally. However, with the growing emancipation of psychology that took place in the 1960s, there has been a revival in the psychology of religion. This recent period has not seen any major psychological theories of religion, indeed many would doubt whether they are appropriate. However, there has been a wealth of investigations in many aspects of religious experience and behavior.

1.1 William James

For his *Varieties of Religious Experience*, written at the turn of the century, James (1985) assembled a large quantity of autobiographical material about religious experience. Several of his conceptualizations of this material have become permanent contributions to the psychology of religion, such as his distinctions between 'once-born' and 'twice-born' conversion types, and between 'sick-soul' and 'healthy-soul' types. His description of mystical experience as having the hallmarks of ineffability, a noetic quality, transiency, and passivity has also stood the test of time.

However, James' approach has been criticized (e.g., Proudfoot 1985) for his overemphasis on the private nature of religious experience as 'the feelings, acts and experiences of individual men in their solitude.' Whereas James saw religious doctrines and church practices as arising out of individual experience, others have emphasized how much individual experiences are shaped by the religious tradition. These criticisms of James have been reinforced in recent years by the growing awareness of the extent to which experience is 'specially constructed.' There has also been concern about James' over-reliance on vivid but unusual experiences; others would want to place the emphasis on the religious experiences of ordinary religious people. James also focused on the special qualities of religious experience.

In contrast, some would want to emphasize that the hallmark of religious experience is not its unusual phenomenal quality, but simply the way in which a religious frame of interpretation is applied to experiences of an ordinary kind.

1.2 Sigmund Freud

Another rather separate strand in the psychology of religion that goes back to the early twentieth century is represented by the contribution of Freud, and the psychoanalytic tradition stemming from him. Freud published several books on religion, but his most enduring contribution has probably been *The Future of an Illusion* (1962). There, he argues that religion is a form of wish fulfillment, and that God is a projection of the human mind. These were not altogether new ideas, and a similar line had been taken by Feuerbach. However, the fact that Freud approached them from a well-articulated general theory of mental functions gave them a new authority.

Though Freud's views have been very influential, there has been a growing recognition that they are highly speculative, and less authoritative than was initially supposed. It has also become clear that an alternative, more sympathetic view of religion can be developed within the framework of psychoanalytic theory, something that Freud conceded might be possible. The main influence on recent work of this kind has been Winnicott's concept of the 'transitional'

world, that was neither wholly internal nor external, but an illusionistic world that plays a constructive role in adaptation (see Meissner 1984). Though Freud's own work on religion was surprisingly weak in case studies, others have now conducted rich case studies documenting the close parallelism that can often be found between relationships to parents and to God. Of course, this need not be interpreted as showing that God is nothing but a projection of the mind, just that concepts of God are often shaped by personal factors.

1.3 C. G. Jung

Jung took an unusual interest in religious symbols and doctrines. Indeed, one of the reasons for his break from Freud was that he was unhappy at what he saw as Freud's disparaging treatment of religion. Jung interpreted religious symbols in relation to the personal journey of 'individuation,' a journey from ego-centeredness towards the 'Self,' involving the integration of the unconscious with the ego. Symbols are important both in representing the goal of this journey, and also in facilitating it. Central to Jung's approach to religious symbols is his theory of the 'collective unconscious' and its archetypes; Jung does not regard religious symbols as just being features of the personal unconscious.

Jung had a strong interest in symbols of the Self, and saw God and Christ as being such symbols. However, he laments the extent to which religious symbols have now lost their psychological power and are no longer felt to be relevant to the journey of individuation. His work on Christianity included extended essays on the symbolism of the Trinity and the Mass (see Jung 1969). He also took an extensive interest in Eastern religion, where he also found symbols of individuation, though he was opposed to Westerners taking up Eastern practices such as yoga.

Jung's view of religion is markedly more sympathetic than Freud's, though his reformulation of religion is at points decidedly heterodox. He tended to broaden religion to include anything 'numinous.' Also he emphasized that as a psychologist he could concern himself, not with religious metaphysics, but only with psychological realities (see Palmer 1997). Though Jung saw 'God' and 'Christ' as psychic images and symbols of individuation, whether there was a 'metaphysical' God was something about which he had no official view. However, it would be a misreading of Jung to imagine that he thought people could work out their own salvation. He thought the ego was quite unable to secure 'individuation,' and emphasized the radical otherness of the 'Self,' of which God is a symbol.

2. The Contemporary Psychology of Religion

Much contemporary psychology of religion employs empirical research methods, and there follows a brief

review of representative research findings. The fullest guide to the empirical psychology of religion is that of Hood et al. (1996). Beit-Hallahmi and Argyle (1997) is briefer, but also helpful.

2.1 Individual Differences

The study of individual differences has long been an important part of the psychology of religion. The search for a particular kind of personality associated with religious allegiance has generally not been successful, largely because of the marked diversity of religious people. However, there is reliable evidence supporting an association between different personality types and different approaches to religion. This emerged first in connection with social prejudice, where 'intrinsic' religious people were found to be less prejudiced on average than extrinsic; the same is true of committed vs. consensual religious people (another set of terms for a related distinction). There has also recently been considerable interest in the relation of Jung's psychological typology, as measured by instruments such as the Myers-Briggs Indicator, to various aspects of religious life such as prayer and Church leadership.

2.2 Mental Health

Mental health (at least as measured by self-report instruments) has been found to show the same relationship as social prejudice to types of religiousness, with intrinsic religious people having good mental health, but extrinsic religious people having relatively poor mental health. Even where religious people are not subdivided, religiousness tends to be associated with better than average scores on dimensions such as Eysenckian 'psychoticism.' When more objective measures are considered, religious people are often found to have lower levels of formal mental illness and abuse of drugs and alcohol. There is also growing evidence that religion has a positive relationship to happiness, coping, and physical health. There are probably a variety of explanations of the relationship between religion and health. These include 'selection' factors, such as alcoholics being less likely to go to church. However, there may be various ways in which religion can improve health and happiness, such as the therapeutic value of prayer, and the social support provided by the churches (see Loewenthal 1995).

2.3 Developmental Psychology

Children's intellectual understanding of religion has been found to follow the usual path, documented by Piaget for many areas of cognitive development, from concrete to abstract modes of understanding.

Early research showed that this applied to the interpretation of Bible stories, but the same general pattern seems to apply to all aspects of religious understanding, such as prayer and sacraments. There have been attempts to extend such 'stages of development' models to other aspects of religion, and to take them into adulthood. The best-known work of this kind is Fowler's theory of 'faith development.' However, many critics have expressed caution about the proper limits of stage models of religious development. They seem to work best for development in the intellectual understanding of religion, less well for other aspects; they also only seem to work better for religious development in children than in adults. The key issue is whether religiousness changes in a sufficiently predictable and universal way for the concept of development to be appropriate.

2.4 Religious Experience

There has been extensive empirical research on mystical and religious experience, though it is beset by the problem of how such experience should be defined. The initial question used in the research of Hay (1987) is characteristic: 'Have you ever been aware of, or influenced by, a presence or power, whether you call it God or not, which is different from your everyday self?' Most empirical surveys find roughly a third of the population respond positively to such questions. Interestingly, the proportion is not much reduced for atheists and agnostics. The experiences often occur at times of stress, and generate feelings of peace and happiness. One of the most debated matters is whether there is a common core to such experiences that is independent of religious tradition and culture. Psychometric research by Hood suggests that there are two groups of descriptors, one focusing on the experience of unity, the other set of descriptors more influenced by religious background.

2.5 Neuropsychology

The study of the brain processes involved in religion promises to become a lively research area. There has long been evidence that meditation alters people's levels of arousal, though probably not in any unique or distinctive way when compared to other procedures such as relaxation. There has been considerable interest in a possible link between the brain processes involved in religious experience and temporal lobe epilepsy. Though there are similarities in the two sets of experiences, there are also marked dissimilarities, and critics have pointed out that evidence that the same brain mechanisms are involved is weak (Jeeves 1997). d'Aquili and Newberg (1998) have proposed another neural theory in which two cognitive oper-

ators, the 'causal operator' and the 'holistic operator' underpin different aspects of religion. As evidence accumulates about the brain processes involved in religion, there is likely to be debate about whether or not they offer a complete explanation of religion.

2.6 Attitudes

The measurement of religiousness is an aspect of the study of attitudes and involves the vexed question of the relationship between self-report and behavioral measures. It has been claimed by some that religious believing currently exceeds belonging. Though, on some measures, this appears to be the case, it depends on exactly what measures of each are used. One of the methodological principles to have emerged in the general literature on attitude measurement is that single-item measures of expressed attitudes are a poor predictor of behavior, whereas fuller self-report measures predict better, and there is reason to think that this applies to religious attitudes. Attitude change can be studied in relation to religious conversion.

2.7 Conversion

Conversion has long been a central topic in the psychology of religion. It is a multifaceted, and by no means uniform phenomenon. There are well-established differences between sudden and gradual conversion types, with the former being more conservative in religion and in other matters. It has also long been noticed that adolescence is the peak time for conversion, but the interpretation of this needs to take account of the fact that it is probably the peak time for apostasy as well. Conversion often does not represent as complete or permanent a change as is supposed. Also, many of those experiencing a conversion are returning to previously held attitudes; conversions among those with no previous religious affiliation are relatively rare. In recent years there has been particular interest in conversions to new religious movements. In fact, these often seem to be associated with improvements in the sense of well being. There is some evidence of mental health problems in those who leave new religious movements, though this no means always occurs.

2.8 Charismatic Religion

Speaking in tongues (glossolalia) is much the best-investigated charismatic phenomenon (Malony and Lovekin 1985). Psycholinguistic research generally indicates that it is to be regarded as some kind of 'ecstatic utterance' rather than the use of an identifiable language. Social learning is apparently required

before people are able to speak in tongues; this is suggested by the way in which people first watch it before joining in, and also get more proficient at it with practice. It has been suggested that it involves some kind of dissociated state of consciousness, perhaps a trance state or a regressive state, but there is as yet no clear support for such hypotheses. It has been difficult to identify personality characteristics of those who speak in tongues. This may perhaps be because it occurs in different ways in different settings, but there is as yet no generally accepted classification. However, there is quite good evidence that it is associated with positive personality changes, though it is not unique in having such beneficial effects.

3. General Issues

The psychology of religion involves a number of general issues about methodology and interpretation, including the following.

3.1 Relation to General Psychology

The psychology of religion currently lacks integrative conceptual frameworks and general theories. A psychology of religion that is no more than a fragmented study of various particular religious phenomena will never look impressive scientifically. The other pitfall to be avoided is, of course, offering a psychological theory of religion that is too simplistic to handle the relevant phenomena adequately. The kind of theory Freud offered, in terms of religion meeting psychological needs, proved neither convincing nor scientifically fruitful, and is not a good precedent to follow. However, the problems faced in studying religion psychologically are not unique. The study of emotion, for example, faces similar problems, in that emotion is as multifaceted a phenomenon as religion. Broadly conceived 'cognitive' approaches to religion may give useful coherence, as they are currently doing in the psychology of emotion. The psychology of religion interfaces with many other areas of general psychology. Indeed, it can be argued that the subject is pursued most fruitfully when its links with general psychology are strong.

3.2 Relation to Sociology

The separation between sociology and psychology is in some ways an artificial one, and affects the study of many social phenomena, including religion. Most religious phenomena have both social and psychological aspects. For example, conversion and speaking in tongues have been studied fruitfully from both perspectives. However, social and psychological

studies often proceed in isolation from each other; it seems unlikely that either alone will be able to offer an adequate explanation of any religious phenomenon though there is a strong case for the psychology of religion having stronger links with the sociology of religion. This tends to raise the question of whether religion is to be understood in social or individualistic terms. Both perspectives are no doubt needed for an adequate understanding of religion, and the psychology of religion does not exclude a social approach. Though the increasing interest in the brain processes in religion are likely to pull the psychology of religion in a biological direction, the psychology of religion, like other aspects of psychology, will need to remain both a social and a biological science, and to hold together the different methodologies involved.

3.3 Relation to Theology

Lastly, what should the relationship be between the psychology of religion and theology? Different countries have different traditions about the relationship between theology and religious studies, some maintaining a sharp distinction between the 'insiders' perspective of theology and the 'outsiders' perspective of religious studies (including the psychology of religion); others have tried to maintain links between them. This issue is affected by the postmodern turn in philosophy, which is casting doubt on the possibility of any wholly detached, objective study of anything, including religion. The psychology of religion has been slow to accommodate itself to these general intellectual developments, though it is hard to see that it can stand aside from them indefinitely. One particular issue is whether there is scope for insiders' and outsiders' explanations to run alongside one another. Charismatic phenomena represent an example. It is not clear that the study of the psychological processes involved in charismatic religion excludes a complementary religious account in terms of the activity of the Holy Spirit.

3.4 The Nature of Explanation

Many of these issues are brought together in questions about the nature of explanation in the psychology of religion. Explanations in psychology are seldom complete explanations, and are certainly unlikely to be such in the psychology of religion. This means that religion will not be reduced to psychology, or 'explained away.' Equally, religion is not a 'natural kind,' and all explanations in the psychology of religion will therefore be culturally contextual, and depend on interpretations of the nature of religion; the psychology of religion can never hope to provide a science of religion that is a 'view from nowhere.'

Nevertheless, there is no sharp boundary between the explanation and interpretation of religion, and it is inherent in the nature of religion that it will adopt a mixed approach.

Religion, Sociology of

Though central to the concerns of the founding fathers and to such major mid-twentieth century figures as Talcott Parsons and Robert Merton, religion has, for some time, been regarded as of marginal interest within the discipline of sociology. However, the recent resurgence of ethno-religion and of militant variants of major world religions has incited mainstream reconsideration of the salience of the topic thereby directing attention toward the sociology of religion as a specialized area of research. Meanwhile, the subdiscipline has acquired a significant role in the generation of insights and perspectives among theologians, historians of religion and exponents of *Religionswissenschaft*.

1. *The Role of the Classics*

With roots in the earliest versions of sociological thought, the sociology of religion remains strongly influenced by the classics and Durkheim and Weber still supply the main axes of intellectual tension within subdisciplinary theoretical discourse (O'Toole 1984). The former's concern with religion's role in social cohesion, group stability, and the reproduction of sociocultural forms is complemented by the latter's preoccupation with its part in radical, large-scale social and cultural transformations. Their writings are constantly ransacked for insights while their ideas, often elaborated or even creatively misinterpreted, continue to permeate contemporary discussion of such topics as secularization, sectarianism, civil religion, new religious movements, ecclesiastical organizations, ritual, and religious transformations.

Through the scope of their theories and the depth of their insights, the classics inevitably breed rival readings and multiple interpretations, e.g., while Durkheim and Weber are often viewed as exponents of the secularization thesis, both offer ammunition for its adversaries. The ambiguity of Durkheim's legacy is evident in attempts to explain his fundamental theory of religion. Here, metaphorical parallelism battles symbolic realism as defenders of a materialist Durkheim confront those who proclaim him an idealist thinker.

Though Durkheim and Weber constitute the twin pillars of the subdiscipline's classical legacy, other figures have played significant, though more circumscribed roles. When articulation and development of the Weberian church-sect distinction was a central subdisciplinary obsession, Troeltsch's *The Social Teaching of the Christian Churches* (1923) universally was accorded classic status as the charter document of the study of religious organization. Today, Troeltsch's volumes attract attention, less for insights into church establishment and sectarian voluntarism than for their exploration of 'the secret religion of the educated classes.' With its cultic and mystical components, Troeltsch's treatment of this topic presciently anticipates a contemporary concern with religious individualization and privatization and thus deserves continuing scrutiny.

Rarely granted subdisciplinary recognition until the 1970s, the writings of Marx and Engels may now be said to have achieved minor classical standing. They have influenced theoretical discussion as well as inspiring a minority scholarship whose neo-Marxism is characterized by a sense of the 'relative autonomy' of religion and a belief in continuity rather than conflict between the views of Marx and Weber (O'Toole 1984).

Alexis de Tocqueville has long lurked in the background of sociological discussions of American religion but, until recently, his *Democracy in America* (1835) never achieved the subdisciplinary classic status of Niebuhr's *The Social Sources of Denominationalism*

(1957). Whereas Niebuhr is now largely neglected, however, Tocqueville increasingly is commissioned in the service of a current fascination with the 'vitality' of US religion and the sources of a supposed 'American Exceptionalism' in the religious realm. In its assertion of the significance of religious disestablishment and voluntarism, his work is esteemed as the fountainhead of a perceived 'New Paradigm' in the study of American religion (Warner 1993).

Long invoked without ever approaching the subdisciplinary standing of Durkheim or Weber, Simmel, too, is the subject of revived interest attributable to the uncanny timeliness of his writings (Simmel 1997). Reflecting his resistance to that domination of the objective spirit over the subjective which characterizes modernity, his focus on a diffused religious attitude in preference to institutionalized religious forms has a decidedly contemporary resonance. Careful to distinguish between formal creeds and the subjective experience of pious individuals, Simmel explores religiosity as well as religion, portraying the latter as a co-creation of acting believers which bridges the private and the public. In a subdiscipline currently grappling with issues of religious individualization, autonomy, fragmentation, and *bricolage*, Simmel's potential contribution has perhaps never been greater.

While many sociologists of religion are content to continue a conversation with the classics, others are impatient to break the intellectual spell of what they perceive as the increasingly irrelevant products of a passing industrial era. Those intent on subdisciplinary transcendence of the classics are acutely aware, however, that scholars accustomed to invoking this legacy as new problems arise will not relinquish it lightly.

2. *Definitions*

In most definitional surveys, discussion hinges upon the merits of functional vs. substantive definitions. Within these frameworks, the relative advantages of inclusive or exclusive conceptualizations are assessed while specific formulations are examined for theoretical coherence and empirical integrity. Since its inception, the sociology of religion has been the scene of such a prolonged battle between the proponents of these strategies for defining religion that, in a sense, the debate between Durkheim and Tylor has been interminable. Contemporary substantivist formulations focus on such elusive phenomena as the sacred, the transcendent, the supernatural or the superempirical. Functional definitions portray religion as an indispensable source of social consensus and cohesion which aids human adaptation to the environment and ensures societal survival by explaining the meaning of existence and providing answers to questions of ultimate concern.

The question of how inclusive a definition may be while still retaining analytical utility is one that may be

directed against both functional and substantive formulations. On the substantivist side, the categories of the supernatural and superempirical are notoriously open-ended while, in the most inclusive functional definitions, society itself assumes a religious character. Debate over the relative merits of definitional strategies often hinges on the issue of how closely sociological usage should adhere to societal understandings. On one side, scholars express frustration that sociological usage of the term 'religion' is often remote from and counter-intuitive to anything which ordinary people would recognize as 'religious.' On the other, it is argued that 'religion' is a culturally specific term with no resonance in many societal contexts and that, in any case, no definition of general utility can be expected to conform to the specific demands of ordinary language usage.

Although subdisciplinary practitioners are accustomed to pursuing their research in a continuing context of definitional disagreement, it is an error to believe that lack of consensus in this area has no practical effect. The degree of social and cultural significance which sociologists of religion currently attribute to religion is influenced, to a great extent, by their definitional predilections.

3. Major Themes

In the period of its greatest growth, since the 1960s, the sociology of religion has exhibited both continuity and change. The classics remain a continuous presence although their range of application has expanded. A Judaeo-Christian emphasis is still clearly discernible but it has become self-consciously circumscribed within more globally comparative ambitions. The functionalist tone of earlier theoretical discussions has given way to a polycentric approach that critically assesses the merits and defects of rival perspectives claiming a hearing. Most notably, the variety of topics examined under the subdisciplinary rubric has widened significantly. Whereas the sociology of religion was previously directed largely toward familiar subject matter, it now increasingly ventures into mysterious territory and assumes novel theoretical and methodological challenges. It cannot be said that the sociology of religion has been unresponsive to the unfolding religious processes and transformations of the latter half of the twentieth century. On the contrary, its evolution has been largely propelled by such reactions. The present generation of subdisciplinary specialists is engaged in research on many fronts. While continuing to investigate such phenomena as mainline religion, civil religion, millenarianism, conversion, and the changing role of clergy, its representatives also are exploring energetically a wide array of new topics generated by the turmoil of the last quarter of the twentieth century. E.g., events in Eastern Europe and the former Soviet Union since 1989 have underlined

religion's potency in the forging of ethnonationalism, thereby provoking numerous studies of the contemporary fate of religion in specific former Iron Curtain countries.

Although, in its strict American Protestant sense, it has claimed a longstanding subdisciplinary interest, 'fundamentalism' has also captured scholarly attention in its contemporary comparative meaning, particularly since the Iranian revolution. Adopting a blanket term coined by the mass media, sociologists of religion have participated in a number of subdisciplinary and interdisciplinary projects which examine the currently politically-charged topic of religious extremism (Christian, Jewish, Muslim, Hindu, etc.) under this heading. The effort to discern its underlying characteristics has raised the crucial question of whether the fundamentalist impulse toward differentiation and totality represents an assault on modernity, a manifestation of modernism or an intriguing combination of both.

Subdisciplinary practitioners exhibit an enhanced capacity for scrutiny of specific religious developments within a large-scale comparative context and in terms of more general theoretical debate. The study of Pentecostalism, e.g., is no longer confined to the margins and backwoods of Western societies. In the works of contemporary specialists, it emerges as a movement which offers a serious challenge to mainline religions in the West, is rapidly transforming the religious maps of Latin America and Africa and is making a serious spiritual, social and economic impact on parts of Asia. Sociologists of religion have been forced by world events to situate their subject matter in an increasingly international, comparative, and global framework whether their interest is in fundamentalism, charismatic Christianity, New Religious Movements, or any other major topic of research. It is unsurprising, therefore, that they have led the way in promoting globalization as a concept of central theoretical importance, not just for their subdiscipline but for sociology as a whole.

Born in the political alienation, generational conflict, and crisis of values which characterized the era of the Vietnam War and its aftermath, the study of New Religious Movements (NRMs) revitalized a subdiscipline which appeared to have exhausted the possibilities of the church-sect approach to religious organization. Over the last quarter of the twentieth century, sociologists of religion have continued to study Unificationists, Scientologists, Rajneeshis, Transcendental-Meditationists, Hare Krishnas, and many other movements of religious innovation and experimentation. In the process, they have accumulated a mass of ethnographic material documenting their inner dynamics, recruitment practices, resource mobilization, and ideological development while simultaneously struggling to discern the broader theoretical import of this information. Originating amidst heady notions of an emerging 'new religious con-

sciousness,' another 'Great Awakening' and an imminent 'Return of the Sacred,' NRM research has long subscribed to more sober assessments of its subject matter. Nonetheless, scholars in this field reject suggestions that they are engaged in a mere pursuit of the trivial and exotic. The significance of NRMs is believed to lie in their role as indicators of broader sociocultural trends but, unfortunately, there is wide disagreement concerning their overall significance for contemporary and future religion. For some commentators, they represent a decisive blow to the secularization thesis, their very existence contradicting any notion of a 'disenchantment of the world.' For others, they constitute strong evidence in support of the secularization thesis, confirming by their tiny membership, syncretic ideology, and cultural marginality the inability of religion to restore its fortunes in any significant way.

What might be considered a 'second wave' of NRM research has focused, more recently, on such topics as Satanism, Witchcraft, neo-Paganism, and various manifestations of 'New Age' spirituality. Such studies provide intriguing comparisons and contrasts with first-generation NRMs as well as with occultic movements formed at the end of the nineteenth century. They also examine phenomena such as Wicca and neo-Paganism as indicators of such broad religious trends as individualization, privatization, and *bricolage*, thereby suggesting their essentially post-industrial or postmodern character. A growing fascination with New Age spirituality as a highly individualistic and experiential enterprise has perhaps played a part in the encouragement or revival of subdisciplinary interest in such topics as healing, the natural environment, the human body, and collective memory as they relate to religious issues. As sociologists of religion increasingly have shifted their attention in these directions, the possibility of fruitful interchange between students of NRMs and analysts of so-called 'New Social Movements' from other subdisciplines has been raised. Though the response to this challenge has been rather muted, such cooperation might facilitate a greater infusion of general theoretical ideas into the sociology of religion.

4. Methods and Theories

Within the sociology of religion, methodology and theory typically have been implicit rather than explicit. Perhaps partly due to a certain insulation and isolation, the kinds of self-consciously theoretical disputes which occur in other subdisciplines rarely have been witnessed. Nonetheless, since the unraveling of functionalist orthodoxy in the 1970s, the subdiscipline has experienced significant, if civil, discord which stubbornly resists efforts at securing synthesis.

The subdiscipline employs a wide range of quantitative and qualitative methodological techniques including large-scale social surveys, participant-ob-

servation, and textual analysis of contemporary and historical materials. Here, as in sociology generally, one investigator's sophisticated device is another's blunt instrument, although open debates on this theme are rare. For the most part, a wall of indifference segregates quantitative from qualitative methodologists although it has been breached occasionally. In the broadest methodological sense, the reciprocal relationship between sociological research and religious activity merits attention though it is often ignored on the basis of a glib distinction between religious sociology and sociology of religion formulated in a religious context less bewildering than the current one. To what extent sociologists of religion see their own reflection in the religious realm on which they report is a sensitive issue which surfaces in a number of ways. Thus, in asserting the impact of societal reality upon sociological method, some observers suggest that a purported contemporary transition from institutionalized to individually autonomous forms of religion necessitates a shift from qualitative fieldwork directed at groups to quantitative surveys aimed at individuals. In contrast to this, other commentators ponder the possibility that perception of a rise in privatized religion may itself be partly a product of specific, widely disseminated research techniques directed toward discernment of the dimensions of individual religiosity.

While the complexities and subtleties of the reciprocal relationship between observers and those they observe have come to the fore most notably in discussions of scholarship and partisanship in the NRM field, they are equally evident in other religious settings. Students of Liberation Theology and Base Communities, e.g., are often confronted by sociological ideas in explicit use by those under observation. More generally, widespread use of the term 'secularization' by mainline churches seems to offer an excellent example of social science rebounding upon society. It also provides a cautionary tale of the manner in which societal embrace of a sociological notion may possibly inspire a self-fulfilling prophecy.

In any general assessment of the theoretical situation within the sociology of religion, it is difficult to overcome the impression that scholars are traveling in all directions at once and that every assertion eventually evokes its exact opposite. Empirical-analytic, historical-hermeneutic, and critical conceptions of science are all in evidence and the major tendencies in contemporary sociological theorizing are represented in varying degrees (e.g., functionalism, conflict theory, Marxism, critical theory, symbolic-interactionism, phenomenology, rational-utilitarianism). In such a situation, it is difficult to ascertain the main drift of theoretical innovation but recent important developments may be noted.

A mood of skepticism toward Grand Theories and Grand Narratives appears, in some quarters, to have intensified suspicions of deduction and prediction to a

point where the initial nomothetic impulse of the subdiscipline has been supplanted by an idiographic 'historical turn.' This involves a strategy of methodological individualism, a stress on individual autonomy and creativity, and an overall preoccupation with agency rather than structure. In a parallel development, longstanding inductive and interpretive tendencies have experienced reinvigoration and reinforcement as theorizing has taken a decidedly 'cultural' direction. In their efforts to take seriously the meaning of religion in the lives of believers and practitioners, proponents of this perspective employ the insights of cognitive and phenomenological theory while simultaneously drawing upon anthropological sources and material derived from the field of Cultural Studies. Fundamental to this cultural approach is a fervent antireductionism which rejects the notion of religion's epiphenomenal character and refuses to regard religious phenomena as really something else. Vigorously endorsing methodological individualism and deductive scientific logic, rational-choice theory has had an undeniably profound impact on the sociology of religion during the 1990s. Appointing Adam Smith to the subdisciplinary classical pantheon, its advocates employ economic metaphors to describe, explain, and predict religious behavior. Led by de Tocqueville's identification of a causal link between voluntarism and vitality in the American religious experience, they indicate the paramount importance of choice and competition in US religious 'exceptionalism.' Extending their analysis in a comparative direction, they strongly oppose suggestions of the inevitability of secularization, linking dynamic religious growth to a process of 'deregulation' in the religious realm. While it has won many converts, rational-choice theory has left many unconvinced by either its specific market analyses of religious profit-and-loss or its fundamental assumptions concerning religious behavior. To its most severe critics, its basic propositions appear embedded in ambiguity and tautology while its claims to universal applicability reflect an unfortunate regression into a presociological mode of analysis. Nonetheless, rational-choice analysis now represents such a significant presence that it is regarded by many of its admirers, and perhaps even some of its detractors, as the central constituent of a new subdisciplinary paradigm.

The themes of secularization and the contemporary transformations of religion have permeated subdisciplinary discussion in all its aspects since the 1960s. The concept of secularization has, for many, proven itself to be a plausible, persuasive, and resilient means for interpreting the fortunes of religion in the twentieth century. From another viewpoint it has been judged a misguided myth whose influence has retarded scholarly progress and whose persistence underlines the subdisciplinary need to transcend the classics. Although its classical provenance is tinged with ambiguity, the secularization perspective has long held a

privileged position within the sociology of religion, being described frequently as a dominant 'paradigm.' Logically dependent for its meaning on the definition of 'religion,' the concept has an intrinsic inclination to ambiguity which is often reinforced by vague and careless usage. Despite the best efforts of its proponents to articulate the main elements of the secularization thesis with analytical exactitude, debates over its validity frequently are characterized by argument at cross-purpose. While the validity of empirical evidence is occasionally at issue, facts are not typically in dispute and discussions tend to hinge on the interpretation of various social patterns.

What is new about the current debate is that proponents of the secularization thesis are now decidedly on the defensive. The undermining of the secularization thesis has occurred gradually through the efforts of scholars ranging theoretically from functionalists to phenomenologists but this process has accelerated in the last decade as a result of the arguments of rational-choice theorists and a new subdisciplinary awareness of the historical record. Indeed, some sociologists of religion discern, in the current convergence of these tendencies, the emergence of nothing less than a new subdisciplinary paradigm destined to displace the secularization thesis. Whether this new outlook, which combines deductive theory with social history, may accurately be described as a paradigm is in dispute. There is little doubt, however, that it captures a certain *fin de siècle* subdisciplinary mood of stock-taking and reassessment in which the prospects of religion appear much brighter than a few decades ago. Perhaps the 'new paradigm' is best understood within the context of changing attitudes to modernity. As a by-product of current postmodernist debate, the concept of modernity has experienced revival and refurbishment, a situation with significant consequences for the study of religion. The familiar conception which assumed that as a result of differentiation and relativization, secularization was an inextricable and inevitable component of modernity has given way to a revisionist version of modernity which neither precludes the persistence of religion nor constrains its vitality. Although its significance is challenged by defenders of the secularization thesis, mounting evidence of the vigor of religion on the international scene encourages subdisciplinary embrace of a more encompassing vision of modernity.

Interestingly, this vision is complemented by an increasingly broad conception of religion. Any attempt to portray religion's changing face since the 1970s must stress the extremely wide range of phenomena currently accommodated under the religious rubric before tracing those trends which constitute the common currency of all analyses of the contemporary religious scene. These include the processes of disestablishment, individualization, privatization, fragmentation, and globalization as well as a number of

variants and counter-themes. In the process by which a primarily institutional conception of religion has given way to a far more inclusive and elusive subdisciplinary formulation, the impact of Luckmann's 'invisible religion' thesis cannot be overestimated (Luckmann 1967). Where earlier functionalist definitions had focused on such vast notions as 'ultimate concerns' and 'grounds of meaning,' Luckmann raises the stakes even higher by identifying the transcendence of biological nature by the human organism as a religious phenomenon. He thus describes a general anthropological condition that links the creation of religion inextricably with the formation of the individual and the self. In various guises, this has been a major subdisciplinary theme during the years following the promulgation of his provocative thesis.

