Schematic diagram illustrating a mechanism of sympathetically generated phantom limb paresthesias. Spontaneous sympathetic activity or excitatory inputs descending from cortex (e.g., due to the perception of a salient event, loud noise, thought, feeling, etc.) increase the discharge rate of preganglionic (pg) sympathetic neurons with cell bodies in the lateral horn (LH) of the spinal cord and terminals in the sympathetic ganglion (SG). These neurons excite postganglionic noradrenergic (NA) cutaneous vasoconstrictor (cvc) and cholinergic (ACh) sudomotor (sm) fibers that impinge on effector organs (vascular smooth muscle and sweat glands) in the stump and on sprouts from large diameter primary afferent (pa) fibers that have been trapped in a neuroma. The release of ACh and NA on effector organs results in increased electrodermal activity (EDA) and decreased blood flow (BF) to the stump. Release of these chemicals in the neuroma activates primary afferents that project to spinal cord dorsal horn (DH) cells subserving the amputated parts of the limb. These neurons, in turn, feed back to the preganglionic sympathetic neurons and project rostrally where the impulses contribute to the perception of phantom limb paresthesias. If DH cells have been sensitized due to injury, or nociceptive primary afferents are activated, then the perception may be one of dysesthesias

Source: Adapted from Fields 1987, with permission

triggered by emotional distress as long as seven years after amputation. A combination of progressive relaxation training and Electromyographic (EMG) bio-feedback of stump and forehead muscles produces significant reductions of phantom limb pain and anxiety, which are sustained for up to three years.

Psychological or emotional processes can bring about transient but profound alterations in the quality and intensity of phantom limb sensations. These

processes include concentration, distraction, relaxation, fright, forceful reminders of the events that led to amputation, and witnessing cruel and violent acts. One amputee, interviewed by the present writer, described his reaction to an accident involving his wife by reporting 'goose bumps and cold shivering down the phantom [leg]. It went through me. Everything emotional will get you that.' Another amputee stated, 'It's like everything I feel goes there—the good and the bad' (Katz 2000).

2.5 A Centrally-triggered Sympathetic-efferent Somatic-afferent Mechanism

The model schematically represented in Fig. 2 outlines a mechanism through which cognitive and affective processes associated with higher cortical and limbic centers may alter phantom limb sensations. The reciprocal connections between cortical, limbic, and lateral hypothalamic structures are well documented. The lateral hypothalamus is involved in the control and integration of neural activity associated with affectively charged behavior, and has direct projections to the lateral horn of the spinal cord. The intensity of phantom limb paresthesias and dysesthesias may thus be modulated by higher brain centers involved in cognitive and affective processes via a multisynaptic network of descending inputs, which impinges on preganglionic sympathetic neurons, producing diffuse peripheral autonomic discharge and activation of primary afferent fibers located in stump neuromas.

3. Summary and Conclusions

The phantom limb is not perceived as a static entity but as a frequently changing perceptual experience dependent upon the current sensory input, emotional state, and past experience of the individual amputee. Phantom limb phenomena range from simple, diffuse sensations of tingling to perceptually complex experiences of pains and lesions that originally were felt in the limb prior to amputation. While phantom pains and other sensations frequently are triggered by the perception of salient events, thoughts, and feelings, there is no evidence that the painful or painless phantom limb is a symptom of a psychological disorder. The sympathetic nervous system may provide an important link between higher brain centers involved in cognitive and affective processes and phantom limb sensations through its peripheral actions on primary afferents located in stump neuromas.

Phenomenology in Human Science

Conceiving of phenomenology as a methodology of the human sciences imposes two types of constraint on the treatment of phenomenology. Since both types have formal as well as thematic implications they deserve a few introductory words of clarification.

1. The Asynchronism of Phenomenology and the Human Sciences

Relating phenomenology with the social and behavioral sciences involves a many-sided problem of *asynchrony*. When phenomenology emerged as a philosophical enterprise at the end of the nineteenth and the beginning of the twentieth century there were no social and behavioral sciences. At best there were currents at thought, hardly disciplines, that only very much later, after significant modifications and paradigmatic shifts, were categorized as social or behavioral sciences. There was, however, for instance psychology, known, criticized, adapted, or rejected by early phenomenologists, and those attitudes were reciprocated (Spiegelberg 1960). Above all, psy-

chology was not (and never became) a unitary science, but a set of competing (and changing) schools of thought. A similar variety and changeability holds for early sociology. Also phenomenology changed and has kept changing, sometimes with one and the same author, Husserl himself being the most notorious example (Embree et al. 1997).

Hence it happened that the psychology to which the ‘early Husserl’ referred was quite different from the ones the ‘middle’ or even the ‘late’ Husserl was confronted with. This variety increases considerably if different phenomenologists are considered, such as Husserl, Pfänder, Scheler, Heidegger, Merleau-Ponty, Sartre, and Schütz. Excepting Husserl, their names indicate that these philosophers were not only, at least not always, phenomenologists. If one defines, as it is done within the scope of this article, phenomenology as a methodological attitude the latter can be adopted for a specific purpose, but does not necessarily make its user a phenomenologist for good. Historically seen, ‘doing phenomenology’ (Spiegelberg 1960) is—for philosophers as well as human scientists—a much more appropriate characteristic than ‘being a phenomenologist.’ After all phenomenology has, according to Spiegelberg (1960), been a movement rather than a school. Variety has always been greater than unity.

Also in the sciences with which phenomenology got related there has been considerable variance. The early psychology, for example, of associationism and elementism had so little in common with gestalt psychology which, in turn, was so different from behaviorism or from modern cognitivism that for each of them the relationship with phenomenology has carefully to be redefined, in fact from both ends.

In sociology, whose relationship with phenomenology has been more intensive and durable, it is important to identify carefully the theoretical position with which phenomenology is related. More than is the case in other social sciences sociology provides approaches and specialties engendered or influenced by phenomenological thinking, such as ethno-methodology and conversation analysis and, above all, there is an academically established phenomenological sociology which, mainly thanks to the oeuvre of Schütz (1962/66), has been considered the prototype of phenomenology in the context of social sciences. ‘Phenomenological Psychology,’ however, as it was introduced by Husserl (1925/1977) will have to be disregarded in this article, as far as it is the name for a branch of transcendental philosophy. The prominent exception remains Gurwitsch’s (1964, 1966) creative synthesis of gestalt theoretical psychology and phenomenology.

At the end of the twentieth century we register many unilateral as well as mutual influences between phenomenology and the human sciences—the latter term, by the way, popularized by phenomenologists like Merleau-Ponty, Strasser, and Ricoeur. Among these sciences there are many of very recent origin. The

phenomenology with which they relate may be of any vintage (idealistic, realistic, existential, hermeneutic), sometimes treated in an eclectic manner. The responsibility, however, for the resulting phenomenological eclecticism rests with the human scientists.

To summarize the references to the first type of constraint: whoever is interested in the relationship between phenomenology and the human sciences must keep in mind its asynchronous historicity and multiplicity.

2. Phenomenology as Methodology

The second type of constraint is the limitation to *methodology*. On the one hand, this should be self-evident if one considers the number and variety of the sciences involved (Natanson 1973). An encyclopedia of phenomenology (Embree et al. 1997) lists phenomenological approaches and tendencies in about two dozen nonphilosophical disciplines, most of which belong to the human sciences. It is their inequality in terms of age, formalization, homogeneity, empiricism, and affinity with natural or cultural sciences that renders their comparability with phenomenology so complicated.

On the other hand, the limitation to methodology should not be too constraining; phenomenology itself is widely considered a specific methodological approach. Even if occasionally phenomenology is ontologically demarcated and referred to as the *systematic study of human consciousness or experience*, this is not much of a constraint if one accounts for *intentionality* with which phenomenologically (almost) all mental processes (perceiving, thinking, judging, remembering, feeling, desiring, willing) are endowed, namely, as meaning-something-as-something in being aware of it. Both this perspectival meaning-relatedness and the corresponding 'horizon of all horizons,' the *lifeworld*, in which 'things appear in terms of their experiential qualities, values, and uses' (Welton 1997), have become criteria of a phenomenological approach or orientation in the human sciences. The terms of 'approach' and 'orientation' are given preference to the totalizing (and hence overdrawn) designation of a phenomenological psychology, sociology, etc.

3. Performing the Epoché

Before these criteria can be exemplified a brief look into the central (Husserlian) method of *epoché* may be permitted although its proper field of application, transcendental phenomenology, is beyond the scope of this article. Yet the basic idea of *epoché* and of the related method of *reduction* provides the master-key to phenomenological methodology.

As agents in their everyday life human beings experience the world, including their own acting,

perceiving, feeling selves, as really existing. Husserl (1977) considered this universal belief in the actuality (*Wirklichkeit*) of the world the general thesis of the *natural attitude*. For the purpose of a phenomenological analysis, this belief has to be suspended (as far as possible). Suspension means neither negating nor doubting the existence of world and self. The belief, normally pervading all acts and states of consciousness, is merely 'bracketed,' that is, put out of operation. These metaphors are to signify the transition from the natural to the phenomenological attitude. By means of this transition world and self are transformed into, that is, reduced to, mere phenomena.

4. Criteria of a Phenomenological Approach

While the transcendental-phenomenological purpose of performing the *epoché* is of little or no interest in the human sciences and even phenomenologists like Merleau-Ponty (1962) have done their phenomenological analyses without performing *epoché*, the suspension of beliefs is an important methodological tool which is operative in what traditionally have been called the functions of a phenomenological approach in human science: (a) the critical, (b) the descriptive, and (c) the interpretive function. Although critique, description, and interpretation are distinct methods which for many purposes must be kept apart, under phenomenological premises they turn out to be inter-related.

4.1 The Critical Function

Given the fundamental postulate 'to the things themselves,' the primordial method is some kind of *epoché*. Critical is here the practice of disbelief with respect to all explicit and silent assumptions one has held so far about the matter to be studied, the theories, hypotheses, and methods, provided by the pertinent science, but also a self-critical avoidance of personal habits and predilections of thinking that may bias or distort the required 'fresh look' at the phenomenon in question. Equally critical the phenomenological observer has to be with respect to the language in which the unbiased observation has to be described. The theories that are to be suspended are often implied in the concepts that are intended to be descriptive, but actually are interpretive. A special difficulty arises here for the psychologist since the language for mental states and processes is predominantly metaphorical.

4.2 The Descriptive Function

As anticipated these critical caveats are also an introduction into the problem of phenomenological description in the human sciences. Although as old as

phenomenological methodology one caution has to be reiterated, since its disregard has turned out to be one of the most obstinate prejudices, namely that a phenomenological (-psychological) approach amounts to a method of introspection. The opposite is closer to the truth: phenomenological or 'intentional(ist)' description focuses on persons, selves, or others, as they are encountered in everyday situations. To clarify what this means a synthesis will be presented of conceptual-methodological recommendations that can be gathered from the writings of Husserl, Gurwitsch, Löwith, Merleau-Ponty, and from the phenomenological approaches in human science, mainly in psychology, psychiatry, and sociology.

The methodological foundation of phenomenological description was laid by Husserl who, in his 'principle of all principles,' demanded to describe things as they are experienced, strictly within the limits, but also to the full extent in which they are experienced. A merely consequent, but historically influential specification of this postulate was given by Gurwitsch who, in his doctoral dissertation of 1929 (a study of relations between phenomenology and gestalt theory) had adopted the *field concept* (see *Lewin, Kurt (1890–1947)*) and applied it to Husserl's concept of noema: a 'theme' in the center of what one is aware of is always experienced within a 'thematic field' and further 'marginal' objects of consciousness (Gurwitsch 1964). His study of the relationship between theme and thematic field explicates what Husserl since his 'Ideas' has developed as the *horizontal structure of consciousness*.

Closely connected was Gurwitsch's thematization of *perspectivity (avant la lettre)*: an object, perceived from different angles and distances, that is, from varying viewpoints, presents itself as identical in a system of noemata. Both conceptions, perspective, and horizon, have become essential guidelines for phenomenological description:

(a) Whatever is experienced (perceived, cognized, remembered, imagined, anticipated), is experienced from a given viewpoint (an epistemological insight going back to Leibniz) and as the same from varying (i.e., successive) viewpoints.

(b) Whatever is experienced from a given viewpoint is experienced in an horizontal structure that corresponds to and changes with the point of view or perspective. Horizon means, as the everyday usage suggests, both limitation and openness of experience. Moving one's 'standpoint' leads to a shift of horizons, which holds for physical, bodily, as well as mental locomotion.

(The fact that human beings are inevitably *en route* to the horizon without ever reaching it, only the places where it was, has been made a topic of phenomenological anthropology by van Peursen 1954.)

Both perspective and horizon have become interrelated structural elements of the phenomenological conception of *situation*. Whatever or whomever a

person experiences is encountered in a perspectively structured situation. The essential *situatedness of experience* entails that in everyday experience, there is no 'decontextualized' object (thema): human beings coexist with nonhuman objects and, inversely, objects, as utensils, refer to their users, as Heidegger (1962) has shown.

Karl Löwith, a student of Heidegger, was one of the first who, in his study of *The Individual in the Role of Fellow Human Being* (1928), developed a phenomenological (i.e., nonbehavioristic) concept of human behavior or comportment (*Verhalten*). He distinguishes between three ways of relating in behavior: (a) with others (fellow human beings), (b) with nonhuman objects (e.g., utensils), and (c) with oneself. He demonstrates that and how each of these intentional directions involves the other two. For example, relating with a fellow being involves not only objects belonging to him or her or to oneself, but also a modification, although not necessarily conscious, of one's self-concept.

Decades later, in a simplified version, the social psychologist T. M. Newcomb, who had developed a model of communicative acts, in which two persons communicate about something, argued that for social psychology there is no (purely) interpersonal relation in an environmental vacuum, nor any object-relation in a social vacuum.

Löwith's conception of the interdependence of the world of fellow human beings (*Mitwelt*), the world of things (*Umwelt*), and self, was further elucidated and made relevant for phenomenological description in Gurwitsch's study of the 'encounter of fellow human beings within the horizon of the natural surrounding world,' in which the world of utensils (*Zeug-Umwelt*) is a prototype of what Max Scheler—in critical opposition to Husserl's 'platonizing' phenomenology—had introduced as 'milieu' (from which Gurwitsch derived his (German) title of the *Milieuwelt*). Not unintentionally, Scheler (1973) had made use of the term 'milieu.' After its misuse in deterministic theories of descentence, Scheler reinstated milieu as a relational term: milieu is what has effects on an organism. For humans, only those objects constitute the milieu which correspond to the values of human attitudes.