Concerned for so long with religion's role in the creation, preservation, and perpetuation of collectivity and community, many sociologists of religion have transferred their attention to the role of the individual and the dimensions of personal religiosity. As with other major subdisciplinary developments, this shift of attention is a product of perceived changes in societal reality as much as theoretical logic. It is not necessary to subscribe to the secularization thesis in order to be aware of the profound crisis which has beset the major institutional forms of religion in Western societies since World War II. Moreover, the vastly diminished role of religion as the 'ideology of community' has become increasingly evident. Thus, the new direction taken by the subdiscipline is part of its effort to cope with the rapid transformation of religion under conditions of postindustrialism and postmodernity.

One aspect of this new reality is starkly evident in the work of Bellah et al. (1985) whose insight into the success and decline of American 'civil religion' has expanded into a concern with the collapse of community. Viewing dwindling involvement in religious organizations within the broader picture of a general decline in participation in political parties, trade unions, voluntary associations, and community groups, Bellah and co-workers perceive religion as increasingly a matter of private concern and personal idiosyncrasy.

This theme is echoed in all current investigations of institutionalized religion, particularly in its 'mainline' forms. Although there is no immediate prospect of the collapse of organized religion, its future arguably depends on its ability to accommodate new attitudes to religious authority and revised forms of religious involvement. Commentary on the contemporary religious climate demonstrates considerable consistency in detecting a number of key related processes at work. Some observers describe individualization and privatization. Others refer, in a US context, to a 'third disestablishment' involving an expansion of personal autonomy. Fragmentation frequently is explored and a growing tendency among believers to 'mix and match' elements from a variety of denominational and

religious traditions is emphasized. The terms *bricolage*, religion *à la carte*, and consumerism are also utilized in portraying the extent to which individuals privately construct personally meaningful syncretic systems of belief for themselves. In examining the dilemmas of organized religion, many scholars discern a disinclination toward total acceptance of any denominational or religious belief system either through inheritance or conversion. This denotes a fundamental alteration in the popular conception of religion. No longer regarded as a source of authoritative meaning, increasingly it is considered instrumentally as a broad, pliant, cultural resource at the disposal of autonomous individuals. Moreover, the accuracy of this assessment is underlined by researchers who document an accelerating incidence of 'belief without belonging' as a mode of religious commitment.

The future of organized religion is precarious and unpredictable but with the waning of the secularization thesis, it is less often discussed in terms of inevitability. Though it seems certain to remain a major player on the religious scene for the foreseeable future, increasingly it will share the subdisciplinary limelight with more 'diffuse' and 'invisible' forms of religion. Often under the general umbrella of 'the sacred,' the attention of sociologists of religion focuses increasingly on uninstitutionalized forms of religion and their involvement in the transformation of the self. In this regard, studies of popular, 'common,' and 'implicit' religion, along with investigations of diffuse versions of spiritual and mystical experience, are now a noteworthy part of the subdisciplinary agenda. They are accompanied by efforts to discern the presence of the sacred in such secular settings as 'self-help' and therapy groups, fitness centers, weight-loss clinics, and healthfood stores which are often depicted as instruments in the pursuit of individual self-perfection.

True to form, however, there is no subdisciplinary consensus on an overall or inevitable passage into more privatized forms of religion in the postindustrial era. On the basis of evidence drawn from Poland, Spain, Brazil, and the US, Casanova (1994) perceives an intersection of religion and politics and a revival of 'public religion' in the modern world. This conception is given credence by globalization theory that regards both privatization and politicization as products of the modern global condition.

Whether religion's privatization or individualization will accelerate or whether its former capacity as a source of authoritative meaning will reassert itself and inspire novel, enduring, and significant forms of collective and public spiritual expression remains to be seen. One thing is certain: reappraisal of the past and adjustment to the present have ensured that, in the sociology of religion, the future is not what it used to be.

R. O'Toole

Religiosity: Modern

The *Shorter Oxford English Dictionary* defines 'religiosity' as 'Religiousness, religious feeling or sentiment.' Taking this as a cue, 'modern religiosity' is defined by contrasting it with modern forms of traditional religion. Thus modern religiosity is taken to refer to forms of religion which emphasize experience rather than the doctrines of the religious traditions of modern times; and which are relatively inchoate, indeterminate, or formless rather than being spelled out by way of authoritative belief systems. Religiosity, that is to say, is detraditionalized, the established, spelled-out, regulatory orders of the traditional not being much in evidence, if at all. Instead of living in terms of authoritative orders, religiosity is very much to do with the sphere of consciousness. And the fact that religiosity is so integrally bound up with the life of the person means that it is very much in the hands of the experiencing subject. It largely operates beyond tradition: that is to say, autonomous subjects—not traditions—are authoritative, subjects developing their own religiosities by way of the test of their own life requirements. In sum, rather than

heeding the injunctions of religious tradition, modern religiosity concerns self-based exploration of life's meaning; the autobiographical experience.

1. *Contrasting Modern Religiosity and Modern Religion*

Writing at the beginning of the twentieth century, Emile Durkheim drew a distinction between 'a religion handed down by tradition, formulated for a whole group and which it is obligatory to practice' and 'a free, private, optional religion, fashioned according to one's own needs and understanding' (cited in Pickering 1975, p. 96). With modifications, this contrast provides the basis for distinguishing between 'modern religion' and 'modern religiosity.'

1.1 *Modern Religion*

To begin with the more familiar term, modern religions provide tradition-informed, institutionalized forms of religious activity: the church, chapel, monastery, mosque, or temple. Unlike more insulated premodern religions, however, few modern religions are 'formulated for a whole group' or are 'obligatory to practice' (as Durkheim puts it). For with modernity, information and population flows have greatly increased, this meaning that globalizing and pluralizing processes have provided most people, in most cultures, with a whole range of religions from which to select. This said, however, modern religions strive (to varying degrees and with varying degrees of success) to ensure that participants remain faithful to the tradition on offer. Participants, that is to say, are instructed in a particular, clearly articulated, path to salvation. Examples include long-established forms of tradition (such as Catholicism) as well as more recent developments (such as those new religious movements dating from the nineteenth century, the Mormons providing an illustration, or those organizations that have developed during the later twentieth century, the Japanese 'new new religions' here serving to illustrate).

1.2 *Modern Religiosity*

Generally speaking, modern religiosity flourishes in realms beyond the institutionalized and traditionalized territories occupied by modern religions. Rather than going to church, chapel, or temple, at least to any significant degree, those involved draw on widely available cultural resources—books and magazines, films and videos—to develop their own religiosities. Or those involved resource themselves by way of 'new spiritual outlets,' turning to practitioners who provide spirituality (healings, meditations, empowerments) in

a relatively informal, weakly institutionalized and nondirective fashion. Then again, there are those who exercise their imaginations to conclude that there must be 'something' more to life than the merely mundane.

Reliance on cultural resources and detraditionalized new spiritual outlets goes together with the fact that a key characteristic of modern religiosity is that those involved think of themselves as exercising their own authority to develop their own religiosities (or spiritualities). As Robert Wuthnow (1989) makes the point with regard to North America, 'the religion practiced by an increasing number of Americans may be entirely of their own manufacture' (p. 164). In order to resource their lives, individuals might draw on magical, occult, or esoteric teachings and practices; New Age themes to do with the sacralization of the Self or the importance of connecting to the spirituality of nature; the mysterious forces of 'X-file' culture; notions such as 'spirituality,' 'vital force,' 'higher power,' 'life force' or 'soul,' and even 'angels'; or the 'inner wisdom' of religious traditions. In addition, individual religiosities can include the not-so-obviously religious in the quest for finding meaning in life, self-fulfillment or well-being: a point also made by Wuthnow when he writes of the growing popularity of meaning systems which involve, for example, an 'eclectic synthesis of Christianity, popular psychology, *Reader's Digest* folklore, and personal superstitions, all wrapped in the anecdotes of the individual's biography' (Wuthnow 1989, p. 164).

Although the term 'modern religiosity' can be taken to include vague 'there must be something more' beliefs, which have little direct bearing on the lives of those concerned, modern religiosity primarily dwells on what it is to be 'alive.' Durkheim ([1915] 1971) thought that the future lay with 'a religion which will consist entirely in internal and subjective states, and which would be constructed freely by each of us' (p. 47, my emphasis). What Durkheim is referring to is clearly very much to do with personal life: all those subjectivities which comprise 'being alive.' Now in the words of Wuthnow (1991), who is explaining what he means by the 'subjective' or 'lived realities' dimension of the religious: 'by "subjective", I mean an understanding of religion that privileges its connection to the individual, its location within the inner part of the individual (beliefs, outlooks, felt needs, emotions, inner experiences), and its role within the individual's personality (providing meaning, wholeness, comfort, psychological compensations, even a sense of attachment or belonging)' (p. 272).

Religiosities (or spiritualities) of life are most obviously in evidence among those who are not involved in strong—obeying the Other—traditionalized modern religion. For whereas traditionalized religious institutions serve to liberate people from their 'merely' human lives—as 'fallen,' or, in many Eastern traditions, as contaminated by 'attachments'—in favor of what lies beyond, modern re-

ligiosity concerns the autonomous subject, liberated from the demands of tradition and intent on exploring and developing what it is to be alive. This said, however, modern religiosity is by no means absent within less strongly traditionalized forms of modern religion. Peter Berger (1969), for example, in his discussion of liberal Christian teachings, notes that 'religious "realities" are increasingly "translated" from a frame of reference of facticities external to the individual consciousness to a frame of reference that locates them *within* consciousness' (p. 166). And to the extent that subjectivization or internalization is taking place within modern religions, so too does the divide between modern religion and modern religiosity become undermined.

2. Modern Religiosity and Peoples' Lives

Turning to how religiosities can serve peoples' lives, four main life focuses can be briefly summarized. The first concerns the life of the individual person. What matters in this regard lies with finding religiosity/spirituality within oneself. What matters is addressing personal 'growth,' divorce, illness, ageing, by engaging with what one's own spirituality has to offer. The second concerns the life of the relationship. Religiosity is here put to work to enhance personal relationships, or to operate in therapeutic fashion. The third concerns relationships with nature. The emphasis here is on living in terms of the life of the natural; that life which informs nature from trees to species to the cosmic. And the fourth concerns what life has to do with work, increasing attention being paid in countries like the USA to exploring ways of bringing 'life back to work' by way of religiosity or spirituality.

3. The Growth of Modern Religiosity

Not enough research has been done to provide anything approaching a clear picture as to how modern religiosity is faring on a global scale. It is probably true to say, however, that in much of the world, where religious traditions—Islam, Hinduism, 'popular' Buddhism—remain strong, modern religiosity is relatively unimportant. But even in Islamic countries like Bangladesh, its role should not be neglected: many people could well combine components of Islam with folk beliefs and practices to do with improving the quality of personal life; and Tagore, the great figurehead of the nation, taught a 'religion of humanity' which is a powerfully relational form of life spirituality.

The one thing that is reasonably clear is that modern religiosity is well in evidence in countries where various processes of modernity—rationalization, differentiation (between the religious realm and the political, for example), democratization, pluralization, consumer-

ization, and materialization—have weakened the hold of religious traditions. Indeed, in such countries modern religiosity could well be expanding. The reason is simple. More people are ceasing to participate in institutionalized, traditional religion than are becoming atheists or agnostics, it following that the number of those who are 'somehow' religious without being significantly involved with institutionalized religion has increased.

Northern Europe would appear to provide a major site for growth of this kind. In Britain, for example, the number of those regularly attending institutionalized religion dropped by 30 percent between 1950 and 1990, but the numbers of those becoming atheists or agnostics only increased by some 10 percent (entailing that there has been an increase of some 20 percent in those who are somehow religious without attending). It is true that many of these nonattenders might still be involved with modern religion, reading their Bibles at home, for example. But there are distinct signs that religiosity is growing: belief that 'there is some sort of spirit or vital force which controls life' has now overtaken the (traditional) 'There is a personal God' (Bruce 1996, p. 270), and New Age spiritualities of life are expanding (see Heelas, 1996). Or consider Finland: 15 percent are regular church attenders, with the figure in decline, while 63 percent believe that the 'best way to get in touch with God' is by being 'in' nature, such beliefs apparently gaining in numerical significance (Heino, 1997, p. 21).

Turning to the USA, research by Roof and Gesch (1995) provides convincing evidence of growth. Concentrating on the baby-boom generation, namely those 75 million (or so) people born between 1946 and 1964, by the 1990s approximately half were involved with traditional religion. Of the remainder, namely the 'religious individualists,' approximately half have turned to 'a deeply mystical conception of the Deity,' having little if anything to do with 'organized religion' (p. 141). As for elsewhere, it is highly likely that much the same picture of growth applies to countries like Canada and Australia, or to cities like Rio de Janeiro and Tokyo. Finally, on the question of growth, it is important to note that modern religiosity is also developing within modern religion: see, for example, Donald Miller's (1997) discussion of the (rapidly expanding) 'postdenominational churches' of North America with their strong emphasis on being alive in the right kind of way: 'purity of heart is more important than purity of doctrine' (pp. 127–8).

4. Explaining the Turn to Religiosity

Of the many factors that have contributed to the growth of religiosity, attention is paid here to what is called 'the cultural turn to life.' The key to the argument is that modernity has resulted in very high

value indeed being ascribed to life. In the words of Georg Simmel ([1918] 1997), 'this emotional reality—which we can only call *life*—makes itself increasingly felt in its formless strength as the true meaning or value of our existence' (p. 24). And given its value, life has quite naturally come to serve as the 'home' for religiosity for many of those who remain religious without participating in modern religion.

Looking at this argument in somewhat greater detail, Simmel and Max Weber, then Arnold Gehlen, Peter Berger, and Thomas Luckmann, have claimed that modernity has resulted in significant numbers becoming disillusioned with what the 'primary' institutions of society have to offer. From modern religion (loss of faith seen in secularization) to political ideologies, to the nuclear family, to the workplace (Weber's 'iron cage'), the claim is that the institutional order no longer succeeds in providing adequate sources of identity, purpose, or value in life. Accordingly, so the argument goes, people have been 'thrown back' on themselves as the key source of significance. With little to have faith in beyond themselves, what matters becomes a matter of what lies within: one's psychology, one's personal ethicality ('being true to oneself'), the quality of one's emotions, the importance of being authentic, the value of finding out what one truly is and capable of becoming; becoming 'whole' or healing oneself.

It is but a short step to explain the growth (in certain sociocultural contexts) of religiosities or spiritualities of life. Other than atheists and agnostics, those who have come to have 'ultimate' faith in what their interior or personal lives have to offer are going to seek out those forms of the religious which sacralize experiences of what it is to be alive.

Religiosity, Sociology of

1. Introduction

Religiosity is a broad and sweeping concept that unites much of the subject matter in the psychology and sociology of religion; consequently, the idea includes much more than it excludes.

1.1 Definition

In the most general sense, religiosity is a term that is used to refer to socially relevant manifestations of: (a) individual beliefs in a supernatural or transcendent reality; (b) relations of individuals to 'high-intensity values' (Roof 1979, p. 18); (c) 'beliefs about the nature, meaning, and purpose of reality' (Glock and Stark 1966, p. 3); and (d) all the behaviors that flow directly from them. Synonyms for the term in the literature of the social sciences include—among others—religiousness, religious affiliation, attachment, commitment, conviction, devotion, interest, and involvement.

2. Conceptualization and Measurement

2.1 Dimensions of Religiosity

Beginning in the 1950s, social scientists of religion directed a great deal of attention to elaborating definitions of religiosity that extended understanding of the concept beyond a mere count of people in the pews of churches and synagogues. Advances accumulated quickly and, according to one review (Roof 1979, p. 17), the 1960s became 'a pace-setting decade in this area.' In particular, sociologists had set to work crafting indicators of religiosity that took account of more than one aspect of religious commitment. After mid-century, scholars encountered an empirical religion that was, more than anything else, multi-dimensional.

2.1.1 Associational vs. communal religion. Some of the most basic quantitative studies of the postwar religious scene in the United States were the work of Gerhard E. Lenski (see, e.g., Lenski 1953). Lenski's major analysis of religious belief and behavior in Detroit, *The Religious Factor* (Lenski 1963 [1961]), gauged two fundamental types of religious involvement: associational (established through attendance at church services and meetings of church-related groups); and communal (the development of a religiously homogeneous circle of primary attachments). He additionally recognized two religious orientations among his respondents: one that stressed doctrinal orthodoxy, or right belief; and another, devotionism, that located religiosity in personal contact with God (Lenski 1963, pp. 22–6; see also Burwell 1999b, Deconchy 1987, p. 35, Roof 1979, pp. 19, 20–1).

2.1.2 5-D and its critics. Also among the earliest examples of religiosity conceived theoretically and captured empirically in more than a single questionnaire item were the efforts of Charles Y. Glock and his colleagues to portray religion along up to five dimensions (Glock 1962, Glock and Stark 1966; see also Burwell 1999a, Deconchy 1987, pp. 33–43, Gorsuch 1984, pp. 232–34, Hilty et al. 1984, p. 252, Roof 1979, pp. 20–2). Initially, Glock proposed that there were at least four distinct ways in which a person could be religious. Religious commitment, he postulated, could take the form of religious emotion or 'direct knowledge of ultimate reality' (the experiential dimension); fidelity to a certain body of beliefs (the ideological dimension); participation in divine worship, prayer, and other ceremonies (the ritualistic dimension); and indications of the 'secular effects' of religion on the individual and society (the consequential dimension).

To this array he later added an intellectual dimension (Fukuyama 1961), because the believer would be expected to be 'informed and knowledgeable about the basic tenets of his faith and its sacred scriptures.' Although Glock admitted that this fifth dimension was 'clearly related' to religious ideology, he insisted that the two were separable, for religious belief demanded familiarity with something in which to believe (Glock 1962, p. S99). Indeed, each of the five dimensions represented to Glock a theoretically and empirically distinct aspect of religiosity; he explained at the outset that 'being religious on one dimension does not necessarily imply religiosity on other dimensions' (Glock 1962, p. S100).

Later studies referred to these constructs together as 'Religiosity in 5-D' (Faulkner and DeJong 1966, Roof 1979, pp. 22–9, Weigert and Thomas 1969). The results of several (see, *inter alia*, Hilty et al. 1984, King and Hunt 1990) offered new or augmented models for research, but the most prominent critics (Clayton and Gladden 1974), aided by large-scale surveys and data

reduction through factor analysis, concluded that there was little empirical warrant for most of the presumed dimensions.

2.2 Meaning Systems and the Religious Imagination

Considering the manifold difficulties and relatively modest benefit in measuring religiosity as socially normative behavior within the confines of churches, sociologists—including Charles Glock himself—in the 1970s and 1980s devoted themselves to fashioning research techniques that would incorporate the broader connotations of the concept. A salient example of this approach is the innovative study by Robert Wuthnow (1976) on the meaning systems to which individuals routinely resort to lend structure and order to their experiences. Using data from the San Francisco Bay area, Wuthnow's survey could discern four different ways of making sense of causation in life (see Deconchy 1987, p. 39, Roof 1979, pp. 33–5). Respondents who attributed events to the intervention of divine agents (God or the devil) in human affairs were classified as ratifying theism. In contrast, those who believed that persons created the conditions of their own lives were said to back individualism. Believers in the explanatory power of social science traced the origins of personal situations to their surroundings in society, while people whose meanings came from mysticism relied on direct experience of the sacred and its mediation through nature, the creative arts, and fantasy.

A somewhat different stream of research has employed sets of interview questions to derive scales that purport to measure the symbolic and narrative basis of religion—what Andrew M. Greeley has termed 'the religious imagination.' Although formal theology is organized into series of logical statements, Greeley contends that personal religiosity predates and often overpowers tame instruction in dogma and doctrine because it is rooted in an imaginative appreciation of stories that renew hope in human actors. Religion is thus primarily composed of 'images that are prior to and perhaps more powerful than propositions' (Greeley 1981, p. 1).

To reach this imaginative capacity scientifically, Greeley and his collaborators have devised combinations of survey items that summarize varying images of God (see also Vergote et al. 1969), chart the perceived 'warmth' of different religious images, probe perceptions of religious figures like Jesus and the Virgin Mary, and describe the degree to which respondents regard heaven as a pleasurable place and the relationship between the divine and the human as 'grace-filled' (Greeley 1981, pp. 23–9).

2.3 Civil and Public Religiosity

Another aspect of religiosity that is sometimes overlooked because it lies just outside the institutional

boundaries of formal faith is what Robert N. Bellah (1967) has termed civil religion (see also Deconchy 1987, pp. 38–9, Roof 1979, pp. 29–31). Civil religion may be defined as a religious perspective that places the past, present, and future of the nation against the backdrop of transcendent values. Commenting on the United States, Bellah (1967, pp. 3–4) maintains that the components of civil religion in America ‘provide a religious dimension for the whole fabric of American life, including the political sphere.’ A special category of symbols and rituals that pertain to the identity and purpose of Americans thereby attains a sacred status in collective life.

In such a perspective nations not only have histories, they have destinies. Although a patriotic citizen may also be civilly religious, belief in the civil religion is different from simple patriotism. Despite, too, the frequent mixture of politics and piety (Glock and Stark 1966, pp. 82–6), civil religion is usually more than the casual consecration of secular aims. In the eyes of an adherent to the civil religion, a nation’s official philosophies, public policies, and international statecraft all invite the intervention of Providence—at the same time that their consequences promise to come under divine judgment. A kind of religious significance thus permeates the entirety of the public realm yet is dependent on no single church or denomination for its vitality.

2.4 Types of Religious Orientations

2.4.1 Intrinsic vs. Extrinsic religion. To a larger extent than sociologists, psychologists of religion have concentrated on the questions of how and why people hold the religious beliefs that they do. Central in this tradition of inquiry has been Gordon W. Allport’s distinction between Intrinsic (I) and Extrinsic (E) religious orientations (Allport and Ross 1967; see also Batson and Ventis 1982, pp. 140–9, Deconchy 1987, pp. 37, 40, Hunt and King 1971, Roof 1979, p. 20). ‘No approach to religiousness has had greater impact on the empirical psychology of religion,’ one scholar observes; Allport’s scale to measure religious orientations, furthermore, is ‘one of the most frequently used measures of religiousness’ (Donahue 1985, p. 400). Another pair of commentators (Kirkpatrick and Hood 1990, p. 442) concurs that the I/E comparison ‘currently represents the backbone of empirical research in the psychology of religion.’

As the labels imply, intrinsically religious persons are those for whom religion is an end and not a means. Religion is ‘their master motive’ that provides the guide to understanding all of life. In contrast, extrinsically religious persons engage in religion with the hope for something else, such as peace, protection, or status in the community. For them, a religious faith ‘is lightly held or else selectively shaped to fit more primary

needs’ (Allport and Ross 1967, p. 434). Extrinsic religion, notes one psychologist (Donahue 1985, p. 400), ‘is the religion of comfort and social convention, a self-serving instrumental approach.’

An enormous amount of research on the I and E scales has been conducted in nearly 50 years. Perhaps the most famous set of these studies has linked the Extrinsic religious orientation to expressions of prejudice. But one of the main complaints about the formulation reverts back to its first appearance—as a more value-laden contrast by Allport (1950) between ‘mature’ and ‘immature’ religious faith. The implication is that Intrinsic religiosity is somehow genuine and ‘pure’—unencumbered by ulterior motives, while the Extrinsic brand is phony, selfish, and manipulative. In the descriptions of I and E, the Intrinsic believer is clearly preferred to the Extrinsic; as Michael J. Donahue (1985, p. 416) concedes, the E scale ‘does a good job of measuring the sort of religion that gives religion a bad name.’ James E. Dittes (1971, p. 375) is much more harsh: to him, I and E struggle beneath a ‘heavy contraband load of value judgment that simply will not be sloughed off.’

Add to this problem of bias the repeated statistical finding that I and E are not two poles of the same continuum, but rather two variables with only a limited correlation (Allport and Ross 1967, p. 437, Donahue 1985, pp. 401–4, Kirkpatrick and Hood 1990, pp. 448–50, 454). For these and other reasons, I and E may survive in the scientific study of religion solely in an amended shape.

2.4.2 The ‘Quest’ variable. Dissatisfied with the dual categories of Intrinsic and Extrinsic religiosity, psychologist C. Daniel Batson has developed a third type of religious orientation that he dubbed Quest (Batson and Ventis 1982, pp. 149–68; see also Deconchy 1987, p. 40, Donahue 1985, pp. 411–14, Gorsuch 1984, pp. 234–5, Kirkpatrick and Hood 1990, p. 447). A person who conceives of religion as a quest is one who actually welcomes ‘a readiness to doubt and to be self-critical’ and who acknowledges the ‘incompleteness and tentativeness’ of religious faith at any moment (Batson and Ventis 1982, p. 149).

2.4.3 Other varieties of religious experience. One of the oldest traditions in the social sciences of religion attempts to study, with precision and objectivity, experiences of the sacred. The subjective nature and ordinarily fleeting passage of religious experiences, however, makes this goal extremely difficult to achieve. Yet the pioneering psychologist and philosopher William James tried, and his classic work, *The Varieties of Religious Experience* (James 1902), is the product.

In spite of this distinguished start, studies of mystical and ecstatic experiences have not yet culminated in a secure body of knowledge. It is nevertheless possible to specify several recurring features of religious experiences, as distilled from numerous cases. People who have experienced a mystical episode remember feeling as if it occurred outside the physical constraints of space and time. In this special state, they recall a spirit of peace and even elation enveloping them. Further, they report receiving personal illumination or enlightenment of unquestioned authority, while still assimilating seemingly contradictory or paradoxical perceptions. They apprehend a sacred presence, and commonly recount a sensation that all of reality was merging into oneness. In the single greatest barrier to researchers, though, mystics also contend, after their re-entry into normal consciousness, that the essence of their experience was indescribable (see Stace 1960, Stark 1965).

3. A New Religiosity?

Many of the ideas and approaches that social science devised in the last half-century to handle religiosity are slowly falling into disuse today, as both conceptions of religion in social science and evidence of its effects are changing.

More and more, scholars in disciplines such as psychology and sociology (e.g., Roozen et al. 1993, pp. 45–8) are describing a contemporary style of religious belief and practice that is at heart individualistic. Although people in plural societies have always had available to themselves a range of religious choices, seldom in the past have these decisions been so free of influence from social factors in one's background like family, ethnicity, or language. Rather, the assumption of a religious affiliation in the current circumstance is increasingly voluntary; it amounts to an expression of identity, and often a private or highly personal one at that.

Thus recent years have seen an abundance of religious pursuits, especially among the so-called 'baby boom' generation (cohorts born between 1946 and 1965), that have an eclectic quality. Popular varieties of faith combine elements of meditative practices, environmental activism, 'New Age' consciousness, and self-awareness with a therapeutic flavor. In the twenty-first century, many who no longer consider themselves conventionally religious nevertheless claim to possess a deep 'spirituality.'

4. Conclusion

Current research and theorizing in the scientific study of religion seeks to depart from older approaches to religiosity that anchored the topic in categorical contrasts, whether bipolar or multidimensional. Instead, sociologists and psychologists are busy tailoring

strategies and tools for research on a concept of religion that is personal more than institutional, amorphous and fluid rather than historical and orthodox, and not static but changing.

In an age when religiosity assumes both a ubiquity in common concerns over truth and authenticity, and an idiosyncrasy in multiplying paths of personal development, flexible ideas and methods of interpretation are definitely needed. Yet, now as before, the challenge for social scientists is to pursue analyses of the sacred into the meanings with which humans endow it and through the actions that proceed from these commitments.

Religious Fundamentalism: Cultural Concerns

‘Fundamentalism’ is the name applied to characterize a variety of modern religious movements internationally, but its use is contested in some cases. The key feature in these movements is their reactive

character. That is, they are not simply traditional, classic, conservative, or orthodox. Scholars and others usually speak of fundamentalism only in cases that find sets of religious people responding to certain kinds of challenges. The challenges may vary, but they tend to be variations on what the reactors or observers ordinarily would call ‘the modern,’ ‘modernity,’ ‘modernization,’ or ‘modernism.’

1. The Term ‘Fundamentalism’

One of the most controversial features of the movements called fundamentalist is the term most widely used to designate them. There are two main reasons for some participants in the movements, people in statecraft, and scholars to have reservations about the use. First, the name is derived from a reactive movement in American Protestantism, and for some decades after the 1920s remained chiefly related to them. To some, the transfer of this term to other religious contexts looks like one more example of a Western linguistic imperialism that needs to be resisted. Others contend that features peculiar to a specific Protestant conflict differ in so many respects from those in other reactive movements that only confusion could result from the use of the term. The second reason why many are reluctant to accept the term as their self-description or for scholarly purposes has to do with the fact that it can be used pejoratively and stigmatically. In a way, this resistance is ironic, since in the American context and, by analogy, in other religions and cultures, those who formed and originally adhered to such militant movements originally wanted to be stigmatized, and still may want this, but on their own terms.

Thus, in an American controversy in the 1920s, partisans in denominational warfare regularly complained that while the majority of their fellow-believers claimed to be conservative, as conservatives these did not do battle for the divine cause. Since they were too and compromising, it was argued, a new term had to be coined and applied. This term would help provide boundaries around the movement and create distance between it and conventional conservatism—or against anything else that implied a potential for compromise and comfortable assimilation. But because the strategy of setting boundaries and deliberately seeking to offend others went so far that it often ran counter to some of the positive purposes of the movements, many became discontented with the self-chosen name. Some sought moderating terms. In the American case, ‘neo-evangelicalism’ and then ‘evangelicalism’ served this purpose.

The term will not be found in dictionaries or encyclopedias, even encyclopedias of religion in America, before the time of a fundamentalist–modernist controversy in the US, one that came to a

climax around 1925. When the word does make its way into reference books after that period, for example in German or French dictionaries, all the meanings of fundamentalism get reduced to something about a battle over the verbal inerrancy and literal interpretation of the Christian Bible—a reduction abhorrent to members and confusing to observers of Islamic, Jewish, or other religions' factions.

Given these burdens associated with the term, there is good reason to ask about its continued usefulness and appropriateness. Several reasons are cited in defense, among them the following: first, the word is 'there.' So widespread is the use among reporters, scholars, and politicians that it is not likely to disappear because of discontent over its use by many. Better to clarify what is meant, it is said, than to invent new coordinating terms that will meet similar resistance in due course. The second reason has to do with the need for some such coordinating designations. To mention that need is, of course, to open the door to the many controversies over comparative methods. James (1902) typically made a defense of the practice of typifying and classifying. Without classifying, it is hard to understand many features of phenomena. At the same time James warned against the danger of losing the individual and particular character of the objects studied.

In the case of fundamentalism, the interest in coordination is almost entirely formal, not substantive. That is, one notices aspects of certain religious movements by studying characteristic features while being well aware that these movements all differ from each other in respect to content. Indeed, a Muslim fundamentalist will be 'doctrinally' more distant from a Protestant fundamentalist than modernists in both religions would be to each other. So there is no point in using the word 'fundamentalist' to characterize the central teachings of these religious expressions.

Even here, however, the line is a bit fuzzy. Thus, through comparison one can generalize that all the fundamentalisms, apparently paradoxically because they resist that which is modern, and though electronic media result from modern invention, are adept at using radio, television, film, and the Internet to hold their groups together, seek converts, and express themselves to outsiders. That observation grows out of formal comparison. But a second generalization, that all the fundamentalisms are not only patriarchal but that in their talk about God, they stress God's maleness while moderate and modernist movements play down masculine references to deity does show that there can be certain kinds of substantive similarities.

A third reason for using the term, say its defenders, is that no clear alternative is apparent. Some reporters, trying to avoid the word, will use something like 'militants,' appropriate for one dimension of some of their life. But these words do not signal anything of cultural context: one can be militant about revenge,

the search for territory, or any number of themes that have nothing to do with religious reaction.

Further defense of the term comes from those who say that all words travel, and globally people would make little sense of each other if they did not have terms that could be reappropriated in a variety of cultures. Thus words like 'nationalism,' 'liberalism,' 'colonialism,' 'conservatism,' 'radicalism,' 'democracy,' and 'republicanism' are born within Western contexts and are translated for usage elsewhere. The People's Republic of China means something very different with the term 'Republic' than do those who speak of America as a republic. Yet there are reasons for people to use the term in both contexts—and then clarify what they mean and point to differences.

Attempts to replace the term usually are specific and cannot be used for coordinative or comparative purposes. Thus, one might speak of 'radical revolutionary nationalist Islamic reform,' using other borrowed terms, and then find that they do not relate to phenomena in the Catholic or Hindu world. Mention of such instances suggests why many choose to use 'fundamentalism': it has acquired some rather specific meanings, meanings that deserve examination.

2. The Originating Instance in America as a Case Study

American Protestantism, having been divided into many denominations from the beginning, experienced some transdenominational conflicts in the nineteenth century. The first great breach occurred between the North and the South in the Civil War, when churches on each side inspired, monitored, provided morale for, and negatively defined the other side in religious terms. But all through the century another split was taking shape, thanks to latent tensions between theologically more liberal and more conservative parties.

These tensions increased with the arrival in the US after the middle of the nineteenth century of Darwinian evolution, the higher criticism of the Bible, and various forms of political progressivism. Many conservatives massively resisted theories of evolution, in part because these were seen as assaults on the Bible. They all rejected biblical criticism as a threat to the foundations of the faith. And progressivism did not do justice to apocalyptic messages in the Bible. Meanwhile, modernist parties began to develop toward the turn of the twentieth century. These were strongest at the prestigious theological schools such as Harvard, Yale, and Chicago—but rather dramatically not at Princeton University and Princeton Theological Seminary, from which some intellectual impetus for fundamentalism was to come.

Between 1910 and 1915 the conservative parties issued an influential set of booklets called *The Fundamentals*. From then on the accent on funda-

mentals grew. In 1919 a World's Christian Fundamentals Association was born. In 1920 during a battle for power in the Northern Baptist Convention a Baptist editor proudly chose and publicized the term 'fundamentalist' for his faction. The Presbyterians and to a lesser extent other mainstream Protestant denominations entered into the battle. The celebrated Scopes trial in Tennessee in 1925, one that featured conflict over the teaching of evolution in public schools, was the best known event in the formation and publicizing of fundamentalism.

This is not the place to trace in detail the outcomes of the struggles. Fundamentalists lost the battles for control, but inventively went their way developing their own Bible colleges, seminaries, mission boards and, thanks to schisms, denominations. They were a presence but not a vivid one during this period. In 1941 some formed an American Council of Christian Churches, which engaged in rivalry with a more moderate National Association of Evangelicals born in 1942. Still then seen by nonfundamentalists as marginal, eccentric, and withdrawn, fundamentalists remained generally aloof from politics. However, during the 1970s most of them reversed their stance and began to adopt political interventionist stances. They have been a prominent presence ever since.

To detail this case study further might well bias the case of those who charge that global and interreligious use of the term fundamentalism is too reliant on the American experience. But one could study cognate movements elsewhere—typically the Muslim Brotherhood in Egypt—and find similar reasons for Islamic conservative groups there to move into reaction. A description of elements that make up what is called fundamentalism in any religion will be more profitable, however, than would extending the number of case studies.

3. A Phenomenological Approach to Fundamentalist Features

By phenomenological here is meant a pattern of observation in which the analysts 'bracket' their presuppositions—in this case, for example, assumptions about the positive or negative aspects of fundamentalism—and as if naively asks: what stands out in the phenomena that have been called fundamentalist? Another way to put it is: what phenomena developed in the twentieth century that occasioned the need for fresh naming—since words like conservative and traditional had been easily available? These questions enable one to escape the charge that a priori definitions color the observations. These are some of those features. First, while fundamentalisms originally were dismissed by others as 'the old time religion' and while some parade themselves as traditional, they differ in significant respects from conservatism. In the eyes of doctrinal, political, and sometimes even armed mili-

tant partisans, conservatives may be too passive. They are too content to let the world go about its business not reckoning with them. If in any particular instance the cause being challenged is seen as divine—and we are here dealing only with *religious* fundamentalisms—for anyone to be content with tradition is a betrayal.

Fundamentalisms rise when historically conservative religious movements experience something that challenges them to their core. In Iran and elsewhere in the Middle East after the late 1970s, the challenger might be 'the Great Satan' of Western imperialism, specifically in its American form. In hyper-Orthodox Israel the threat to Jewish identity itself appears to parties such as Gush Emunim to come from non-observant, compromising Jews who might even let some of the land of Israel slip away in diplomatic negotiations. In the US the challenge in the 1920s came in more doctrinal ways, through contests over biblical literalism. But in all these cases, the threat had to be seen as total; fundamentalists do not bother much about trivial issues.

Since the challenge was total, the response had to be drastic. Fundamentalisms characteristically are reactive. They rise among communities that have been acted upon, and they act back. Very often they use the very instruments that had presented the challenge. If a nation-state is the ominous force, they make efforts to win power, through the ballot if possible and through weaponry if necessary. (Let it be noted that not all fundamentalisms take on any form of military or terrorist guise. Some even shun the political arena if they feel that they can convert sufficient recruits from that worldly zone or win their way simply through cultural militancy, as with disputes over 'values' and media.) Again, fundamentalists tend to use some of the weapons that have brought change, whenever, for example, they take instruments of mass media, the agents that penetrated their homes and consciousness, and become sophisticated in using these to fight back.

Somehow, in every case, they react. Not to be reactive is to be not fundamentalist. George Marsden, the foremost historian of the American version, describes a fundamentalist as 'an evangelical who got mad.' In reaction, the fundamentalist seeks ammunition for defense and aggression. Here is where the fundamentals come in. Fundamentalists reach back to foundations, some in the Qur'an, some in Torah, some in the New Testament, still others in classic events of the past, and claim them for their own. In every case in their eyes there had to be some sort of golden moment or precious book to which arguing parties can resort in efforts to determine winners and losers.

Acting upon these fundamentals, members of the group then engage, as noted, in setting boundaries. They are often described as bearing a Manichaean cast. This means that the cosmos is divided into God versus anti-God, good vs. evil, our people vs. everyone else. They may not necessarily withdraw into enclaves,

but they will tend to use code-words, slogans, informal testing devices that help them screen out the most dangerous persons and forces: the moderates. The total outsider, the infidel, the Great Satan is useful for mobilizing forces, but is not a threat the way a compromising modernizer is seen to be.

With the setting of boundaries comes the claim that participants are an elect people, God's own instrument. They know something of where history is going; it has been revealed to them by sacred books in which they find the fundamentals. By the way, it is easier to be fundamentalist in 'religions of the book' such as Judaism, Christianity, and Islam, than it is in faiths such as Hindu and Buddhist, where no single divine scriptural revelation is foundational.

The elect people, called to represent God, must keep themselves pure, try to recruit others, and, to use the words from the American struggle in the 1920s, 'do battle for the Lord.'

The battles may vary in character. Thus in most cases in the Islamic world, the enemy has not been the Great Satan of the US. In Algeria, Egypt, and elsewhere, the foe is a regime seen as corrupt, secularizing, and compromising even though all its leaders are themselves practicing Muslims. In Israel, the parties called fundamentalist may engage in warfare against Arab Muslims, but they take most pains to define themselves over against compromising Jews.

Action may be hortatory, prophetic, political, military, or terrorist, though it is often only the latter two that draw the world's attention.

4. Accounting for Fundamentalisms in Culture

No scholar claims that modern fundamentalisms have no counterparts or analogues in the past within the various religions. All of them have times and forces of traditionalist reaction and conservative aggression. It is valuable to study these analogues. But the word fundamentalism has more appropriately been reserved for responses to what has been seen as modern. One way to put it: these are reactive movements that appeared after the modern academy thought there would be no more like it, that the religions that survived would be small, weak, and always compromising.

Psychologists have on occasion assessed persons in the movements or the movements and generalized about their mentality. Participants tend to be people who cannot tolerate ambiguity, paradox, contradiction, or doctrinal and moral 'fuzziness.' Yet it is difficult to reduce fundamentalisms to this psychological cast, given the fact that people with such predilections in one culture turn religious fundamentalist and those in others do not.

Political and social scientists perceiving fundamentalisms in culture often relate the rise of such movements to class conflict. Marxist interpretations,

for example, can see them as futile resistances by people who take resort in other-worldly solace when they can do little to gain in this world. It is true that in many instances it is the poor and apparently powerless that turn to fundamentalism. But it is also true that those who react may do so from the comfortable confines of Princeton Theological Seminary and Princeton University, as the intellectual definers of early American fundamentalism did. And one will find fundamentalists of wealth in many an American city and note that some of these extravagantly fund fundamentalist projects. Class analysis does contribute to understanding the phenomena, but most scholars again resist reductionism of a sort that fundamentalists are 'nothing but' this or that.

Instead, they give evidence that they are complex responses and reactions to many kinds of cultural stimuli and as such manifest features that are best appraised with a variety of perspectives and disciplines. Among these would be humanistic efforts to bring to bear history, philosophy, and religious studies. These are, after all, self-described religious movements, and seen to be such.

One way to approach the study is to listen as anthropologists do for 'agent's description.' Someone who pays attention to, records, and coordinates the testimony of fundamentalists in many religious contexts will find that the issues that evoke response begin very close to the self of the believer. Diplomats, reporters, and scholars often begin at the furthest extensions of fundamentalisms, as when some engage in terrorism or revolutionary military action.

Instead, whoever is alert to fundamentalist witness will be indeed close to the ego's center. The believer begins by defending a world-view, including one that has been recently changed thanks to conversion. The world looks different to someone who is an initiate, 'born again,' in some versions, than it does to someone else who is distant from or quiet about religious impulses. Very close to that egocenter is the question of personal, social, and cultural identity? To whom do I belong? Whom can I trust? With whom can I check signals and from whom do I draw inspiration? Those who ask such questions in the erosive climate and culture of late-modernity find that identity becomes a major question. They also note that it is threatened by forces such as travel, modern mass communications, mass higher education, especially where the challenges of pluralism and relativism are fierce.

As close to the center of the person as are world view and identity is the issue of gender. Fundamentalists preoccupy themselves with what it means to be a man or a woman. The Manichaean differentiation is strong: there is no room for ambiguity in defining gender. The fundamentalisms, for example, all reject homosexual expression. From gender they move to defense of family. In all the cultures studied by fundamentalist scholars, 'family values' and shoring up the family, however defined, is central to the program.

From the orbits of gender and family one moves to other challenges. Thus, one's mind and habits are shaped by mass communications, and fundamentalists tend to react by trying to screen out uncongenial images, to engage in boycotts, or attempt legally to censor and exclude broadcast or published materials that they believe to be evil or subversive of their values.

Education is another zone in which fundamentalists do battle. They start their own schools to protect and nurture their own young and often engage in efforts to subvert the character of others', especially the public's schools, when their teaching and habits are offensive. Similarly, many of them have challenged modern medical practices, and make the clinic their arena of conflict. They organize against abortion, euthanasia, and many forms of treatment that violate their view of the body as God's temple.

In the sphere of economics it is harder to generalize. Some religious texts favored by fundamentalists—notably those detailing *shari'ah*, Islamic law—may be explicit was when they proscribe the taking of interest. But some fundamentalist movements promote communal, one might say communistic economic patterns, while others, notably in North America, often align themselves with *laissez-faire* economic forces. But when they perceive economic circumstances as a threat to them, they may adopt any number of strategies, and find their holy books less defining and definitive.

When it comes to efforts to change politics, for example, it is through the use of the instruments of political propaganda, the ballot, and constitutional revision, that fundamentalists find themselves reckoned with most strenuously. Where they cannot take over a regime, they may in God's name undertake revolutionary activity. It is activity of that sort that elicits headlines about fundamentalist militants around the world.

Religious Nationalism and the Secular State: Cultural Concerns

According to a widely held view, 'nationalism' is an aspect of the process of secularization, which limits the role of religious ideas and institutions in public life. Religious nationalism is therefore considered inimical to the 'secular state,' which is uninvolved with or neutral in religious matters. Empirical evidence how-

ever, reveals, that the relationship is complex and context sensitive. This article examines this complexity with special reference to South Asia where the two kinds of nationalism have long been in conflict and where both secular and religious states exist. Comparative perspectives from the West and the Middle East help frame the argument.

1. European Origins of Nationalism and its Diffusion

Although emphases differ, definitions of nationalism generally converge on the idea of a people's identification of themselves as a 'nation' that already is, or is expected to become, an autonomous state with its own territory. Moreover, the individual's emotional identification with the nation, and loyalty to the state, are of crucial importance. They find expression in the ideology of nationalism, which is a blueprint for the capture and use of political power for furthering common interests.

It has been argued that without nationalism there would be no nations or nation-states—that nationalism 'invents nations where they do not exist' (Gellner 1964, p. 169) and holds them together where they do. It is recalled that in Western Europe, the eighteenth century marked not only 'the dawn of the age of nationalism,' but also 'the dusk of religious modes of thought' (Anderson 1983). Ironically, secular nationalism everywhere, since the French Revolution, has displayed the characteristics of a religion both structurally (doctrine, myth, ritual, etc., are present) and functionally (an overarching moral order is provided). This is illustrated by the growth of 'civil religion' in America (Bellah 1970), transforming a historically developed national political system into a moral order.

In the articulation of nationalism, particular dimensions of collective identity (geographical, historical, cultural, or ethnic), or particular combinations of them, are highlighted. These emphases are variable not only from place to place, but also over time in the same place. One of the identity makers everywhere is religion, but religious nationalism is considered an anomaly, and not seen to be the most suitable cultural setting for a modern secular state in which individual identity is clothed in citizenship rights that override religious and ethnic distinctions.

One of the key questions about nationalism concerns its beginnings. Some scholars have argued for a Western European origin, whereas others maintain that England was the first modern nation ever. Still others consider North America to be its true place of efflorescence: the notion of the nation was implicit in that of 'the people' in the Declaration of Independence and is central to the American Constitution of 1789. Its inspiration is said to have been a unique combination of secularization, industrialization, capitalism, print technology, etc., that 'created the possibility

of a new form of imagined community, which in its basic morphology set the stage for the modern nation' (Anderson 1983, p. 49).

The Western origins and secular character of nationalism have been questioned. Kohn (1955) argued for Hebrew and Greek origins of the concept 2000 years ago, but affirmed that, as a fully fledged ideology, it came into play in England in the seventeenth century. Hastings has written that the Bible presented 'in Israel itself a developed model of what it means to be a nation—a unity of people, language, religion, territory, and government' (Hastings 1997, p. 18). For him the nation and its ideology are 'characteristically Christian things' (Hastings 1997, p. 186).

One of the many strands of Hastings' argument is that since Christianity did not have a sacred language, the availability of the Bible for translation and the activities of the local clergy in different parts of Europe resulted in the fostering of a 'sense of shared local, provincial, or national identity' (Hastings 1997, p. 192). He maintains that nations and nationalism outside the Christian world bear witness to the 'imitation of the Christian world,' although the mimesis may be regarded as westernization (Hastings 1997, p. 186). According to Hastings, while 'Christianity has of its nature been a shaper of nations, even of nationalism; Islam has not, being on the contrary quite profoundly anti-national' (Hastings 1997, p. 187). Orthodoxy notwithstanding, Muslims have embraced nationalism in many places in the twentieth century, e.g., in Turkey, where it appeared as a secular ideology in the 1920s, and in India, where religious nationalism became the basis for the partition of the subcontinent.

2. Secular and Religious Nationalism in South Asia

2.1 India, Pakistan and Bangladesh

For 100 years, beginning in the middle of the eighteenth century, British colonial territories in the Indian subcontinent expanded steadily through conquest and annexation. An image of Indians as a congeries of religious communities, castes, and tribes was assiduously cultivated. District gazetteers, compendiums of tribes and castes, and census reports recorded the divisions among the people. Such divisiveness was welcome from the colonial point of view as it helped strengthen the hold of the alien ruling power.

Ironically, however, British rule itself helped regenerate an Indian national consciousness, a prototype of which had been discernible in the heyday of the Mughal empire (seventeenth century). Establishment of law and order under the aegis of a centralized authority structure, in place of the chaotic conditions that characterized the disintegration of that empire in the first half of the eighteenth century, was one such

major factor. Also important were the introduction of railways, postal and telegraph services, education through the medium of English modeled on British schools and colleges, and newspapers in the nineteenth century. Resentment over the denigration of India's cultural heritage as 'an unmixed evil' (Henry Maine's phrase) by civil servants and Christian missionaries helped create a shared sense of common identity vis-à-vis the British. By the 1870s, 'a feeling of nationality,' in the words of a colonial magistrate, 'had sprung up in India' (see Mehrotra 1971, p. 144).

One of the main objectives of the Indian National Congress, established in 1885, was 'the fuller development and consolidation' of 'sentiments of national unity' (Mehrotra 1971, p. 413). The fact that it was attended by delegates from virtually all parts of the country, who included Hindus, Muslims, Parsis, and Christians, seemed credible evidence of (as a newspaper put it) 'the existence of something like a nation in India' (Mehrotra 1971, p. 419). Indeed, a year later, the highest British official in India, viceroy Dufferin, wrote of his sympathy for 'the aspirations of a nation so similarly circumstanced as my own [the Irish]' (Mehrotra 1971, p. 398).

The secular character of the Congress soon came under severe strain owing to the refusal of certain prominent Muslim leaders of northern India to join it. The position of the Congress was that 'the common benefit' of the people of India transcended the interests of any particular community, and that the two sets of interests were not necessarily in conflict. The emergence of secular nationalism had been preceded by the assertion of a sense of common nationality among Hindus, overriding significant regional and sectarian differences among them. Many of them brought residues of Hindu nationalism into the Congress strengthening Muslim fears.

Muslim separatism led to the formation of the Muslim League in 1906 with the aim of furthering the community's interests. In the course of time the viewpoints of the Congress and the League came to be designated as 'nationalism' and 'communalism,' respectively. Whereas the former considered territorial unity the crucial element of nationalism, the latter considered it irrelevant in Indian conditions and focused on religious identity.

The foregoing antagonism eventually led to the 'theory' that Hindus and Muslims were two nations, irreconcilably divided by history and culture, and each legitimately aspiring to be a nation-state. British rule ended in 1947 with the partition of the subcontinent into India and Pakistan. India created for itself a secular state in which citizenship rights stand above ascribed identities. Contrary to the stated secularist views of its founder, M. A. Jinnah (died 1948), Pakistan was proclaimed an Islamic state where traditional Islamic law would have precedence over other laws, and where Sunni Muslims emerged as the privileged community.

Pakistan was a unique state as it comprised two wings separated by 1,000 miles of Indian territory. The fragility of religious nationalism became obvious within a year of its founding in the context of a *lingua franca*. The people of East Pakistan, who accounted for more than half of the country's population, resisted the declaration of Urdu, the mother tongue of the urban Muslims of northern India, as the national language. Bengali was therefore accorded the status of the second language. Culture and language became rallying symbols for discontented East Pakistanis, who increasingly complained of economic exploitation and denial of political rights at the hands of a succession of 'central' governments that had their seat in West Pakistan and were dominated by the natives of that wing.

Eventually, Pakistan split in 1971, and a new nation-state, Bangladesh, came into existence. Bangladesh adopted a constitution that was secular in character. The original considerations that legitimized partition in 1947 survive, however, and are exploited by some political parties. Islamization of Bangladesh's national culture, and the constitutional redefinition of the state as one that derives its legitimacy from Allah, emphasize the obstacles that confront the secular state in South Asia.

It has been argued that the enormous cultural and religious diversities of India necessitate a pluralist ethos and the secular state, and indeed guarantee them. The Constitution (Article 25) grants every citizen the fundamental right to profess, practice, and propagate the religion of her or his choice. It also prohibits discrimination between one citizen and another on the basis of religion. All major political parties that have held power at the state or union (federal) levels uphold the concept of the secular state. One of them, the Bharatiya Janata Party (BJP), is widely considered communal in view of its following, which is virtually exclusively Hindu, and its adherence to the ideology of Hindutva (lit. 'Hinduness'). Originally put forward in 1923 (BJP itself is a post-independence party), Hindutva equates Indian identity with Hindu identity, and defines the latter in terms of a combination of territorial and cultural criteria (fatherland and holy land should be one). The ideology points to political domination through cultural homogenization, and is hostile to pluralism. BJP emerged as the leading partner in the coalition union government that was formed in 1998. The exigencies of coalition politics have resulted in the de-emphasizing of Hindutva but not its abandonment by BJP. The ideology is synonymous with religious nationalism and therefore a threat to the secular state.

2.2 Sri Lanka

The Sri Lankan Constitution also is broadly secular in character. Although a 1972 constitutional amendment

recognized 'the foremost place' of Buddhism as the religion of the majority, there is no state religion, nor discrimination in respect of citizenship rights between the followers of different faiths (Buddhism, Hinduism, Islam, and Christianity). The fact that the ethnic Sinhalese constitute 70% of the population and are Buddhists has been a source of communal strife and has imposed severe pressures on the state.

Beginning in 1953, when the call for replacing the secular state by a Buddhist one was first made, politically organized Sinhalese have carried on campaigns against the Tamils of the northern and north-eastern regions of the country (mainly Hindus and Christians) for their secessionist ambitions (the Tamils in turn complain of Sinhalese domination) and against a succession of governments for not being sufficiently responsive to Sinhalese aspirations. Prime Minister Solomon Bandaranaike, a convert from Christianity to Buddhism and more sympathetic to such aspirations than his predecessors, was nevertheless assassinated in 1959 by a Buddhist monk. Altogether the Sinhalese nationalists won many concessions during the 1960s and 1970s.

A watershed in the ethnic strife was the countrywide anti-Tamil upheaval of 1983 that had its epicenter in Colombo. It followed the killing of a dozen Sinhalese soldiers by Tamil militants. By official count several hundred Tamils were killed; the Tamils claimed that thousands died. Sinhalese militancy represented by Janatha Vimukhti Peramuna (JVP; People's Liberation Front) was eventually brought under control in 1989–90 by President Premadasa (himself a Buddhist) through accommodation of sections of the Buddhist leadership and ruthless suppression of JVP cadres. But he, too, paid with his life for his resistance to the secessionist movement led by the Liberation Tigers of Tamil Eelam (Nation).

3. Comparative Perspectives

The conflict between religious nationalism and the secular state is vividly illustrated by the wide range of events in South Asia in the second half of the twentieth century. Religious nationalisms are present elsewhere too in confrontation with a secular state or in association with a religious state that is modern in some of its objectives (economic development, political stability) and methods (elective government).

The Iranian revolution of 1978 established an Islamic state after overthrowing the modernist regime of the Shah. The earlier ouster of King Farooq of Egypt in 1952 had been followed by the establishment of a secular government under Gamel Nasser, which set out to suppress religious nationalist groups such as the Islamic Brotherhood. Although his successor, Anwar Sadat, made many concessions in their favor,

he died at the hands of Muslim extremists. Religious fundamentalism and nationalism are a considerable combined force, but President Mubarak has so far succeeded in holding it at bay. In Turkey, too, the secular state founded by Kemal Ataturk remains intact but religious revival has made significant inroads into Turkish society and nationalism. Although the patterns vary, religious nationalism today is a force to reckon with among the Muslim nations.

Religious nationalism played a significant role in the disintegration of the former USSR and the emancipation of East European countries from totalitarian socialist regimes. It obviously is not an essentially reactionary force in all circumstances. The comparative perspective brings into question many assumptions about the western origins and secular foundations of nationalism. Religious nationalism is a mixture of diverse elements, not all of which are present everywhere. Some of them are in principle unexceptionable, such as the emphasis on the moral dimensions of political behavior. The overall record of religious nationalists, however, is marked by their opposition to pluralism, which is one of the primary conditions of humane governance, particularly in ethnically plural societies.

Religious Organizations

Religious organizations seek to establish, promote, and regulate relations between human beings and divinities, supernatural orders, or supreme metaphysical principles. This article explains why religious organizations have been distinguished from non-religious organizations and why their distinctiveness lies mainly in their varied patterns of authority and leadership.

1. Diversity

Religious organizations are immensely varied but they typically aim to promote worship, prayer, meditation, teaching, healing, and spiritual well-being in accordance with authoritative revelations, texts, codes, laws, and principles. They range from the groups of 'clients' who regularly consult self-appointed healers, gurus, and shamans to worldwide ecclesiastical bureaucracies such as the Roman Catholic Church. Informal and irregular religious practices can be nested inside highly formal religious organizations.

The distinctive 'products' of religious organizations are equally diverse: sacred knowledge, transcendental experiences, prophecies, worship and meditation, rituals with the power to cleanse or heal, rites of passage, religious ethics, recruiting missions, political, welfare, and educational outreach, local fellowship, and so on. They also have much in common with nonreligious organizations in so far as they face the need to secure adequate resources, to train and control staff, to retain their authority, to cope with dissent and conflict, to interact with other organizations in their environment, to defend their share of the religious 'market,' and to deter 'free riders,' and unwelcome takeovers. Religious organizations have therefore established schools, seminaries, hospitals, welfare agencies, publishing enterprises, and missionary orders in order to extend and protect their boundaries.

2. History

The history of studies of religious organizations can be divided into two streams. The first is concerned primarily with the distinctiveness of religious organizations and with their subtypes. The second, which has flourished since the 1950s, deals with the internal dynamics and shifting fortunes of religious organizations in their social environments.

2.1 Types and Subtypes

The intellectual rationale for the pioneering and highly influential studies written by Max Weber (1864–1920) and Ernst Troeltsch (1865–1923) had its roots in their respective interests in the interplay between modernity and religion. Having established the crucial but unintended contributions of Ancient Judaism and Christianity towards the forms of modern rationalization, Weber analyzed the ironic implications of rationalization for the differentiation of religion from other institutions and value spheres. Secularization, bureaucratization, and the disenchantment of the modern world were all shown to have reduced the cultural and social significance of religious organizations. Weber perceived clearly that church-type organizations (large, territorially based, and inclusive in membership terms) had the potential to exercise power but were constrained by their ties to the secular world from translating their Christian ethics into uncompromising programs of action. By contrast, sect-type organizations (voluntaristic, relatively small, and exclusive in membership terms) were capable of maintaining a distinctive and often radical version of Christian theology and ethics but were prevented from exercising much influence on the world around them because they distanced themselves from it.

Troeltsch was less preoccupied with rationalization as a process and more concerned with the historical evolution of the social forms of 'church,' 'sect,' and 'mysticism' in which the New Testament's ethical message had found expression. Troeltsch was particularly exercised by the question of whether liberal Protestantism was robust enough and sufficiently well adapted to the conditions of modernity to serve as an effective vehicle for Christian ethics in an increasingly secular world.

The concepts of 'church' and 'sect,' plus numerous variants and subtypes such as 'established sect' and 'denomination,' have played an important part in many attempts to explain patterns of change in Christian organizations throughout the twentieth century. Some scholars have tried to apply these concepts to the analysis of religions other than Christianity, but it remains questionable whether this is appropriate in the case of religions lacking strong notions of membership and corporate authority. Yet, refinements of the sect concept have undoubtedly helped to explain the highly varied developments of minority religious movements, not only in Western societies but also in East Asia. Bryan Wilson's (1970) scheme of seven subtypes of sects has proved particularly fruitful and influential. The concept of 'cult' has also undergone extensive refinement, coinciding initially with public interest in the new religious movements which became controversial in many Western countries and Japan in the 1970s.

A further impetus for sociological studies of 'sects' and 'cults' began to develop in the 1980s when

proponents of rational choice theory claimed that previous usage of these concepts has been largely *ad hoc* and untheorized (Iannaccone 1988). On the assumption that people rationally try to attain their ends by the least costly means, in religion as in any other area of life, the theory holds that people incur the costs of participating in religious organizations in order to derive supernatural compensators which purport to give answers to questions of ultimate meaning. In this theoretical perspective, churches are believed to offer answers which conform with prevailing norms, whereas sects and cults allegedly deviate from the norms and incur sanctions or costs which are nevertheless experienced by their followers as selective benefits unavailable to members of 'lax' churches. The historical formation of sects (by schism) and cults (by innovation) can be accounted for in rational choice terms as a never-ending process of competition between religious organizations standing in different degrees of tension with society.

By comparison, the sociological concept of 'church' underwent relatively little change in the twentieth century. Moreover, little interest has been shown in refining or even applying the kind of cognate concepts of 'ecclesiola in ecclesia,' 'fraternitas,' and 'order' that Joachim Wach (1898–1955) and others elaborated. Nevertheless, studies of Christian organizations in Africa, Asia, South America, and the former Soviet Union have brought to light the importance of such organizational forms as 'independent churches,' 'base ecclesial communities,' and 'underground churches.' The continuing significance of relations between religious organizations, nations, and states in some countries has also preserved a place for 'church' in analyses of, for example, civil society (Casanova 1994) or international relations (Johnston and Sampson 1995). And extensive research in North America has thrown light on numerous aspects of 'denominations' as distinctive organizations. Beginning with the embeddedness of denominations in social classes (Niebuhr 1929) and ethnic groups, studies have analyzed the organizational conditions of schism, the ambiguous position of theological seminaries, the differential responsiveness to female clergy, the increasingly complex webs of 'interorganizational fields' in which denominations operate, and tensions between religious hierarchies and functional agencies. Another rich vein of research has investigated the contributions of denominations towards ideologies of pluralism, pluralistic provision of social welfare, social movements, and the 'independent sector.'

The study of religious organizations has been understandably less important in relation to religious traditions which tend to lack the formality, corporate authority structures, and membership principles characteristic of Christianity. Nevertheless, common foci of scholarly interest have emerged in the study of Muslim 'orders,' brotherhoods, and charitable endowments (*waqf*); Buddhist monastic institutions

(*sangha*); Hindu devotional groups (*bhakti*) and nationalist organizations; Jewish and Sikh communal organizations; and Shinto parishes.

2.2 Dynamics of Religious Organizations

The emerging concern with the organizational dynamics of religion in the 1950s was partly a reflection of the growing salience of 'organization theory' in the burgeoning social sciences, and partly a function of Christian theological interests in 'ministry' as a modern profession and in churches as complex organizations responding to rapid social change (Harrison 1959, Winter 1968, Beckford 1975). Yet the impact of these analyses of religious organizations on the development of organizational theories in general was modest. This state of affairs began to change slightly in the mid-1970s when notions such as 'organizational climate' and 'organizational culture' directed attention towards the significance of cultural factors which had always loomed large in analyses of religious organizations but which were emerging as important influences in virtually all kinds of organization. Investigations of communes gave a further impetus to research into the force of strong commitments and normative beliefs among organizational participants. Subsequent discoveries about the importance of rituals, retreats, flexibility, and networking in many organizations have only enhanced the interest that religious organizations now have for some organizational analysts (DiMaggio 1998). This minor rapprochement between the study of formal organizations and the study of religious organizations received a further boost in the 1980s when so-called New Age and quasireligious business began to attract attention for their practice of combining profit seeking with ethical business practices and of contributing towards the 'spiritual development' of their staff and clients. And fresh insights into the tensions between the 'religious' and 'agency' structure of US denominations (Chaves 1993) offer the prospect of explaining comparable tensions between the normative and functional bases for coordination and compliance in other organizations as well.

Two inter-related aspects of religious organizations stand out as the central foci for past and present research: authority and leadership. This does not mean that issues of organizational effectiveness, efficiency, and complexity are irrelevant in the case of religious organizations. It simply means that organizations purveying allegedly timeless truths and the highest normative commitments tend to be relatively more preoccupied than nonreligious organizations with establishing, reproducing, and defending their teachings and practices against corruption, subversion, or apathy.

3. Authority

Like profit-seeking organizations, religious organizations are engaged in competition with purveyors of rival versions of ultimate truths and in conflict with opponents, but they are also obliged to monitor and police their own members or followers. This is why questions of authority are central to religious organizations and why change often meets with strong resistance. In this sense, religious organizations are distinctive, if not unique, for the extent to which the connections between their founding truths and their organizational structure and everyday activities are constantly rehearsed in rituals, symbols, exegesis of sacred texts, preaching, prayers, teaching, meditation, and the training of leaders.