'Milieu' came to be replaced by *Umwelt*. This term was introduced into biology by von Uexküll (1909) to signify the subjective environment that corresponds to the structure and state of an organism's 'inner world.' As sensory *Merkwelt* and as motor *Wirkwelt* Umwelt is species-specific. Uexküll himself generalized the concept to the meaningful ambient of persons. As the environment-as-experienced-and-acted-upon by human (and animal) beings *Umwelt* is quasisynonymous with the phenomenologically conceived situation. Beyond phenomenology, it has been adopted for *The Study of Relations in Public* by Erving Goffman (1971) and, within the 'dramaturgical model'

of social life, by Rom Harré (1979). In the context of gestalt theory K. Koffka (1935), for whom phenomenology meant 'as naive and full a description of direct experience as possible,' introduced a distinction between the 'geographical' and the 'behavioral' environment. The famous exemplification is the German legend of the man who during a snowstorm rode over the frozen Lake Constance but dropped dead when he learnt what he had just done. The 'geographical' environment was a lake, the 'behavioral' environment a snow-covered plain. In other words and phenomenologically, the horseman's behavior was 'a riding-over-a-plain, but not a riding-over-a-lake.' Koffka's example, although fictitious, once more illustrates the validity of the 'postulate of all postulates' and the full applicability of intentionality to behavior and environment.

Without regarding his own approach as phenomenological, Charles Taylor (1964) refers to Koffka (as well as to Merleau-Ponty), when he proposes the method of 'intentional description' for the analysis of 'intentional environments.'

The globalization of the environment as it is experienced and acted upon is to be seen in one of the major meanings of *lifeworld*, the world as the ensemble of what is taken for granted. Its structures have been analysed by Schütz and Luckmann (1973/1989).

4.3 From Description to Interpretation

Since the taken-for-grantedness is a significant, but normally latent feature of everyday situations its analysis goes beyond mere description. In a phenomenologically oriented psychology and psychiatry the *situated person*, conceived as body-subject in meaningful and spatiotemporally articulated environments, has since Merleau-Ponty (1962) and the Utrecht School (Kockelmans 1987) been in the focus of interest (Herzog 1992, Herzog and Graumann 1991). The situated person's intentional relatedness in its various manifestations of perceiving, acting, desiring, feeling, remembering, communicating, and sharing their situation with others, has become the topic and task of phenomenological studies in the human sciences. Phenomena, however, are, as Heidegger (1962, §7) argued, only partly and certainly not initially apparent, but hidden. Also what is taken for granted is hidden from attention. To uncover the implicit efficacy of the partly hidden, *heuristic categories* have been developed, some of which will be briefly indicated.

A subject in intentional relation to objects and/or other persons is the minimal constitutive structure of a situation. As has been argued before, the subject has a place from which the situation is perceived or acted upon which, in turn, implies that the subject is or has a body occupying that place (as viewpoint) at a given time and for a certain duration and at a distance from whatever or whomever the body-subject experiences.

Following the implications of these few situational features will reveal a host of possible conditions or determinants of the experiences to be studied. To name a few: the body-subject *per se* is of a given gender, age, state of health, mood, civil or social status, group or class or ethnic membership, plus any of a set of psychological, for example, personality characteristics, etc. Some of these features will be relevant for the experience or behavior to be studied, some will not. But none of them, however inconspicuous or hidden, must *a priori* be considered irrelevant or even 'taken for granted.'

The same careful attention is to be paid to the other elements of the situation: its spatiotemporal articulation, its historicity, and last, but not least, its sociality and communicative structure. Since the latter term covers a wide range from spoken and written language to nonverbal communication and silence, the categories developed in philosophies and the techniques provided by the various sciences of language and signs may help to identify and to elucidate the variety and the intricacies of situated discourse and communication.

5. Concluding Comments

While it is true that many researchers, mainly those from an experimental tradition, shun the time, the effort, and the expense necessarily connected with phenomenological description and hermeneutic interpretation, it is equally evident that phenomenological methodology has been established firmly in social and behavioral sciences with a long-standing exchange with phenomenology (like psychiatry). But this methodology is also gaining a foothold in sciences without this tradition (like behavioral geography, ecology, political science, and even artificial intelligence). One may speculate whether the increasing interest in phenomenological methodology is a consequence of the generally growing realization that many of the traditional natural sciences, at least, to the extent that human beings are involved in natural and technical processes, are also human sciences.

C. F. Graumann

Phenomenology in Sociology

1. The Origins and Scope of Phenomenological Sociology

Phenomenological sociology is the prescientific study of social life and the process by which humans interpret, experience, and understand their individual and collective realities. The work of the social philosopher

and sociologist Alfred Schütz (1899–1959) provides the most important foundation for phenomenological sociology. Framed in the general atmosphere of the debate between scientific and antiscientific movements that arose in the late nineteenth century, phenomenology places the social sciences in the context of everyday life (Thomason 1982). Strongly influenced by Henri Bergson, Edmond Husserl and William James, Schütz argues that a prescientific understanding of everyday life provides the only means by which a science of society is possible. 'The sciences that would interpret and explain human action must begin with a description of the foundational structures of what is prescientific, the reality which seems self-evident to men remaining within the natural attitude. This reality is the everyday life-world' (Schütz and Luckmann 1973, p. 3).

Just as the natural scientist must first understand the composition and interactions of subatomic particles in order to understand the nature of chemical reactions, the sociologist, Schütz argues, must understand the common-sense world. Unlike the subatomic world, however, the world of everyday life is permeated with the understandings given by those who constitute it. The task of the phenomenological sociologist is to understand how people make sense of their own lives. According to the phenomenologist, these subjective sense-making activities in everyday life are based on taken-for-granted knowledge passed down from generation to generation. In order to understand scientifically these subjective social actions the scientist must replace common sense explanations with objective scientific constructs derived from social theory (see *Theory: Sociological*). The phenomenologist seeks to understand social action in its own subjective terms, yet to describe this world scientifically using the tools of an objective science of society. The foundation of all social science, according to the phenomenologist must be the life-world.

2. The Life-world

Schütz states that the life-world (*Lebenswelt*) can be understood as 'that province of reality which the wide-awake and normal adult simply takes for granted as common sense' (Schütz and Luckmann 1973, p. 3). The everyday life-world provides us with a sense of the 'real.' It is through our position in, and experience of the life-world that we are social beings engaged and affected by the social and natural worlds. The most important characteristic of the life-world, according to Schütz, is that it is taken-for-granted. By this he means that individuals apprehend their worlds and its problems as self-evidently real—'that's just the way it is.' As a result, most individuals, most of the time, give little thought to the 'true' nature of the world around them. 'It is the unquestioned givenness of the life-world for its denizens, including those whose business

it is, in professional terms, to analyze problems of the social world, that phenomenology finds the ground of the social scientist's activity' (Natanson 1973, p. 40).

Taken-for-grantedness arises out of the typification of the phenomenal world. That is, our perceptions are categorized from a shared stock of knowledge as 'this' or 'that' type of thing. Our typifications, however, are only of an approximate nature. Such categories are held only until further notice. If contravened by future experiences, typifications must either be abandoned or reformulated. Taken-for-grantedness is further enabled through the use of time tested recipes for social action. Of the unlimited realm of potential social action open to individuals, most potential actions are circumscribed by a taken-for-granted sense of what is possible and not possible in such typical situations.

The universe of potential recipes for social action is also part of the social stock of knowledge from which typifications are drawn. An important point to be made is that the social stock of knowledge complete with its typifications and recipes for social action is pragmatic in nature. We simply tend to do what works and to avoid what does not work. Through typification and the use of recipes for social action the world becomes unproblematic and a matter of common sense.

3. Phenomenology and Science

A phenomenological study of the social world is one that addresses how humans experience the life-world. In contemporary sociology, phenomenological research has largely been identified with any research addressing the subjective perspectives of social actors. This, however, is a misunderstanding. Properly understood, phenomenology is prescientific, an attempt to ground the social sciences in human experience, a subjective appreciation of the human condition (Embree 1988, p. 270). Schütz (1962a) argues that if we are to understand social reality all social scientific constructs must not only be linked to what people experience, but how they experience it. Scientific understandings must be connected to the experiential process through which people in their everyday lives actually experience the world. He states, 'correctly understood, the postulate of subjective interpretation as applied to economics as well as to all other social sciences means merely that we always can—and for certain purposes must—refer to the activities of the subjects within the social world and their interpretation by the actors in terms of systems of projects, available means, motives, relevances, and so on' (Schütz 1962a, p. 35).

Phenomenological sociology has sometimes been inappropriately labeled as 'anti-scientific.' This misconception stems from the anti-scientific intellectual climate from which phenomenology arose (Thomason 1982). Sensitive to these movements, Schütz indeed

understood the dehumanizing possibilities of science. His answer to this problem, however, was not to abandon science, but rather to ground the social science in the motives and realities of everyday life. Phenomenology does not necessarily attempt to replace or debunk science, but rather to provide a foundation for empirical investigations.

4. The Contribution of Phenomenology in Sociology

The possibility of a phenomenological sociology has been partially realized in two current sociological traditions: social constructionism and ethnomethodology. While both approaches address the life-world and its subjective realities, neither has fully realized the potential Schütz saw for a truly phenomenological sociology. That is, both have addressed the subjective nature of the social world, but neither has been the foundation of an objective science of society.

4.1 Social Constructionism

Phenomenological interest in the mediated and negotiated nature of all knowledge gave rise to social constructionism in sociology. Social constructionism, simply stated, is the study of the way in which people agree upon and define what reality is. Perhaps the most important work in this field is *The Social Construction of Reality: A Treatise in the Sociology of Knowledge* (Berger and Luckmann 1966) (for example, see *Sociology, Epistemology of*).

At the heart of social constructionism can be found one of phenomenology's most important concepts, the epoch. The epoch amounts to a radical skepticism not unlike Descartes' method, where belief in the 'realness' of the world is suspended. Schütz (1962c, p. 102) however, claims that Descartes was 'not radical enough,' that Descartes conclusion '*cogito, ergo sum*' ['I think therefore I am'] failed to doubt and analyze the thought itself. By methodologically setting aside or 'bracketing' the everyday world and even the nature of thought itself, the phenomenologist seeks to 'go beyond the natural attitude of man living within the world he accepts, be it reality or mere appearance' (Schütz 1962c, p. 104). The purpose of the phenomenological reduction (epoch) is to strip through the world of belief to the realm of consciousness and to examine the resulting contents.

Thomason (1982) points out that social constructionism in sociology stemming from the epoch can best be described as a methodological constructionism. Unlike ontological constructionism, methodological constructionism does not question the existence of a real world, but rather suggests that what we know of the world is always mediated and indirect. Methodological constructionism most closely resembles

Schützian phenomenology. Schütz states 'I am afraid I do not exactly know what reality is, and my only comfort in this unpleasant situation is that I share my ignorance with the greatest philosophers of all time' (Schütz 1964, p. 88, Thomason 1982, p. 4). That is, the methodological constructionist examines the agreements people make about the world, but does not question that a real world exists. Social constructionism remains an important field of inquiry in the natural and social sciences, but is of particular importance in sociology.

4.2 Ethnomethodology

Ethnomethodology is the second intellectual tradition linked to phenomenology. Ethnomethodology is also connected to the epoch, but most importantly to Schütz's commitment to the importance of the everyday life-world. However, unlike the prescientific and proscientific work of phenomenology, ethnomethodology as formulated by Garfinkel (1963) represents a radical break from the traditional models of social science with which Schütz had once tried to reconcile (Lynch 1988, p. 93). Ethnomethodology seeks to understand the method by which individuals construct, negotiate, and agree upon reality, but questions the possibility of an objective science of the subjective human condition. As a radically subjective pursuit, ethnomethodology falls short of the objective science of the life-world Schütz envisioned. Concerning such radically subjective endeavors Schütz (1962b, p. 52) maintains 'a method which would require that the individual scientific observer identify himself with the social agent observed in order to understand the motives of the later, or a method which would refer the selection of the facts observed and their interpretation to the private and subjective image in the mind of this particular observer, would merely lead to an uncontrollable private and subjective image in the mind of this particular student of human affairs, but never to a scientific theory.' While ethnomethodology remains an important influence in sociology, as currently formulated it falls short of the phenomenological sociology Schütz envisioned.

Without question, phenomenology has had a major impact upon modern sociology. Social constructionism and ethnomethodology each display a commitment to the epoch and the fundamental importance of the life-world, and therefore can directly be traced to phenomenological thinking. Both methods of analysis remain viable sociological traditions, and will no doubt continue to inform social research.

Phenomenology: Philosophical Aspects

Phenomenology has been one of the most influential twentieth century philosophical traditions. It began with the appearance of Husserl's *Logical Investigations* in 1900–01 and of Pfänder's *Phenomenology of Willing: A Psychological Analysis* in 1900, and continued with the work of philosophers such as Johannes Daubert, Adolph Reinach, Moritz Geiger, Max Scheler, Edith Stein, Gerda Walther, Roman Ingarden, and Wilhelm Schapp. These phenomenologists were active in Munich and Göttingen and the movement to which they belonged is often called 'realist phenomenology.' Throughout the century

phenomenology has been the object of a variety of increasingly far-reaching transformations: by Husserl himself, whose ideas in 1913 marked a turn towards an idealist and transcendental form of phenomenology and then by Heidegger, Sartre, and Derrida, among many others. Among phenomenologists who remained faithful to realist phenomenology were Ortega y Gasset, in Spain, and Felix Kaufmann and Alfred Schütz in Vienna, where Brentano's teaching at the end of the nineteenth century had launched the project of an exact descriptive psychology and caught the imagination of Austrian philosophers such as Meinong, Ehrenfels, Twardowski, and Husserl. In all its forms phenomenology has continued to influence sociology and the philosophy of the social world.

Phenomenology was initially conceived of as the careful description of the mind—act phenomenology—and its objects—object phenomenology. Successful description, it was thought, would lead to an account of the main types of mental phenomena, the main types of their objects, and of the necessary and often *a priori* interconnections between these. In Husserl's *Logical Investigations* knowledge, verification and logical structures are described as though they could in principle be instantiated by a solitary subject or even by solitary mental acts. But phenomenologists quickly began to describe the social aspects of mental phenomena and to analyze the nature of social objects.

Among the most important results of the early phenomenologists are their accounts of awareness and understanding of other minds, motives, social acts, collective intentionality, the main forms of social life, and the nature of social objects. These contributions to the phenomenology of social phenomena were also employed in discussions of social and political philosophy and in the creation by Scheler of the sociology of knowledge (for partial overviews see Toulemont 1962, Theunissen 1977).