3.1 Sources of Authority

Christianity is virtually unique among the world's religions for the extent to which its practice has been controlled by centralized, formal organizations cutting across ethnic, tribal, and political groupings. By contrast, Hinduism, Judaism, and Shinto crystallized slowly out of predominantly tribal and ethnic cultures, giving rise to temples, synagogues, and shrines as centers of rites and ritual worship rather than as agencies of civil administration. Diasporic Judaism, lacking the authority previously vested in the Temple at Jerusalem and its hereditary priests, regrouped around rabbis as teachers of the law and around synagogues as ritual centers. Communal organizations have played a major role in preserving the ethnic and religious identity of Jews under persecution, but centralized organizations to control Jewish beliefs and rituals are relatively weak.

Buddhism and Islam emerged from more deliberate attempts to cultivate religious and philosophical systems partly at odds with prevailing culture and social arrangements, and this feature of their historical emergence may help to account for the fact that they have been closely allied with political regimes at various times. Thailand and Japan, for example, have had something approaching Buddhist parish systems. Modern Japan has also seen the rise of massive, hierarchical organizations of Buddhist laypeople such as Risshō Kōsei-kai and Sōka Gakkai. But elsewhere in Asia, Buddhism functions like a diffuse folk religion supported by monastic institutions and temples.

The organization of Islam is subtle, multistranded and variable by region of the world. As a conversion faith Islam has been interwoven with political regimes, but it does not have a single, authoritative organization. There are multiple, competing sources of theological, legal, spiritual, and moral authority in Islam, for the authority of learned experts, jurists, hereditary sheikhs, leaders of brotherhoods and clergy (among the Shi'ites) are all part of the complex

organizational tapestry of Islam. This high degree of complexity makes it difficult for any single organization to claim convincingly that it represents all Muslims. Now that tens of millions of Muslims live as religious minorities in the predominantly Christian countries of Europe and North America, pressure may be increasing for would-be representative organizations to seek to represent all Muslims in their collective relations with nation states, nongovernmental organizations, and the European Union.

3.2 Forms of Polity

The variety of organizational forms and processes which translate these concerns with authority into action is bewilderingly wide. They range from loosely structured fellowships to vastly complex and formal organizations which require their members to accept centrally imposed dogmas and rituals mediated by authoritative officials. In practice, most religious organizations fall somewhere on a continuum between these two extreme positions, but their precise location may change in response to factors internal or external to the organizations. Moreover, the time-honored distinction between church- and sect-type organizations cannot be mapped on to the distinction between religious organizations with either strong or weak systems of authority.

The convention of classifying the polity of Christian churches as Episcopal, Presbyterian, or congregational relates to the distribution of authority as laid down in their respective theologies and legal constitutions. In particular, the distinction between ordained clergy and laity is given theological justification, and the differential authority accorded to different grades of religious professionals is explained in the same terms. Yet this classification can only be a starting-point for social scientific analysis, since the readiness of subordinates to comply with authoritative commands from their superiors is variable, and pressure from outside the churches may make it necessary to modify the practical implementation of the ecclesiastical principle. For example, the Episcopal polity of churches in the worldwide Anglican communion conceals a wide diversity of relations between bishops and other church members. Presbyterian and congregational polities have also come under pressure to adapt the exercise of authority to prevailing socio-cultural values and conditions. Thus, critics of the patriarchalism allegedly underpinning many forms of Christian organizational polity have challenged the gendered distribution of authority in churches and tried to infuse them with feminist, antihierarchical values (Wallace 1992, Nesbitt 1997). Moreover, the ideal of congregational autonomy finds itself in tension with political or economic pressures to extend the authority of regional or national officials.

3.3 Fundamentalism

The increasing popularity and influence of so-called fundamentalist forms of religion roughly since the 1950s in many parts of the world and in most of the major faith traditions has prompted social scientists to pay greater attention to religious authority (Marty and Appleby 1991). Fundamentalism centers on faith in the authority of certain principles, usually enshrined in sacred texts, to generate unequivocal guidance for the conduct of personal and public life, and it favors assertive leadership and a strong suspicion of anything outside the group of committed believers. Yet the organizational bases of fundamentalism are diverse and subtle. There is no single, monolithic organization in any faith tradition or country which promotes fundamentalism. Instead, it has spread by personal witness, small group discussion, and the use of computerized mailing lists, terrestrial and satellite television and radio broadcasts, video cassettes, email, and the World Wide Web. Fundamentalists utilize modern technology and organizational forms in order to transform the world, and are not traditionalists, 'antimodern,' or withdrawn from the world. On the contrary, their aim is to make the world conform with their authoritative principles, and this calls for forms of organization which are flexible and responsive to local circumstances.

4. Leadership

4.1 Roles

Leadership roles, structures, and training vary widely between faith traditions, between their different 'schools' or denominations and between different parts of the world. The precise pattern of leadership at any level is shaped mainly by prevailing ideas about the source and nature of sacred power. Leaders of religions which identify sacred power exclusively with scriptures and laws derive their authority mainly from the capacity to read and interpret them. Judaism and Islam exemplify this pattern of leadership by scholars, teachers, and jurists. Priesthood, by comparison, is found in religions such as Hinduism, Shinto, Christianity, and Sikhism which combine reverence for sacred texts with belief in the capacity of priests to perform rituals allowing humans to interact in various ways with divinities and sacred power. The office of a priest enables this power to be effective through properly conducted rituals. Prophets and charismatic religious leaders may reform religion by opposing institutionalized practices and beliefs with radically new or different ones. Ministers of religion in most of the Protestant traditions offer leadership mainly through their preaching, exposition of scripture and, at least in evangelicalism, efforts to persuade individuals of their sinfulness and urgent need to seek

redemption. Monks, nuns and 'holy men,' as the 'virtuosi' in some religious traditions, exercise leadership on the strength of their extraordinary discipline, devotion, and selflessness. The *sangha*, or monastic community, remains at the heart of Buddhism in many parts of the world; monastic institutions were the bulwark of Christianity throughout the European Middle Ages; Catholic religious orders were in the forefront of missionary work in Africa, Asia, and South America in the modern era; and monks continue to occupy the highest leadership positions in Orthodox churches. But religious traditions which locate authority in the spiritual freedom of individuals to cultivate their own, relatively independent path to the sacred tend to resist strong notions of leadership, preferring at best to have spiritual exemplars, teachers, or gurus.

4.2 Local Groups

It is common for religious leaders to be attached to a particular building or social center where they conduct teaching, preaching, meditation, workshop, prayer, or pastoral functions. Some also have responsibility for the spiritual oversight of institutions such as schools, seminaries, orphanages, hospitals, refuges, and pilgrimage sites. Christianity went further than other religious traditions in establishing a comprehensive system for delivering religious and pastoral services to geographically demarcated areas known as parishes, which represented subdivisions of national or international churches. The idea that the residents of a locality would belong to a parish and form a congregation of regular worshipers under the leadership of local clergy was especially effective in European regions where the dominant church was closely aligned with political regimes.

4.3 Congregations

Congregations are the basic unit of most Christian organizations in the sense of being the social group with which their members in particular localities feel most closely associated. The precise status of congregations varies with the theology and authority structure of the larger religious organizations to which they belong. The congregations of hierarchical churches are local outlets of ideas and practices controlled by regional, national, and international authorities such as bishops, cardinals, and the Pope. By contrast, religious organizations which have little or no theological justification for hierarchy or central control tend to regard local congregations as relatively autonomous units. This is common among, for example, independent fellowships of conservative Protestants, the Reform Synagogues of Great Britain, and the Christadelphians. The implications of the balance that Christian organizations achieve between centrali-

zation and local autonomy have been extensively researched because it reveals differences in the extent to which congregations can generate resources, mobilize members in campaigns, respond to internal problems, and influence public life (Hong and Roozen 1979).

As Hinduism, Islam, Judaism, and Sikhism are not structured on the basis of inclusive, unitary organizations at national or international levels they have not generated congregations or systems of parishes. Yet, temples, mosques, synagogues, and gurdwaras do function as ritual and pastoral centers for people living in their vicinity or choosing to visit them. Lacking strong integration into higher level organizations, however, these local centers are accountable either to their private owners or to their management committees. Consequently, their religious leaders are retained as professionals or qualified volunteers by local groups rather than as employees of ecclesiastical organizations at a higher level.

4.4 Recruitment and Training

In advanced industrial societies the attractions of work in positions of religious leadership are weakening, and the rate of applications for training as religious professionals has been declining since the middle of the twentieth century. At the same time, the characteristics of recruits to religious leadership in Christian churches have also changed. They now include a much greater proportion of women, of people over the age of 30, of people retiring early from other occupations, and of people from a wider range of ethnic and social class backgrounds. The 'feminization' of religious leadership is occurring in many churches in so far as the proportion of women entering theological training and Christian ministry has been rising steadily since the 1960s (Wallace 1992). Yet the upper echelons of most churches are still controlled by men, and there is evidence that various mechanisms still prevent women from enjoying genuinely equal opportunities for professional advancement. Women are even more strongly excluded from leadership roles in the other world religions, although they have been admitted to the rabbinate in some traditions of Judaism.

It is only in developing countries that there is still a relatively strong supply of young men and women for theological training and preparation for the ministry or monastic vows. The disproportionately large numbers of trainee priests and ministers originating in developing countries may mean that the organizational 'center of gravity' of some large Christian organizations is in process of shifting away from Europe and North America. In effect, the new international division of labor is affecting religious organizations as well as transnational businesses.

5. Questions About the Future

Three emerging trends in religious organizations call for special comment. The first concern settlers in countries of large-scale immigration who seek to establish their own faith communities or congregations (see Warner and Wittner 1998). How far will these communities conform with prevailing forms of religious organization in their new setting? How far will their forms of organization come under pressure to meet the criteria laid down by stage agencies if they wish to deliver health, welfare, or educational services? And to what extent will their forms of organization influence longer established religious groups?

The second concerns the effect of new information technologies on the capacity of religious organizations to extend their influence to virtually all parts of the world. Will satellite broadcasting, video recordings, and the Internet increase competition between religious organizations? And will they cultivate a globally standardized form of these organizations?

The third emerging trend is for the appeal of 'special purpose' agencies to cut across the boundaries between Christian congregations and between denominations in the USA, thereby making ideological differences *within* religious organizations more challenging than the differences *between* these organizations (see Wuthnow 1988). Is there evidence of this kind of restructuring in other world religions? Does this repositioning of organizational 'fault lines' facilitate or hinder transnational religious developments?

Religious Specialists

'Religious specialists' is a generic term referring to select individuals or a category of individuals within different world faiths who undertake a particular responsibility for religious functions such as teaching, contemplation, transmission of scriptures, leadership, pastoral care, or ritual, on behalf of the religious community they serve. The nomenclature used to describe religious specialists differs according to the various religious traditions, but the idea of prophets, teachers, a priesthood and/or contemplative monastic orders is common to many world religions. Most religious specialists either will have inherited their role or will have responded to a sense of Divine calling to a particular and often strict way of life and adherence to religious disciplines.

1. The Scope of Different Religious Specialists

A community of people who share a particular ontological understanding of the world have often been inspired by prophets or religious teachers who have acted as intermediaries between the Divine and earthly realms. The prophetic role has often involved receiving revelations, and acting as an exemplar of these revelations. As religious communities grow in size numerically and geographically, and become increasingly complex, a need arises for individuals with particular knowledge and authority to oversee the religious belief and practice of the group. The need for a range of different religious specialists may become apparent, e.g., to regulate religious activities, to preserve and recite scriptures, or to lead worship, and in time, a hierarchy of different specialists with a specific authority and leadership may emerge. Access to particularly significant holy sites and shrines, or sacred texts, may be limited in some traditions to

religious specialists only. In many ways, prophets are the direct opposite of priests, since the former are often a force for change in society, challenging existing practices and beliefs, while the latter serve as representatives of a religious community and seek to maintain existing practices. Charismatic religious specialists in some ways stand between prophets and priests, since they are often the source of new ideas and practices, but within existing frameworks of community and belief.

In the major monotheistic religions of the world today, Judaism, Christianity, and Islam, there is a range of religious functionaries. Despite the common link between these three faiths, there are some significant differences in the various types of religious specialists that have emerged in each. In Judaism, a rabbi does not, strictly speaking, have a priestly role, but rather a responsibility for teaching and spiritual guidance. Historically, alongside the Hebrew prophets, were sages or wise men whose writings comprise, among others, the Book of Proverbs.

In Christianity, there are two principal avenues for professional religious activity, namely pietistic contemplative, and priestly. Amid the diversity of Christian traditions, the Orthodox, Catholic, and Anglican denominations in particular have a history of contemplative monastic orders for both men and women. These orders have often been inspired by the examples of saints such as St. Francis of Assisi, and members of these religious communities aspire to follow the exceptional qualities of their founders. Other religious specialists in Christianity include priests or clergy whose role often combines a range of functions, such as pastoral care, leading worship, and teaching, generally focused around a church or place of worship.

In Islam, there is no such priestly equivalent, but there is nevertheless a range of religious specialists. An imam may be regarded primarily as a ritual specialist with particular responsibility for leading congregational prayers in a mosque. The title also has honorific connotations, perhaps in denoting the leader of a particular community or group. Among Shi'ite Muslims, the term imam has yet another meaning as an intercessor between Allah and humanity. The framework for Islamic life and conduct, individually and communally, is shaped by the Shari'ah, or Islamic law. Scholars with a particular knowledge of Islamic law and teachings, known collectively as ulema (singular alim) assist with the development of Islamic thought, while muftis are legal functionaries empowered to make fatwas or legal rulings. In the Sufi or mystical tradition of Islam, the spiritual leader of a community is often known as a sheikh.

Even between the three major monotheistic traditions, there is a clear diversity in the type and remit of different religious specialists.

Indian religions, especially Hinduism and Sikhism, share the concept of a guru or teacher. Sikhism is

founded upon the teachings of 10 successive Punjabi gurus during the sixteenth and seventeenth centuries, while in Hinduism, the term guru has a more generic connotation as a religious teacher who gives personal instruction to devotees. Brahmins are at the top of the Hindu caste system, and as religious professionals their role principally involves the transmission of sacred Sanskrit texts and the performance of priestly sacrificial rituals.

The monastic life is perhaps the defining feature of religious specialists in the many traditions of Buddhism, whether Tibetan, Zen, Theravadin, or Japanese. Not surprisingly, therefore, many of the titles associated with Buddhist religious functionaries relate to the hierarchy of the monastic order. With Buddhism becoming increasingly popular in the West, different titles such as Ajahn, Bhikkhu, Roshi, Lama, and Rinpoche are becoming more widely known and understood.

In traditional societies and communities, shamans are religious specialists with the supernatural power to contact the spirit world during ecstatic trance states, often induced through dance, intoxicants, drumming, or chanting. They are not priests, nor medicine men, but are said to have the ability to foresee and predict the future, to quell the forces of the spirit world, and undertake extreme privations without feeling pain.

Despite the wide variations among religions in terms of religious functionaries and their various roles, there are some common sociological features of professional or specialist religious activity.

2. *Becoming a Religious Specialist*

Those who dedicate either all or part of their lives to religious work are often regarded as having a vocation rather than a job. Social scientists are not so concerned with the theological or supernatural implications of vocation, but rather with visible and measurable aspects of professional religious life, such as recruitment and training. In his study of American Catholic clergy, Fichter notes that 'the ecclesiastical vocation is not only a supernatural calling, a state of life and social status. It is also a specialised social role through which the manifold functions of the Church are performed. Obviously then, he (the priest) is engaged in a full-time profession or occupation which can be submitted to sociological comparison and analysis' (Fichter 1961).

2.1 *Recruitment and Training*

Personal connections and example often have a bearing on recruitment to professional religious life. This partially explains why vocations often cluster in families and kinship groups. In some world religions, religious roles are inherited through a lineage of teachers or leaders. Entering professional religious service is a lifelong commitment in many instances,

while in others an individual may through tradition or personal choice undertake to become a religious specialist for only a short period of time. A good example of the latter can be found in the Theravadin Buddhist tradition where it is common for young boys of school age to be ordained as monks for a limited period during their youth.

Most religious traditions have well-established and well-known expectations and qualifications for people interested in becoming religious functionaries, either in terms of knowledge or ethical conduct. As a step towards learning to become a religious specialist, it is common to undergo a period of isolation, training, and/or renouncing of worldly attachments. In both Buddhism and Christianity, those wishing to become monks or nuns often undertake a trial period of training as novices prior to ordination. In religious traditions where scholarly knowledge is a particular feature of professional religious activity, new recruits will often undertake an extensive period of specialist training to acquire the necessary knowledge and skills. Therefore, theological colleges or seminaries are common to the monotheistic traditions. Training institutions may be geographically isolated, or may be fully integrated into local communities, but the shift towards the latter as the locus for professional religious development is becoming more evident. This is partly due to the closing of the gap between lay communities and religious professionals, and the concern that communities have for specialists who are relevant and effective in modern societies.

2.2 *Ordination and Other Rites into Professional Religious Life*

Having successfully completed the necessary training period, whatever form that may take, some form of ceremony, initiation, consecration, vow-taking, or ordination into the religious profession is common. A number of symbolic actions or practices may take place, most of which have the function of setting apart the new religious specialist from the lay community. For example, the wearing of religious garb, such as a monastic habit or robe, or the marking of the body in some way, serves both ecological and structural purposes in 'locating' the individual within a community of fellow specialists. At the same time, a new name or religious title may be taken, and in some religious traditions, kinship terminology may be prevalent, such as 'Brother' or 'Sister.' These actions and rituals are part of the process of transformation into a socially recognized religious specialist.

3. *Religious Specialists—Some Sociological Characteristics*

Despite becoming socially recognized religious adepts, in many traditions it is common for religious specialists

to have a spiritual guide or teacher. This is a reflection of the life-long commitment that individuals make to their vocation, and the pursuit of spiritual development and perfection. The balance between, or combination of, self-centered and socially-centered spirituality and action will depend upon the characteristics of the professional role. Often there is no such thing as 'retirement' for religious professionals; they may retire from active functions certainly, but the nature of their calling entails a continuation of the religious role until death.

3.1 Status and Prestige

Most religious professionals share the social status of the group to which they belong. For example, the prestige and social standing of religious specialists in immigrant minority groups tends to rise or fall as a reflection of the upward or downward mobility of the migrant group. However, religious specialists who have subsidiary secular functions, such as social work or healthcare, may acquire recognition and status through these roles, rather than in their primary religious capacity. In some senses, religious specialists are classless individuals since generally they do not acquire status through earning nor, in the case of celibates, through favourable marriages. This does not mean, however, that they lack the possibility of status, since they can acquire other forms of recognition and prestige such as authority and other attributes of stature and power.

3.2 Professional Qualities and Hierarchies

Religious specialists can be considered as 'professionals' on a number of grounds. They are involved in a nonstandard product—religion. They undertake tasks and services that often cannot be repeated exactly, their work involves personal commitment and dedication, and they are required to have a broad knowledge of a specialized field and have authority both inside and outside the religious community. As specialists, they are often aspiring to personal development and improvement, and generally they share solidarity with other religious professionals. Like most professional groups, religious specialists, particularly in community contexts, are part of a hierarchical structure. Age, length of service, or the responsibilities particular to a role or office often determine hierarchy. The specialists who also have a leadership function face particular challenges in securing conformity, maintaining authority, and religious management of internal and external goals. The most senior members of the hierarchy generally have responsibilities that extend beyond the immediate community to a wide geographical area.

3.3 The Proliferation of Religious Specialists

In modern secular societies there has been a proliferation of work specialization. The study of careers in themselves has become a further branch of knowledge and expertise. The religious professional is yet another specialized career, and within it, there are further specialist activities, such as teaching, missionary work, or care of the sick. For example, some clergy within the Christian church feel called to chaplaincy roles often requiring a particular concern for groups of people in some way set apart from the rest of society, e.g., through imprisonment or hospitalization. The world of chaplaincy has in turn become more complex as society has become more fragmented and 'full-time personnel of the Church have been carried along on a wave of extra-ecclesiastical professionalism' (Fichter 1961).

In most cases, religious specialists are regarded as having a positive influence upon religious communities and society, in as much as their example and ministry inspires action and behavior that is socially beneficial. Most religious specialists are associated with having outstanding personal qualities of kindness, patience, tolerance, concern, holiness, devotion, sensitivity, intelligence, and wisdom. However, amid the proliferation of new religious groups and sects—most requiring leadership—some religious specialists have been so idealized, sometimes through their deliberate flouting of conventional norms and the employment of bizarre rituals, that their humanity and fallibility may be denied, and they are followed with unquestioning loyalty by groups of believers. The dangers of such an attitude have been manifest through the ages in collective acts of destructive or unconventional behavior inspired by the religious specialist or leader. There is sometimes a fine line between being a holy fool and a saint.

3.4 Religious Specialists and Gender

In most world religions, authority and power has been the preserve of men and most religious specialists in history have been male. In some world religions, nearly all formally recognized religious professionals are still men, and in these cases the situation does not seem likely to change in the immediate future. However, in other religious traditions and denominations, women increasingly are taking on roles as public religious professionals, through ordination, particularly in the lower strata of the religious hierarchy. Some of the exceptions to this historical bias towards male religious specialists are the monastic traditions of Buddhism and Christianity where separate orders for women have long been in existence and women have gained credit for their virtuoso religiosity. In various religious traditions over the course of history, individual women have been respected for their wisdom and devotion, such as the Muslim saint and mystic

Rabi'a of Basra (d. 801), and in some instances they have, informally, been the teachers of men. But rarely has this led to their admission into the select community of male religious specialists or scholars. Women have through time often done a great deal of unseen religious work, particularly in prayer and in the care of the sick. The increasingly professional and public role of women in religious life is a reflection of changing social attitudes and the senior roles that some women have achieved in other realms of public life.

4. Religious Specialists in the Contemporary World

The role of religious specialists today is carried out in social settings marked by a greater global awareness, increasing religious diversity, and pressures from within and outside the religious community. The impact of these pressures are manifold and have affected different religious traditions and religious professionals, collectively and individually, in various ways. It is beyond the scope of this article to examine these in detail, but some distinctive features of being a religious professional in modern society can be highlighted.

4.1 Religious Leadership in Minority Contexts

Historically, religious communities and faiths were often separated from each other through geographical distance, but the advent of modern communications has brought traditions together on a new and unprecedented scale. Most large cities around the globe will have a community of believers associated with the major religious traditions. In these contexts, religious specialists face the challenge of maintaining authority in a situation where religious professionals from other faith traditions also claim authenticity and authority.

There is evidence to show that over time religious specialists serving diaspora communities are often influenced by the dominant professional roles of the religious majority. For example, many of the rabbis serving Britain's well-established Jewish community have long-since expanded their primary teaching and education role, and they have a far greater involvement in pastoral care than historically and traditionally they once might. The idea of a 'Jewish chaplain' serving on a prison or hospital chaplaincy team is now commonplace. Even amongst religious communities with a much shorter history in Britain, there is evidence that the roles of religious professionals are changing. The largely ritual responsibilities of Muslim imams, based in mosques, is beginning to change as they too become more involved in public religious affairs, community support, and pastoral care in public institutions. In this respect, the gradual combining of pastoral care

with teaching and leadership of rituals indicates the influence of the dominant professional roles of the religious majority, namely the established Church of England.

4.2 Religious vs. Secular Professionals

Through an ongoing process of social differentiation, many of the functions of the religious professional have been usurped by other, nonreligious professionals or by the state. The marginality that religious professionals may face as a consequence, particularly in modern industrial societies, can and does have an impact on future recruitment and vocation. One of the consequences of the decline in the numbers of religious professionals (in some societies and religious traditions), has been an inevitable need for ordinary, lay members of religious communities to become more actively involved in tasks that were formally part of the priestly role.

A good example of how the remit of religious professionals has changed can be seen in the post-Second World War period, particularly in the West, with the dramatic expansion of interest in holistic and alternative therapies with counseling and psychotherapy part of a new industry of self-development. As Davie (1994) notes this has had two effects, namely, 'in usurping some of the traditional functions of a pastor and, secondly, in obliging that pastor—if he wishes to keep on terms—to acquire skills (including an extensive vocabulary) of a novel and essentially unreligious nature.' The curriculum for those undertaking theological training will now almost certainly require study of counseling, bereavement care, and other forms of pastoral care in order to be able to keep abreast of secular professionals working in the fields of therapy and self-development.

Religious Stratification

1. Introduction: Two Forms of Stratification

We can distinguish usefully between two separate sociological issues, namely the hierarchical stratification of religious roles in terms of their authority, and the stratification of religious communities within a general system of social stratification. The first line of inquiry considers the hierarchical organization of charismatic power within religious traditions; the second involves the historical and sociological study of the stratification of religious communities, especially in terms of social class and ethnicity. Both forms of religious stratification are analyzed from the sociological perspective of Max Weber (1864–1920).

For further treatment of these topics see *Religion, Sociology of*; *Religious Specialists*; *Charisma and Charismatic*; *Religion and Economic Life*.

2. Virtuoso and Mass Religion

The sociology of social stratification is concerned with the distribution of scarce resources and with the formation of social hierarchies by the processes of social closure and exclusion. The most common illustration of social stratification would be the unequal distribution of economic resources, resulting in a simple formation of economic classes. However, stratification also involves cultural distinctions such as education, lifestyle, and cultural consumption. Weber made an original contribution to the sociology of religion by treating charisma (a 'gift of grace') as a religious value that is also characterized by scarcity. Because these religious values are unequally and unevenly distributed in human societies, there is religious stratification. In *The Social Psychology of the World Religions*, Weber (1991, p. 287) asserted 'that men are *differently qualified* in a religious way stands at the beginning of the history of religion... the sacred values that have been most cherished, the ecstatic and visionary capacities of shamans, sorcerers, ascetics, and pneumatics of all sorts, could not be attained by everyone. The possession of such faculties as "charisma," which, to be sure, might be awakened in some but not in all. It follows from this that all intensive religiosity has a tendency towards *status stratification*,

in accordance with differences in the charismatic qualifications.'

Religious gifts (charisma) are in demand because they bring healing and salvation, but they are inevitably in short supply. The resulting hierarchy of spiritual gifts creates a stratification system that differentiates between the virtuoso and the mass, where the latter are, in Weber's terminology, religiously 'unmusical.' This hierarchy of intense religious values stands in contrast to and frequently in opposition to the formal hierarchy of the ecclesiastical organizations of Christianity that attempted to regulate and to control the flow of charisma.

This model of virtuoso–mass religion is connected with the specific forms of salvational drive in the world religions, namely with their soteriologies. Religious systems of soteriology may be directed either toward inner-worldly asceticism or toward other-worldly mysticism. Now all religions that place a special emphasis on rebirth and spiritual renewal will create a special category of religious aristocracy, because charisma cannot be institutionalized in terms of an egalitarian distribution. This virtuoso pattern emerged as a general characteristic of religious communities, for example, among the Protestant sects, the *perushim* in Judaism, the Sufi dervishes of Islam, and the Buddhist monks (see Weber 1965, pp. 151–65). The existence of distinctive forms of internal religious stratification has often evolved in sharp contrast to the official doctrines of egalitarianism and universalism in, for example, Christianity and Islam.

There is demand from popular religion to enjoy the benefits of virtuoso religion such as healing, and thus there develops a distinctive pattern of exchange between the virtuosi and the mass. In return for acts of charity and direct economic support from their followers, the virtuosi offer healing, guidance, and other charismatic gifts. The layman who is completely immersed in the everyday world needs the blessing of charisma, but in return the virtuosi depend on lay tributes merely to exist. This mutual dependency and reciprocity create the conditions whereby virtuoso religion can always be diluted or manipulated to some extent by the laity who demand tangible evidence of charismatic gifts in the form of magical displays. In fact, with the possible exceptions of Judaism and Protestantism, all religions and religious ethics have had to (re)introduce cults of saints, heroes, or functional gods in order to accommodate themselves to the needs of the masses (Weber 1965, p. 103). In Asia the religious teachers or *gurus* function as living saviors, while in Catholicism the veneration of the saints was the real basis of popular religion. In Hasidic Judaism, despite its popular appeal to the ordinary people through, for example, its use of dance as an expression of religious joy, there was also a clear division between the spiritual elite and their disciples. In these examples, Weber recognized a paradoxical tension between the spiritual quest for perfection in the virtuosi, the

pragmatic needs of the laity for healing and material sustenance, and the mutual reciprocity between elite and mass. Weber's sociology of charismatic roles was an application of philosophical critique of Christian morals by the German philosopher Friedrich Nietzsche (1844–1900), who had condemned Christianity as a system of slave morality and as a product of psychological weakness. Slave morals are created out of resentment by a subservient social class, and hence the Christian doctrine of love was analyzed critically as a subconscious doctrine of a resentful social group. Guilt and bad conscience played a pivotal role in Christian ethics. Against this moral system, Nietzsche argued in favor of a revaluation of values from a position of psychological strength. Nietzsche's genealogy of (Christian) morals in terms of a study of the stratification of values between slave and master moralities was translated directly into Weber's social psychology of the world religions (see Staught and Turner 1988). In Weber's treatment of the psychology of religion, he argued that certain social carriers were crucial in the development of the cultural systems of the various religions. In particular, he claimed, for example, that Islam had been carried by warriors, Buddhism by mendicant monks, Confucianism by court officials and the literati, and Christianity by artisans and craftsmen. These occupational groups were particularly important historically in providing the world religions with a specific soteriology. Thus, the world view of Christianity was shaped by the practical rationalism of artisans and craftsmen, and in the long run this rationalism proved decisive in the connection between the Protestant capitalists and economic rationalism. This thesis has been challenged and various historians have attempted to find similar connections between Jewish culture and the rise of capitalism (see Sombart 1951) or between Islam and capitalism (see Turner 1998). The core of the Weber thesis has survived these criticisms insofar as it attempts to identify important cultural connections between religious discipline, class position, and economic rationalism.

3. Religion and Social Stratification

Religious communities or groups can also be analyzed in relation to the general system of secular stratification in terms of social class or caste. There is an extensive and complex debate about the relationship between caste, occupational groupings, notions of pollution, and Hinduism. The conventional view was that concepts of purity in Hinduism functioned to sustain a social division of labor between manual and nonmanual occupations that over many centuries evolved into a complete hierarchy of caste. Although the Hindu caste system was organized in terms of four principal castes (Brahmin, Kshatriya, Vaisya, and Sudra), there was considerable diversity at the village

level, where these castes were typically subdivided into subcastes or *jati*. Castes were ordered hierarchically in terms of ritual separation around a notion of contagious pollution. This traditional pattern broke down in the twentieth century and there has since been some mobility whereby through the adoption of upper-caste cultural practices lower castes can move up the social scale, and the incorporation of marginal cultural traditions into the Brahmanical system. This process is referred to as 'sanskritization.' There is thus a debate about the differences between Asian and Western systems of stratification and the legitimization of such patterns of inequality by religion (see Dumont 1970). Some sociologists argue that the term caste can be applied to any system of rigid stratification where membership is permanent, hereditary, and guarded or legitimized by religious notions of purity. For example, in the southern states of anti-bellum North America, there is a continuing system of racial orders that is reinforced by the stratification of Christian churches along a division between blacks and whites. The National Baptist Convention, the African Methodist Episcopal, the African Methodist Episcopal Zion, and the Colored Methodist Episcopal churches emerged as exclusively black institutions and illustrate the racial stratification of American denominationalism (see Dollard 1998).

Although religion has played a significant role in the legitimization of social stratification, the relationship between religion and class has to be seen in a dynamic and historical framework. There is a considerable collection of historical and sociological research findings that explore the social mobility of individuals and groups as a consequence of their conversion to evangelical Christian sects. H. Richard Niebuhr's *The Social Sources of Denominationalism* (1957) is the classic illustration of this tradition in the sociology of religion. The basic argument is that 'the churches of the disinherited' have traditionally recruited from the poor and dispossessed through active evangelism. As a consequence of religious asceticism and education, individuals from the lower social classes move up the social scale. The same argument applies to the evangelical sects themselves which, as they become dominated by the lower-middle and middle classes, become more respectable. The process of denominationalization whereby sects acquire the characteristics of middle-class denominations in the United States has been paralleled to the social mobility of their individual members. The history of the Anabaptists, Quakers, Methodists, and Salvation Army exhibit this pattern of social change whereby sects become denominations (see Troeltsch 1931).

The churches of the middle class emphasize personal responsibility and individualism in theology, and restraint and formality in ritual. Their social teaching is concerned with individual behavior rather than with social redemption. The sects of the lower classes appeal to the deprivation of the poor through emotional

preaching, healing practices, and a collective eschatology of redemption. However, because these evangelical sects typically socialize the disinherited into the dominant values of a society, the poor rise through the social scale as they acquire the habits of temperance and personal discipline (Johnson 1961). The education of the laity slowly replaces their conversion. There is some support from the history of the evangelical sects for Max Weber's *The Protestant Ethic and the Spirit of Capitalism* because the personal discipline of the Protestant sects results in the social mobility of the disinherited into the lower and middle classes. Habits of saving, frugality, and temperance produced a reliable workforce that was compatible with the needs of capitalist discipline. In particular, the owners of industrial enterprises recognized that factory discipline could be maintained effectively through the employment of sober Christian workers (see Pope 1942).

4. Religion and Class Conflict

There is a close relationship between class membership and religious affiliation in which religious participation functions as a cultural ladder of social mobility. This association between evangelical Christianity and the working class suggested to Karl Marx (1818–83) that the promise of spiritual salvation compensated for the material deprivation of the disinherited. In the famous argument about human alienation in capitalism, Marx (1974, Vol. 1, p. 83) argued that for a society based on private property, 'Christianity with its cultus of abstract man, more especially in its bourgeois developments, Protestantism, Deism etc., is the most fitting form of religion.' Within the system of capitalist exploitation, Christianity was the opium of the people, because its emotional discharge served to obscure the real nature of class inequalities. While Marx treated Christianity in a cursory fashion, Friedrich Engels (1820–95) offered a more extensive treatment of the relationship between class, religion, and political consciousness. For example, he regarded Christianity in its origins as a religion of a class of slaves and oppressed that became eventually the dominant religion of the Roman Empire. There were close historical parallels between the rise of Christianity and the development of the European working class (see Marx and Engels 1955). Engels recognized that in the Reformation the peasant revolts were an expression of real material interests against oppression, and that Christian belief provided the peasantry with a powerful ideology of protest (see F. Engels, *Peasant War in Germany*, 1965). These peasant protests which drew upon the Bible as a source of social and political criticism were important because they provided a model of the millenarian struggles of the seventeenth century and the secular conflicts of the nineteenth century, when working class movements continued to absorb and transform the biblical language of protest

against capitalism. Methodism often provided the training ground for political protest, because the tradition of lay preaching provided a pedagogy of popular opposition. Popular leaders who emerged within the ranks of the Methodist chapels typically were expelled from the church because their secular radicalism was incompatible with the conservative teaching of the Methodist chapels (see Thompson 1963).

In the seventeenth century, the religious sects of the peasantry and yeomanry were important engines of social change in the English civil war. In the eighteenth century, Methodism had through its emotional preaching provided a compensation for this worldly deprivation. In the nineteenth century, there was an unstable alliance between working-class protest and the evangelical sects, whereby the idiom of protest depended more on the Bible than on Marxist ideology. In the English case, these causal connections between politics and religion were summarized in the Halévy thesis, which suggested that Wesleyan Methodism functioned as a social ladder between the nonconformist dissent of the artisan and the Anglican establishment, thereby contributing to social stability and evolutionary political change (see Halévy 1962).

5. Conclusion: Religion, Class and Egalitarianism

Whereas religions like Confucianism and Buddhism have not systematically provided or embraced an ideology of radical egalitarianism, the Abrahamic faiths of Judaism, Christianity, and Islam are regarded as prophetic religions of the book that generate a revolutionary utopia of salvation. Because they create a radical tension between this world and a sacred realm of justice, they have been seed-beds of revolutionary movements. The actual existence of religious stratification is in this sense an offence to the theology of justice in biblical religion. Logically speaking, this tension between existing social injustice and the prophetic promise of the restoration of the faithful and the punishment of their enemies can take two forms—either a theodicy of other-worldly justice in a future kingdom or radical millenarianism in this world (see Mannheim 1997). These images of revenge and renewal provided slaves and the disinherited classes with a profound ideology of political change. However, in the Abrahamic religions the connections between social class, religious ideology, and political protest have remained highly unstable. Periods of revolutionary fervor have been followed by periods of mystical withdrawal, and the pendulum swing between protest and quietism is well illustrated by the complex history of messianism in Judaism, Christianity, and Islam (see Lantieri 1963). In Islam, the tension between the Koranic promise of a radical egalitarianism and earthly justice has proved to be a resilient source of religious protest against the dominant classes (see Marlow 1997). Although Marx and Engels as-

sumed that religious ideologies of class protest would be replaced by secular or scientific visions of political change, religious inspiration of class protest in the twentieth century has been an important aspect of liberation theology in Latin American Catholicism and of Islamic protests against colonialism. Traditional Shi'ite notions of the Hidden Imam and justice within the Islamic community provided a powerful tool in the emergence of the Iranian revolution which was produced by the alienation of the peasantry and the decline of traditional classes such as the merchants (see Kamali 1998). Religious stratification therefore continues to be an important feature of social and political institutions into the twenty-first century, and religious ideologies provide significant cultural components of both social stability and radical change.

Remedies and Damages: Legal Aspects

Remedies can be categorized as monetary or non-monetary. Although much litigation leads to monetary awards, many cases end without a monetary award. Injunctive relief, orders to specifically perform contracts, divorce decrees, probate of wills, and other orders do not necessarily involve damages or monetary payments.

1. Nonmonetary Relief

Several categories of nonmonetary relief exist and their use varies across countries. In contract law, countries divide into three groups with respect to the availability of specific performance: (a) countries, such as Germany and socialist systems, in which specific performance is generally available, subject to exceptions, (b) countries, such as France, which make specific performance available for specific obligations, and (c) common law countries, including England and the United States, in which specific performance is an exceptional remedy, available in limited circumstances.

Nonmonetary relief to prevent injury can be more important than redressing injuries already done. Common law countries address this need by allowing injunctive relief in cases in which irreparable harm can be demonstrated. Other legal systems, such as Germany, Switzerland, Austria, and others influenced by German law, have a general class of actions to prevent threatened injury. Courts in such systems have less discretion to deny preventive remedial relief than do common law courts. Some systems allow remedial relief but lack a coercive component, such as the penalties for violating an injunction, to enforce it (Stoll 1983). Prejudgment nonmonetary remedies, such as attachment and preliminary injunction or its equivalent, are widely available.

2. Damages Rules across Countries

With respect to monetary relief, one cannot completely separate the question of the quantum of damages from the question of liability. Blackstone, in writing about the common law, did not regard damages as a separable ending of the legal process. The right to damages arose the instant the victim was injured. Nevertheless, one can intelligently address many damages issues independently of the question whether any damages should be awarded.

In the last quarter of the twentieth century, damages issues fueled the tort reform movement in the United States and alarmed foreigners doing business in the United States. In many respects, however, damages rules are not strikingly different between the

United States and other countries. All countries seek to compensate victims fully, though most depend more on social compensation systems than does the United States. Most countries allow consideration of the injured person's fault, a consideration similar to the United States doctrine of comparative negligence, and a few (the Netherlands and Sweden) allow for mitigation of damages in view of the parties' financial circumstances and insurance coverage. European and Japanese damages rules governing injury, though less feared than United States rules, are not necessarily simpler (Pfennigstorf 1991). They contain 'a confusing variety of items of non-pecuniary loss and an equally confusing variety of methods for measuring them.'

There are, however, differences in the size of awards. Non-United States systems produce lower and more predictable within-country awards. Courts in several countries observe written and unwritten guidelines with respect to awards. In Japan and Sweden, for example, expert commissions establish consistent guidelines for automobile accidents. Sweden extends this practice to injuries caused by medical mistreatment, by pharmaceutical drugs, and by environmental pollution. Across European countries, however, awards are less consistent. One study estimates that in a wrongful death case involving a 20-year old victim with no dependents, awards across Europe would vary from £210,122 in Italy to £1,250 in England; it also finds that pain and suffering awards vary considerably across countries (McIntosh and Holmes 1990).

3. Social Scientific Study of Compensatory Damages

Media reports, which understandably emphasize extreme awards, promote exaggerated perceptions of large United States damages awards. The media overreport products liability and medical malpractice

cases, exaggerate plaintiff win rates, and distort impressions about the actual distribution of jury awards. Social scientific assessment of damages is critical in helping to ameliorate the effect of this reporting bias.

3.1 General Adequacy of Damages

Despite agreement that awards are higher in the United States, there is little evidence that injury victims are systematically overcompensated in any country. Evidence exists that United States plaintiffs with small losses tend to be overcompensated but that plaintiffs with large losses tend to be undercompensated (Vidmar 1998). Yet it is the large loss cases that tend to be the most controversial. An English study found that serious injuries may not result in substantial recoveries and that minor injuries which do lead to recoveries may have unexpectedly severe consequences (Law Commission 1994). Both findings suggest systematic undercompensation.

3.2 Award Levels and Trends

The most studied system of damages is the tort system in the United States. Concerns about the level of awards, time trends in awards, and the relative competence of judges and juries have generated several studies. Data gathered by the National Center for State Courts from 45 of the largest 75 United States counties, under grants from the Bureau of Justice Statistics (1995, 1999) ('BJS'), provide the least biased sample of awards in litigation. The data allow for meaningful comparisons across case categories. Since the same 45 counties were surveyed in both 1991 and 1996, the data also allow meaningful comparisons over time, discussed below. Table 1 summarizes the

Table 1
Mean and median compensatory damages award, by case category and year, in thousands of 1998 dollars

	1991			1996		
	Mean	Median	n	Mean	Median	n
Auto torts	219	34	1,102	228	21	1,384
Dangerous premises	323	71	394	350	84	441
Products liability	864	319	71	901	363	95
Intentional tort	445	47	91	438	33	112
Medical malpractice	1,424	232	181	1,525	306	172
Professional malpractice	1,303	152	44	392	76	29
Slander/libel	230	23	15	372	19	17
Other torts	447	74	188	11,477	117	186
Contract fraud	774	61	87	488	52	99
Employment relations	412	149	94	537	194	110
Lease	1,963	66	47	239	63	39
Other real estate	205	53	11	154	97	12

pattern of jury compensatory damages awards, in thousands of 1998 dollars, for these 45 counties.

Table 1 shows that damages awards vary substantially by case category. Median compensatory damages awards are highest in cases involving products liability and medical malpractice. Indeed, median awards in these case categories are substantial multiples of the median award in automobile accident cases. The levels of awards are generally modest and are consistent with other comprehensive studies of particular jurisdictions.

3.3 Reliability of Compensatory Awards

In studies that include independent assessments of the defendant's behavior, damages awards correlate with the nature and degree of the wrong. Studies of medical malpractice cases show that those who behaved the worst and caused the most harm are the most likely to pay the most damages. Experimental studies confirm these findings (for example, Wissler et al. 1999). Osborne (1999) uses a different methodology but reaches similar results. His study includes many substantive areas of law and examines the relation of court awards to the pretrial expectations of litigants and their attorneys and to measurable, economically relevant damages. He finds that court awards are highly predictable, as variance in expectations explains much of the variance in awards. The awards also significantly relate to both medical costs and property damage. He rejects the hypothesis of a highly unpredictable court system.

4. Punitive Damages

Punitive or exemplary damages are in addition to the damages awarded to make the victim whole. But normally punishment is left to the state, not to private civil litigation. Thus, many legal systems do not allow damages beyond those necessary to compensate the victim. Little authority exists for punitive damages in Roman law and thus in some of the continental European systems that derived from it. But many countries allow punitive damages or their equivalent (exemplary damages, moral damages) in some classes of cases. And the European Court of Justice has ruled that national courts must be willing to award exemplary damages pursuant to claims or actions founded on Community law, if such damages may be awarded pursuant to similar claims based on domestic law. Nevertheless, punitive damages are substantially less important outside the United States.

The most discussed questions in the recent United States literature on damages relate to punitive damages. Understandably skewed media coverage emphasizing high awards combined with advocacy by lobbying groups has generated enormous pressure on

punitive damages law and helped to shape professional and public impressions. Business lobbying groups have enjoyed some success, with several states enacting provisions raising the burden of proof for punitive damages claims, placing monetary ceilings on awards, and otherwise limiting the likelihood and size of punitive awards.

Social science research on punitive damages expanded as a result of the 1994 award of \$5 billion in punitive damages against Exxon Corporation (now Exxon Mobil) for the 1989 Exxon Valdez oil spill. Exxon funded several leading academics, who produced an impressive body of work that makes important social science contributions. All of this work is critical of punitive damages and supports 'reform.' But the thrust of some of the work seems inconsistent with prior theoretical discussions of punitive damages and some of it has been criticized as methodologically unsound (for example, Eisenberg 1998, Vidmar 1998) and as overstating its implications.

4.1 Rate of Punitive Awards

The social science picture that emerges from systematic studies of actual cases differs in some respects from the implications of the experimental and theoretical results of the Exxon-funded work. Three large studies of punitive damages awards, Moller (1996), Daniels and Martin (1995), and data commissioned by the BJS (1995), cover multiple United States jurisdictions, cover similar time periods, and include case categories that are sufficiently well defined to warrant comparison. Each of the three sources reveal overall punitive damages award rates of less than ten percent in successful jury trials.

In two of the areas of greatest interest to policy-makers, products liability and medical malpractice litigation, punitive awards are especially rare. In medical malpractice cases, the 95 percent confidence intervals for all three sources overlap and show awards in less than five percent of jury trials in which plaintiffs are successful. In products liability cases, all three estimates again overlap at under ten per cent of successful jury trials, and rates under five percent are found in studies of published opinions. Except in case categories dominated by fraud and employment law issues, all punitive award rate levels are likely less than ten percent, and many are less than five percent. These social scientific analyses undermine the belief that punitive damages are frequently awarded.

4.2 Level of Punitive Damages Awards

Large, publicized punitive awards, such as that against Exxon, create the impression that punitive awards are on average much larger than they truly are. BJS data for 1991 and 1996 allow one to assess the level of

Table 2

Mean and median punitive damages award, by year, in thousands of 1998 dollars

	Mean	Mean excluding highest award	Median	n
1991	557	404	58	168
1996	1,887	688	52	119

punitive damages awards. Table 2 summarizes punitive damages awards, in thousands of 1998 dollars, for the years 1991 and 1996. Median punitive damages awards have been more modest than the headline-grabbing awards. In both years they are in the 50,000 dollar range. Mean punitive awards are substantially affected by extremes. Excluding the most extreme punitive award in each year, reduces the mean by over 25 percent in one year and by over 50 percent in the other. In these data, million-dollar awards constitute less than 10 percent of the punitive awards. All studies confirm that the bulk of punitive awards are modest.

4.3 Relation Between Punitive and Compensatory Awards

A criticism of punitive damages is that they bear no relation to the compensatory award—the punishment

inflicted therefore is not proportional to the harm caused. And the United States Supreme Court has indicated that a punitive damages award normally should bear a reasonable relation to the compensatory award. Social scientific analysis suggests that punitive awards do relate to compensatory awards. Figure 1 shows the relation (in logs) between compensatory and punitive awards in the BJS (1995) study of 45 counties. It shows an unmistakable correlation. Other data sets reveal approximately the same relation (Eisenberg et al. 1997).

Punitive damages awards are thus rarer, smaller, and more closely related to compensatory awards than is widely believed.

5. Time Trends

5.1 Compensatory Damages Awards

Table 1 allows study of award trends over time. Popular perception has it that damages awards are ever-increasing. And some empirical study supports the claim. But these studies have been questioned on methodological grounds (Vidmar 1998). Table 1 shows little systematic evidence of increasing awards. In several case categories, median or mean awards decreased from 1991 to 1996. The only statistically

**Figure 1**

The relation between punitive and compensatory damages awards.

significant change in mean awards was in automobile accident cases and here the 1996 mean (in logs) was statistically significantly *lower* than the 1991 mean ($p < 0.001$). Other changes in award patterns were not statistically significant.

Table 1 is limited to state court cases. Awards in federal court cases tend to be higher, at least partially because of jurisdictional amount requirements in federal court. Median trial awards in federal courts products liability cases did increase from the early 1980s to the mid-1990s. The increase also occurred in judge-tried cases and in contracts cases.

5.2 Punitive Damages Awards

Punitive damages, like compensatory damages, are often said to be ever-increasing in number and size. The two years of BJS jury-trial data allow one to compare the rate and size of punitive awards in the 45 large counties covered by the data. Table 2 summarizes the results, in thousands of 1998 dollars, for the years 1991 and 1996. It shows that median punitive awards were substantially lower in 1996 than 1991. Mean awards were higher in 1996 but that is a function of a few large cases. The means (log) are not statistically significantly different. Regression analysis that controls for locale and case category confirms that punitive damages show no statistically significant movement from 1991 to 1996.

Table 2 also shows that the frequency of punitive damages awards decreased in these 45 counties, from 168 in 1991 to 119 in 1996. Thus, even minimal social scientific analysis provides no support for the belief that punitive damages awards are ever-increasing in size or frequency.

6. The Importance of the Adjudicator

It is widely believed that the choice of adjudicator—judge, jury, arbitrator—substantially affects the damages awarded. Higher and more variable awards in the US are attributed to the greater role of jurors as adjudicators. While real differences exist across adjudicator groups, the social scientific evidence supports skepticism about claims of massive differences across adjudicators. The classic Kalven and Zeisel study used questionnaires to presiding judges in about 4,000 actual civil jury trials in the 1950s (Kalven and Zeisel 1966). Their data showed a 78 percent agreement rate between judge and jury on liability, with no revealing pattern in the cases of disagreement. The rate of judge-jury agreement is high compared to other human endeavors. They also showed that jurors awarded on average 20 percent more than judges said they would have awarded. The modest judge-jury differences reduced interest in attacks on juries.

Renewed attacks on the jury's competence to assess damages, and especially punitive damages, re-emerged in the 1980s and 1990s. Research using interviews and experiments finds that different decisionmakers are quite similar and predictable with respect to their judgments of injury severity (Wissler et al. 1999). Such research also finds that jurors' awards lose consistency in translating severity of injury into dollar awards. Other studies suggest somewhat lesser judge-jury differences. Vidmar and Rice (1993) report experimental evidence about jurors awaiting jury duty and legal professionals bearing on pain and suffering awards. In a medical malpractice burn case, they found that six-person juries would give more variable awards than twelve-person juries but that both groups would be less variable than individual legal professionals. Their second experiment involved an automobile accident case and a medical malpractice case. They found no differences between jurors and legal professionals.

Studies of actual cases, which lack the controls of experimental settings but provide the relevant setting, suggest modest adjudicator differences. Osborne's (1999) study compares the predictability of judge and jury awards based on litigant expectations. He finds that one can reject the hypothesis that jury trials are largely random events. Litigant expectations explain more than a third of the variance in awards. And he finds that the behavior of judges is not significantly more predictable than that of juries. Helland and Tabarrok (2000) conclude that most differences between judge and jury awards can be explained by differences in the sample of cases coming before judges and juries but that some suggestive differences exist. Eisenberg et al. (2000) find little meaningful difference in the pattern of judge and jury punitive damages awards.

Exxon-funded research finds experimental evidence of vast judge-jury differences. For example, Hastie and Viscusi (1998) report mock jurors to be much more likely than judges to impose punitive sanctions in a hypothetical railroad accident case. Vast judge-jury differences on liability in these new studies, which contrast with Kalven and Zeisel's and other findings, calls into question the experimental designs' ability to detect socially meaningful punitive damages differences between judges and juries.

7. Overall Assessments and Comparisons of Damages Awards

Greater injuries lead to greater damages awards in all systems for which data are available. With respect to variability in the United States, where variability is regarded as greatest, from half to almost three-fourths of awards' variation can be accounted for by measures of injury severity, as well as by other predictors, but a

substantial random component also exists. Legal systems that rely on schedules of damages for various injuries have lower variability though not necessarily more complete compensation.

Prospects for definitive social scientific comparison of damages rules' operation are dim. Some inherent limitations apply to comparing performance of legal rules across state and national boundaries. The number of differing legal systems will tend to be small—there are, for example, only 50 states and gathering useful damages information about that many countries is an enormous task. Important differences, such as varying reliance on social compensation systems, different mixes of cases reaching court systems, different methods for compensating attorneys, and varying standards of living and purchasing power need to be considered. For the foreseeable future, reasoned analysis of data available for individual jurisdictions and informal comparison across jurisdictions will have to suffice in assessing performance of the damages component of remedial systems.

Remote Sensing

Remote sensing is one of a suite of geospatial technologies that are having a growing impact in a wide variety of areas from commerce to science in public policy. While remote sensing's origins and technological advance are an outgrowth of military and intelligence applications, commercial and scientific applications of the technology have been growing. The field of remote sensing evolved from the interpretation of aerial photographs to the analysis of satellite imagery, and from local area studies to global analyses, with advances in sensor system technologies and digital computing. Today remote sensor systems can provide data from energy emitted, reflected, and/or transmitted from all parts of the electromagnetic spectrum. These data can then be transformed into information products either by manual or machine-assisted interpretation and employed in an analytical or management decision-making context. Examples of applications of these data include population and demography studies, study of archaeological sites, energy studies using hydrological models, urban planning, environmental treaty enforcement, and agricultural yields. This article provides a brief overview of the historical development of remote sensing, emphasizing the increasing complexity of platforms, systems, and tasks. The information provided here has been assembled from previously published sources to give an overview of a rapidly evolving field that has had, and will in the future have, an increasing impact on our global society.

The definition of remote sensing used here, provided by the American Society for Photogrammetry and Remote Sensing (ASPRS), is:

In the broadest sense, the measurement or acquisition of information of some property of an object or phenomena, by a recording device that is not in physical or intimate contact

with the object or phenomenon under study; e.g., the utilization at a distance (as from aircraft, spacecraft, or ship) of any device and its attendant display for gathering information pertinent to the environment, such as measurements of force fields, electromagnetic radiation, or acoustic energy. The technique employs such devices as the camera, lasers, and radio frequency receivers, radar systems, sonar, seismographs, magnetometers, and scintillation counters. (Reeves et al. 1975)

What follows is a brief summary of various sensor systems within the context of an historical background of remote sensing, and a short discussion of the future of remote sensing with some reference to social and behavioral sciences.

1. Sensor Systems

Today, a wide variety of systems are used to detect energy patterns, which provide information about the Earth's atmosphere, oceans, and land surfaces. These systems range from cameras in aircraft to advanced sensor systems in Earth-orbiting satellites. The aerial camera systems typically used for remote sensing research and applications today are highly sophisticated. Most satellite remotely sensed data are acquired by sensor systems such as multispectral scanners, linear array devices, and synthetic aperture radar systems that operate in the visible, near infrared, thermal infrared, and microwave portions of the electromagnetic spectrum.

These remote sensor systems can be broadly categorized into *passive systems* and *active systems*. A camera is an example of a passive system as its film records light energy reflected from an existing source: the sun. Add a flash attachment to the camera and it becomes an active system, since it now provides its own source of illumination. Passive systems record solar radiation reflected from the Earth's surface. Data derived from passive systems such as multispectral scanners provide information on, among other things, land use, vegetation types, distribution and condition of landforms, soils, surface waters, and river networks. Active microwave (radar) systems are used commonly in geological and hydrological applications. Because active systems do not depend on reflected energy from the sun they may be able to acquire data during the day or night. In addition, as the atmosphere does not attenuate microwave radiation as much as shorter wavelength energy, radar systems allow data acquisition in cloudy and rainy weather. This ability to operate day or night, and to create images of the Earth's surface in spite of cloud cover, makes radar sensors particularly attractive tools for improving our understanding of both tropical and polar areas.

Thermal infrared data, which represent a record of emitted energy from surfaces, have been particularly useful in monitoring fires and in improving our

understanding of areas of volcanic and geothermal activity. Surface temperature of the ocean is also related to the dynamics of coastal waters and currents. Over land, plant water stress also induces changes in canopy temperatures, which can be detected by thermal sensors. Thermal imagery from satellites has been used to record the nighttime lights of the globe, giving researchers an indication of the spatial distribution of population centers. Other remote sensing systems detect the earth's magnetic and gravitational fields; these tools are used extensively in oil and mineral exploration. Employing imagery from more than one portion of the electromagnetic spectrum can increase the information derived from an analysis, and is typically referred to as multispectral image analysis. Analyses of such multispectral data can, if properly designed, increase both the quantity and quality of information for given applications.

2. Image Interpretation

Interpretation of remotely sensed data is part science and part art. Manual interpretation of remotely sensed data is fundamental to all image interpretation. Even with the ever-increasing sophistication of machine-assisted image interpretation software, it is still the human that ultimately must label the feature or phenomenon being identified. Not all individuals have equal interpretive skills with respect to aerial photographs or images acquired by remote sensor systems. It is axiomatic, however, that the more one knows about the elements, techniques and methods of image analysis the better an interpreter one will be. In addition, the more one knows about the systems which acquire the data one is interpreting and the subject or discipline area most closely related to the interpretation, the better an interpreter one will make. It is seldom that an interpreter uses only the information in the imagery being analyzed as the basis for their interpretation. Ancillary data in the form of interpretation keys, maps, diagrams, textual material, and other forms of site-specific literature often aid in interpretations. Fieldwork is also a key element in image interpretation and the collection of what is termed 'ground truth' should be accomplished whenever possible and practical.

2.1 Resolution

Resolution is at the core of the successful use of remote sensing data. Resolution, as typically applied by a user, normally involves the question 'can I identify what I need to identify on this imagery?' Often this involves the use of the term *ground resolved distance* (GRD). GRD is used to describe the smallest object that can be unambiguously identified on the ground given good object to background contrast. Object to

background contrast is important here. While it may be possible to see white lines on a black road on one set of images, it may not be possible to see the same size white lines on a concrete stretch of the same road. Resolution is thus dependent upon many things.

Indeed, the level of matching between the spatial, spectral, and temporal resolutions of the measurements and needs of the investigation will determine the usefulness of the derived data/information. Spectral range and resolution as used here refer to the portion of the electromagnetic spectrum being used in the measurement. It must be appropriate to the questions being addressed, for example, thermal range for fire detection, visible or infrared for vegetation health and condition. Spatial resolution determines the level of detail that can be extracted concerning objects in a given scene. As a general rule it must correspond to the sizes of typical objects that must be separately identified. A resolution of a meter or less is needed to identify a single tree, a resolution of five meters for a single-family residence, a resolution of 50 meters might be sufficient for identification of most agricultural fields in North America, while a resolution of 500 meters to a kilometer may be enough for studying ocean surface features. A necessary compromise between area to be covered and ground resolution of the measurement must take into account the volume of data which will be generated by, say, a large area coverage—millions of km²—using high resolution data—one to 30 meters.

The frequency of the data acquisition must also match the natural frequency of change in the landscape and the physical, social, or cultural phenomena of interest. For traffic studies, timeframes of minutes can be important. Hourly observations might be of interest for certain meteorological conditions. Daily observations may be needed for an assessment of plant evapotranspiration associated with irrigated agricultural crops, while observation once every year could be sufficient for land cover change assessment.

2.2 Geographic Information Systems

The synergy between geographic information systems (GIS) and remote sensing comes into play here. To be interpreted accurately, remotely sensed data are often supplemented with other data. Often these ancillary geospatial data can be found or included in a GIS for analysis. But to be more valuable in decision-making contexts, GIS data layers should be up-to-date as is practical. Remotely sensed data are a key technology for updating many types of GIS data. Thus when environmental planners, resource managers, and public policy decision-makers want to measure, map, monitor, or model future scenarios in order to facilitate better management decision-making, remote sensing is being employed more and more within the context of a GIS as a decision support system.

3. Historical Development

In the most general sense, the field of remote sensing begins with the invention of photography. Joseph Nicéphore Niepce took the first photograph of nature in 1827. It is a picture of the courtyard of his home in the village of Saint Loup de Varenne, France, with an exposure time of eight hours. In 1829 Niepce and Louis M. Daguerre signed a partnership agreement to work on a practical method of taking photographs. Niepce had been working on what he called Heliography, or sun drawing, and Daguerre on dioramas, which he constructed with the aid of a camera obscura. The process they pioneered was called direct positive image. The result of their collaboration, called the *daguerreotype*, was finalized in 1839. Also in 1839, an Englishman named William H. Fox-Talbot and a member of the Royal Academy invented the *calotype* (from the Greek: *kalos* for beautiful and *typos* for impression). Talbot's positive negative process is essentially the same as that used today, yet at the time the images produced by the two processes were not comparable.

In 1858, Gaspar Felix Tournachon, also known as Nadar a Parisian photographer and balloonist, took the first known aerial photograph from a captive balloon at an altitude of 1,200 feet over Paris. During the late 1870s, German foresters used aerial photography taken from balloons to both map and measure the aerial extent of tree species. This is an example of the earliest known application of both aerial photographic interpretation and photogrammetry (the science of making precise measurements from remotely sensed data).

The use of rockets to launch cameras first occurred in 1906 when Albert Maul launched a rocket propelled by compressed air that was equipped with a camera. The camera took a picture from an altitude of 2,600 feet and the camera was then returned to the ground by parachute. In 1909, Wilbur Wright took one of the first photographs from an airplane in Centocelli, Italy. By 1915, cameras devoted to aerial photography were being produced. World War One saw an explosion in the use of aerial photographs. During the Meuse Argonne offensive some 55,000 aerial photographs were taken and delivered to Allied Expeditionary Forces over a four-day period. During this period thousands of photo interpreters were trained. These interpreters laid the groundwork for the applications of aerial photographic interpretation that began to expand after the end of World War One.

In the early 1920s the first books and articles on the applications of aerial photo interpretation began to be published. Lee's 1922 *The Face of the Earth As Seen From the Air* work 'shows familiar scenes from a new angle,' and contains chapters on mountain features, coastal mud flats, plains, and submerged landforms. Joerg's 1927 work, 'The use of the air plane in city geography,' was published in the *Annals of the*

Association of American Geographers. This work focused on the application of aerial photography for urban studies. In 1927 Bergen published his work on 'Aerial surveys for city planning' in the *Transactions of the American Society of Civil Engineers*, and in 1930 the American Geographical Society published the work by Platt and Johnson, 'Peru from the Air.' While providing a regional overview of the country this work also focuses on archeological sites. Of a more general nature is the work by Fairchild (1927) in the May issue of the *Annals of the American Academy of Political and Social Sciences* entitled: 'Aerial photography, its development and future.' This article discusses potential applications of aerial photography from highway planning to water supply management. During this period, however, by far the foremost applications of aerial photography discussed in the literature are for mapping and geological exploration, particularly on the uses of aerial photography in oil exploration, structural and engineering geological analyses, land feature mapping, and soils mapping.

It is in the late 1920s and early 1930s that the agencies of the US Government begin to make significant use of aerial photography for operational applications. At this time the Agricultural Adjustment Administration began to systematically photograph farm and ranch lands across the entire USA. This use of aerial photography for documenting agriculturally active areas has continued at five to 10-year intervals since this time. This historical record has been very significant in many types of studies, but has been particularly useful in a variety of legal actions where the documentation of land use and/or land cover conditions and changes through time are in question. At the same time, the US Forest Service began to use aerial photography to document much of the nation's timber reserves. Studies such as this began in other nations as well, notably Canada. In this timeframe the US Geological Survey began to photograph many areas of the country in order to make topographical and geological maps based upon photogrammetric techniques and interpretation. The Tennessee Valley Authority and other regional agencies began to use aerial photography for planning purposes, as did state and metropolitan planning agencies. The *Master Plan of Residential Land Use*, published in 1943 by the Chicago Planning Commission, was based largely on data interpreted from aerial photographs.