1. Empathy, Understanding, and Motivation

In what does Mary's awareness of Sam's sadness consist? Phenomenologists of nearly all stripes attempted to defend two claims about such awareness—sometimes called 'Einfühlung' or 'empathy'—which also, they thought, hold of awareness of physical objects. Awareness of other minds can be, and often is, direct and perceptual. Together the two theories constitute direct realism about other minds. Critical realism about our awareness of physical objects is the claim that we do not directly see things but infer from sensory data to their existence. Similarly, critical realism about other minds is the theory that we are not directly aware of other people or their mental states but infer to these on the basis of sensory data. On the phenomenological view, Mary can directly see Sam and his sadness and her perception need involve no

judgement or conceptualization and thus no inference. This view rests on the arguments given by early phenomenologists to show—against Kant and Helmholtz—that visual perception of things and events need involve neither inference nor concepts.

Traditionally the most popular variant of critical realism about other minds has appealed to reasoning from analogy. On the basis of observed analogies between her own behavior and mental states and observation of Sam, Mary is capable of attributing sadness to Sam. The locus classicus for criticisms of accounts of this kind is Scheler's 1913 appendix to his *On the Phenomenology and Theory of Feelings of Sympathy, 'On the other I.'* Scheler's own view contains the claim that Mary's awareness of Sam's sadness is as direct and as subject to error as her awareness of her own mental states (see on this Schütz's papers on Scheler in Schütz 1970, 1973). Less ambitious and more sober defenses of direct realism were provided by Edith Stein (1917/1980), who gives a subtle account of the relation of expression between mental states, on the one hand, and behavior and gestures, on the other hand; by Husserl (1973), who argues that Mary sees Sam's body as similar to her own body without judging this and thus without any reasoning from analogy; and by Schütz (1932). Phenomenological accounts of empathy also discuss the claim that some types of awareness of the feelings of another person involve make-believe feelings. Of the Gestalt psychologists influenced by phenomenology, Köhler (1947, Chap. 8) and Koffka (1946, Chap. 1) retain the claim that awareness of other minds need involve no judgement or inference but endorse critical realism. Bühler (1927, §9) defends both parts of the direct realism of the phenomenologists but within a naturalist and biological perspective that takes into account the dynamics of understanding other minds and the role of both steering mechanisms and criteria in bringing about 'mental contact.'

No account of empathy is complete without an account of what it is to understand other people. From the beginning, phenomenology was concerned with the analysis of the nature of motives and motivation and understanding thereof. In particular, the task was seen to be to provide an account of the relation between the internal causation of mental states and behavior, on the one hand, and motivation, on the other hand. The relation of motivation or justification was held to involve a number of distinct possible moments: the optimal case, where a mental state or disposition such as an intention, does indeed justify an action; conflict among motivations; the case where a mental state, for example, an emotion, is not justified by the subject's beliefs or perceptions. Many views were discussed and endorsed by different phenomenologists: what motivates and what is motivated are never the possible terms of a causal relation, for example, because they are ideal propositional contents; what motivates and what is motivated can be the

terms of a causal relation because they are concrete instantiations of ideal contents; the relations of causality and of motivation are always distinct but may have the same terms; there is a relation of superposition between motivation and causal relations; relations of motivation are causal relations but mental causality differs from physical causality. Finally, it was argued that motivational justification differs from both inductive and deductive justification, in particular because it often connects terms that cannot stand in the last two relations. Husserl himself thought that it was a 'basic law' of all psychological phenomena that they could stand in relations of motivation (Pfänder 1900, Husserl 1913/1969, Stein 1917, 1980).

In his 1932 *Der sinnhafte Ausbau der sozialen Welt: Eine Einleitung in die verstehende Soziologie* [The Phenomenology of the Social World. An Introduction to 'verstehende' Sociology], Alfred Schütz made use of the phenomenology of temporal experience in his analysis of motivation and understanding. 'In-order-to motives' explain how actions come about, genuine 'because-motives' explain by reference to preceding experiences how a practical project comes about. The present in which Sam is aware of his own motives, projects, and the states of affairs which are the objects of projects, provides him with a temporal perspective which is not available to Mary. This does not, Schütz thinks, amount to a denial that Sam's motivation can be grasped by Mary, only to the claim that her temporal perspective on his motivation and behavior must be segmented and discontinuous (Schütz 1932/1974, see also Grathoff 1995).

A further step towards accounting for the connection between understanding and temporal perspectives was taken by Wilhelm Schapp in his 1953/1976 book *In Geschichten verstrickt* (*Entangled in Stories*) in which such traditional phenomenological categories as action, its horizons, intentionality, and states of affairs are reworked in narratological terms.

2. Social Acts

Promises, Hume said, are the cement of society. But what is a promise? Reinach's 1913/1989 reply to this question is the most impressive piece of philosophical analysis ever penned by a phenomenologist (see Mulligan 1987). Like orders, requests, questions, and answers, promises are social acts. Such acts are typically addressed to someone, grasped by another person and are performed in the very act of speaking. They bring about changes. Thus a promise creates both an obligation and a claim. Actions of different sorts bring about states of affairs that satisfy or fulfil social acts; execution of the behavior commanded satisfies a command. Reinach warns against possible misunderstandings of the category of social acts due to dragging in the ideas to which we are accustomed. A command is neither a purely external action, nor is it

a purely inner experience, nor is it the announcing to others of such an experience (Reinach 1983, p. 19).

Reinach's account of the variety of social acts and of their effects is only the first step in his demonstration of their role in social intercourse. The second step is provided by his analysis of six possible modifications of social acts. In his analyses of such solitary mental acts as seeing or judging, Husserl had already noted that such acts could be modified. Thus one modification of seeing is visual imagining, one modification of judging is supposing. Similarly, argues Reinach, each type of social act can be modified in various ways. A promise may be a sham or pseudo promise, the promisor does not really intend to do what he promises to do. A command may be a conditional command: 'In the event that such and such occurs, I order you to do such and such.' The social act of informing someone that something is the case, however, is not subject to this sort of modification. A conditional social act is to be distinguished from a social act that has conditional content, for example a promise to do one thing if some other thing occurs. A social act may be performed by more than one person.

[We] have here to do with the case where each of the persons performs the act 'in union' with the others, where each knows of the participation of the others, lets the others participate and participates himself, we have one single act which is performed by two or more persons together (Reinach 1983, p. 24).

Similarly, a social act may be addressed to more than one person. Finally, a command or a promise, for example, may be performed in the name of another person; there are representative social acts.

3. Collective Intentionality

The intentionality of acts and states, their relation to an object or state of affairs, is always the intentionality of one subject. But whereas the intentionality of solitary acts such as judging, inferences, or seeings typically involves only a more or less explicit awareness of the self—if I judge that it is raining, I am aware that I am judging, although this is not part of what I judge—there are acts, states, and activities which involve a more or less explicit awareness of others whether these are presented as 'you,' 'she,' 'they,' 'one' or 'us.' This phenomenon, nicely expressed in German by conjoining 'Mit' (with) and many a psychological verb, noun, or adjective (e.g., 'Mitschuld' collective guilt), is now called 'collective intentionality.' One example of the phenomenon, as we have seen, is furnished by joint social acts. Reinach also points out that in the case of actions that are not social acts it is possible to speak of several performing subjects of one and the same action. There is a way of acting 'in union.' The criminal law's concept of 'complicity,' as it seems to us, has to base itself on this, and such collective actions are also important for public law,

administrative law, and international law (Reinach 1983, pp. 24–5).

But the starting point for an account of collective intentionality is not ‘Mithandeln’ (joint action, co-action) but the analysis of the mental acts and states involving affective participation such as ‘Mitgefühl,’ fellow-feeling or sympathy, those involving shared beliefs and those involving trust, confidence, or belief in someone or something (see Scheler 1966, IV B 4, Reiner 1934, pts. 1 and 2).

Scheler’s 1913 account of sympathy distinguishes between identification of emotional contagion, vicarious feeling, feeling something together with someone (‘*Mit-einanderfühlen*’), fellow-feeling (‘*Mitgefühl*’), benevolence or love of humanity, and personal love, and argues that these stand in different sorts of relation of dependence or foundation to each other (see also Walther 1922).

The phenomenologists made three important claims about collective intentionality. First, although for every type of collective intentionality implicit awareness of feeling, believing, willing, or acting together with others is to be distinguished from thoughts containing the concepts expressed by the different personal pronouns, such concepts depend on the relevant types of implicit awareness. Representations employing ‘we’ and ‘they’ presuppose presentations which help to fix the reference of our uses of the personal pronouns and cognate forms as in ‘Cosa Nostra,’ ‘Sinn Fein,’ ‘Mare Nostrum,’ and ‘Pater Noster.’ Second, collective intentionality cannot be reduced to mutual belief or knowledge. There is, Scheler claims, a type of ‘co-experiencing something’ which cannot be understood by saying that A experiences something that is experienced by B, and that both, in addition, know of their experiencing it (Scheler 1913/1973, p. 526).

Finally, the sense or feeling of togetherness may be actual or habitual, in which case it constitutes a type of habitual background (see Walther 1922). The notion of background, like that of horizon, was first explored within phenomenology in connection with perceptual experience.

4. Emotions and Explanation: Ressentiment

Of all the psychological phenomena analyzed by phenomenologists, emotions and related phenomena enjoyed by far the most attention. One reason for this is the conviction that a philosophy of mind which concentrates exclusively on beliefs, inferences, and desires can only scratch the mind’s surface and that explanation and understanding within the human sciences will suffer from any such limitation. This conviction in turn relies on the claim that emotional dispositions, tendencies, long-standing states and sentiments, both those directed towards the past and those directed towards the future, determine desires

and preferences. In order to mark the importance of emotions Scheler emphasizes that mind or spirit (‘*Geist*’) comprehends not only cognitive phenomena but also the will and affective phenomena, an emphasis also prominent in the fiction and essays of the Austrian thinker Robert Musil.

One important illustration of these claims is provided by Scheler’s analysis of resentment and subsequent interest in the topic. Building on suggestions of Nietzsche and the historical sociologist Sombart, Scheler takes resentment to be a long-lasting psychological attitude that comes into being when emotions and sentiments such as envy, rancor, revenge, resentment, and spite are repeatedly bottled up and lead to ‘value-illusions’ and false evaluations. In particular, it is a felt impotence or incapacity to realize or live up to certain values that leads the woman of resentment to false evaluations. In the (slightly modified) example from La Fontaine’s fable, the fox initially sets a high value on the grapes and changes its mind about their value solely as a result of its inability to obtain them. Scheler’s account relies on his view that value judgments are true or false—‘cognitivism.’ It is indeed essential to the mechanism described that it involves a re-evaluation, and not merely one or another type of change of preference. But it is not necessary to assume cognitivism. A weaker version of the account would simply have it that resentment involves a transition from an attribution of value to an attribution of disvalue (or vice versa) that is caused in the way described by Scheler and is thus, in the absence of any other justification, unjustified, unmotivated, or irrational. The central historical example discussed by Scheler is Nietzsche’s claim that early Christianity was characterized by pervasive resentment. One of the many other examples he discusses is the claim that the disinterested disposition to assist in the punishment of criminals and a certain sort of moral indignation together with the relevant evaluations emerge from lower-middle class envy. This claim was the object of extensive empirical investigation by the Danish sociologist Svend Ranulf (1930, 1938), who castigates Scheler’s almost complete disregard of the canons of empirical inquiry.

5. Types of Coexistence

Scheler’s taxonomy of forms of social coexistence draws on distinctions to be found in the classical writings of Tönnies, Weber, and Simmel and on his own philosophy of mind and ethical psychology. In particular, four types of coexistence are distinguished with reference to different types of collective intentionality: masses, communities, societies, and super-ordinate entities such as nation-states, state-nations, empires such as the Belgian Empire, and the Catholic Church. A mass is characterized by affective contagion, its members do not behave as autonomous

persons. The community—families, tribes, clans, peoples—displays such forms of collective intentionality as sympathy, trust, piety, loyalty, and collective responsibility rather than individual responsibility. A community forms a milieu or niche within which certain shared values are prominent. Empathy and understanding are there, typically automatic and unreflective. Philosophers have often assumed that the choice between the two accounts of empathy distinguished above is exclusive: either awareness of other minds is always immediate or it is always a process involving inference, for example analogical reasoning. Scheler rejects the assumption and argues that although the former account fits communities, the latter is typical of societal relations. Within societies self-interest, mistrust, and a lack of solidarity go together with the predominance of the artificial relations engendered by social acts such as promising and contracts which connect autonomous, individually responsible persons. The relations that constitute a community, unlike those created by promises and contracts, have no determinate temporal duration or terminus. In his account of such ‘collective persons’ as the nation—state—an account that he only sporadically attempts to make consistent with the requirements of ontological individualism—these are said combine certain traits of communities and societies. They resemble communities in that they are not typically held to enjoy a determinate duration and in the affective importance their members attach to the past. But like the autonomous persons standing in societal relations they enjoy personal responsibility. Finally, each form of coexistence is characterized by different values: the vital values of the community—its life, survival, flourishing, and death—contrast both with the values of civilization—utility, agreeableness, sociability—of society and with the spiritual values of nation—states and state—nations—culture, law, language. (On the relation between the account of values given by Scheler and by the founders of sociology, see Boudon 2000.)

These forms of coexistence are related, Scheler thinks, in the following ways. Societies are founded on communities, states on communities, and societal unities. Thus the societal relations created by promises and contracts rely on the fact that the persons standing in such relations have some familiarity with the phenomenon of trust characteristic of communities (see Scheler 1966, VI, B 4, Scheler 1963, 334ff., Stein 1970).

6. Sociology of Knowledge

Scheler’s extensive writings on sociology in the 1920’s, in particular his *Problems of a Sociology of Knowledge* and other papers collected in his 1925 *The Forms of Knowledge and Society*, display a growing appreciation for American Pragmatism. Together with the work of Karl Mannheim they established the sociology of

knowledge. Scheler employs his accounts of collective intentionality and of affective phenomena in order to set out a comprehensive formulation of the view that scientific knowledge and technological knowledge are inseparably bound up with the ‘instinctual structure’ of the bourgeoisie, the desire to dominate nature, and with the predominance of vital values. Scientific knowledge and its sociology is opposed to philosophical and cultural knowledge (*‘Bildungswissen’*) and to religious knowledge (*‘Heilswissen’*) and the sociologies of the spiritual values essential to these, all of which rest on the natural world view and natural language. His account of the link between science and mastery of nature and his distinction between scientific and a superior, non-scientific knowledge have proved remarkably influential throughout the century (see Leiss 1994). But on two points Scheler differs from the majority of his many successors. He retains a realist view of scientific knowledge. The values he distinguishes from those of science, in his philosophy as in his sociology, are spiritual: salvation is not emancipation and philosophy does not involve hearkening to the voice of being.

7. Social Objects

What sort of an entity is a social object? There are, it seems, social entities of many different kinds—enduring ‘substances’ such as judges and the unemployed, processes such as electioneering, events such as voting, states such as ownership. But, as Reinach pointed out, neither of the two venerable philosophical distinctions, physical vs. psychological, temporal vs. ideal, is of much help if we want to understand the status of, for example, the claims and obligations created by promises.

Through the act of promising something new enters the world. A claim arises in the one party and an obligation in the other. What are these curious entities? They are surely not nothing ... but they cannot be brought under any of the categories with which we are otherwise familiar. They are nothing physical; that is certain. One might rather be tempted to designate them as something psychical or mental, that is, as the experiences of the one who has the claim or the obligation. But cannot a claim or an obligation last for years without any change? Are there any such experiences? Recently one has begun to recognize again, in addition to the physical and psychical, the distinct character of ideal objects. But the essential mark of these objects, such as numbers, concepts, propositions, is their timelessness. Claims and obligations, by contrast, arise, last a definite length of time, and then disappear again. Thus they seem to be temporal objects of a special kind of which one has not yet taken notice (Reinach 1983, p. 9).

Husserl baptized such entities ‘bound idealities.’ Unlike ‘free’ idealities such as numbers, bound idealities such as word types, word meanings, and other

cultural entities such as institutions and tools come into being at a particular time and are 'earth bound ... bound to particular territories'; if there were men on Mars there would be 'Mars bound' idealities (Husserl 1973, §65). Like many free idealities, bound idealities such as word meanings, rules, and types of ceremonies are multiply instantiable. The most thorough account of such entities is Ingarden's (1931) ontology of word-meanings and of works of art.

If social entities are brought into being then it is plausible to say that they are mind-dependent entities. But since mental activities belong to the category of episodes it might seem that social entities must all have the reality of episodes. This 'actuality theory,' from the German psychologist Wilhelm Wundt, was rejected in the two most substantive phenomenological ontologies of the social world, *A Contribution to the Ontology of Social Communities*, by Gerda Walther (1922), and *Foundation of the Theory of the Social Bond* (1932) by Husserl's Japanese pupil, Tomoo Odaka. Social entities are, they argue, brought into being and sustained by the mind, but do not all belong to the category of episodes. A thorough criticism of holism about social entities within the framework of Husserl's theory of objects is given by Felix Kaufmann (1929/30, Kaufmann's (1936, 1944) philosophy of the social sciences is, however, closer to the ideas of the logical positivists than to phenomenology).

What type of mental activity is responsible for social entities? According to Walther and Odaka, collective intentionality, implicit and explicit, and in particular we-intentionality, is a necessary condition for the emergence and maintenance of social entities. What, runs Walther's influential question, makes a group of laborers working for a constructor, who interact, know this, pass bricks along and receive such social acts as orders, into a community? What are the marks of a common form of life? Among the thirteen features she puts forward is the sense of togetherness or collective intentionality, a feature also necessary for the existence of all products of a community.

8. Sociology and History of Phenomenology

A notable sociological feature of phenomenology is the role played by female philosophers. A later parallel is the role of women within analytic philosophy, phenomenology's most influential rival.

Many of the distinctions, approaches, and theses of the phenomenologists were rediscovered within analytic philosophy. Reinach's analysis of social acts anticipates John Austin's account of speech acts. The phenomenological discovery of collective intentionality anticipates the work of John Searle and Raimo Tuomela. Similarly, the claim that social entities depend for their existence on collective intentionality has been defended by Searle. Jon Elster's work on such phenomena as resentment and on emotions in general (see Elster 1985, 1999) confirms the phenom-

enologists' conviction that a desire-belief-inference psychology and sociology are inadequate. A variety of theories of motivation and of its relation to causality have been canvassed since Wittgenstein. Scheler's account of communities and their relations to other types of social formation anticipates many of the contemporary varieties of communitarianism. Thus phenomenology is now by and large of interest only to the historian.

Philanthropy, Economics of

Philanthropy is defined as benevolent behavior, usually in the form of charitable gifts, toward others in society. Charitable giving accounts for a significant fraction of income in the USA and other nations, and is often directly encouraged through government tax policy. This entry discusses the motives, causes, and influences of philanthropic behavior. Special emphasis is placed on how government policy, through the charitable deduction on income taxes and through direct grants to charities, can affect the amount of philanthropy in the economy.

1. Introduction

In the late 1990s the media tycoon Ted Turner announced a gift of one billion dollars to the United Nations, software titan Bill Gates donated five billion dollars toward health and education in the developing world, and Oseola McCarthy, an 89-year-old laundry-woman from Mississippi, gave her life savings of \$150,000 to establish scholarships for black college students in her state. These are examples of philanthropic, or charitable, behavior—individuals freely giving money to help others. Most people are, in fact, philanthropists, although not on the scale of the three mentioned above. Through the last few decades of the twentieth century, over two-thirds of Americans donated money to charity in any given year, with households giving over two percent of income on average. In 1997, those that gave to charity averaged donations of over \$1,000. In fact, people spend more on charitable giving than they do on electricity, telephones, or car insurance.

In addition, the government is an active partner with private donors in funding the charitable sector of the economy. It does this in two ways. First, are direct grants to charities. In 1994, for instance, charitable

organizations reported receiving \$51.9 billion in government grants. The second way the government spends money on charity is by excluding income spent on charitable donations from income tax. The US tax code was modified in 1917 to allow taxpayers to deduct their charitable donations from their taxable incomes, and by 1998 individuals were claiming over \$86 billion in charitable deductions.

This entry will describe how economists think about and do research on philanthropy, what economists know about charitable giving, and how public policy influences it. The focus will be primarily on gifts of money and assets by individuals, although corporations and other institutions also make charitable gifts (see Boatsman and Gupta 1996), and people also give by volunteering time (see Brown and Lankford 1992). In addition, the discussion will center on philanthropy in the USA, since a large majority of the academic research has centered on the US experience (for information on charitable organizations internationally, see Anheier and Salamon 1996). Finally, the entry will highlight what challenges remain ahead for the study of philanthropy.

2. An Economist's View of Charitable Behavior

Economics is founded on the view that people are self-interested. Economists assume that since individuals have a choice in how they behave, they must always make the choices that they think are the best at the time. This assumption, called the 'axiom of rationality,' provides the bedrock from which economic models of behavior are formed.

Applying this framework to philanthropic behavior, we can ask why would people who work hard for their money simply turn around and give it away? Does this not contradict the assumption that individuals are self-interested? Maybe. But by the axiom of rationality, we should first look for ways in which an individual believes that giving to charity is the best thing to do with that money at that time.

One possibility is that people desire more of the service provided by the charity. National Public Radio (NPR), for instance, is a charitable organization that survives largely on donations. Over a million people a year give to NPR, with most giving under \$100. Are these givers getting their money's worth? Certainly not. Anyone can listen to NPR broadcasts, even without donating, and anyone who gives \$100 is unlikely to notice any increase in broadcast quality as a result. It follows that a self-interested person is better off giving nothing and taking a 'free ride' on the donations of others. Hence, this alone cannot be an adequate explanation for why people give to charity (Andreoni 1988).

A second reason is that individuals may be getting something directly from the charity in exchange for their contributions. For instance, big donors to the opera may get better seats, or donors to a university

may get buildings named for them. While this must surely matter for large donors, most individuals only receive tokens (a coffee mug?), if anything, in exchange for donations.

A third reason could be that individuals get some internal satisfaction—a 'warm-glow'—from giving to their favored charity, and the more they give the better they feel (Andreoni 1989). This would mean that giving to charity is like buying any other good, such as ice cream. We easily accept that people have a natural taste for ice cream, so why not a natural taste for warm glow? If we accept this, then we can analyze charitable giving just like any other consumer good—when income goes up people should want more, and when the price goes up people should want less.

Scholars have examined preferences for giving from a number of different approaches, and it seems that warm glow is in fact a core economic motivation for giving (see Andreoni 1993). That is not to say it is the only reason for giving. People may also give from a sense of religious duty, from pressure at work or from friends, or as a signal of social status (Rose-Ackerman 1996). At the heart of all of these processes, however, seems to be a basic human interest in helping others or doing one's share. This, of course, raises a deeper question that may require a broader social science perspective to answer: why do people enjoy acting unselfishly? This is a question that, fortunately, we do not have to answer to continue with this article. We can take as our launching point that people get joy from giving, and we can apply our economist's tools for analyzing consumer behavior to begin studying charitable giving.

3. The Facts about Philanthropy in the USA

How do we learn about charitable giving? One source is surveys of consumers. The Independent Sector for instance, surveyed about 2,500 households by telephone. Surveys are valuable since they can obtain information on age, education levels, and other personal characteristics of respondents. A disadvantage is that individuals must rely on imprecise memories when answering questions, or may be reluctant to give true information about their incomes or donations.

Table 1
Sources of private philanthropy, 1998

Source of gifts	Billions of dollars	Percent of total
Individuals	134.8	77
Foundations	17.1	10
Bequests	13.6	8
Corporations	9.0	5
Total for all sources	174.5	100

Source: Giving 1999

Figure 1

Giving by individuals, 1968–98^a. Dollars are inflation-adjusted to 1998 values.
Source: Giving 1999

A second important source is samples of tax returns. Since individuals who itemize their tax returns in the USA can take a charitable deduction, we can learn about donations for this sector of the economy. The advantage of tax returns is that the information on them is precise, as long as people do not cheat on their taxes. (Slemrod 1989 explored this potential problem

and found that, while there is some evidence of cheating by overstating charitable deductions, the effects are small and do not appreciably affect the analysis.) The disadvantage to this data is that tax returns contain very little information about the personal characteristics of the filers that would be helpful in explaining giving, such as education levels or religious affiliation, nor can we learn about the giving habits of those who do not itemize their tax returns. Since no data source is perfect, economists must conduct many studies on many data sources in order to uncover the ‘facts’ on charitable giving.

3.1 Sources, Totals, and Trends in Giving

Charitable donations can come from individuals, charitable foundations, corporations, or through bequests. While all are significant, by far the dominant source of giving is from individuals. Table 1 shows that in 1998 individuals gave over 134 billion dollars to charity, or 77 percent of the total dollars donated. The second biggest source, foundations, was responsible for only 10 percent of all donations.

The trends in giving over the last 30 years can be seen in Fig. 1. Total giving has been on a steady rise,

Table 2

Private philanthropy by income, age, and education of the giver, 1995

	Percent of households who give	Average amount given by those who give	Percent of household income
All contributing households	68.5	1,081	2.2
<i>Household income</i>			
Under \$10,000	47.3	324	4.8
\$10,000–\$19,999	51.1	439	2.9
\$20,000–\$29,999	64.9	594	2.3
\$30,000–\$39,999	71.8	755	2.2
\$40,000–\$49,999	75.3	573	1.3
\$50,000–\$59,999	85.5	1,040	1.9
\$60,000–\$74,999	78.5	1,360	2.0
\$75,000–\$99,999	79.7	1,688	2.0
\$100,000 and above	88.6	3,558	3.0
<i>Age of giver</i>			
18–24 years	57.1	266	0.6
25–34 years	66.9	793	1.7
35–44 years	68.5	1,398	2.6
45–54 years	78.5	979	1.8
55–64 years	71.7	2,015	3.6
65–74 years	73.0	1,023	2.9
75 years and above	58.6	902	3.1
<i>Highest education of giver</i>			
Not a high school graduate	46.6	318	1.2
High school graduate	67.2	800	1.9
Some college	74.1	1,037	2.1
College graduate or more	82.3	1,830	2.9

with especially big jumps coming in 1996, 1997, and 1998. When measured as a percentage of income, however, giving seems much more stable. Since 1968 giving has varied from 1.6 percent to 2.1 percent of income. In the most recent year shown, 1998, giving ticked up to 2.1 percent of income, the highest in 30 years.

3.2 Who Gives?

Surveys reveal that 68.5 percent of all households gave to charity in 1995 and that the average gift among those giving was \$1,081. Table 2 shows that the more income a household has, the more likely the household is to give to charity, and the more it gives when it does donate. This table also reveals an interesting pattern typically found in charitable statistics. Those with the lowest incomes give over four percent of income to charity. As incomes grow to about \$50,000, gifts fall to 1.3 percent of income, but then rise again to 3.4 percent for the highest incomes.

What could cause this 'U-shaped' giving pattern? One explanation is that those with low incomes may be young people who know their wages will be rising, hence they feel they can afford more giving now. It may also be due to the composition of the types of charities to which people give, since lower-income people tend to give significantly more to religious causes. Hence, it will be important to account for all the factors that may explain giving before offering explanations for the averages seen in these tables.

Table 2 also illustrates that giving varies significantly with the age and educational attainment of the givers. As people get older they are typically more likely to give to charity and to give a greater fraction of their incomes. Likewise, those with more education give more often, give more dollars, and generally give a higher fraction of income. Note that the table does

not show a smooth acceleration of giving with age. Again, age, education, and income all vary with each grouping in the table and will have to be considered jointly.

3.3 What Do They Give To?

In 1997 over 45,000 charitable, religious, and other nonprofit organizations filed with the US government. Table 3 attempts to categorize these charities by the types of service they provide. This reveals that, among all types, households are most likely to give to religious organizations and to give them the most money—48 percent of all households give to religion and 59 percent of all charitable dollars go to religion.

4. Taxes and Giving

How can taxes encourage philanthropic behavior? Taxpayers in the USA who itemize their deductions can deduct their charitable giving from their taxable income (and from 1982 to 1986 the law also allowed nonitemizers a limited charitable deduction). If someone in the 15 percent marginal tax bracket gives \$100 to charity and takes a charitable deduction, this person will save \$15 in taxes, making the net cost of the gift \$85. If the person was in the 31 percent tax bracket then the \$100 gift would have a net cost of \$69. Thus, the higher one's tax rate, the lower the net cost of giving. In this way the tax rate acts as a subsidy rate to giving, and those in higher tax brackets get bigger subsidies. (Note that state income taxes often add additional subsidies. See Feenberg 1987.)

Since the tax deduction subsidizes giving, we should expect that those with higher subsidies will make larger contributions. It is also natural to expect that those with higher incomes will make larger contri-

butions. However, those with higher incomes will typically also have higher subsidies, so when we see richer people giving more how can we know whether their income or the subsidy is causing the change? If we can compare people with similar subsidy rates but different incomes, and similar incomes but different subsidy rates, we can apply statistical techniques to separate the influences of income and the subsidy.

Disentangling these is, of course, very important for policy makers. If, for instance, the subsidy does not increase giving at all, then the policy is costing the government tax dollars without benefiting the charities. If, on the other hand, the subsidy lifts giving significantly, it may be an effective tool to increase social well-being. Generally, policy makers look for the increase in contributions due to the subsidy (the benefit) to be larger than the loss in tax dollars (the cost). The next section discusses how economists explore this issue.