World War Two led to developments in aerial photography, with a special interest in new and higher resolution film emulsions and thermal infrared imagery. Kodak patented the first false color infrared sensitive film in 1946. The 1950s saw developments in technology that allowed multispectral imagery to be taken. Thermal infrared and side-looking airborne radar systems began to be acquired by the US military. Around this time, research personnel at the US Office of Naval Research coined the term 'remote sensing' to

cover the expanding range of sensor systems and technologies for acquiring images of the world around us. This was the same year that the Soviet Union launched Sputnik, the first Earth-orbiting satellite. Civilian use of remotely sensed data during this period produced some of the first studies on the application of aerial photography for population estimation.

As early as 1946 the US Government began to pursue an operational space-based imaging system when the US Air Force asked the RAND Corporation to explore the possibility of launching an object into orbit. An early experiment in satellite land remote sensing was conducted from the Explorer 6 platform in 1959. The synoptic images of Earth's weather patterns acquired by the Television and Infrared Observational Satellite (TIROS-1), launched in April of 1960, captivated the American public and demonstrated the capability and necessity of earth observation from space. Also in 1960 the first experimental spy satellite, a component of what would later become known as the Corona Program, was launched and, shortly thereafter, classified as secret. These data were withheld from the public until 1995, when the imagery and documentation were released to the public under Executive Order 12951. In 1965 NASA initiated the Earth Resources Survey Program (ERS). This early program sought to develop methods and applications for remote sensing. The Department of Agriculture researched the use of remote sensing for geological, hydrological, geographical, and cartographical applications. In 1966 the Department of Commerce began to participate in the ERS program by establishing the Environmental Sciences Group within the Environmental Sciences Administration (the predecessor to NOAA). Also in 1966, the Department of the Interior initiated the multi-agency Earth Resources Observation Satellite Program, which studied the potential of Earth-observing satellites for natural resources applications.

During the 1960s and into the mid-1970s NASA and a number of other Federal Agencies focused a significant amount of attention on applied remote sensing research. This was, in part, aimed at justifying the need for civil land satellite remote sensing systems and cataloging the variety of fundamental and applied science questions that could be addressed by such systems. It is during this period that efforts began to develop computer-assisted image interpretation techniques. Results of these activities, and the state-of-the-art practice of remote sensing during this time period, are documented in the American Society of Photogrammetry's first edition of the *Manual of Remote Sensing* (1975), as well as other sources.

The first Earth Resources Technology Satellite (ERTS-1) was designed originally as a research tool. When it was launched in July of 1972, however, this satellite ushered in a brief era of emphasis by NASA on the demonstration of operational applications using this series of satellites. Through 1974, ERTS-1

(later renamed Landsat 1) transmitted over 100,000 terrestrial images covering 75 percent of the Earth's land surface. Between 1972 and 1978, major research efforts utilizing this new civil land remote sensing data were conducted in agriculture, forestry, water resources, and geology. Other notable regional-scale applications research in the 1970s included the Large Area Crop Inventory Experiment (LACIE); Agricultural and Resource Inventory Surveys Through Aerospace Remote Sensing (AgRISTARS); and the Western Snow Melt Application System Verification Test (ASVT).

In 1975, Landsat 2 was launched and the Ford Administration approved budget appropriations for Landsat 3, which was launched in 1978. In March of 1979, President Carter announced the Administration's commitment to maintaining the continuity of civilian terrestrial satellite remotely sensed data and recommended the transition of the program to the private sector. This initiated the process of program commercialization that would come to fruition in the mid-1980s. In 1981, the Reagan Administration accelerated the pace of Landsat commercialization by essentially rejecting the Carter Administration's commitment to an operational civilian land remote sensing program and advocating the immediate end of government funding for the Landsat Program.

By the middle of the 1980s, it was clear that satellite remote sensing could provide globally consistent, spatially disaggregated, and temporally repetitive coverage of the land surface of the Earth. Landsat 4, with the first Thematic Mapper instrument, was launched in 1982. Higher spatial resolution multispectral imagery was now publicly available and could be applied by scientists and professionals to the assessment of terrestrial ecosystems and land cover. A number of researchers began to develop techniques to employ the spectral information from Landsat to measure green vegetation status, and phenology, as well as inter-annual variation in these parameters. These studies then led researchers to the development of vegetation measures that provide an index of condition and, in part, describe absorption of sunlight, photosynthetic capacity, and evaporation rates. With this research, the science community began to understand that space-based Earth imaging can and does provide such information concerning the spatial and temporal patterns associated with land processes. During this period of capability demonstration, researchers noted that the possibility of developing fully integrated land-ocean-atmosphere monitoring and modeling capabilities were essentially realized.

In March 1984, Landsat 5 was launched and in July of that year the US Congress provided the legislative authority to transfer the Landsat program to the private sector. Thus began the nearly decade long period of 'commercialization' of the US civil land remote sensing program. Commercialization (and the

subsequent price increases for Landsat data) caused a shift in scientific research emphasis. Researchers began to move away from Landsat imagery and began to design experiments utilizing NOAA polar orbiting meteorological satellites and their Advanced Very High Resolution Radiometer (AVHRR) sensor system as a primary data source for scientific research. This shift was the result of increased costs, greater restrictions on sharing and more limited availability of Landsat data to both the basic and applied land remote sensing community.

The US Government would not regain operational control of the Landsat program until the late 1990s. Essentially, though the law changed in 1992, the governmental control of any orbital assets did not occur until Landsat 7 was launched in April 1999. The commercial pricing and data sharing restrictions prior to this transition back to government pricing had a negative effect on the developing research and application programs at the time which sought to utilize satellite imagery but could not employ it due to the high data cost. It would not be until the twenty-first century that the Landsat program would begin to come under the control of an operational land-oriented federal agency, the United States Geological Survey (USGS).

Despite these difficulties, research using Landsat data during this time included work in many disciplines and application areas. Organizations important in formulating the types of research conducted at this time include the Intergovernmental Panel on Climate Change (IPCC), the International Council of Scientific Unions (ICSU), the International Geosphere Biosphere Program (IGBP), and the Human Dimensions of Global Change (HDGC) project. Of particular significance was the research that validated the use of multitemporal Landsat and other data to monitor and assess tropical deforestation; and also unambiguously demonstrated the value of time series data to provide information on change occurring in every area of the world.

Other countries entered the space imaging arena with the launch of the French *Système Probatoire de la Observation de la Terre* (SPOT) satellite in 1986 and the Indian Remote Sensing Satellite (IRS-1) in 1988. In 1990, the French launched SPOT 2; a year later the European Radar Satellite (ERS-1) was launched, aimed primarily at oceanographic applications, followed shortly after by the Russian radar satellite *Almaz*; 1992 saw the launch by the Japanese of the first Japanese Earth Resources Satellite (JERS-1). In 1995, ERS-2 was launched and Canada launched *Radarsat*, with a primary objective of aiding navigation of shipping in the far north.

The most recent advances, at the end of the twentieth century, involved the launch by US agencies and organizations of Landsat 7 with the Enhanced Thematic Mapper (ETM+) system, the Shuttle Interferometric Synthetic Aperture Radar (IFSAR) mis-

sion, Earth Observing System-1 (now named Terra), and the one-meter commercial IKONOS satellite (all in 1999). The Landsat ETM+ data are already proving useful in a variety of studies from fire fuels mapping to deforestation and urban change monitoring. IFSAR data will be employed to improve the quality of topographical maps between about 60° N and 60° S of the Equator. Terra data is being employed to give continental to global-scale land cover change information with a temporal frequency never before available. IKONOS data give civil researchers the opportunity to see features and objects from space that could only be seen if aerial photography or intelligence satellite data were available to the user. These satellites will add immeasurably to our ability to measure, map, monitor, and model our Earth system as never before.

4. Future Directions

What is even more important is that by 2006, some 20 governments and organizations are expected to launch civilian and commercial high spatial resolution satellites in an attempt to capture a share of the growing market for remote sensing imagery. These satellites will have sensor systems with spatial resolutions that range from several kilometers to less than a meter. It is clear from developments such as these that a number of the long-standing restrictions that the military and intelligence community placed on satellite remote sensing are being put aside as technology advances and becomes more accessible, creating greater transparency among nations of the world. With this increasing transparency the opportunity for both positive and negative uses of remotely sensed data increase. On the one hand it may be easier to detect and identify violations of international agreements, while on the other it may be easier for states to gain tactically important information on their neighboring states.

There is already a growing interest in these data among social, economic, and behavioral users. This interest stems from the realization that whereas remotely sensed data cannot provide all the data/information needed to resolve or answer given questions it may, when combined with other information, allow data to be more reliably interpreted across space and through time. Indeed, an important aspect of remote sensing is its value as a historical record—applications in legal proceedings involving environmental contamination and ownership liability are one example. There is a growing diversity of applications to which remotely sensed data may be applied, in social, economic, or behavioral science, from population estimation, famine early warning and disaster assessments to inventorying industrial capacity, assessing transportation infrastructure, and monitoring of environmental laws and treaties.

There have been a great many advances in the field of remote sensing over the years since the invention of the camera. Yet, from an analysis of the materials covering the field of remote sensing, it is clearly evident that users interested in questions in the physical and biological sciences have been (and continue to be) able to use these data more than users in the social, economic, and behavioral sciences.

The reasons for this disparity are many and varied. They range from the inability of remote sensing to provide needed data/information to practitioners in the social, economic, and behavioral sciences to an unwillingness on the part of users in these areas to take the time to learn both the capabilities and limitations of the information that can be extracted from remotely sensed data. For some applications the spatial and temporal scales of data acquisition are not appropriate; for others the models to translate the data collected into meaningful information specific to a given need have yet to be developed. Remote sensing cannot see what is in the human mind. It can, however, document actions that we as human beings take in response to some stimuli. For example, it cannot tell us what crop a farmer may plant in a given year, but it can, in many instances, given appropriate dates of image acquisition and timely interpretation, tell us what has been planted before the crop is harvested. Indeed, given adequate ancillary data and models it can also give us an indication of how good the farmer's harvest may be.

As our ability to collect data at higher spatial, spectral, and temporal resolutions increases, so too does our ability to derive useful information from remote sensing data. Remote sensing will never replace other, more traditional methods of data collection, such as census and survey instruments. Yet it is a proven, powerful method of collecting data which, when properly interpreted and evaluated, can provide a wide variety of useful information. Information which, when taken alone or when augmented by other data/information collected by more traditional means, can create more useful data sets for social, economic, and behavioral scientists.

Remote Sensing and Geographic Information Systems Analysis

Remote sensing is the science and art of obtaining information about the Earth's surface through the analysis of data acquired by a device which is at a distance from the surface. Images from Earth observation satellites and aerial photographs are most commonly used. These instruments measure the electromagnetic radiation reflected or emitted by the

surface, at different wavelengths (or frequencies). Geographic information systems (GIS) are computer-based systems that are used to capture, store, analyze, and display geographic information. These two techniques are used widely to assess natural resources and monitor environmental changes. Their main fields of application for terrestrial ecosystems are geology and mineral exploration, land-cover mapping, agricultural statistics, the management of irrigation, forest inventories, and the monitoring of natural disasters such as fires, droughts, floods, landslides, or volcanic activity. Remote sensing and GIS are also used for archeology, land-use planning, urban management, and in the transportation sector. Social scientists can gain insights into fine spatial and temporal dynamics of land-use changes and related social phenomena by analyzing time series of remote sensing data and by linking remote sensing to socioeconomic data using GIS.

1. Remote Sensing Systems

A number of satellite sensors have been acquiring multispectral data over the entire globe since the 1970s, at a spatial resolution of dozens of meters. The most widely used among these sensors are Landsat Multispectral Scanner (MSS) (resolution of 80×80 m), Landsat Thematic Mapper (TM) (resolution of 30×30 m), and SPOT High Resolution Visible (HRV) Imaging Instrument (resolution of 20×20 m for the multispectral product and 10×10 m for the panchromatic product) (Colwell et al. 1983, Lillesand and Kiefer 1994).

Radiance data measured from the Advanced Very High Resolution Radiometer (AVHRR) on the NOAA series of orbiting platforms have been used widely for monitoring changes in the attributes of the Earth's surface. These data cover the period from June 1981 to date. The daily NOAA AVHRR Local Area Coverage (LAC) data have a spatial resolution of 1.1 km at nadir, which is well suited to monitor seasonal vegetation dynamics at the scale of the landscape. Other useful sensors with a 1 km resolution are ERS's Along Track Scanning Radiometer (ATSR), SPOT VEGETATION and the Moderate Resolution Imaging Spectroradiometer (MODIS).

Several active microwave sensors are also available: the Synthetic Aperture Radar (SAR) on the ERS-1 and JERS-1 satellites, and the Advanced Synthetic Aperture Radar (ASAR) sensor as part of the forthcoming ENVISAT mission. The cloud-penetrating capability of microwaves make them an ideal tool to work in areas with a permanent cloud cover. Both active and passive microwave sensing are used. Active systems supply their own source of energy or illumination while passive systems sense energy that is naturally emitted or reflected from the Earth's surface, at extremely low levels however. Note that this

enumeration of sensors used for land applications is not exhaustive (see Colwell et al. 1983, Lillesand and Kiefer 1994).

A new generation of fine spatial resolution sensors is due to be launched around the turn of the twenty-first century. These sensors are capable of generating imagery with spatial resolutions as fine as 1 m in panchromatic mode and 4 m in multispectral mode. These systems are also characterized by high geometric precision, short revisit intervals, and rapid data supply. Such imagery will provide greater spatial details on the land surface and open new applications relevant for social sciences (e.g., for urban studies).

2. Land Surface Attributes Measured by Remote Sensing

The electromagnetic radiation reflected and emitted in different wavelength ranges by the surface is controlled by surface attributes, such as the nature of the material, surface moisture, state of the vegetation, canopy structure, etc. Different features can be identified on an image based on the specific 'spectral signature' of different surfaces. A good understanding of the biophysical processes controlling the radiation of a surface is necessary to interpret the remotely sensed signal in terms of surface attributes.

2.1 In the Spectral Domain

In the visible and near-infrared range of the electromagnetic spectrum, the land surface generally is characterized using vegetation indices, which are arithmetic combinations of spectral bands. The most widely used of these indices is the normalized difference vegetation index (NDVI). Vegetation indices derived from remote sensing data are related to several variables quantifying vegetation activity and state, such as the fraction of photosynthetically active radiation absorbed by the vegetation canopy, canopy attributes (e.g., green biomass or green leaf area index), state of the vegetation (i.e., vegetation vigor or stress) and instantaneous rates associated with the activity of the vegetation. Seasonal variations of vegetation indices are related to vegetation phenology and biome seasonality.

In the thermal range of the spectrum, land surface 'skin' brightness temperature (T_s) can be derived from the thermal channels of satellite sensors. T_s is related, through the surface energy balance equation, to surface moisture availability and evapotranspiration, as a function of latent heat flux. Empirical studies have demonstrated the usefulness of thermal data to locate dense forest boundaries and monitor the growth cycle of crops, including for irrigated systems.

In the microwave range of the spectrum, the intensity of microwave returning from a given surface

depends on the geometric characteristics of the surface (i.e., shape and orientation of objects, as well as their surface roughness) and its electrical characteristics (i.e., reflectivity and conductivity of materials, as measured by their complex dielectric constant). The all-weather capacity of microwave remote sensing combined with the fine spatial resolution of the data opens promising avenues for land cover assessment and monitoring. This technology has however not yet reached the same operational level as optical remote sensing.

2.2 In the Spatial Domain

A major attribute of a landscape is its spatial pattern—i.e., the arrangement in space of its different elements. The concept of landscape spatial pattern covers, for example, the patch size distribution of residual forests, the location of agricultural plots, the shapes of fields, or the number and configuration of landscape elements (i.e., their spatial heterogeneity). Landscape spatial pattern is seldom static due both to natural changes in vegetation and human intervention. Remote sensing offers the possibility to analyze changes in spatial pattern at the scale of landscapes. Textural information of fine spatial resolution remote sensing images can be measured using a variety of indices such as variance, variograms, mathematical morphology, or fractals.

3. Processing and Analysis of Remotely Sensed Data

3.1 Preprocessing

Technical issues of geometric correction and rectification, radiometric correction, geometric and radiometric enhancement, and multispectral transformations of image data are described in Richards (1993). The purpose of these operations is to geo-reference and to transform the image data in a form that can be readily interpreted in terms of Earth surface attributes. The analysis and interpretation of remote sensing data typically is performed through image classification, to generate land-cover maps, or through change detection, to monitor land-cover changes.

3.2 Image Classification

Classification is a method by which labels are attached to spatial sampling units (i.e., the pixels) in view of their character. This character is generally their spectral response in different spectral ranges. It may also include their spatial attributes (i.e., texture) or temporal changes. This labeling is implemented through pattern recognition procedures, the patterns being

pixel vectors. The most commonly used classification methodology is based on the maximum likelihood, a probabilistic classification method (Richards 1993). More advanced classification techniques have been developed. For example, contextual classifiers label a pixel in the context of its neighbors in space. They exploit spatial information of an image. Neural networks are classifier networks, having a decision tree structure, where a collection of simple classifiers is brought together to solve a complex problem.

3.3 Change Detection

Time series of remote sensing data can be created to monitor changes in landscapes at local to regional scales. Classic land-cover change detection techniques are based on the comparison of sequential land cover maps derived from remote sensing data or other sources for the same area. For every sampling unit of the maps, the land cover categories at the two dates are compared. The comparison of successive maps fails to detect subtle changes within broad land-cover classes. Thus, rather than detecting changes on the basis of land-cover categories, change detection is better performed on the basis of the continuous variables defining these categories, whether these are reflectance values measured by a satellite sensor or biophysical attributes derived by model inversion. Coppin and Bauer (1996) review techniques used for this comparison. Recent studies have detected changes in land-cover between successive dates by combining different methods (e.g., Macleod and Congalton 1998).

4. Components of a GIS

A GIS is a powerful tool for handling spatial data. It is designed for the collection, storage, and analysis of objects and phenomena where geographic location is an important characteristic (Aronoff 1989, Maguire et al. 1991). The data input component of a GIS converts data from their existing form to one that can be used by the GIS. Two types of data are entered in a GIS: spatial data such as points, lines and areas that represent the geographic locations of features, and associated nonspatial attribute data that provide descriptive information. The data management component includes those functions needed to store and retrieve data from the database. In a GIS, data are maintained in a digital format. The representation of the spatial component of geographic information follows either the raster model—the homogeneous units are regular cells—or the vector model—the spatial units are the points, lines, and polygons. The data analysis and manipulation functions determine the information that can be generated by the GIS. A GIS automates certain activities and data interpretation procedures. Some of the most commonly used GIS functions are classification, overlay operations, neighborhood operations, spatial interpolations, geo-

statistical analyses, and connectivity functions. The output or reporting functions of a GIS produce maps, tables, or statistical results.

GIS facilitates the interpretation of remote sensing data, by linking biophysical information measured by remote sensing to maps of natural and cultural landscape attributes (e.g., soil type, topography, accessibility as measured by various distances), to field measurements (e.g., crop yield or water quality) and to socioeconomic information derived through household surveys (e.g., indicators of well-being, rate of population growth, agricultural input use). For a discussion of the ideas and social practices that have emerged with the development of new forms of data handling and spatial representation in GIS, see Pickles (1995).

5. The Contribution of Remote Sensing and GIS to Social Science Studies

The scientific literature is becoming increasingly rich in case studies using remote sensing to study social phenomena. Actually, remote sensing techniques are growing in importance for studies aimed at understanding land use dynamics, its driving forces and its impact on society (see Behrens 1994, Liverman et al. 1998). The output of remote sensing and GIS analyses are major inputs for spatial models. Remote sensing data is supporting land-use change analysis in a variety of ways.

5.1 Land-cover Mapping

Remote sensing is used widely to map land cover, land use, and agricultural patterns. The current classification algorithms succeed in identifying from 10–15 land-cover classes, including several succession stages of vegetation. Achieving this level of detail requires however a set of georeferenced field observations on a sample of locations. Current sensors do not identify very well settlements or different cropping systems. Spatially heterogeneous or fragmented classes are identified as mosaics of cover types. The further analysis of land use/land cover maps can lead to the separation of ‘landscape units,’ characterized by different combinations of land use and biophysical attributes.

5.2 Monitoring Land-cover Change

Remote sensing facilitates the introduction of a dynamic perspective in land use studies, by monitoring changes in the spatial patterns of landscapes caused by land use. Sequential remotely sensed data allows to detect changes in land use, such as an expansion of the area under permanent or shifting agriculture, urban growth, or increase in eroded areas. For example, quantitative estimates of rates of deforestation are

derived from time series of remote sensing data. The spatial extent and location of secondary growths on abandoned plots is also well detected by remote sensing. Remote sensing has been used in semi-arid regions to assess dryland degradation and to identify transformations of land use and cultivation. Measuring rates of dryland degradation is a complex challenge, however, given the strong interaction between erratic fluctuations in rainfall due to climatic variability and anthropogenic changes in vegetation cover.

5.3 Identification of Land-cover Change 'Hot Spots'

Land-cover change 'hot spots' are defined as areas where high rates of land-cover changes have been observed. Remote sensing-based methods for identifying land-cover change hot spots at broad spatial scales have been developed. Such methods are based on a series of indicators, such as land-cover fragmentation, occurrence of fires, opening of new roads, etc., which are detectable, by remote sensing. Deforestation, for example, is strongly related to the proximity to forested/deforested edge, the proximity to an access and the degree of fragmentation of forests. Forest fragmentation can be quantified easily from remote sensing data.

5.4 Identification of Land-use Attributes

Remote sensing allows identification and measurement of key socioeconomic and ecological characteristics of land use systems. In the Guinea Highlands, Gilruth and Hutchinson (1990) have been able to discriminate, on the basis of remote sensing techniques, between permanent agriculture (in the form of home gardens) and shifting cultivation. The spatial distribution of shifting cultivation areas can also be mapped from fine to medium resolution satellite data. Guyer and Lambin (1993) succeeded in discriminating and quantifying the total area and proportion of tractor-cleared and hand-cleared fields in a region of Nigeria by using several shape criteria derived from multispectral SPOT data. These authors also computed the crop-fallow cycle and the importance of the land reserve using a remote sensing-based land-cover map.

5.5 Spatial Stratification and Spatial Extrapolation

Remote sensing allows testing of how widely local observations apply to larger areas. Actually, a common problem of in-depth investigations of land-use dynamics is that it requires a large data collection effort in the field, at the household and plot levels. Remote sensing, through the measurement of indicators of land use, helps to define regions characterized by a similar land use, that can lead to a spatial stratification of a study area in terms of land use

patterns. As a result, findings obtained over specific sites within a stratum, that is homogenous in terms of land use, can be extrapolated with more confidence to that stratum. If such a spatial stratification is performed before field surveys, it is a powerful tool to design a sampling strategy and locate villages or households that will be used for in depth data collection and investigation. This leads to an optimization of the field data collection effort.

In a study of land use intensification (Guyer and Lambin 1993), remote sensing analysis provided a means of matching the patterns from a haphazard sample of households to the population, based on a few variables that were estimated both by household survey (on the sample) and by remote sensing (on the entire population). The results tended to give greater confidence to inferences from the sample about ecological dynamics.

5.6 Input into Spatial Models

The spatial patterns, which are detectable at a variety of spatial scales on remotely-sensed data, provide the most obvious link between spatially-explicit land-use change models and remote sensing analysis. With the application of remote sensing technology to the monitoring of land-use changes, it becomes possible to integrate more explicitly spatial relationships into models of land-use change. It is also possible to apply and test these models at a finer spatial resolution and with samples comprising smaller geographic units—e.g., at the scale of individual landscape units.

Spatial, statistical models are born from the combination of remote sensing, GIS, and multivariate mathematical models. Their emphasis is on the spatial distribution of landscape elements and on changes in landscape patterns. The goal of these models is the projection and display, in a cartographic form, of future landscape patterns, which would result from the continuation of current land-management practices or the lack thereof. The approach analyses the location of land-cover changes in relation to maps of natural and cultural landscape variables in a GIS. A model is built to describe the relationship between the dependent variable—e.g., land-cover changes—and the independent landscape variables. Spatial, statistical analyses of tropical deforestation or dryland degradation have already been developed for several tropical regions (see review by Lambin 1997). Spatial models of desertification hazard have also been developed by integrating indicators of water and wind erosion, vegetation degradation, range utilization, and human settlement.

5.7 Validation of Spatially-explicit Models

Dynamic spatial simulation, actor-based models have been developed to predict spatial patterns of land-use

changes at the landscape scale—e.g., for tropical deforestation in roadside areas occupied by shifting cultivators (e.g., Wilkie and Finn 1988) or in regions of official resettlement schemes associated with road development (Southworth et al. 1991). These grid-cell models combine spatially-explicit ecological information with socio-economic factors related to land use decisions by farmers. The modeling is based on rules of behavior determined by locational attributes, land tenure system, and vegetation successions. Remote sensing offers a powerful tool to calibrate and/or validate these models by comparing actual and predicted land-use/cover patterns, and by comparing the level of fragmentation of the landscape.

6. 'Socializing the Pixel'

By 'socializing the pixel' one means to discern information embedded within spatial imagery that is directly relevant to the core themes of the social sciences, and use it to inform the concepts and theories pertinent to those themes (Geoghean et al. 1998). Creating a direct link between spatially-explicit land cover information, as derived by remote sensing, and information on land-use change processes requires the development of new methods and models which are merging landscape data with data on human behavior.

6.1 Linking Household-level Data with Remote Sensing Data

A synthesis of the methods for merging socio-economic household survey data and remote sensing-based information is given in Liverman et al. (1998). The major challenges of this approach are: (a) the definition of the appropriate spatial observation units, i.e., the appropriate level of aggregation of information derived from the domains of social phenomena and natural environment, and (b) the development of the appropriate linkages between household-level and remote sensing datasets. While conceptually straightforward, these links can be difficult to implement operationally. In remote sensing, the unit of observation is the pixel that is not directly associated to any social science unit of observation, e.g., individuals, households, or villages. Establishing the correspondence between biophysical and socioeconomic variables requires taking into account the unit of decision-making, units of landscape transformation, and the spatial scale of ecological processes (e.g., a watershed).

Linking remote sensing observations to socio-economic data at the scale of the administrative units which were used for the collection of socioeconomic data leads to a loss of information as it obscures the variability within the units. More recently, research

efforts have attempted to integrate remote-sensing observations and field surveys at finer levels of aggregation, i.e., at the scale of individuals, households, or villages (e.g., Entwisle et al. 1998). There are difficulties in relating remotely-sensed patterns of land-cover changes with field observations of land-use changes since, in many cases, people live in nucleated villages away from their fields, since households may cultivate multiple non-contiguous plots and since people move—especially pastoralists. For this reason, the integration of the two datasets is generally performed at the village level.

Individual household data allow for a better understanding of the land-use practices within each village, as most land-use decisions are made by individuals and households. Moran and Brondizio (1998) have investigated the linkages between remotely sensed data and traditional field methods in the social and biological sciences. Their results have led them to new research questions, including examination of the role of the developmental cycle of the household in shaping their trajectory of land-use and deforestation.

6.2 Landscape Spatial Patterns

The spatial pattern of a changing landscape have some information content on the processes of land-cover change. Certain categories of land-use changes tend to fragment the landscape (e.g., expansion of smallholder farming, small-scale logging, overgrazing around deep wells). Other land-use changes increase landscape homogeneity (e.g., mechanized cultivation or ranching over large areas). There is a good correlation between remotely-sensed spatial patterns and some important characteristics of farming systems. For example, Lambin (1988) found statistically that, in Burkina Faso, spatial patterns interpreted from Landsat MSS data correlate more closely with ethnic groups than with any other physical or cultural landscape variables. Other authors demonstrated that the analysis of the spatial pattern of forest-nonforest interfaces allows identification of regions affected by different deforestation processes, which are controlled by different driving forces.

The spatial patterns of fires, which are well detected from space, are also good indicators of human activities. In tropical forests, regions of fire concentration indicate frontier areas and variations in the spatial organization of fires are associated strongly with political boundaries and farming practices.

6.3 GIS for Health and the Environment

An emerging area of research concerns the application of remote sensing and GIS techniques to analyze the

relationships between people, their environment and their health (de Savigny and Wijeyaratne 1995). GIS provides information about the spatial distribution of and interaction between disease risk factors, patterns of morbidity and mortality, and the allocation of health resources. Vector-borne diseases (e.g., malaria, trypanosomiasis) have received most emphasis so far, as their occurrence is strongly controlled by environmental attributes which are detectable by remote sensing (Barinaga 1993). However, there is a large potential for GIS application on any environment-related health problem. A classic example is the spatial correlation between cholera deaths and contaminated water supplies.

E. F. Lambin

Renaissance

Two nineteenth-century historians were instrumental in giving the term 'Renaissance' the content that it retains to this day. In his 1855 *Histoire de France*, Jules Michelet (1798–1874) chose the word for the period of the *découverte de l'homme et du monde*, the sixteenth century. But the Swiss Jacob Burckhardt (1818–97) was even more important. His famous book *Die Cultur der Renaissance in Italien. Ein Versuch* (1860) became a milestone of research. Burckhardt sketched a monumental fresco that located the origin of modernity in fifteenth century Italy—in conscious distinction from Hegel's philosophy of history, which posited that the German Reformation marked the beginning of the modern age. Burckhardt referred to the conditions in the Italian ministates as 'masterpieces of statecraft,' in which he saw the preconditions for the 'emergence of the individual' as the most important and far-reaching development of the modern age. He presented the Renaissance, with the many-faceted Humanistic movement as its intellectual substrate, as a period that forced the pace of modernization and secularization and as the beginning of the modern

world in which he himself lived and whose negative sides he analyzed perhaps more acutely than any other thinker of his time.

1. The Development of the Concept of the Renaissance

1.1 Renaissance

Burckhardt's thought-provoking image of the epoch exerted substantial influence, not only on the study of history, but also on literature and philosophy, in particular on Nietzsche's thinking. It remains the more or less explicit background of discussions of the term 'Renaissance,' though it soon roused dissension. For example, in the book *Franz von Assisi und die Anfänge der Renaissance in Italien* (1885), Henry Thode (1857–1920) attempted a romantic reinterpretation, placing the *poverello* and the religious movement he inspired at the beginning of the epoch. Thode and his followers saw the Renaissance more as a reform movement on a medieval-clerical foundation, eliminating its character as an epoch of its own. Thode rejected the idea that classicism and rationality fundamentally constituted the Renaissance and divided it from the Middle Ages. He posited an individualism of piety and sensitivity to beauty, in contrast to Burckhardt's subjects becoming aware of themselves.

But the prospect of another, religious side of the Renaissance had already existed before Thode and did not completely contradict Burckhardt's view. In his influential essay collection *The Renaissance* (1873), Walter Pater (1839–94), an admirer of Ruskin presented several artists and thinkers he considered representative of the Renaissance. The essay on Botticelli became essential to the incomparable cult of this painter, which thrived throughout Victorian society, and not solely among the Pre-Raphaelites. Botticelli's art seemed to correspond to a 'metaphysical need' in the modern, industrialized world of Victorian England.

The inventions of the historians and literary writers stimulated broad segments of the educated bourgeois class. Florence became the preferred destination for an international cultural tourism. People built in the Renaissance style, surrounded themselves with splendid interiors in the style of the fifteenth and sixteenth centuries, and purchased original works of art. Especially in the second half of the nineteenth century, collections of important Renaissance art were amassed from Boston to Berlin. The 'Renaissance' was not only a focus of scholarly interest, but also part of a lifestyle.