4.1 *The Effect of the Subsidy on Giving*

Economists began conducting detailed empirical studies of giving in the 1970s in an attempt to isolate the effect of the subsidy on giving (see Clotfelter 1985 for a review). You can imagine asking the counterfactual policy question this way: consider a proposal that would allow a taxpayer to deduct only 70 percent (or 50 percent or 20 percent, etc.) of his or her charitable contributions for tax purposes, rather than the 100 percent allowed now. This means that the net cost of a \$100 contribution would rise. For someone in the 28 percent marginal tax bracket, for instance, the cost would rise from \$72 to \$80. We would expect that this higher cost would discourage giving, but by how much?

The first generation of studies to explore this counterfactual relied on cross-sectional data, primarily from tax returns. Observing income and deductions for thousands of people in a given tax year, the researchers used the variations in income and cost to estimate how, on average, individuals would respond to such a change in policy. There were several limiting features of the data used in these studies. Of particular importance is that the samples, for reasons of confidentiality, typically did not include extremely wealthy people.

Depending on the source of the data, the years studied, the size of the sample, and the statistical approach, the results naturally varied. It has been generally agreed, however, that the prediction that best characterizes the results is that a policy that would increase the cost by 10 percent for all taxpayers—without affecting the other income taxes paid by the individual—would reduce contributions by about 13 percent (Clotfelter 1990). This suggests that behavior is quite responsive to the incentives offered by the tax deduction, and that the response is large enough to

satisfy the policy criterion noted above. In particular, if the government pays an additional 10 percent of the cost of giving and if people respond by giving 13 percent more, then the policy generates more new charity than it costs the government in tax revenue.

These studies also confirmed that giving increases with income. If after-tax incomes were to rise by 10 percent, estimates are that giving would rise by about 8 percent (Clotfelter 1990). Notice that this quantifies the left-hand part of the U-shaped giving curve discussed in Sect. 2—since giving rises by a lesser percentage than income, giving as a percentage of income (all else equal) must be declining.

Later studies were able to supplement these findings using data from surveys rather than tax returns (see Clotfelter 1990, Steinberg 1990). Although the survey results varied, they generally confirmed the policy predictions stated above. In addition, they revealed the importance of other individual characteristics in explaining giving. Most strikingly, they consistently found that giving increases with the age and the education of the giver, again as suggested in the tables above. It could be that those who are educated have more interest in charity or that interest in charity changes with age. A more plausible explanation, however, is that researchers have no information on individual wealth. Since wealth is correlated with both age and education, it is likely that the influence of wealth is being filtered through these other variables.

A second generation of studies, conducted mostly in the 1990s, has begun to shift the consensus view noted above. Unlike the earlier studies that relied on cross-sectional data, these newer studies used panel data, that is, data with observations on the same set of individuals over several years. Panel data is generally seen to be superior to cross-sectional data. The reason is that by observing the same people at different points in time the researcher is able to get a more precise measure of how behavior responds to changes in the environment.

The most influential study with panel data is by Randolph (1995). Using tax returns on about 12,000 people from 1979 to 1988, and using statistical techniques designed explicitly for panel data, he identified a much weaker effect of the subsidy and a much stronger effect of income. His results indicate that a policy that would increase the cost of giving by 10 percent would reduce giving by only about 5 percent, whereas if income were to rise by 10 percent, giving would rise by 11 percent. Others using panel data have found similar effects. Hence, at the end of the 1990s the literature on the effect of the subsidy to giving was in a state of flux. More studies with panel data are needed to reconcile the early and later findings, and to reach a new consensus on the effects of the subsidy.

Finally, these studies cannot reveal all of the subtle and complex influences on giving. Other things outside of these studies clearly matter, such as the social circles

to which people relate, the religious organizations to which they belong, and the activities of fundraisers. While many of these influences lie beyond the scope of economic analysis, when economists have examined social factors the effects seem to be small and do not appreciably change the predictions for policy (Andreoni and Scholz 1998). Still, studies that examine noneconomic influences could lead to new insights on policies toward giving.

4.2 The Effects of Tax Reforms on Giving

During the 1980s there were two major tax reforms that dramatically changed the two important variables discussed above: the cost of giving and after-tax income. Prior to 1980 there were 25 tax brackets, with the top bracket at 70 percent. This meant that a wealthy giver, after the deduction, would pay only 30 cents of each dollar donated. The first tax reform came in 1981. This created 14 tax brackets, with the top rate falling to 50 percent. The second major tax reform, the Tax Reform Act of 1986 (TRA86), was more dramatic. It reduced taxes to two rates, 15 percent and 28 percent. (Actually, it also included a 'bubble bracket' of 33 percent for those between \$71,900 and \$192,930 of annual income, before returning to 28 percent for incomes above this. A 31 percent bracket was added in 1991. Subsequent changes in the law mean that in 1999 there are five brackets: 15 percent, 28 percent, 31 percent, 36 percent, and 39.6 percent.) Hence, most people, but especially those in high tax brackets, had the net cost of their charitable contributions rise.

With the costs of giving going up, many feared that there would be calamitous decline in giving. Auten et al. (1992) and Randolph (1995) looked at the experience from the 1980s and made several interesting discoveries. First, people were sensitive to the anticipation of an increase in their cost. In 1981, for instance, wealthy people saw that the cost of a \$100 donation would rise to \$50 in 1982 from \$30 in 1981, and thus moved up a sizable share of their giving to 1981. For those earning over one million dollars (in 1991 inflation-adjusted dollars), average charitable deductions rose by \$32,000 from 1980 to 1981, but fell by \$64,000 in 1982. This same sector also anticipated the TRA86, raising deductions by \$37,500 in 1986, then reducing them by \$52,500 in 1987. Similar, although less pronounced, patterns can be seen in most other income groupings as well. In fact, Randolph (1995) shows econometrically that individuals are far more responsive to short-term (or temporary) changes in the cost of giving than they are to long-term (or permanent) changes.

How did giving change overall in response to the tax reforms? As seen in Fig. 1, dollars given tended to rise over the 1980s, despite this increase in the cost for most individuals. But this does not tell the whole story. First, even though the cost of giving went up, after-tax

Figure 2
Changes in the Distribution of Giving: 1979–90
Source: Auten et al. 1992

income also rose for middle-income people, and this should counter the effect of raising the costs. In addition, incomes in general were rising throughout the 1980s. Also, this analysis cannot account for the behavioral response of charities that may have increased their fundraising efforts in response to the tax changes.

Fig. 2 shows one more piece of information that is masked by the averages; that is, that the distribution of giving across income groups also changed. The figure shows that giving by the middle-income group, which is by far the most populous, actually increased as a percentage of income over the 1980s. However, the giving by the wealthy fell quite substantially. To balance this, however, far more people were entering the ranks of the super-rich—the number of tax filers with incomes over one million dollars more than tripled from 1980 to 1989.

4.3 Giving by the Very Wealthy

Auten et al. (2000), in a study of giving by the wealthy, report that in 1994 the 1 percent of US households with the highest income was responsible for over 16 percent of all dollars given. As one might imagine, describing giving by the wealthy in more detail can be complicated, in part because many give through trusts and carryover deductions through several tax years. The most distinguishing characteristic of wealthy givers is perhaps that a great deal of their giving is of appreciated assets, such as art, real estate, or stocks. Donations of appreciated assets are often a heavily tax-favored form of giving (O'Neil et al. 1996). First, the giver can take a deduction on income taxes for the current market value of the asset, not the purchase price, in the year the gift is made. In addition to this, the giver does not have to pay any tax on the capital

gains made on the asset. This means gifts of appreciated property often generate two forms of tax savings. Those who had taxable incomes over \$2.5 million in 1995 had average charitable deductions of \$248,069, 44 percent of which was appreciated property. People with annual incomes of \$50,000–\$100,000, by comparison, deducted \$1,823 on average, of which only 15 percent was appreciated property.

Another distinguishing characteristic of wealthy donors is that their giving is highly variable from year to year. In any given year the median contribution of those making over \$2.5 million is only 0.7 percent of income—half the rate of those in the \$50,000–\$100,000 range. But the 95th percentile gift of the rich is almost 21 percent of income—twice the rate of those in the \$50,000–\$100,000 range. When averaged over a longer period, however, these numbers become a lot more similar. This indicates that perhaps the super-rich save up their donations over a number of years in order to give bigger gifts when they do give. Why? One reason might be to gain recognition from the charity, such as a brass plate, for being a major donor. Another reason is that large donors are often asked to serve as board members of charities, hence larger gifts can lead to greater control over the future of the organization.

5. Do Government Grants Displace Private Philanthropy?

There are several reasons to suspect that government grants to charities might depress private donations. First, if givers are aware of the grants, then they may perceive the charity as less in need of their donations, leading them to keep the money or give it to a different cause. This is known as the ‘crowding out’ hypothesis (Warr 1982, Roberts 1984, Bergstrom et al. 1986). A second reason giving may decline is that the charity may be less aggressive in fundraising after receiving a government grant. Both effects would lead to government grants to offset private philanthropy.

There are also reasons to think that government grants could have the opposite effect. Citizens who are unsure about the quality of a charity could see a grant as a ‘stamp of approval.’ Alternatively, the grant could be used as ‘seed money’ that will allow the charity to expand into a bigger operation by, for instance, constructing new buildings or opening branches in different cities (Andreoni 1998). In both of these cases, government grants could actually encourage private philanthropy.

From an empirical standpoint, the question of crowding out has been a challenge, and no study to date has been definitive. Three recent studies illustrate the difficulties of this area, and the wide array of findings. Kingma (1989) studied a special sample of givers to National Public Radio (NPR) in 1986. This data is unique in that it ties each giver directly to his or her local NPR station and the grants it receives. He

finds that if a typical station were to receive a \$10,000 grant, private giving would fall by about \$1,350, that is 13.5 percent crowding out.

Two studies using panel data on donations received by charities came to different conclusions. Khanna et al. (1995) used observations on 159 charities in the UK and found that government grants actually encouraged rather than displaced private giving. Payne (1998), using a 10-year panel of 430 US charities, applied special statistical techniques to account for the fact that government grants to charities may be caused by the same needs and interests as private giving. Without accounting for this ‘simultaneity,’ researchers may underestimate crowding out. Payne’s analysis predicts about 50 percent crowding out.

This is clearly a difficult area to study, and all of the researchers must do the best they can with incomplete data. Moreover, researchers have thus far been unable to account for how charitable fundraising, apart from givers’s willingness to donate, responds to government grants. These analyses await future study.

6. Conclusions and Future Research

Philanthropy is a significant factor in the US economy, accounting for about 2 percent of income over the past 30 years. Government and private givers are in a partnership to fund the services of over 45,000 charitable organizations. This entry has discussed the economic influences on private philanthropy and how it interacts with government policy.

The most important finding is that individuals are indeed sensitive to the charitable deduction in the US tax system. By subsidizing giving, the tax deduction has clearly increased giving by the private sector. Because policies and preferences change with time, new studies are always needed to assess the impact of the deduction. In the 1970s and 1980s, dozens of studies led to a consensus view that the subsidy was highly effective—a 10 percent reduction in the cost of giving led to a 13 percent increase in giving. In the 1990s, new data and new econometric analysis have challenged this view, suggesting that a 10 percent reduction in the cost leads to a 5 percent increase in giving. More studies are needed to clarify the picture about how responsive givers are to the charitable deduction.

The literature on the crowding out of private giving by government grants is also far from settled—some say the crowding out is substantial, at 50 percent, while others find government grants encourage rather than displace private giving. This research makes clear that the study of philanthropy needs to be expanded to consider the role of the charitable organizations more actively in the analysis. Not only do individuals respond to changes in tax policy, but fundraisers do too. How do charities adjust to changes in tax rates or government grants, and how responsive are indivi-

duals to fundraising efforts? Exploring these questions will deepen our understanding of philanthropy and help sharpen government policy.

Of course, to accomplish these important research goals, new and better data will be needed. There has not been a large national survey of individual philanthropic behavior since 1973, and another survey could yield many new insights. In addition, data is needed that ties together the actions of fundraisers, private donors, and the government. Such data would allow researchers to learn about the whole market for charitable giving—both supply and demand—and could help form policies to strengthen the partnership between the public and private sector for providing much needed charitable services.

Philosophy, Psychiatry, and Psychology

From the very beginning, scientific psychiatry has raised fundamental questions within the fields of philosophy and psychology, namely as regards the nature of the 'psyche.' The question of what it means to say that something is 'psychical' leads to speculation in psychiatry insofar as special heuristic aspects are involved.

1. Philosophical Aspects of Psychiatry

In accordance with Brentano's basic idea that the psychical can be identified with the 'intentional' (Brentano 1874), one might argue that psychiatry is so important to philosophers because the disturbances of intentionality in various domains of the mental world of humans are what might be termed 'negative images' of the psychic functions which normally operate in the human mind. The special method by which Karl Jaspers (Jaspers 1913) elaborated this view of the human mind is the 'phenomenological approach' to various kinds of disturbances of mental functioning in psychiatric patients (deficiency model of psychic dimensions in Jaspers's *General Psychopathology*).

However, this is not the only way in which the relationship between psychiatry and philosophy can

be construed. The other aspect is the issue of the potential role of psychic 'normalcy' in social life. As a fluctuating criterion for assigning people to a psychiatric context, normalcy cannot be regarded as a phenomenon of 'average' and represents merely the concept of 'ideal typology' (Blankenburg 1971). From a philosophical point of view, the subject of psychiatric 'normalcy' constitutes a major problem, since it raises the issue of the existence of an 'individual norm' in the sense of the 'alterity of the other' (Lévinas 1987). Seen in this way, psychiatric disorders are not simply 'defects' but represent variants of normal psychic life which—when exaggerated—are interpreted as disorders and treated by psychiatrists.

This concept fits in with the approach of evolutionary psychiatry which considers that psychiatric disorders have evolved because they relate to psychic functions which—in their submaximal expression—yield advantages where natural selection is concerned. Viewed in this way, psychopathology does not constitute a 'statistical, average norm' but an 'individual norm,' as has been pointed out by Blankenburg (1971). In a similar sense, Spaemann and Löw (1981) have argued that health itself contains a teleological notion: 'If 99 percent of the population suffered from headaches, headaches still would not be "normal".' Philosophical concepts in psychiatry therefore have to address the problem of 'normalcy'; they face the difficult challenge of acknowledging deviant cognitive and mental events merely as expressions of the alterity of the other.