Around 1900, the international Renaissanceism reached a zenith. Burckhardt's classic was reprinted, and novels like Heinrich Mann's 'Göttinnen' depicted the sixteenth century as a foil for the contemporary 'decadent' *fin de siècle*. The closing nine-

teenth century saw itself not only in a strange spiritual kinship with the Renaissance: the fiction of a 'lascivious,' 'unscrupulous' epoch paradoxically appeared to offer counterimages to the usual bourgeois existence, taking shape in princes of commerce, patrons, *condottieri*, and courtesans.

At this time, the term 'Renaissance,' was loaded with a plethora of sometimes contradictory meanings, triggering associations of 'gold and purple,' as Johan Huizinga said. The patronage of the Medici, the magnificence of the papal court, and the art of the Renaissance with its heroes Leonardo, Raphael, and Michelangelo provided new cult objects for religious worship in a demystified world. At the same time, the word recalled the art of power and *Realpolitik*, as Machiavelli had analyzed in his trailblazing work. Racist ideas of a victory of hard men and cunning women over decline and enfeeblement were inherent in this image of the epoch. A widely read literature in the succession of Carlyle, Count Gobineau, Nietzsche, and others popularized the cliché of the 'blond beast,' the amoral 'Renaissance man' up to mischief.

The myth of the Renaissance thus offered models for Caesarism and imperialism. It was no coincidence that a nationally-oriented writing of history took up Italy's *Signorie* and identified them with the precursors of the modern military and power-wielding state. But the iridescent construct of the 'Renaissance' also offered fragments for a historical foundation of modern civic societies. As early as the beginning of the nineteenth century, the Swiss Sismonde de Sismondi had described the Italian city republics in this way, and travelers from England and the USA thought they were tracing the ideal roots of their own nations when they came to Florence. It is hardly surprising that the *inglesi* were the largest group among the tourists. The Florence of the Medici was long a primarily Anglo-American myth.

Examples of the ideological interpretation of the Renaissance with an unmistakable relationship to current history are also found in the works of Hans Baron, a German Jew who emigrated to the USA. In the essay he published in the middle of World War II, he saw the crisis of Italian 'freedom' caused by the aggression of the Visconti *signoria* in the early Quattrocento as the precondition for the formation of a modern, pluralistic state system on the Italian peninsula. In Baron's view, the high degree of citizen participation in Florentine politics was a precondition for this most important result of the struggle against the tyrants: He saw it as a kind of Italian America winning the upper hand over Visconti/Hitler (Baron 1955).

1.2 The Revolution of the Medievalists

More recent research on the Renaissance has tried to free itself of mythologizing. Insight has been sought into the clientele systems of the clan that enabled

Cosimo de' Medici and above all Lorenzo the Magnificent to exercise an authoritarian power behind a republican façade (Wackernagel 1938, Thomas 1995), whereby special attention was paid to the patrons commissioning the art (Esch and Frommel 1995). But art history tended to go its own way. Wölfflin and others separated Renaissance art from the cultural-history context and treated it primarily as a problem of style, and thus of aesthetics.

The conception of the art historian Aby Warburg (1866–1929) remained fragmentary and accessible only in a very few essays. It aimed once again at the great synthesis and still provides impetus for new research. He located the epoch in a long-term process of civilization that experienced its climax in the Apollonian beauty of the art of the High Renaissance. In the triumph of the Olympic gods, Warburg saw an important step toward overcoming 'oriental,' 'medieval' irrationality. He was interested in the difficult breakthrough to the Enlightenment, humanity and reason in the history of the West. Warburg saw works of art as documents of the states of the human psyche, and he believed that, through subtle analysis, he could uncover the *Zeitgeist* preserved in them. Warburg's works addressed aspects previously not or only marginally considered. The role of the patron became a theme, along with what Michael Baxandall (1972) calls 'troc': the market of intellectual and material goods where what we call 'Renaissance art' took shape. Warburg sought to illuminate the dark side of the epoch—its interest in divination, astrology, and magic, to which Burckhardt had devoted only a few passages. Equally important was that he conceived the emergence of Renaissance culture as a transfer process and thus examined not only the Orient, but also the culture of the North—the courts of Burgundy, France, and the Netherlands. This underscored what is now the general possession of research: the cultural physiognomy of the Renaissance as an amalgamation of varying influences. Italy remained important, but it was placed in the context of a network cast across the continent (Porter and Teich 1992).

This geographical expansion, the focus on the 'occult Renaissance,' and above all his constant question of the beginnings led Warburg to avoid drawing the boundary between the 'Renaissance' and the 'Middle Ages' too sharply. Although his works had no discernible importance for it, he prepared the ground for what Wallace K. Ferguson has termed a 'revolt of the medievalists' (Ferguson 1948). This debate, characteristic of the 1920s, adopted aspects of the image of the Renaissance as sketched by Thode, Sabatier, and other researchers. It pointed out, for example, that the tradition of antiquity was never completely buried and recalled that various 'renaissances' were palpable between the ninth and thirteenth centuries, in which ancient forms clearly stand out as elements shaping culture. Some researchers, including Etienne Gilson and Johann Nordström saw the

Renaissance as a mere continuation of currents existing in the twelfth century. In this famous book *The Waning of the Middle Ages* (1919), the Dutch writer Johan Huizinga drew an image of the fifteenth century diametrically opposed to Burckhardt's conception. Contemplating the courtly world of Burgundy, France, and the Netherlands, he depicted the epoch as a flowering 'autumn' of burgeoning color, rather than as the spring of a new age.

2. *A Movement of the Happy Few: The Sociohistorical Dimension*

Discussion thus ensued on the boundaries of epochs; it was the hour of the deperiodizers, who made the Renaissance their preferred target. George M. Trevelyan went as far as to locate the turn from the Middle Ages to the Modern Age in the epoch of the Industrial Revolution, the eighteenth century; and for other researchers as well (like Delio Cantimori), the Renaissance of the fourteenth and sixteenth centuries lost its meaning as a significant turning point. A more differentiated sociohistorical research underscored that Renaissance societies were more 'medieval' than widely conceived. Additionally, this culture had been borne by a tiny minority—one of the reasons Ernst H. Gombrich no longer speaks of the Renaissance as an epoch, but as a movement.

It is indeed indisputable that epochs named for styles can describe little more than the cultural stances of an often compoundly interwoven elite. Social history has provided glimpses of the world of the majority of the 'Renaissance people'; these reveal little 'Renaissance' quality (e.g., Herlihy and Klapisch-Zuber 1978, Davis 1982, Squatriti and Merideth 1999). Recently, the theme of gender has also been considered more intensely (see King 1991, with comprehensive bibliography); here, research focuses not only on the 'Renaissance women,' the princesses and courtesans who populate the mythological scenario, but also on other women who lived at the time—witches and saints, nuns, artists, authors, and women in working life in general (Ferguson 1986).

3. *'Modern Individualism' and the Concept of the Renaissance Today*

3.1 *Art Historical Findings*

Despite the still current discussion of the term 'Renaissance,' the concept has prevailed as the name of a cultural epoch (cf., e.g., Burke 1972, Delumeau 1967, Hale 1993). What arguments can be adduced for or against the concept of the Renaissance? The most conspicuous are the findings of art history, and they

were what gave the essential impetus to construe the epoch in the first place. Thus, it is beyond doubt that the painting of Giotto and Massaccio and the sculpture of the Pisani in the fourteenth and fifteenth centuries marked a fundamental transformation. What was decidedly new in painting was that dependence on the Byzantine model was overcome. Here, Flemish influences played a major role, and the Renaissance in general increasingly appears as a complex amalgamation of transfer processes embracing Europe, the Middle East, and finally the New World. The early Quattrocento brought the introduction of a central perspective formulated with geometric precision, a Florentine invention. The goal was to create the illusion of 'real' living beings, objects, and spaces.

One of the most important arguments for Burckhardt's old 'individualism hypothesis' is still that not only did artists' signatures appear even more frequently, but also that, in the fifteenth century, initially in the Netherlands and Italy, portraits were painted that appear closer to nature than anything since classical antiquity. Since the Trecento, sculpture once again clearly approached antiquity's conceptions of the body, and, increasingly frequently, portrait busts clearly strove to convey the individuality of the person portrayed. While it cannot be claimed that the 'modern individual' was invented in the fifteenth century, if we also adduce literary testimony in the broadest sense, for example Ghiberti's *Autobiography* and Giovanni Rucellai's unique *Zibaldone*, we do note that reflection on the self gained decisively in importance (Davis 1986 is highly differentiating; see also Schulze 1996, Porter 1997, Schweikhart 1998).

In architecture, the building forms of classical antiquity reappeared first and initially exclusively on the Italian peninsula. Only at the beginning of the sixteenth century was anything remotely comparable found north of the Alps, starting with the buildings commissioned by the Fuggers in Augsburg. Regional variant forms emerged rapidly. Their common denominator was a more or less clearly articulated reference to antiquity. With Mannerism, the Renaissance flows into a typically European style (cf. Sect. 5).

3.2 The Revolution in Discourse and Renaissance Humanism

The art of the Renaissance developed in a complex content with a theoretical discourse that, on the one hand, used texts from antiquity, for example Vitruvius' theory of architecture. This was new and genuinely Italian. In the fifteenth and sixteenth centuries, no other European country produced a theory and critique of art whose quality and differentiation were even remotely comparable. Italy was also the first place with a palpable group of collectors, art agents,

and patrons who, for aesthetic considerations, acquired real or putative ancient objects. These inspired an almost romantic veneration and learned discussion and correspondence. One of the earliest representatives of this modern phenomenon of collecting was the Florentine Niccolò Niccoli (1364–1437).

Interest in ancient and contemporary art was part of the humanistic culture that was closely tied to the Renaissance. The term *studia humanitatis* is of ancient origin and refers to education in the broadest sense, the acquisition of knowledge as well as of 'good' ways of living. The fifteenth and sixteenth centuries saw the emergence of the social type of the *humanista*, the scholar concerned with the canon of humanistic studies—grammar, rhetoric, poetics, history, and moral philosophy—with recourse to the authors of classical antiquity. Humanistic scholars and humanistically educated elites became the real bearers of the Renaissance. They gave art, architecture and literature essential elements of form and content (see e.g., Wind 1968, Panofsky 1962). Modern research sees the first beginnings in upper Italy in the second half of the thirteenth century. But Francesco Petrarca (1304–74) was the first thinker to unite in himself the essential aspects of the humanistic movement. The older idea that the humanists were a group of traveling scholars staging a revolution against scholastic theology and Church doctrines is no longer tenable. Social history cannot view the host of humanists as homogeneous, even as early as the fifteenth century. The majority of the humanists of Florence, the 'capital' of the Renaissance, were economically well off (Martines, 1968). Monks, prelates, princes, university scholars, urban jurists, and many others spread the *studia humanitatis* in Europe, and in many places humanism established itself as a national movement with national characteristics.

Humanism, and with it the culture of the Renaissance, were in no way pagan. The vast majority of humanists were firmly based in Christianity, and this did not change with the Reformation (Verdon and Henderson 1997). Significantly, pictorial subjects remained mostly religious during the Renaissance. In the sixteenth century, however, we note their gradual dwindling (Burke 1972), a telling indication that Renaissance humanism contained substantial potential for secularization. The great expansion of the spectrum of questions discussed and written about in the fifteenth and sixteenth centuries was of long-term importance. Theology and religion still dominated, but texts on every possible aspect of life increasingly moved to the foreground; finally, and again with recourse to ancient thinkers, a new theory of politics developed (Pocock 1975). This 'differentiation of discourse' did not depend on the Gutenberg Revolution, but began much earlier. In a certain way, the invention of the letterpress with movable type can be viewed as a response to a market ravenous for written material.

4. *The Research Problem of the Genesis of the Renaissance*

A question equally fascinating and controversial is why the beginnings of humanism and the Renaissance lay in Italy and what led to the formation of these movements. As Burckhardt had already underscored, there was the multiplicity of *signoria* and city republics, whose political rivalry sought artistic representation. Ancient monuments, statues, and other relics also provided models. Italy and Flanders, the regions in which the new culture developed, were probably the richest in Europe at the time, so here is where the economic prerequisites for extensive patronage were given. But the connection between art and economy should not be absolutized. There is no necessary parallel between the unfolding of Renaissance culture and a general economic upswing; Roberto S. Lopez (1963) even attempts to interpret the Renaissance as an attempt to compensate for crisis-like developments. The financial position of the patrons was decisive (see e.g., Roover 1963). The *condottieri* wars in fifteenth-century Italy resulted not merely in a destruction of resources, but also in processes of redistribution from the great centers to small seats of courts like Urbino and Bergamo, where successful military commanders spent astronomic sums on books and in patronizing the arts. It is difficult to estimate the significance of the dynamics of economic shrinkage triggered by plague epidemics and failed harvests in the first half of the fourteenth century. Along with the resulting acceleration of urbanization, the consolidation of capital in the hands of the survivors contributed to the financing of early Renaissance art—in part as an ‘investment in saving one’s soul,’ which must have suggested itself and seemed necessary against the backdrop of the crisis of Church hierarchy and the experiences of the plague era. The Renaissance, humanism, and the Reformation thus appear as varying answers to one and the same problem, namely the determination of the human position in a fundamentally changed world. The writings of Giannozzo Manetti and Pico della Mirandola, the political theories of Machiavelli, the primary Reformation writings of Luther and the invention of the realistic portrait and of central perspectives thus all had the same preconditions.

5. *The ‘Mannerist’ Renaissance*

The question of the end of the Renaissance is no less complex and controversial than that of its beginnings. Art history sees indications of a metamorphosis to the ‘Mannerist Renaissance’ or to mannerism as early as the second decade of the sixteenth century (Shearman 1967, Arasse and Tönnemann 1997). Literary history usually locates the end of the epoch around 1600. And music history, too, has its difficulties with the question

of the definition and temporal boundaries of mannerism (important but controversial, see Maniates 1979). National differences in particular must be differentiated. Setting the boundaries of the epoch is also made difficult by the fact such important intellectual currents constitutive of the Renaissance as humanism and such aesthetic ideals as the orientation toward the standards of Greek classicism lived on after 1600 and experienced their own renaissances.

There has been no lack of attempts to set the stylistic transformation of the sixteenth century in direct relationship to political and societal changes (the best known is Arnold Hauser 1979). Structural changes at least in the art market and thus in the relationships between artists and patrons probably played an important role. Europe’s princes, the rulers of the rising early modern states, moved increasingly into the foreground as patrons. They used the arts to buttress their legitimacy and to display their grandeur: now, in the sixteenth century, the art of the power availed itself of the power of art more than hardly ever before. Political competition also manifested itself as competition among patrons of the arts. The artists’ virtuosity, or *maniera*, had to prove itself in this complicated field.

B. Roeck

Repartnering and Stepchildren

1. Introduction

Sexual unions create children and hence, parenthood. Union dissolution creates single parents and absent parents. When these parents enter a new partnership, they may have a new kind of children—stepchildren—children who are not the joint concern of the couple at the start of the union, as at least one member enters the union as a step-parent. This asymmetry in parenthood is likely to shape the partner dynamics that lead to union formation and hence to affect the calculations of those with children (whether coresident or not) and any partners who might join them in a new union. This asymmetry affects their lives as a couple, particularly whether they have additional, joint children, and also affects whether their union survives. This article on children and new partnerships examines three issues: (a) the role of children in the likelihood that their parents repartner (considering different effects for men and women); (b) the role of such children on the fertility of the unions formed, and (c) the effect of stepchildren on union dissolution.

2. Background

The rapid rise in divorce in most industrialized countries together with the rise in cohabiting unions, which tend to be more unstable than marriages, is creating a new demographic situation for men and women. A union disruption places them in the partner market again, which is particularly challenging for those who are the parents of young children. Although historically, high mortality often left young parents widowed, divorce creates twice as many new prospective partners. Further, whatever wisdom had accumulated for those facing this challenge, has likely been lost. The divorce revolution that began in the 1960s and 1970s in the industrialized countries in the west followed a half century or more of rapidly declining mortality, which sharply reduced widowhood for both sexes and concentrated it at ages when children are older, or even adults. In addition, the early years of the increase in divorce rates disproportionately involved couples without children far more than has been the case in the 1980s and 1990s (Andersson 1997). Hence, the effect of existing children on new partnerships is not well understood, either in the community of scholars of the demography of the family or in the communities experiencing the new situation. Little is known about how children affect their parents' repartnering, and not much more is known about those partnerships as they develop over time in terms of their fertility and stability. The research community has been further hampered by a lack of appropriate data to study these issues.

The numbers involved are substantial. In the United States, it is estimated that 40–50 percent of all marriages dissolve and a substantial minority of all children spend some time in a single-parent family (Bumpass and Raley 1995). Half of both previously married cohabiting couples and remarried couples have children in the household and many of the rest have children living elsewhere (Bernhardt and Goldscheider 1998). Although such rates are higher in the US than in other industrialized countries, they are rising rapidly outside the US (see *Demographic Transition, Second*), while US levels appear to have reached a plateau in the last two decades of the twentieth century. At whatever level, these trends mean that a substantial proportion of adults are at risk of entering a new partnership, and many of those who do will have children, either living with them or dependent upon them financially. Those considering forming a union have to take their potential partner's children into account.

A critical question might be whether the presence of children increases the likelihood that the unions formed are cohabiting ones. There is some evidence that this is, in fact, the case. Although the rise in cohabitation has not fully offset the decline in proportions married among the never married, the offset is total among the formerly married, suggesting that remarriage is being replaced by cohabitation (e.g., see *Demographic Transition, Second*). However, most research, and most of the data on which research could be based, has made it difficult to study cohabiting partnerships that involve children. Research on 'single-parent' families has frequently studied only 'unmarried' parents. The most common control for resources in families was 'family income,' which typically excluded the income of 'non-family' members, i.e., cohabiting partners. New surveys, such as the Family and Fertility Surveys (FFS), should overcome these difficulties.

3. Repartnering of Parents

Nearly all research on repartnering when pre-existing children are involved has considered only women with coresident children, focusing almost entirely on remarriage and on the US. These studies have typically found that the presence and sometimes the number of children reduce women's likelihood of marrying, with effects often depending on the ages of the children and of the mother. One of the few studies that considers cohabitation suggests that children reduce the partners' commitment to the union, decreasing the risk of getting married but increasing the risk of cohabiting (Bennett et al. 1995).

There is much less evidence on how children affect men's likelihood of union formation. A major problem for men is distinguishing between coresidential and

non-co-residential children, a distinction that has been less important for women. One study examined widowers, where presumably fewer of the children lived with other relatives (Smith et al. 1991). That analysis showed that having dependent children reduces middle-aged (< 60) men's likelihood of remarriage after widowhood, although the reduction was much less than is the case for women with children. However, more recent research on both the US and Sweden, which has included divorced and never-married men with coresident children, as well as widowed men, has found that such men enter partnerships significantly more quickly than men without children (Goldscheider and Sassler 2000, Bernhardt and Goldscheider 1999). This suggests that the effects of coresidential children on union formation are quite different for men than for women.

There is even less research on how non-coresidential children affect union formation, although this is a particularly important issue for men (and the women who consider entering unions with them). The studies mentioned above also examined this issue, and found that in both the US and Sweden, men with non-coresident children are significantly more likely than otherwise comparable men with no coresident children to enter a union than to remain outside a partnership. In Sweden, such men are also more likely to enter a union with either a woman who has coresident children or one who does not than to remain unpartnered; in the US this effect does not appear for union entry for women without children. The few women who have non-coresident children are also more likely to enter a union than to remain outside a partnership. In this case, however, at least in Sweden, they are much more likely to choose a partner with no coresident children, although this effect may reflect the small numbers of nonpartnered men who live with their children.

Perhaps a more important question, however, is the broader one: what factors affect entry into a union with a partner who has children? Research on the US and Sweden shows that two family-related factors distinguish men by whether the partnerships they enter into include children: their parents' marital history and their own marital history (Bernhardt and Goldscheider 1999, Goldscheider and Sassler 2000). Men who experienced a nontraditional family structure in childhood are significantly more likely to form a marriage that converts them into stepfathers than one that does not, and the same general difference appears for cohabitation.

US men who have been previously married resemble those who are already parents, in being very likely to enter a union (Goldscheider and Sassler 2000). If they marry, there appears to be no difference in the likelihood that their partner has children or not. If the new union is a cohabiting one, however, they are more likely to enter one with children. In fact, divorced men are more likely either to marry or cohabit with children

than to remain unpartnered; and they are significantly less likely to cohabit without children than to remain outside a partnership. Similar results were obtained for Sweden (Bernhardt and Goldscheider 1999).

Men who enter unions with children are not simply different in terms of their family histories, however; the evidence for both Sweden and the US suggests that they are also drawn from among the less educated, but the studies do not show why. In Sweden, those with a post-gymnasium education are the most likely to enter a union with a partner without children but the least likely to enter a union where the new partner has children (Bernhardt and Goldscheider 1999). This pattern is the same for US men; college graduates are more likely to enter a union than to remain outside a partnership if the woman does not have children. They are more likely, however, to remain outside a partnership than to enter a union with a woman who has children (Goldscheider and Sassler 2000).

These results suggest that there are important differences in the likelihood of repartnering for those with and without children, with patterns that differ between men and women. Children, whether co-resident or not, increase repartnering for men, but only non-coresident children do so for women; for them coresident children have the opposite effect. This suggests that surveys need to go beyond providing information in their partnership histories about whether partners brought children into the union and at least also provide information on whether partners have children living elsewhere. Such children clearly affect union formation; it is likely that they would also affect partnership dynamics (fertility and union stability), though this cannot yet be assessed fully, as we shall see in the next section. It is also likely that other characteristics of the children, such as their sex, might affect their parents' repartnering. No studies to date, however, have assessed whether the gender of the child(ren) matters. This question will take on increased importance later in this review.

More fundamentally, it becomes increasingly important to understand the reasons why children reduce the likelihood of repartnering, which we now see is only the case when they are coresident children and are children of the woman and not the man (unless he is older and widowed). How important is the fact that, although in most industrialized countries stepfathers have few legal rights or responsibilities vis-à-vis their stepchildren, most men realize that the children will be claimants on their incomes, at least while they remain in the household? The effect of having coresident children appears to be less for Swedish women than for women in the US (cf. Bernhardt and Goldscheider 1999 and Bennett et al. 1995). It may be that the greater support provided to children of all kinds by the Swedish state offsets some of the perceived liability for prospective stepfathers.

A perhaps equally important problem is ambiguity over the nature of stepfather-stepchildren relation-

ships. Stepfathers are discouraged from assuming parental responsibilities for their stepchildren's lives by the children, their mothers, and by the larger society in most western, industrialized countries. Paternal involvement is an important factor in family dynamics, particularly for union stability, and we will examine this topic below.

A further interesting question is how much of the decline in marriage formation is a result of the increase in potential partners with children? Most studies that have examined whether the quality of the partner market has declined have considered women's decisions and have examined trends in the earnings of unmarried men who would be their potential partners. It might be equally interesting to study men's decisions and examine whether trends in men's marriage likelihood are influenced by the changing composition of potential female partners, as increasing proportions have children living with them.

4. Fertility of Couples with Children from Previous Relationships

There have been more studies on the effects of children from a previous union on childbearing in a new union than on repartnering. Few, however, distinguish between coresident and non-coresident children, and none have taken into account the selectivity of repartnering when children are already present as revealed in the studies reviewed above. Nevertheless, these studies have assembled an impressive set of results for a wide range of industrialized countries in Europe, as well as in the US.

Not surprisingly, the general finding is that couples in later unions have lower fertility within those unions than do couples in otherwise comparable first unions, which indicates clearly that many individuals have childbearing goals they do not want to exceed. Their previous children are considered in their decisions to continue childbearing. This result has appeared in studies in Germany, Czechoslovakia, the US, France, and Sweden (cf. references in Vikat et al. 1999).

How much previous children matter and whether it makes a difference whether they are coresident or not remain open questions. They are much more difficult questions to assess for the moment, as there is rarely information on previous children for both members of a couple, particularly on their non-coresident children. The most complete study is a recent analysis of Swedish data (Vikat et al. 1999), which, although it only had data on non-co-resident children for one member of the couple, produced a number of interesting findings.

First, the study found that the effect of previous children is definitely not total, as couples in Sweden appear to have at least one shared biological child independently of previous childbearing by either

partner. The authors interpret this result as indicating that joint children are an important element of a union. Second, the authors were able to rule out some alternative reasons for childbearing in later unions. There was little evidence that the risk of having a first child in a union was higher when one of the partners was childless, suggesting that Swedes do not have a child simply as an indicator of adult status. Further, there was little evidence the couples have a child to produce a sibling for a pre-union child, although couples did appear to avoid having only one shared child. This was interpreted as suggesting that it is full siblings that are considered important by Swedish couples in new unions, not half-siblings. Research on the US indicates that while stepsiblings remain fairly close to each other in adulthood, they are much less close than full siblings (White and Riedmann 1992), although it is unclear how much this difference reflects their different histories prior to coresidence and how much it reflects problems in their relationships while sharing a home. It was not possible to assess how much fertility in repartnerings is affected by co-resident as opposed to non-coresident stepchildren, as full information on the latter was not available.

Fertility in repartnerings is clearly a complex subject, and one that might depend not only on the numbers of children each of the partners has had previously and where they live, but also the genders of those children. Strong gender effects appear in research on stepfamily relationships, and there is evidence that gender of children affects union dissolution (Brooks-Gunn 1994). No studies to date, however, have assessed this issue, as no research has addressed the selectivity of repartnering.

5. Stepchildren and Union Dissolution

One of the most widely observed characteristics of second partnerships is that they are less stable than first partnerships. Although many have speculated that this pattern was the result of one or more elements reducing commitment (from religious prohibitions to personal orientations toward divorce), a landmark study found that most of the difference in marital satisfaction and in stability could be attributed to the presence of stepchildren. Previously childless persons who repartnered had very little greater risk of union dissolution than those in first partnerships (White and Booth 1985). Studies of union dissolution since then have generally included indicators of the presence of non-joint children as well as joint children, and found that whatever protective effect joint children might have does not characterize stepchildren, who increase the risk of separation. Little research has been done, however, on what types of stepchildren contribute more to this effect. Are the ages of the children a factor? Is their sex? Does the involvement of the step-

parent and/or of the non-coresident parent matter? An even more important element might be the parenting practices of the new partners. Two studies of paternal involvement that was restricted to first partnerships showed that greater involvement of a father with his children increased the wife's marital satisfaction (Harris and Morgan 1991) and their children's well-being (Amato 1994); stepfathers are normally less involved with their stepchildren than are biological fathers (Marsiglio 1991).

Related to this issue is a startling finding—that couples with daughters are more likely to divorce than couples with sons (Morgan et al. 1988). The key to this result appears to be paternal involvement with children. Men tend to spend more time with their sons than their daughters, both in one-on-one conversation and in terms of participation in *family* activities, sharing more meals, leisure time, and home activities with them (Cooksey and Fondell 1996). In a sense, stepchildren may be like daughters for many men, children who they wanted less, who they do not relate to as closely, and who they can leave more easily. This may also account for the commonly observed phenomenon that sons often benefit more by their mother's remarriage than daughters (Brooks-Gunn 1994). Given the increased importance of repartnering in the lives of children and their parents in western, industrialized societies, understanding this phenomenon needs to be a high priority.

Replication

'Replication' refers to the repetition of the same or very similar research study. The term 'replication study' refers to a study conducted specifically to verify the results of an earlier study. The concept of replication of research studies is central to the scientific study of psychology and the social and behavioral sciences more generally, as many authors have pointed out in Neuliep (1991).

1. The Importance of Replication

Scientists of all disciplines have long been aware of the importance of replication to their enterprise. Now, thanks to the efforts of science writers for daily newspapers and reporters for network news, even the general public has become aware of the importance of replication in all the sciences.

The undetected equipment failure, the rare and possibly random human errors of procedure, observation, recording, computation, or report, are known well enough to make scientists wary of the unreplicated experiment. When we add to the possibility of the random 'fluke' common to all sciences, the fact of individual organismic differences and the possibility of systematic experimenter effects, the

importance of replication looms larger still to the behavioral scientist.

What shall we mean by 'replication'? Clearly, the same experiment can never be repeated by a different worker. Indeed, the same experiment can never be repeated even by the same experimenter. At the very least, the participants and the experimenters themselves are different over a series of replications. The participants are usually different individuals, and the experimenter changes over time, if not necessarily dramatically. But to avoid the conclusion that there can be no replication in the social and behavioral sciences, we can speak of relative replications. We can rank order experiments on how close they are to each other in terms of participants, experimenters, tasks, and situations. We can usually agree that this experiment, more than that experiment, is like a given paradigm experiment.

Replications may be crucial, but some replications are more crucial than others. Three of the variables affecting the value, or utility, of any particular replication are:

- (a) when the replication is conducted
- (b) how the replication is conducted
- (c) by whom the replication is conducted.

1.1 When the Replication is Conducted

Replications conducted early in the history of a particular question are usually more useful than replications conducted later in the history of a particular research question. Weighting all replications equally, the first replication doubles our information about the research issue, the fifth replication adds 20 percent to our information level, and the fiftieth replication adds only 2 percent to our information level. Once the number of replications grows to be substantial, subsequent investigators' felt need for further replication is likely to be due not to a real need for further replication but for a real need for the more adequate evaluation and summary of the replications already available.

1.2 How the Replication is Conducted

It has already been noted that replications are possible only in a relative sense. However, there is a distribution of possible replications in which the variance is generated by the degree of similarity to the original study that characterizes each possible replication. If we choose our replications to be as similar as possible to the study being replicated, we may be more true to the original idea of replication but we also pay a price; that price is external validity (see *External Validity*).

If we conduct a series of replications as exactly like

		Result of replication	
		Successful	Unsuccessful
Precision of replication	Fairly precise	Supports the theory	Damages the theory
	Fairly imprecise	Extends the theory	Limits the theory

Figure 1

Effects on theory of the success of replication and the precision of replication

		Result of replication	
		Successful	Unsuccessful
Precision of replication	Fairly precise	Supports the investigator	Impugns the investigator
	Fairly imprecise	Supports the investigator	Impugns the investigator very little

Figure 2

Effects on original investigator of the success of replication and the precision of replication

the original as we can, we have succeeded in ‘replicating’ but not in extending the generality of the underlying relationship investigated in the original study. The more imprecise the replications, the greater the benefit to the external validity of the tested relationship if the results support the relationship. If the results do not support the original finding, however, we cannot tell whether that lack of support stems from the instability of the original result or from the imprecision of the replications. Figure 1 summarizes the consequences for the theory that is derived from the initial study of (a) successful vs. unsuccessful replications, and (b) the precise vs. the imprecise nature of the replications.

Figure 2 summarizes the consequences for the original investigator of (a) successful vs. unsuccessful replications, and (b) the precise vs. imprecise nature of the replications. Compared to the theory tested by the replication, the investigator has much to lose if a fairly precise replication is unsuccessful since such failure is often associated with ascriptions to the original investigator of having been careless, incompetent, and in some cases, even dishonest.

1.3 By Whom the Replication is Conducted

So far in our discussion of replications we have assumed that the replications are independent of one another. But what does independence mean? The usual minimum requirement for independence is that the participants in the replication studies be different persons. But what about the independence of the replicators? Are 10 replications conducted by a single investigator as independent of one another as 10 replications each of which is conducted by a different investigator? This issue of potentially correlated replicators bears additional comment.

1.4 The Problem of Correlated Replicators

To begin with, an investigator who has devoted her life to the study of vision, or of psychological factors in somatic disorders, is less likely to carry out a study of verbal learning than the investigator whose interests have always been in the area of verbal learning. To the extent that (a) experimenters with different research interests are different kinds of people, and to the extent

		<i>First study</i>	
		$p > 0.05^*$	$p < 0.05$
<i>Second study</i>	$p < 0.05^a$	A Failure to replicate	B Successful replication
	$p > 0.05$	C Failure to establish effect	D Failure to replicate

Figure 3

Common model of successful replication: judgment is dichotomous and based on significance testing (*by convention 0.05 but could be any other given level, e.g., 0.01; ^a in the same tail as the results of the first study)

that (b) it has been shown that different kinds of people, experimenters, are likely to obtain different data from their subjects, we are forced to the conclusion that within any area of behavioral research, the experimenters come pre-correlated by virtue of their common interests and any associated characteristics. Immediately, then, there is a limit placed on the degree of independence we may expect from workers or replications in a common vineyard. But for different areas of research interest the degree of correlation or similarity among its workers may be quite different. Certainly we all know of workers in a common area who obtain data quite opposite from that obtained by colleagues. The actual degree of correlation, then, may not be very high. It may, in fact, even be negative, as with investigators holding an area of interest in common, but holding opposite expectancies about the results of any given experiment.

A common situation in which research is conducted nowadays is within the context of a team of researchers. Sometimes these teams consist entirely of colleagues; often they are composed of one or more faculty members and postdoctoral students, and one or more predoctoral students at various stages of progress toward the Ph.D. Experimenters within a single research group may reasonably be assumed to be even more highly intercorrelated than any group of workers in the same area of interest who are not within the same research group. Perhaps students in a research group are more likely than a faculty member in the research group to be more correlated with their major professor. There are two reasons for this likelihood. The first is a selection factor. Students may elect to work in a given area with a given investigator because of their perceived and/or actual similarity of interest and associated characteristics. Colleagues are less likely to select a university, area of interest, and

specific project because of a faculty member at that university. The second reason why students may be more correlated with their professor than another professor is a training factor. Students may have had a large proportion of their research experience under the direction of a single professor. Another professor, though collaborating with colleagues, has most often been trained in research elsewhere by another person. Although there may be exceptions, even frequent ones, it seems reasonable, on the whole, to assume that student researchers are more correlated with their advisor than another advisor might be.

The correlation of replicators that we have been discussing refers directly to a correlation of *attributes* and indirectly to a correlation of *data* these investigators will obtain from their subjects. The issue of correlated experimenters or observers is by no means a new one. Nearly 100 years ago Karl Pearson spoke of 'the high correlation of judgments...[suggesting] an influence of the immediate atmosphere, which may work upon two observers for a time in the same manner' in his 'On the mathematical theory of errors of judgment with special reference to the personal equation' (Pearson 1902, p. 261).

2. The Meaning of Successful Replication

There is a long tradition in psychology of our urging one another to replicate each other's research. But, although we have been very good at calling for replications, we have not been too good at deciding when a replication has been successful. The issue we now address is: when shall a study be deemed successfully replicated?

Successful replication is ordinarily taken to mean that a null hypothesis that has been rejected at time 1

is rejected again, and with the same direction of outcome, on the basis of a new study at time 2. The basic model of this usage can be seen in Fig. 3. The results of the first study are described dichotomously as $p < 0.05$ or $p > 0.05$ (or some other critical level, e.g., 0.01). Each of these two possible outcomes is further dichotomized as to the results of the second study as $p < 0.05$ or $p > 0.05$. Thus cells A and D of Fig. 3 are examples of failure to replicate because one study was significant and the other was not. The problem with this older view of replication is that two studies could show identical magnitudes of the effect investigated yet differ in significance level because of differences in sample sizes.

2.1 Contrasting Views of Replication Success

The traditional, not very useful view of replication modeled in Fig. 3 has two primary characteristics:

(a) It focuses on significance level as the relevant summary statistic of a study.

(b) It makes its evaluation of whether replication has been successful in dichotomous fashion. For example, replications are successful if both or neither $p < 0.05$ (or 0.01, etc.), and they are unsuccessful if one $p < 0.05$ (or 0.01, etc.) and the other $p > 0.05$ (or 0.01, etc.). Psychologists' reliance on a dichotomous decision procedure accompanied by an untenable discontinuity of credibility in results varying in p levels has been well documented, for example, by Nan Nelson, Robert Rosenthal and Ralph L. Rosnow (1986).

The newer, more useful views of replication success have two primary characteristics:

(a) A focus on effect size as the more important summary statistic of a study with only a relatively minor interest in the the statistical significance level.

(b) An evaluation of whether replication has been successful made in a continuous fashion. For example, two studies are not said to be successful or unsuccessful replicates of each other, but rather the degree of failure to replicate is specified.

Representation: History of the Problem

Philosophers and social scientists have always been concerned about the relation of their knowledge about the social world to (the rest of) this world. This concern has sometimes been phrased as the question of the representation of the social world in and through the writing of scholars, or as the *adaequatio intellectus et rei*, being the objective of scientific inquiry. From Plato and Aristotle, and then Thomas of Aquinas, this *problématique* stretches into the positivism of the social sciences of the nineteenth century as well as its critical alternative, scientific Marxism. With important qualifications, it was revived in the neopositivism of the twentieth century and the unified science program that tried to (re-) integrate the social sciences with the natural sciences.

Despite this continuity of concern, the very concept of representation of the social world has also been heavily criticized. At several points in intellectual history it appeared as if the whole idea needed to be abandoned, because there is no way to verify the relation between the world and thoughts about the world other than again by thought. Thus, knowledge of *adaequatio* is in principle unattainable. In most recent debate, during the closing decades of the twentieth century, the accumulation of such doubt has often been labelled 'crisis of representation,' implicitly and misleadingly pretending novelty of these doubts. Through all of earlier such crises, however, the *problématique* keeps reviving, often with new qualifications, and those who revive it often argue that it cannot be entirely abandoned either, since otherwise

the status of statements about the (social) world would become entirely unclear.

1. Representation in Philosophical Modernity

Even though this debate has been going on virtually through all of the history of philosophy, the break that came with the radical skepticism characteristic of what can be called the philosophy of modernity is often seen as shifting the terrain. Between the middle of the seventeenth century, Descartes's time of writing, and the end of the eighteenth century, Kant's time, the ground on which representation could be possible was systematically explored. Descartes's *cogito ergo sum* radically subjectivized knowledge claims. Nevertheless, he was able to develop on that basis a rationalism according to which mathematical representation was adequate to the world. Kant's distinction between *noumena* and phenomena has sometimes been interpreted in a similar way, that is, by considering *noumena*, although they cannot be experienced, as theoretical entities the relations between which are governed by laws. A science developing such laws would then be truthfully representing the world. Arguably, however, the more significant impulse from these one and a half centuries of debate was a deep crisis of representation, at least within the philosophical mode of reasoning. This crisis of representation stemmed from the increasing gap between the perceiving and knowing subject and the world.

The combined outcome of the Cartesian and the Kantian moves, namely, was that, on the one hand, philosophical reasoning appeared to have exhausted its possibilities, at least for the time being. At the end-point of this reasoning, on the other hand, a space had been opened for a different form of inquiry. The gap between the subject and the world, or between the *noumena* and the phenomena, permitted, maybe even invited, attempts to fill it by positive, empirical knowledge, elaborated in systematic, conceptually guided ways (see *Positivism, History of*). It allowed the subjectivation and historicization of knowledge claims, which in turn made the social sciences possible, as psychological inquiry into human perception and experience of the world and as sociohistorical collection and systematization of the 'facts' of human social life. Much of the social sciences of the nineteenth century, often devoid of any explicated philosophy of the social sciences, indeed worked on such foundations.

2. Representation in Political Modernity

While philosophical debate opened the possibility for developing a conception of representation of the social world through social science inquiry, roughly parallel political transformations made such a representation appear as an increasingly urgent necessity. These transformations made the concept of representation

increasingly problematic in political thought and practice, a culmination of this process and a turning-point being reached with the American and French revolutions.

A concept of representation had been almost completely absent from political thinking in Europe and the Mediterranean region during antiquity and the Middle Ages. First elements of such a *problématique* gradually emerged with the rivalry between various sources of religious power during the era of the schism, and between religious and political power with the contest between the pope and the emperor. Representation here, most broadly, refers to the relation between a holder of authority to that over which this authority is exercised. Employing the concept of representation for this question presupposes that authority is not held in its own right, but for something or somebody else. The disputes during the late Middle Ages and early modern times were largely cast in terms of the legitimate representation of God, as the uncontested supreme authority, on earth. William of Ockham may have been the first to conclude on the impossibility of deciding in the face of competing claims for representation and, thus, to have opened up a political version of the crisis of representation.

As in the philosophical debate about the knowledge of the world, the period between the middle of the seventeenth and the end of the eighteenth century is of crucial importance for a recasting of the issue of political representation. The first systematic attempt to solve the issue in modern form, that is, by fully acknowledging both the exigency of representation and the undecidability of the question of the sources of authority, was made by Thomas Hobbes. Faced with the religious wars and thus a violent contest over the rightful representation of God, he ruled out any religious source, but insisted on the need for unity in the polity to avoid persistent warfare. The idea of state sovereignty, prepared by Bodin, and of the unitary state represented by the monarch were the key ingredients of his solution to the problem. By making the constitution of the state itself, however, dependent on a contract between individuals, he had opened the breach for individualism, as Carl Schmitt observed. The idea of popular sovereignty, as developed by Locke and Rousseau, should indeed turn Hobbes's reasoning around and prepare the intellectual ground for the political transformations of the late eighteenth century.

Quite analogous to the situation in general philosophy, the development of political philosophy was, on the one hand, stalled with the full explication of an individualist liberal political theory, that is a political theory of modernity (see *Liberalism: Impact on Social Science*). On the other hand, however, insufficiencies of the liberal assumptions, particularly visible in the post-revolutionary situation, lent themselves to the development of the social sciences as means to deal with those insufficiencies by other means, through a

kind of 'empirical political philosophy' namely (Wagner 1998).

Liberal political philosophy was insufficient in the sense that the set of rules on which viable political institutions could be built, starting out from individuals and their potential diversity, needed propositions beyond those that could be derived from the basic assumptions of individualist liberalism. The concept of self-determination needed, for instance, procedural rules of participation in communication and in deliberation. Since such rules could not unequivocally be derived from the principles themselves, the issue of representation emerged much more forcefully than ever before. In response to the French Revolution, Burke (1993) still argued that, while there was a practical issue of representation, best handled in line with grown traditions, there was no specific legitimacy attached to representation. Paine (1993), in contrast, linked most forcefully the idea of the sovereignty of the people to the representation of the people in the governing bodies. The controversy between Burke and Paine 'marks the turning point of two ages of representation' (Sternberger 1971, p. 594). As soon as any position closer to Paine than to Burke was accepted, debates on modes of representation, such as those that had already occurred in both the American and the French constituent assemblies, became inevitable.

And it was in conjunction with this inevitability of disputes over representation that the creation of social effects of the liberal rules moved to the center of attention. The identification and the analysis of these effects called for social science inquiry and conceptualization. The observation of actual, empirical structures of representation also served the interest of enhancing some stability and certainty in political procedures that could appear to be opened to all contingencies by the abolition of any legitimacy of preordained orders (see *Freedom/Liberty: Impact on the Social Sciences*). Two main strategies for rediscovering certainties can be identified: systematic observation and reflective conceptualization. The one was more typical for American thinking, where the structure of the vote was of key interest, whereas European social thinkers focused on what came to be called social structures behind the vote. These two intellectual responses to the political *problématique* of representation inaugurate two modes of social theorizing, the behaviorist and the structural-functional one.

In sum, thus, during the nineteenth century an increasing overlap of concerns between cognitive representation, that is, the truthful representation of social reality, and political representation, that is, the need for a social map to draw up rules for electoral representation can be observed. One may speak here of the gradual transformation of a philosophical conception of representation, based on the political philosophy of the Enlightenment, into a sociological one, based on the sociology of industrial and mass

society emerging at the end of the nineteenth century (d'Arcy and Saez 1985). This rephrasing of the problem of representation was brought again into crisis, however, by the turn of the nineteenth century and, yet again, in the late twentieth century. These crises, although they were also crises of philosophical representation, showed specific features of a crisis of the representation of the social world—and this was again related to political issues of representation.

3. *A Crisis in Modern Representation and its Temporary Solution*

From the late nineteenth century on, a shift in political orientations, which entailed a declining faith in the viability of liberalism, was paralleled in epistemology by a renewed skepticism about the other central tenet of the Enlightenment tradition, the intelligibility of human action and the social world. The period around the turn of the century is now known as an intellectually extremely fruitful, even a classical era in many fields of social science, most notably sociology, psychology and economics. At that time, however, much of the work was driven by a sense of crisis, a feeling that many of the assumptions of earlier social science were inadequate.

In terms of epistemology, social science saw itself forced largely to abandon the idea of representing social reality and accepted the view that conceptual constructions were dependent both on the means and forms of observation and perception and on the interest of the observer in the social world. American pragmatism is possibly the most explicit case of such a reorientation, but similar, often much more tension-ridden, discussions were led in European debates, a prominent example being Max Weber's methodological writings. As a consequence, the turn-of-the-century approaches were less convinced about a determinist course of human history than earlier social science, and also less persuaded of the direct insight into any laws of the social world from empirical observation. Such uncertainty also entailed a crisis in the usability of social knowledge for purposes of action. The earlier call had been for better, 'positive' knowledge that would lead to better action; it relied on the conception of an objective social world outside the mind of the observers, but adequately represented by them in social theory and research. According to such a conception, action based on uncertain knowledge should entail uncertain outcomes.

Through the early decades of the twentieth century, however, novel conceptions of the relation between knowledge and action were proposed that were based not least on a critique of what Dewey (1984, p. 195) called the 'spectator theory of knowing.' With this term, he summarized all views, for him characteristic of most philosophy and science, that saw the world as exposed to the human gaze and assumed that it is

exactly this distance between the knowing subject and the object to be known that allows for certain knowledge. The distancing from the sensations of the world had been considered a precondition for the identification of those assumptions on which claims for valid knowledge could be erected. By the same move, the question of epistemology itself had emerged as the problem of the relation between the 'reality' of the world and the 'representations' that human beings provide of the world in their philosophy and science. The preference in the philosophy of science was for a long time, as Dewey points out, for an epistemological formalism that presupposes this distance between the knower and that which is to be known. Pragmatism precisely rejects this assumption of distance.

Similar turns were made in European philosophy during the same period. Ludwig Wittgenstein had hoped to clarify the problem of representation in the *Tractatus logicus-philosophicus*, in which he employs a picture theory of knowing, whereas in the *Philosophical Investigations* he sees our languages as being part of our forms of life, and thus not looking at life from a distance. In *Holzwege*, Martin Heidegger analyzed the modern theory of knowledge as representation comprehensively as the attempt 'to provide oneself a picture' of the world by making a world that is placed in front of oneself. Rather than making 'a picture of the world,' this move 'grasps the world as picture' (see *Imagination: History of the Concept*). In two intertwined processes, the world becomes a picture and the human being a subject. Rorty tried to summarize this reinterpretation of the history of philosophy and the sciences provided by Dewey, Heidegger, and Wittgenstein as the abdication of the attempt of seeing knowledge as 'the mirror of nature' (Rorty 1979, Friese and Wagner 1997, pp. 208–11).

The critique of representation, in this sense, was linked to the fundamental and critical epistemological presupposition that the social world is in important respects not found and discovered but made and invented. This novel combination, however, provided merely for one strand of debate in the social sciences of the first half of the twentieth century, and it did not become dominant. Partly disregarding epistemological issues, partly referring to the 'neopositivism' of the Vienna Circle, the other major strand tried to deal with the problem of representation by methodological means. At this point, the history of the problem of representation links up closely with the history of statistics and of empirical social research.

In statistics, the period between the end of the nineteenth century and the 1930s witnessed intense debates about a seemingly very specific methodological question. The problem was how to generalize observations collected from the study of a part to statements about the whole. Its solution was a number of statistical techniques summarized under the label of representativity. These techniques were developed simultaneously in debates within the statistical pro-

fession and about the design of social insurance arrangements. An institutional, a cognitive, and a political transformation were closely interlinked, 'the nationalization of social statistics, ... the diffusion of the 'representative method' and of random selection, and ... the beginnings of the development of the Welfare State' (Desrosières 1991, p. 228) (see *Statistics, History of*).

During the interwar period, mathematical techniques spread to other areas of empirical research, not least to the emergent fields of opinion research, of business cycle research and of research into the social structure of society. Special research institutes were created, during those years and particularly after the Second World War, that were to provide the data to which those techniques were to be applied. From the late 1920s onwards, thus, the contours of a new social science, which then should dominate the image of those sciences in the second post war era, are recognizable. This social science liberated itself from the doubts of the 'classical period' by methodologically circumventing the problem of representing society. The doubts about epistemological and conceptual issues could not be entirely removed, but they could be dealt with, it was assumed, by starting from the most secure elements one could find, that is the empirical observation and collection of data on the preferences and behaviors of individual human beings. Conclusions referring to the larger scale of society and politics were arrived at by aggregation of those data; and the questions towards the answering of which data were generated or analyzed were derived from policy needs for 'social control.' Thus, a new connection between cognitive and political representation was created. Or, in other words, a 'soft' behaviorism aligned with a similarly 'soft' pragmatism.

4. The Re-emergence of a Crisis of Representation

However, such solution to the problem of representation remained temporary. During the closing decades of the twentieth century, the 'interpretative turn' or, more broadly, the 'linguistic turn' in the human sciences has had strong, though uneven, effects in the sciences devoted to the study of contemporary society. Emphasis on the linguistic constitution of the social world and on the interpretative openness of social representations brings the social sciences back to a period of epistemological, ontological, and methodological reconsideration that shows many parallels to the 'classical era' at the beginning of the twentieth century.

It has been argued that this recent period of intellectual transformation occurs in parallel to an overall process of sociopolitical transformation. Crises of cognitive and of political representation then again occur in tandem (Wagner 1994). During such periods,

it becomes evident that a social science that tightly couples the concern with social order to the solidity of its own representations of the social world applies at best in periods of relative social stability, that is, only contingently. Conceptually, however, the ideas of unanimity or similarity of behavior being established by common material constraints or well mastered by shared ideas (beliefs, representations) or a diversity of actions being integrated through systematic articulation (division of functions, of roles) works with too restrictive definitions of social life (Thévenot 1993 p. 276). Attention needs instead to be directed towards 'the immense historical labor that is necessary to unite disparate beings around the same system of representation, to constitute the reality of such a heterogeneous ensemble, to inscribe it into devices (*dispositifs*) through an intensive effort of objectification and to endow it with a common interest' (Boltanski 1990 p. 70).

It is important to note that many of the authors who recently have renewed the interest in the *problématique* of representation, such as Michel Foucault and Reinhart Koselleck, have done so by emphasising the linkage between cognitive and political representation. In their own research, they have also underlined that the critical relation between these two forms of representation becomes accentuated during the political and intellectual transformations of the late eighteenth and early nineteenth century. This is at the same time the period of the emergence of the social sciences. They were created to deal with this *problématique*, but they remain nevertheless, or for that very reason, marked by it.

Representation of Serial Order, Cognitive Psychology of

Stimuli come and go. The serial order of their appearance is determined by rules in the external world as well as by the actions of the organism experiencing the stimuli. Consequently, successions of stimuli are almost never random but rather comprise some form of structure. Structure allows prediction, and predicting forthcoming events is advantageous because organisms can prepare for what will happen. Thus, sensitivity to serial order can be considered as being one of the basic mechanisms by which humans (and organisms in general) adapt behavior to constraints in the succession of events. That is why the examination of serial learning has a prolonged research history (e.g., Ebbinghaus 1902, Lashley 1951, Miller 1956).

Serial order refers to deviations from randomness in the succession of events. Consider, for instance, the three colored lights green (g), red (r), and yellow (y) as distinct events. The series g–g–r–g–y–g–r–y–y–g–r–... is random, as each of the lights was selected with equal probability in each position. In contrast, the series g–y–r–y–g–y–r–y–g–... presents the highly regular sequence we experience in watching ordinary traffic lights. Knowing the serial order of traffic lights facilitates responding: if we see that the light switches from green to yellow we can expect that it will next switch to red so that we can prepare to stop before we are really forced to do so. Almost all event sequences entail some regularity: clouds are frequently followed

by rain, words follow each other according to grammatical rules, tone sequences constitute melodies, and baking a cake requires an ordered sequence of actions, etc. In this article, first two types of serial order are distinguished, then several effects of serial order on human cognition are sketched, and finally, the main theoretical approaches to account for serial order effects are mentioned.

1. Statistical and Relational Constraints in Serial Order

Statistical constraints refer to the conditional probabilities of events in dependence on preceding ones. Traffic lights are a good example: after 'red' and after 'green,' 'yellow' is certain to follow, whereas after 'yellow' either 'red' or 'green' follows. If one takes two preceding lights into account, however, the light following 'green-yellow' and 'red-yellow' is also safely predictable. An example of more complex statistical constraints is provided by sentences: the next word in a sentence can mostly be predicted with a probability higher than chance but almost never with certainty, regardless of how many preceding words are taken into account. *Relational constraints* refer to regularities in the relations between successive events instead of conditional probabilities. Consider, for instance, an arithmetic series such as 3-8-13-18-23-28. The regularity of the series is based on that between every pair of adjacent numbers the same relation holds. An example of a somewhat less regular relational structure is a digit sequence such as 23461938, which contains only two equally related pairs of numbers, namely 23-46 and 19-38.

2. Serial Order Effects in Human Cognition

2.1 Serial Order Effects in Prediction

In order to examine the adaptation of predictions to serial order, experiments have been performed in which items are successively presented and participants are asked to predict each forthcoming item. Typically, prediction accuracy improves corresponding to the statistical and/or relational constraints in the succession of items. Moreover, the data indicate that constraints in immediate successions are effective before constraints in the succession of items further apart from each other are taken into account. Consider, for instance, a well ordered sequence such as 1-2-1-2-2-3-2-3-6-5-6-5-5-4-5-4. Experimental data show that participants first learn to predict the respective second items of those pairs whose elements are likewise related, (12), (23), (65), and (54). They continue to learn the repetitions of pairs (1212), (2323),

(6565), and (5454). Finally, participants manage to predict the order of the quadruples (Restle and Brown 1970). In other words, serial learning starts by connecting adjacent items into subunits or chunks corresponding to the given relational (as in the present case) or statistical constraints. Following this, constraints in the succession of these elementary chunks results in the formation of higher order chunks, i.e., connections between elementary chunks, which again are subject to chunking, etc. Thus, consecutive chunking may lead to a representation of the whole sequence through a hierarchy of chunks.

2.2 Serial Order Effects in Remembering

Ordered sequences of items are generally remembered better than unordered sequences (see *Memory: Organization and Recall*). For instance, sequences of words are remembered better if they follow the statistical constraints of word order in sentences (Miller and Selfridge 1950), a list of words is remembered better if words belonging to the same category (e.g., names of fishes, flowers, birds, or trees) are presented adjacently (Underwood et al. 1974), and a series of letters will be remembered better if it consists of familiar abbreviations as in FBICIAPHDVIP. In all these cases subsequences of the items to be remembered correspond to familiar knowledge units like word phrases, categories, or abbreviations which are used to reduce memory load. In the latter case, for instance, participants have to keep in mind the four abbreviations FBI, CIA, PHD, and VIP instead of 12 letters. Moreover, the order of the storage units or chunks may provide a useful retrieval plan which additionally helps remembering. In the categorically ordered word list mentioned above, for instance, memory will be further improved if also the categories are presented in a systematic order such as the animals (fishes and birds) first and then the plants (flowers and trees).

However, new and unfamiliar serial constraints also improve memory. Consider, for instance a so-called 'finite state grammar,' which restricts the way in which the letters T, P, V, X, and S are allowed to follow each other in letter strings. For instance, all grammatical strings may start either with the letter T or P, they may finish either with V or S, only the letters X and V may be allowed to be repeated, after letter T only the letters S, X, and V may be allowed to follow, etc. In this way the 'grammar' constitutes a statistical structure which all grammatical strings such as TXS, TSXXTVV, PTVPS, or PVPXVPS have in common. If such letter strings are to be memorized, grammatical strings are remembered increasingly better than random strings and after some training participants are even able to distinguish between grammatical and agrammatical strings fairly well (Reber 1967). The findings clearly indicate that the completely new and arbitrary stat-

istical constraints have been learned and are used to put order into the letter strings to be remembered.

2.3 Serial Order Effects in Motor Performance

In motor performance, similar effects as in predicting or remembering stimulus sequences have been reported: well ordered sequences of actions are executed faster and more correctly than unordered sequences and, even more informative, the timing of sequence execution mirrors its serial order (Rosenbaum et al. 1983). Consider, for instance, the times for pressing a series of eight distinct keys with the index fingers (I, i) and the middle fingers (M, m) of the right and left hand, respectively. The order of the keys to be pressed shall be such that a first pair of keystrokes (e.g., I–m) is to be repeated (I–m–I–m) and then a second pair is to be repeated (e.g., M–i–M–i). In performing such a regular keystroke sequence as fast as possible, execution times are highest at the beginning of the quadruples *ImIm* and *MiMi*, they are somewhat reduced at the beginning of each repeated pair *ImIm* and *MiMi*, and they are lowest for the respective second element in each pair *ImIm* and *MiMi*. The correspondence of this time pattern with the serial order of the keystrokes suggests that the time to execute a motor act in a sequence of acts is determined by hierarchically organized chunks rather in the same way as the prediction of items is: at the beginning of each new chunk execution time increases as prediction accuracy decreases and for items within chunks execution is fastest and prediction is best (see *Motor Skills, Psychology of*).

2.4 Serial Order Effects in Serial Reaction Time (SRT) Tasks

In SRT tasks, participants are required to respond to successively presented stimuli by distinct responses whereby each response triggers the presentation of the next stimulus, which in turn requires the next response, etc. Numerous studies have shown that nearly any kind of serial order in the succession of stimulus–response pairs results in a decrease in response times (Hoffmann and Koch 1998). Serial-order effects in SRT tasks deserve special attention because besides constraints in the succession of stimuli and of responses, also constraints in the succession of the responses and the following stimuli, i.e., in response–effect relations, may contribute to serial learning. Although not much research has been done yet in this respect, the available evidence clearly indicates that consistent response–effect relations do indeed contribute to the acquisition of serial order (Ziessler 1998). This is most noteworthy because consistent response–effect relations are an essential part of any ordinary behavioral sequence.

3. Intentional and Incidental Acquisition of Serial Order

Some of the mentioned cognitive effects surely result from the explicit detection and use of serial order. For instance, if one tries to predict the continuation of a stimulus sequence on the basis of regularities in the preceding series, or if one tries to reduce memory load by parsing a string of letters into abbreviations, the given serial order is explicitly used to improve performance. However, there are other cases in which it does not seem to be necessary that serial order is detected in order to become effective (Stadler and Frensch 1998). For instance, memory for letter strings generated by a ‘finite state grammar’ improves without the grammatical constraints being reportable. Likewise, in SRT tasks participants respond increasingly faster to statistically ordered stimulus sequences without being aware of the statistical constraints, and consistent response–effect relations have also been shown to decrease response times without being detected. Obviously, serial order can become effective in two ways, once via a strategic use of detected constraints and second via more elementary mechanisms by which serial constraints seemingly inevitably affect performance, irrespective of whether they are detected or not.

4. Theoretical Accounts

The mechanisms underlying the acquisition and use of serial order are not yet well understood. However, it is generally acknowledged that serial learning is accomplished by processes that lead to the formation of *chunks*, i.e., to an integration of successive events into coherent subsequences (Miller 1956). The theoretical accounts differ with respect to the processes which are assumed to mediate the formation of chunks as a result of experienced serial constraints. On the one hand, *explicit strategies* for searching for serial order have been analyzed (Simon and Kotovski 1963). From this perspective, the formation of chunks results from the storage and comparison of subsequences explicitly in the search for identical structures which can be generalized to the whole sequence. On the other hand, it has been acknowledged that constraints in the succession of events also become incidentally effective. For instance, an implicit learning mechanism has been assumed that incidentally associates current/preceding and forthcoming events if the former allow the prediction of the latter. Corresponding simulations in so-called *recurrent networks* have proven that adaptations to grammatical constraints may indeed result from such simple associative learning (Elman 1990, Cleeremans 1993). Other accounts have proposed that events are automatically integrated into a chunk if they are frequently and consecutively experienced in the same succession (Servan-Schreiber and Anderson

1990). Finally, the formation of response–effect associations has also been acknowledged as an autonomous process which may contribute to the formation of chunks in the sense of a series of effects which can be reliably predicted as the outcome of a certain sequence of actions (Hoffmann 1993). Thus, one can conclude that the acquisition and representation of serial order certainly is not a result of only a single process but rather the outcome of different mechanisms which all aim at improving the predictability of forthcoming events.

Representations and Rituals of the State

‘The state,’ wrote Michael Walzer (1967, p. 194), ‘is invisible; it must be personified before it can be seen, symbolized before it can be loved, imagined before it can be conceived.’ Like all human institutions, the state is a symbolic construction. It is not something that can be touched, nor does it exist independently of people’s ability to relate individual actions to a complex and abstract set of ideas. In this article the ways in which the state is constructed through such symbolic processes and how political actors make use of a variety of symbolic means to exert control over it are examined.

1. The Role of Symbolism in Politics

This perspective on the role of symbolic processes in understanding the state is not universally shared. From the time of the Enlightenment, and through to the current day, many scholars and other analysts have identified the real stuff of politics with the play of material forces and the formation of groups by people defending their common interests. In this view, the symbolic dimension of politics—the flags, the ceremonies, the songs and insignias—is of little consequence.

Politics, however, is at its root a symbolic process, for both the creation of political groupings and the hierarchies they spawn depend on symbolic activity. Political reality does not come to us already formed. It must be created out of the symbolic framework that we have previously acquired. The selective perception and radical simplification of potentially relevant stimuli are necessary if we are to make any sense at all out of the infinite number of potential observations that we could theoretically make. The state, like other political institutions, groupings, and roles—political party, ethnic group, president, judge, king—requires symbolic work of this kind. The notion that the world is divisible into a series of mutually exclusive states, corresponding to lines on a map, and that any individual can be assigned to membership in one of them, is part of this symbolic construction of reality (Anderson 1983, Scott 1999).

1.1 Politics as Nonrational Action

Given that people’s views of the state are symbolically constructed and the symbols on which they base their

views are manipulated by various political actors, it is misleading to see the state as the product of rational processes. This is all the more true because one of the most salient characteristics of the symbolic process is that it not only fashions certain views of reality, but also invests these perceptions with heavy emotional weight. 'A fine symbol,' wrote one Italian analyst, 'has greater weight than a mediocre fact' (Camillo Pellizzi, cited in Gentile 1993, p. 84).

1.2 The Nature of Political Representations

If, as beings who attempt to make sense of the world, we relate to politics not directly, but only through symbolic means, just how does this process work? Anthropologists have long been interested in such questions, although the pioneering work in this field suggested that it was peoples in small-scale, nonliterate societies who were particularly at the mercy of such symbolic activities in their political life. Meyer Fortes and E. E. Evans-Pritchard, in their 1940 volume, *African Political Systems*, which created the subfield of political anthropology, pointed to the mystical credentials of the African ruler, who served as the symbol of the people's unity. 'Members of an African society,' they wrote, 'feel their unity and perceive their common interests in symbols, and it is their attachment to these symbols which more than anything else gives their society cohesion and persistence' (1940, p. 17).

More recent anthropological investigation of state-level politics has retained the Durkheimian emphasis on the key role that symbols and rituals play in promoting social order. But it has expanded the paradigm in two ways. First, the Fortes/Evans-Pritchard formulation regarding the political role of symbolism has been generalized to apply to all societies, no matter how large or complex. Second, it is now recognized that the symbolic process is just as crucial in bringing about political change as it is in maintaining the political status quo. Clifford Geertz's work has had a major impact here. 'At the political center of any complexly organized society,' he wrote, 'there is both a governing elite and a set of symbolic forms expressing the fact that it is in truth governing ... they justify their existence and order their actions in terms of a collection of stories, ceremonies, insignia, formalities, and appurtenances that they have either inherited or, in more revolutionary situations, invented' (1985, p. 15).