2. Aspects of Greek Philosophy

The focus of Greek philosophy is on the individual, thinking and acting intentionally, and self-reflection is thus the cornerstone of ancient Greek thought. On the basis of the hypothesis of quasi-determinism, the Athenian philosopher Socrates (470–399 BC) asserted that the will responds to the dictates of reason. He developed the Socratic—or 'maieutic'—method which elicits truths that lie hidden in an individual's unconscious by means of a process of question and answer. This method—in a completely different context—later became the basis of Sigmund Freud's psychoanalysis and the nondirective psychotherapy of Carl R. Rogers. Socrates' disciple Plato (427–347 BC) differentiated—for example, in his *Phaedo*—between the spiritual and material worlds and applied this dichotomy to man by postulating that the psyche (soul), together with its logical functions, possesses a pre-existence before the birth of the individual and survives into immortality (Plato 1966). In *Timaios*, Plato defines madness (*manteia*) as a disturbance of the vegetative components of the soul (which are located in the liver) but in the later *Phaidros* he tells us that it can also be sent by the gods as an elevating spiritual force. The aim of Plato's philosophical

psychology is to create harmony between the different psychic activities. Whereas Plato's *idealism* defines ideas as the only true reality, his pupil Aristotle (384–322 BC) based his psychology partly on empirical investigation, thus representing a type of *realism*. In his systematic discussion *De anima* (*On the Soul*), Aristotle describes the soul as the *entelechy*, the self-contained purpose of the body. This purpose must be fulfilled in order to achieve *eudaimonia* (bliss). In Aristotelian thinking, philosophical self-reflection leads to psychological self-actualisation, and in his *Ethica Nikomacheia* Aristotle states that the purpose of ethics is not knowledge but action (Aristotle 1984).

Although Aristotle was the most systematic Greek philosopher and had an enormous influence on the development of modern science, the treatment of psychological matters in post-Aristotelian Hellenistic philosophy is often described as eclectic. Stoic and Epicurean philosophy, in particular, must be considered as practical psychology. Given that the increasingly urbanized Hellenistic world had a greater resemblance—in some ways—to modern society than the middle ages, this practical psychology is still of interest. Epicureans and Stoics tried to find ways to alleviate anxiety, but their anxiety is less fear of the gods than fear and disturbance caused by a complex but fragile society. Epicurean and especially Stoic thinking played an important role in Hellenistic culture and can thus be viewed as the first widespread popular psychological fashions.

After the fall of the Roman Empire, Christian Europe lost sight of some of Aristotle's major works. The philosophical psychology of the dominant neo-Platonism referred back to the static aspects of Platonism, shifting away from rationalism to metaphysical speculation on the relationship between a tangible and an intangible world, between the soul and God. St. Augustine (354–430) attempted to synthesize neo-Platonism with Christianity. Following on from Seneca and Plotinus, he leaned towards introspection as his philosophical and psychological method, considering that—alongside objective observation—self-observation of inner mental processes could function as the basis of knowledge. He therefore chose self-reflection as the basis of his epistemology, arguing that doubt presupposes the existence of the doubter (Augustine 1984), an idea that later became extremely influential as Descartes famous *Cogito ergo sum*.

3. Metaphysics of Middle Ages and the Mind–Body Problem

The philosophical psychology of the Middle Ages was metaphysical and—at the same time—deductive. The changeability of the soul and of world were interpreted philosophically as an inevitable but inferior property of the unchangeable, and consequently Christian dogmatism and neo-Platonism showed no interest in

the experience of psychological interaction. With the foundation of the first universities from the thirteenth century onwards, the process of philosophical debate increased and a more dynamic philosophical psychology developed as Aristotelian thinking was resuscitated through the medium of Arab philosophy. St. Thomas Aquinas (1225–74) attempted to integrate Christian dogma with elements of Greek and Arab philosophy. Aristotle differentiated between an active immortal intellect and a merely passive understanding one. Aquinas accepted this view, describing the intellect as a passive power, a *tabula rasa* which had to be filled with experience by the five exterior senses. In addition, there exists a rational power—which makes free will possible—and the soul also has vegetative components. In contrast to the neo-Platonic dichotomy of soul and body, Aquinas attempted to define man as a psycho-physical unity, as a body inspired by a soul. Taking his lead from Aristotle, Aquinas defined the soul as the form of the body and as an immortal spiritual entity. According to this theory, the body of a dead person consists of the same material or substance as that of a living person. As a result of this dichotomy, it is impossible to describe the impact of mental acts on real action without becoming entangled in serious logical difficulties. This is the *mind-body problem*: the issue of whether or not the soul or mind is an incorporeal substance, a nonmaterial entity obeying laws other than those which govern the material world. Discussion of this problem has continued until the present day.

4. Modern Philosophical Psychology

Modern philosophical discussions related to psychiatric problems already at its beginning. René Descartes (1596–1650) reflected on the fundamental nature of illusions and the constitution of reality. He posed the questions of certainty of reality and compared the reality of dreams with the consciousness in wakefulness. In his *Meditations on first Philosophy* Descartes arrived at the irreducibility of the cogito, putting an end to the infinite regress of doubt about possible fictional realities (Descartes 1996). As a consequence of this concept the modern subjectivistic understanding of consciousness has evolved, leading to the split between *cogitatio* and *extensio*, between soul and body, between the mental and the physical world, a split which represents one of the unresolvable fundamental problems in psychiatry. In this sense the dualistic understanding of the mind-body problem represents one of the central challenges, difficult to overcome in philosophical psychiatry.

Refuting earlier deductive speculation, the empirical philosophy of John Locke (1632–1704) again emphasized the Aristotelian view that the human mind is like a blank sheet of paper and that all the material of reason and knowledge comes from observation, ex-

perience, and reflection. David Hume (1711–76) described ideas as the copies of sensory impressions. Most of our beliefs go beyond current impressions, but all that we can be certain of is perception, meaning that it is impossible, for example, to comprehend the *self* as a separate identity. Radicalizing this point of view, the positivism of Auguste Comte (1798–1857) postulated that the sensible comprises the whole range of knowledge and that any knowledge that cannot be comprehended by the senses must be rejected.

Immanuel Kant (1724–1804) in his precritical anthropology speculated about constitutional aspects of psychiatric disorders. In his *Critique of Pure Reason* he tried to deduce the *a priori* conditions of the possibility of experience (Kant 1974). This type of categorical analysis of mental life has been decisive for all subsequent philosophical considerations about the formation and constitution of subjectivity and consciousness.

In this sense idealism represents one of the possible forms of reactions to Kantian philosophy. For example, Georg Friedrich Hegel (1770–1831) developed an ontological approach to intellectually reconcile all elements of existence with one another within a systematic structure in which all contradictory moments of reality appear as dialectic mediations of the universal mind (Hegel 1973). The philosophical psychologist Franz Brentano (1837–1917) elaborated a comparatively modest conceptualization of the difference between the mental and the physical, thereby developing a fundamental concept of philosophy of the psyche, namely the concept of ‘intentionality.’ In his work *Psychology from an Empirical Standpoint*, he argued: ‘Each mental phenomenon is characterised by what the scholars of the middle ages called the intentional (also probably mental) inner existence ... of an object, and which we ... would call the reference to content, direction toward an object’ (Brentano 1874).

One may argue that the main characteristics of psychiatrically ill patients are disturbances of intentionality in Brentano’s understanding of this term, that is, psychic functions are ‘intentional’ insofar as they refer to an (‘internal’) object; they can ‘mean’ something, can refer to something. If this fundamental function of mental life is disturbed, i.e., the *intentio recta* is disturbed, a psychiatric disorder can be anticipated.

The Danish philosopher Søren Kierkegaard (1813–55), deeply aware of Hegel’s philosophical concept of the absolute and at the same time vigorously writing against it, developed a concept of subjective reality, prestructuring the later existentialistic conceptualizations of subjectivity, defining it as synthesis of soul and body, carried by spirit. His pioneer work about personal freedom formulated the questions as to *The Concept of Anxiety* (Kierkegaard 1980). As has been pointed out by Hersch (1989) these basic ideas are represented by ‘existence’ and ‘moment,’ in which the

subject works through to the moment of the 'reality of freedom,' the condition of 'anxiety.' That means that 'anxiety' cannot be understood primarily as an emotional state but rather an existential condition, an intensified form of existence, leading to an autonomous subject ('choosing the self'). Kierkegaard influenced mainly the French school of philosophical psychology (Sartre, Merleau-Ponty, Camus), whereas Brentano founded, together with his student Husserl, the German school of 'Phenomenology,' essential to the history of psychiatry (Husserl 1950). In this context 'Phenomenological reduction' has to be understood as the attention to the 'nature of the condition of things' and thus the 'things as phenomena.' A great and far-reaching concept in philosophical psychology, the philosophy of the 'language game,' has furthermore been elaborated within the philosophy of language by Ludwig Wittgenstein (1898–1951). Jaspers has pointed out the importance of philosophy of language, emphasizing that language is the 'work of man.' The universals of language also play a role in the philosophy of Arnold Gehlen (1904–76) who referred to man as a 'non-determined animal,' whereby Gehlen interprets the human nature as creating its own world as an 'open world' (Gehlen 1987). Of special importance for psychiatric philosophical psychology is the concept of Helmuth Plessner (1892–1985) who developed the idea of 'positionality' of human subjects. Whereas animals show a 'centred positionality,' human beings live, according to Plessner, in an 'eccentric positionality' (Plessner 1970). This concept plays a relevant part in psychiatric psychopathology, since disorders like delusions of reference and ideas of persecution may be interpreted as a disordered eccentric positionality (Emrich 1992). In Jean-Paul Sartre's (1905–80) *Being and Nothingness*, the 'decentering of the world' plays a fundamental role in the phenomenological analysis of the 'glance' (Sartre 1996). Sartre's analysis of the interpersonal relationship ends up in an intersubject fight of 'glances.' Later Emmanuel Lévinas (1905–95) acknowledged the 'otherness of the other' in the dimension of 'face': 'The epiphany of the face is itself a word of honour in a certain way' (Lévinas 1987). This view of responsibility in the interpersonal encounter is of great importance in psychiatry; it conceptualizes an understanding of empathy in therapeutic relationships.

As a new academic discipline, psychology was obliged to assert itself against the established materialist sciences, especially medicine and biology. Positivist thinking consequently led to strongly anti-mentalistic and anti-introspectionist tendencies in psychology. The theory that it is only via *objective* observation that scientific method can formulate hypothetical laws from which it can then derive deductive arguments led to the radical behaviorist position that nothing that is the product of *subjective* introspection can be accepted. Positivism thus reduced psychology to a science that deals with behavior and

which aims to predict and control that behavior. As a result of behaviorism as represented by John Watson (1878–1958) and B. F. Skinner (1904–90), academic psychology drifted away from philosophy, becoming more practical than theoretical and more concerned with predicting and controlling behavior than with understanding it (Watson 1998, Skinner 1999). The contemporary philosophy of science, however, would claim that it is an illusion to believe that science can be reduced to a simple, *objective*, and entirely rule-bound methodology. Thomas Kuhn argued that such opinions are based on science textbooks that simply fail to tell the truth about the history of science (Kuhn 1996). In contrast to academic psychology, psychiatry has retained a more heterogeneous—even if contradictory—theoretical background. The main question at the start of the twenty-first century is whether psychology and psychiatry can only be governed by certain particular scientific methodologies or if it is possible to accept the existence of different approaches to the acquisition of knowledge. Paul Feyerabend pointed out that 'the idea that science can, and should, be run according to fixed and universal rules, is both unrealistic and pernicious' (Feyerabend 1980). In actual fact, therapeutic practitioners—in particular—find it unsatisfactory to consider introspective experience and objective behavior as mutually exclusive, as if they were distant continents with no contact between them. Modern therapeutic theories are thus becoming increasingly eclectic, and the gulf which used to exist between introspective psychoanalysis and behavior therapy, for example, is in the process of disappearing.

5. Self and Identity

Philosophical concepts of the 'self' have led to psychological consideration of the possible nature of 'identity.' Disturbances of the inner equilibrium of the components of the self which shape identity, brought about by processes of re-presenting by remembering, therefore make clear the potential for explanation inherent in a theory of the processes of identity formation based on a psychology of the self. As Lévinas in particular has shown (Lévinas 1987), however, this cannot be restricted to a theory of the structure of the 'self'; rather it must take account of interpersonality, the existence of others (the 'trace of the other' referred to in the title of Lévinas' book). Any attempt to describe the danger to processes of identity formation posed by the existence of the other from the perspective of the psychology of the self must take account of the 'ontology of the in-between' already developed by Martin Buber (1994). For, as Theunissen (1965) demonstrates in his major work on intersubjectivity, taking the other seriously in its own being involves transcending the intentionality mode.

This philosophical/psychological concept is based

on the assumption that components of a person's self can manifest themselves in others and can exist further in them.

The basis of this primary interpersonal constitution of the psyche is the mother-child dyad of early childhood. In a way, people unconsciously always retain parts of their childhood dyad 'within them,' although they nevertheless consider themselves to be ego-centered 'individuals.' In a system of ideas in which the *cogito* is identified with the empirical ego, the 'interpersonal self' cannot be conceived. This primary (but extremely repressed or internally never realized) interpersonal constitution of the self has consequences for how people deal with what is familiar and unfamiliar, both in the other and within themselves, where aggression is concerned. Christian Scharfetter, referring to Graumann's theory of subjective perspectivity, rightly refers to the fact that precisely the most intimate personal area of a person, his own unconscious, constitutes an alien entity, an unfamiliar area of sinister, threatening mystery. Scharfetter (1994) puts this as follows: 'The other is not simply an alien entity, however. The other may very well be familiar; it can be close, it can be experienced as analogous (not homologous). Indeed, the alien is able to strengthen and reinforce the self. It is through the 'You' that the 'I' recognizes itself. This is an important factor where psychotherapy is concerned. However, confrontation with the alien within the self is painful; it requires not only cognitive efforts (Hegel's 'strenuous toil of conceptual reflection'), but also psychological effort in the form of crises in identity development.

An extremely effective defense mechanism here is that of 'projective identification.' This means that the unknown, the sinister, within the subject is discovered in others by projection and combated there. Streeck-Fischer says, for example, that 'the confrontation with the alien has become a shock experience, one which hampers successful interaction with the alien (Streeck-Fischer 1994). The alien is threatened as a means of stabilizing one's own threatened self.' As Streeck-Fischer shows, this mechanism becomes particularly effective, is in a sense multiplied enormously, when one's own position is not only under pressure from the danger posed by crises in the formation of identity but is also reinforced because of social pressure. Social devaluation of specific features of the self can significantly increase projective identification in the sense of the development of aggression. Hans-Joachim Maaz, for example, shows how in East Germany 'social constraints under a repressive authoritarian system led to the self becoming alien and the alien becoming one's own.' Maaz describes the resulting aggression as follows (Maaz 1994): 'violence and hatred of other people are always evidence of internal tensions within someone, of his no longer being able to find and develop the self and the essential but of having to live a life too much of which is imposed by others.'

One of the great figures in the theory of mimesis is René Girard. In various works, notably *La violence et le sacré*, Girard developed a theory of mimetic occurrences (Girard 1977). If one accepts his thinking, the main point of the Oedipal drama, which in Freudian theory is said to mold early childhood, is not the Oedipal aspect as such—the desire for the mother in the Freudian sense—but the mimetic rivalry with the father. In an early work of 1961, *Mensonge romantique et vérité romanesque*, Girard elaborated on a discovery central to the entire development of his theory. He was able to identify a phenomenon of 'mimetic desire' in nineteenth and twentieth century novels from Stendahl to Flaubert and Proust. The novels he examined shared a peculiar basic structure: the main characters desire someone else, but their feelings are directed toward a third person, a 'mediateur.' Analyzing Stendhal, Girard says: 'in most cases of Stendhalian desire, the *mediateur* himself desires the object, or could desire it. This desire, whether real or assumed, is precisely what makes the object infinitely desirable in the eyes of the subject.'

Desires, needs, preferences, and yearnings are thus described as being something not genuinely given, something brought forth internally by drives or make-up, but are 'read,' taken on from a third party because of mimetic dependency. The basic events in the process of identification can thus be described as follows: if we can understand the other in a recreative sense only by putting ourselves into the other's intentions, into that person's world of desires, this means that we have to identify with that other. The amazing consequence of this is that processes of identification are necessary for a proper interpretation of reality. In this sense, one can say that a rational explanation of the world is possible only if there is a fundamental willingness to identify with others.

As a result, one can argue that in psychiatric patients this rational world access is hampered by their impaired interpersonal relations, that is, due to disturbed mimetic processes (Emrich 1995).

Phonetics: Articulatory

Articulatory phonetics is the branch of phonetics concerned with describing the speech sounds of the world's languages in terms of their articulations; that is, the movements and/or positions of the vocal organs (articulators). There were independent early Sanskrit, Arabic, and Western European traditions of articulatory description, often motivated by a desire to preserve pronunciations of an earlier stage of a language, e.g., for ritual purposes. More recently, it flourished in the nineteenth century, motivated by such goals as spelling reforms, dictionary making, language teaching, and language and dialect description, and continues in this tradition to the present.

1. Phonetic Transcription

A system for articulatory phonetic description comprises the set of vocal organs deemed to be important for speech, and the set of their movements or positions capable of characterizing the various speech sounds. A. M. Bell's *Visible Speech* (1867), a speech teaching aid for the deaf, used quasi-iconic phonetic symbols to notate positions of the lips, tongue, and soft palate. However, the most influential system of articulator-based notation has been that of the International Phonetic Association (IPA), founded in 1886. In the IPA system, the symbols are not articulatorily iconic, being instead based on Roman letters, but they encode a well-developed system of articulatory description.

1.1 International Phonetic Alphabet

The articulators specified in the IPA system are the lungs, the larynx, the two lips, the upper surface of the oral cavity from the teeth back to the uvula (divided into alveolar ridge, hard palate, and soft palate), the uvula, the pharynx and epiglottis, the tongue (divided into the tip, blade, front, back, root, and sides), and the vocal folds (or cords). These are divided conveniently according to their functions in speech as follows.

Respiratory (or initiatory): The respiratory system provides an outward pulmonic airstream with a roughly constant pressure; however, since other articulators, such as the larynx, can also be used to initiate airflow, this is sometimes also called, more generally,

CONSONANTS (PULMONIC)

Where symbols appear in pairs, the one to the right represents a voiced consonant. Shaded areas denote articulations judged impossible.

VOWELS

Where symbols appear in pairs, the one to the right represents a rounded vowel.

the airstream process. Sounds are described in terms of the source and direction of movement of their airstream.

lates the pulmonic airstream to produce a sound source called voicing; the rate of this vibration is perceived as the pitch of the voice, and the mode of vibration is perceived as voice quality. Sounds are described in terms of the presence/absence, and if

present, the quality, of voicing; larger spans of speech are described in terms of the pitch of voicing (e.g., tones, intonation—see *Suprasegmentals*).

Articulatory (in a narrower sense): Structures above the larynx, including the pharynx walls, the tongue (and its subparts), the jaw, the velum (or soft palate—sometimes classified separately as the oro-nasal process), the uvula, and the lips, which move within the vocal tract to modify the shape, and therefore the resonances, of the airway. In addition, stationary articulators—upper teeth and hard palate (and its

subparts)—provide contact sites for these movable articulators. Within a given sound, the articulators may be classified as active vs. passive, with the active articulators moving toward the passive and often forming a constriction or narrowing along the vocal tract. (While stationary articulators are necessarily passive, movable articulators may be active or passive.) For most sounds, the extreme or target positions of the active articulators relative to the passive are taken to suffice to characterize the sounds. For example, labiodental means active lower lip to passive

upper teeth; velar means active tongue body to (presumably) passive soft palate (the velum); a front vowel has the tongue as a whole to the front, relative to the surface of the palate. These locations must be further qualified according to how close the articulators come together. For example, in a stop consonant, they touch, whereas in a vowel they are still relatively far apart. These two dimensions of the location of the active articulator are sometimes called the location or place, vs. the degree, stricture, or manner, of the constriction.

The IPA uses these articulatory dimensions (and others not presented here) both to describe speech sounds, and as a basis for defining phonetic symbols to represent those sounds. These dimensions serve as a row and column labels on the well-known IPA chart, the most recent (1996) version of which is reproduced here as Fig. 1. This chart comprises two consonant charts, a vowel chart, and lists of other symbols. Each symbol represents the combination of articulatory properties expressed by the row and column labels of its chart. Square brackets are usually used to show that a symbol is part of a phonetic alphabet. Thus the first symbol on the IPA chart, [p], represents a *bilabial* (column label—made with the two lips approaching each other) *plosive* (row label—an oral stop; i.e., made with complete closure between the active and passive articulators, and the soft palate raised to prevent nasal airflow) which is *voiceless* (leftmost symbol in its cell—made without vocal fold vibration).

The consonant chart can be seen as a grid representing the articulatory space, with sounds made in the front of the mouth located toward the left of the chart, and sounds made in the throat (pharynx) located toward the right of the chart, and the degree of openness of the vocal tract given from top to bottom of the chart. The vowel chart's layout also gives a similar articulatory grid. However, rather different articulatory descriptions are given for consonants vs. vowels, even when the same articulators are involved, as can be seen from the different row and column labels. The basic descriptive dimensions for vowels are the overall vertical and horizontal position of the active articulator (the tongue), and the position of the lips. While the position of the tongue is judged implicitly relative to passive structures, these are not referred to overtly; only the active articulator, the tongue, is discussed. Thus what might be called a 'close palatal vowel with bilabial approximation' is instead nowadays generally called a 'high (close) front rounded vowel.' Not all phonetic systems make this kind of functional differentiation of vowel vs. consonant articulations, and the issue remains controversial.

The IPA system aims to provide a symbol for every phoneme of every language. However, it is a crucial property of this system that the descriptive framework is independent of the particular symbols chosen to fill the cells; other symbols could be substituted for these

as long as they were defined appropriately, and the charts provide places for sounds that, while possible, have not been assigned symbols.

For further explication of this chart and the IPA system, including its resources for description of suprasegmental phonetics (see *Suprasegmentals*) and of the range of speech sounds found in the world's

languages, see the *Handbook of the International Phonetic Association* (IPA 1999), a phonetic textbook such as Ladefoged (2000), or a phonetics chapter such as that in Fromkin (2000). For more on how these and other articulatory dimensions can be used to classify speech sounds, see *Phonology*.

1.2 Nonsegmental Transcription

Speech tends to consist of alternating closings (significant constrictions) and openings of the vocal tract; these are called consonants and vowels respectively. It is a fundamental observation that the actions of the various articulators are somewhat asynchronous. That is, it is generally not the case that all the articulators move into and hold their positions for one sound, then move into and hold their positions for the next sound, and so on. The dominant traditions of phonetic description, including the IPA, assume that speech consists of sequences of separate speech segments whose diverse articulations can overlap in time. It is possible to represent much of this overlap with a phonetic alphabet (e.g., Kelly and Local 1989) but it

requires cumbersome use of diacritical markings around the alphabet symbols. In contrast, competing articulatory phonetic systems do not bundle the articulatory properties into separable but overlapping segments, nor do they assign phonetic symbols to such segments. Instead, they try to record the temporal articulatory patterns of speech by using more complex representations (see, e.g., Anderson 1985; also *Phonology, Nonlinear*).

2. Study of Articulation

In most systems for articulatory phonetic description, both the identities of the articulators in general, and their positions in particular sounds are often presented in terms of static diagrams based on side-view X-rays or other images. Figure 2 gives a Magnetic Resonance image (MRI) of the vocal tract (the part of the body used in sound production), along its midline, of a speaker of American English making the fricative consonant[s]. This scan shows the larynx, the pharynx, the tongue, and the oral cavity, along with some other landmarks. Figure 3 shows tracings of the tongue and

other relevant structures made from other MRI images of the same speaker, but in this case during the English lateral approximant consonant [l] (which looks similar to [s]) and the English central approximant consonant spelled 'r' (a sound with an unusual tongue shape found in few of the world's languages). Note that, though such pictures are static, that does not mean that the articulations are necessarily held for any appreciable length of time in real speech—think of this as the frame, from a movie, which shows the most extreme displacement. In some sounds, such as stop consonants, articulations are held; in others, such as trills, movements of articulators are crucial to sound production. Direct evidence about other aspects of speech articulation can be gained using other laboratory techniques, from those dating to the nineteenth century and earlier, to the latest medical advances. For example, Fig. 4 shows successive frames from a video recording of vocal fold vibration taken with a video stroboscope.

Much of the current effort in articulatory data collection is focused on model building. Models vary in their physicality (whether they model the movements of realistic structures controlled by muscles, or whether they perform more abstract tasks), but all seek to gain insight into the kinematic and dynamical behavior of speech, either as an instance of refined motor control, or as an important part of language.

Articulatory activity ultimately serves the acoustic ends of sound production and propagation. Each speech sound has its defining acoustic properties that result from its defining articulatory properties. The different configuration of articulators define different resonance patterns of sounds, and interruptions and modifications of the airstream differentiate sounds in other ways. Static articulatory data, especially 3-D imaging of the entire vocal tract, is used in building models of the relation of articulation of acoustics—how the articulatory positions determine the acoustic properties. Models such as those of Fant (1960), and now Stevens (1998), can be applied in articulatory synthesis of speech. There is some effort to recover articulatory phonetic information from acoustic signals so that it can be used in speech recognition systems.

Phonology

Phonology is concerned with the sound structure of words and utterances within individual languages, the way distinctions in sound are used to differentiate linguistic items within a language, and the ways in which the sound structure of the 'same' element varies as a function of the other sounds in its context. While both phonology and phonetics are concerned with the role of sound in natural language, they differ in that phonetics deals with the articulatory, acoustic, and perceptual properties of sounds from a general, language-independent point of view (see *Phonetics: Articulatory*), while phonology studies the ways in which these properties are distributed and deployed within particular languages.

1. Goals of Phonology

The study of a language's particular sound properties has a number of aspects. First, it must be able to characterize the language's *inventory*: which phonetically possible sound types occur in utterances in the language? Second, it must characterize matters of *contrast*: which of the phonetic differences that occur in the language can serve to distinguish utterances (words, sentences, etc.) from one another? Third is the matter of *contextual limitation*: even though some property P occurs in language L, are there some environments from which P is excluded? And when P is apparently a property of (some part of) some element but that element occurs in a position from which P is excluded, what other property—if any—appears in its place? And finally, there is the description of *alternation*: when the 'same' linguistic element appears in different overt forms in different environments, what systematic differences occur? What conditions govern the range of phonetically

distinct forms that can count as the 'same' word, morpheme, etc.? Different answers to these questions yield different phonological theories.

It should be noted that the present article is limited to the sound structure of spoken languages, and ignores the expression systems of manual or signed languages (see *Sign Language*). This is misleading in important respects; research has shown that most of the basic principles of spoken language phonology are also characteristic of the organization of the expression systems of signed languages as well (Coulter 1993). Just as words are composed of sounds, and sounds of component properties, signs are also composed from structured, language-particular systems of more basic constituent elements. Units such as the syllable have close parallels in signed languages. While there are clear differences that depend on modality, these appear on further examination to be relatively superficial. A comprehensive theory of phonology as a part of the structure of natural language ought to take these broader issues into account. Until quite recently, however, the possibility of deep structural parallels between speaking and signing has not been raised, and the discussion below reflects this (undoubtedly unfortunate) limitation as well.

1.1 Some History

Prior to the early twentieth century, studies of sound in language concentrated on the ways in which sounds are made (articulatory phonetics), often confusing the letters of a language's writing system with its sounds. Toward the end of the nineteenth century, however, increasing sophistication of measurement techniques made it possible to explore a much wider range of differences among sounds, and to lay out the structure of speech in vastly greater detail. Somewhat ironically, perhaps, the explosion of data which resulted from the ability of phoneticians to measure more and more things in greater and greater detail began to convince them that they were on the wrong track, at least as far as increasing their understanding of particular languages was concerned.

Much of what was found, for example, involved the observation that speech is continuous, such that whatever is going on at any particular moment is at least a little different from what has gone on just before and what will go on immediately afterwards. A full characterization of an utterance as a physical event requires the recognition of a potentially unlimited number of distinct points in time, but it is clear that our understanding of an utterance as a *linguistic* event is hindered, rather than helped, by the recognition of this continuous character of speech. Speech normally is represented as a sequence of a small number of discrete segments, strung out in consecutive fashion like beads on a string; such a *segmental* representation vastly facilitates the discovery of regularity and coherence, but it must be emphasized that there is no

direct warrant for it in either the acoustic or the articulatory observable data of speech, and it constitutes a fairly abstract (though undoubtedly appropriate) theory of how sound is organized for linguistic purposes.

It is clear that the role of particular sound differences varies considerably from one language to another. Thus, in English, the vowel sound in the word *bad* is much longer than that in *bat* (more than half again as long), but such a difference in length is always predictable as a function of the following sound, and never serves by itself to distinguish one word from another. In Tahitian, in contrast, essentially the same difference in length is the only property distinguishing, for example, *paato* 'to pick, pluck' from *pato* 'to break out.' A theory of sound that attends only to physical properties has no way of clarifying the quite different functions these properties may have across various languages. This is not to suggest that phonetics is wrong, but rather that there is more to be said.

1.1.1 De Saussure and the 'phonemic principle.' The great Swiss linguist Saussure (1916) was the first to stress that in order to understand the role of sound in language it is necessary to focus not (just) on the positive properties of sounds, but on their differences. He suggested that in the study of individual languages, as opposed to general phonetics, utterances should be characterized in such a way that two such representations might differ only in ways that could potentially correspond to a difference between two distinct messages in the language in question. Thus, since long and short vowels never (by themselves) distinguish two distinct utterances in English, the difference should not be indicated in that language; while for Tahitian, it must be. A representation with this property will be called *phonological*; it will obviously be specific to a particular language, and the distinctive elements that appear in it can be called the *phonemes* of that language.

While de Saussure enunciated this principle quite forcefully and persuasively, he provided few specific details of just what a phonological representation should look like. There are in fact a variety of ways in which his insight could potentially be realized, and much subsequent discussion in phonology hinges on these differences of interpretation.

1.1.2 The development of phonology as a theory. Various individual investigators arrived at conclusions similar to de Saussure's about the importance of attention to language-particular sound contrasts. One of these was the Polish linguist Baudouin de Courtenay (1972), whose work actually antedated de Saussure's, but attracted little attention due to his isolation in Kazan. He developed a sophisticated view of the relation between phonetics and phonology both in individual grammars and in linguistic change. As

transmitted by his later students, Baudouin's views on the nature of the phoneme constituted an important strand in thinking about language as this developed in Russian linguistics in the early years of the twentieth century. This, in turn, provided the background from which the work associated with the Linguistic Circle of Prague grew in the 1920s and 1930s.

Two of the most prominent members of the Prague Circle were Trubetzkoy (1939) and Jakobson (1941). In their studies of Slavic languages and their histories, they stressed the notion that the collection of potentially contrastive sound types in a language was not simply an inventory, but a highly structured system. This system is organized in terms of a small number of mutually orthogonal dimensions (such as voicing, stop vs. continuant, nasality, etc.), each of which serves in parallel fashion as the basis of multiple contrasts. The notion that the fundamental terms of sound structure in language are these properties themselves and not (or at least not only) the complete sounds they characterize has remained an important component of most subsequent theorizing. The analysis of phonological structure in terms of its constituent basic contrasts, in turn, has served as a model for a variety of other disciplines in the Humanities and the Social Sciences apart from linguistics.

1.1.3 American structuralist phonology. Early thinking about sound structure in America was dominated by the anthropological interests of Franz Boas, and focused on an accurate rendering of the sound contrasts in the comparatively 'exotic' indigenous languages of the new world. Boas's student Edward Sapir, however, was concerned to place the study of language in the broader context of an understanding of the human mind and society. As such, he stressed (Sapir 1925) the notion that the elements of sound contrast in a language should be regarded as having a primarily mental reality, part of the speaker/hearer's cognitive organization rather than as external, physical events.

The rise of positivist views of science in the 1930s, and especially of behaviorist psychology, made Sapir's sort of mentalism quite marginal, and replaced it with more rigorous operational procedures for investigating notions of contrast. Especially associated with the ideas of Bloomfield (1933) and later structuralists such as Bloch and Harris (1951), the result was a theory of the phoneme based exclusively (at least in principle) on a set of mechanical manipulations of corpora of observed linguistic data, from which a set of contrasting minimal elements was to be derived. The central notion of this theory was a phonemic representation related to surface phonetic form in a way that would later be formulated explicitly as a condition of *Bi-uniqueness*: the requirement that given either a phonetic or a phonemic representation of an utterance in a given language, that could be converted uniquely

into the other (disregarding free variation) without additional information. The perceived rigor of this notion led to its being widely taken as a model not only for the study of other areas of linguistic structure, but for other sciences as well.

1.1.4 Generative phonology. The phonemic theories of American Structuralists provided a way to characterize linguistic contrasts, the inventories of sound types used in a given language, and the ways sounds can be combined into larger structures, but other aspects of sound structure were less satisfactorily accommodated within those views. In particular, questions of the ways in which unitary meaningful elements change in shape according to their sound context (or 'allomorphy': see *Morphology in Linguistics*) failed to receive systematic treatment. Since any difference among sounds that could serve to contrast linguistic elements was *ipso facto* a difference between irreducibly basic terms, there was really no way to express the notion that a single item could take a variety of forms (as in the prefixes in *inefficient*, *imprecise*, *irregular*, *illegal*, etc.) except by simply listing the variants. Such a list is undoubtedly appropriate for cases such as the forms of English to be (*am*, *are*, *is*, *was*, *were*, etc.) which are unrelated to one another in form; but in many other cases, the variation is transparently systematic and a function of the sounds in the element's environment. This sort of variation was recognized by structuralist phonologists, but relegated to marginal status.

Beginning with work of Morris Halle, a student of Jakobson, linguists began to question the centrality of surface contrasts in sound structure. The result was a new view that allowed morphophonemic regularities as well as more superficial ones to be accommodated within a phonological description. The success of this more abstract notion of sound structure in dealing with hitherto irresolvable problems in the description of stress (see *Suprasegmentals*) contributed greatly to its success, and the resulting theory of Generative Phonology as developed in the work of Halle together with Noam Chomsky rapidly became the dominant view in the field by the middle of the 1960s.

1.2 Phonology as a System of Rules and Representations

A basic insight in the development of Generative Phonology was the proposal that it is not only the representation of linguistic elements in terms of basic contrasts that matters: an adequate theory must characterize what a speaker knows about the sound system of the language, and that includes regularities of variation and alternation as well as inventories of basic elements. Combining these two aspects of phonological knowledge required the explicit recognition of

a system of rules (expressions of regular patterns of contrast and variation in sound shape) in addition to the theory of representations. Developing an adequate theory of phonological rules, in turn, necessitated a notion of phonological representation that was related to surface phonetic reality in a much more complex and indirect way than the phonemic representations of structuralist linguistics. The central problems of phonological theory came to be articulated in terms of the theory of rules, their nature, and their interaction, and the underlying phonological representations that need to be posited in order to allow them to be expressed in their full generality.

2. *Issues in Phonological Theory*

As reviewed in Sect. 1.1 above, the problem of phonological description was originally conceived as a matter of discerning the range of contrastive sound units in a language, and arranging them in a system that brings out the dimensions of their contrast. When phonology is seen as a form of knowledge, however, as generative phonologists have stressed, the sound structure of natural language takes on quite a different form and presents quite different problems. Among these are (a) the nature of underlying ('phonological' or 'phonemic') representations as well as surface ('phonetic') representations; (b) the ways in which phonological regularities serve to relate phonological to phonetic representation, including the interactions that may obtain among regularities; and (c) the relation between phonological form and other aspects of linguistic knowledge, such as word structure (see *Morphology in Linguistics*) and sentence structure (see *Syntax-Phonology Interface*). Various aspects of these questions are addressed below.

2.1 *The Abstractness of Phonological Representation*

Initial reaction to the proposals associated with generative phonology centered on its abandonment of a phonemic representation based on the condition of bi-uniqueness. Relaxing this defining characteristic of Structuralist phonemics led to phonological representations that were considerably more abstract in their relation to phonetically observable properties. The proposals of Chomsky and Halle (1968) concerning the analysis of English, for example, involved positing final 'silent *e*' in words like *ellipse*, *burlesque* (phonologically /Ellipse/, /bVrleske/), geminate consonants in words like *confetti* (/kVnfetti/), a distinction among /k, s, c/ such that *acquiesce* is phonologically /ækwiesce/, etc. Indeed, there were no constraints whatsoever on the relation between phonological and phonetic form, apart from the desire to set up underlying forms from which as much variation as

possible in the shapes of particular morphological units could be predicted. Since much of this variation is the residue of earlier sound changes that have affected the same element in different ways in different environment, many early generative analyses resembled historical accounts of the language more than they did the knowledge of current speakers.

The perception of such apparently excessive abstractness led to proposals for constraining the operation of phonological rules in grammars, and the kinds of representation that should be posited. Kiparsky (1973), in particular, suggested a variety of conditions that would have the effect of prohibiting rules of 'absolute neutralization' (by which some posited phonological distinction is eliminated uniformly in surface forms, such that it never corresponds to a phonetic distinction) and other abuses of the theory's representational freedom. This led phonologists to seek external evidence for the reality of the representations they assumed, in the form of data from poetic systems, historical change, language games, behavioral experiments, and other sources outside of the phonology itself. Such a notion would have been incoherent on the assumptions of Structuralist phonology, for which the properties of the system are a matter of its internal logic, but became important with the shift to a view of phonological form as a matter of speakers' knowledge.

It is now apparent that phonological representations, while more abstract than assumed by structuralists, are still rather constrained in the extent to which they can deviate from phonetic form. There is no real consensus in the field, however, as to what constraints are appropriate on the operation or form of grammars so as to ensure an appropriate result. In the absence of some motivated grounds for decision in general, the status of specific conditions remains somewhat arbitrary. Replacing the conception of a grammar as a set of rules by that of a set of simultaneously evaluated partially violable constraints, as discussed in a later section, severely limits the potential abstractness of underlying representations in a way that may prove to resolve these issues in a principled way.

2.2 *The Interaction of Phonological Regularities*

In the nature of a Structuralist phonemic representation, all of the regularities expressed in the grammar are mutually independent. That is, it is only necessary to know the phonemic environment of a phoneme to predict its phonetic realization; and it is only necessary to know the phonetic environment of a phonetic segment to establish its phonemic correlate. When the bi-unique relation between these levels of representation is relaxed, however, more complex possibilities arise for regularities to interact with one another.

Consider the formation of English regular plurals, for example. For the three words *cut*, *dog*, *horse*

(roughly [kæt], [dog], [hors] respectively, phonetically) and others like them, the corresponding plurals are *cats*, *dogs*, *horses* ([kæts], [dogz], [horsɪz]). Assume that the phonological representations of the nouns are essentially the same as their phonetic forms, and that the regular plural ending has a single constant phonological form: /z/ for concreteness' sake, though the point to be made is independent of this choice. Now there are two distinct regularities that are involved in determining the pronunciation of the plural ending:

(a) If the noun ends in a sibilant ([s, z, ʃ, ʒ, č, ʝ]), a vowel [ɪ] appears between the stem and the ending; and

(b) If the stem-final sound is voiceless, the ending is voiceless ([s]) as well.

Now consider how these principles interact in determining that the pronunciation of *horses* (phonologically /hors + z/) should be [horsɪz]. In this case, the conditions for both of the rules above, *b* as well as *a*, are met, and we might expect both to apply, yielding (incorrect) [horsɪs]. The relevant observation is the following: the vowel inserted as a result of rule *a* has the effect that the stem and the ending are no longer adjacent, and so rule *b* is inapplicable. That is, the regularity represented by rule *b* in this case presupposes that the set of clusters of consonants which will remain adjacent in surface forms (a matter which is potentially affected by applications of rule *a*) has been determined. This logical relation of presupposition between rules is generally expressed by saying that rule *a* applies 'before' rule *b*, though it is important to note that no claim of temporal priority is thereby asserted, but rather a purely logical notion.

Much of the abstractness of early generative phonological analyses was made possible precisely by the availability of rule ordering as a descriptive device: the possibility of specifying rule interactions such as the above as an independent parameter within grammars. Although arguments for the necessity of such ordering formed an important part of the literature, and particular accounts sometimes involved apparently crucial depths of ordering as great as twelve to fifteen, many linguists felt that (as part of the general campaign to reduce abstractness in phonology) stipulated ordering relations ought not to be permitted as a descriptive device. Despite the existence of cases apparently requiring irreducible specification of relative order (e.g., dialects with the same sets of rules and underlying forms, differing in their surface forms only as a consequence of different interactions among the rules), and the fact that all proposed formulations of principles from which observed rule interactions could supposedly be predicted had obvious and well established counter-examples, a consensus developed in the field that such 'extrinsic' rule ordering statements ought to be prohibited. This has left a number of kinds of empirically observed interactions unaccounted for, a problem which has persisted as phonologists have turned from rules to constraints as descriptive devices.

2.3 The Structure of Representations in Phonology

As already noted, the description of speech at either the phonetic or the phonological level as composed of a sequence of discrete segment-sized units is a significant abstraction from physical reality. Its justification comes not from the observable facts, but from the extent to which it allows the analyst to uncover what is orderly and coherent in linguistic structure. By the mid 1970s, however, it had become apparent that a purely segmental organization of representations impeded the description of linguistic regularity in several respects (see *Phonology, Nonlinear*).

One of the first of these problems to be discussed arose from the analysis of systems of tonal contrasts, common in the languages of China, Africa, and in fact much of the world. Careful analysis revealed two ways in which tonal properties were problematic for strictly segmental models: on the one hand, what appeared to be a single tonal specification might take as its scope more than a single segment (perhaps the vowels of several consecutive syllables, or an entire word); and on the other hand, what appeared to be a single segment (a unitary short vowel, for example) might have a tonal specification involving two or even more consecutive tonal levels. If it is assumed that each of the consecutive segmental units of which a representation is composed bears exactly one specification for each potentially distinctive property, and the specifications of distinct segments are independent of one another, both of these situations are anomalous.

As a result of these observations, the segmental view came to be replaced with an *autosegmental* notion of representation. On this picture, specifications for each potentially distinctive property (or feature) succeed one another discretely, but an additional dimension of representation is the specification of the way these are synchronized or aligned with one another. In the limiting case, where each specification for a given feature is temporally aligned with one and only one specification for each of the other features, the standard segmental picture arises, but more generally, one or more instances of many-to-one alignment may be found. Once this view was articulated, it became apparent that many properties other than those of tone were also most appropriately described in this way. Nasality, in particular, behaves similarly in many languages and the very common phenomenon of assimilation is often best treated as an alteration in the scope of some features rather than a change in their values.

On the other hand, the full flexibility of autosegmental representations predicts much more independence of specification than is actually found. Features of place of articulation typically behave as a unit, despite their logical independence from one another, as do the features characterizing laryngeal activity. This observation gave rise to the notion that phonological features are not just an unordered set, but

instead are organized into a sort of hierarchical arrangement, such that for example features of consonantal place can be referred to as a unit. There is considerable consensus on the overall form such a *feature geometry* should take, but many details and relations among properties remain unsettled.

Another representational issue concerns the existence of structural units larger than the single segment, such as the syllable. Classical generative phonology, as represented by, for instance, Chomsky and Halle (1968), makes no appeal whatever to syllables (or any other unit above the segment). This was not simply an omission on their part, but rather a systematic claim to the effect that segmental specification could always suffice to express any phonological generalization: that is, that any observation involving syllables (of which there are many in Chomsky and Halle 1968) could be satisfactorily reformulated in a way that dispensed with any units other than segments. The boldness of this claim invited immediate attack, and indeed it soon became clear that there were indeed aspects of phonological structure that required reference to syllables and other supra-segmental units. The resulting theory of the *prosodic hierarchy*, by which segments are grouped into syllables, themselves grouped together into *metrical feet*, which in turn form constituents of *phonological words* (perhaps with some additional categories, according to some writers) has become another standard assumption about phonological structure.

2.4 Interactions between Phonology and Other Areas of Grammar

The original conception of a generative phonology was as a component of the grammar that served to map lexically specified syntactic structures onto phonetic form, a representation appropriate to serve as the instructions to the language-independent mechanisms of speech production. This picture logically entails the notion that words, phrases, and sentences are already fully assembled in the input to the phonology. This assumption, however, has proven to be problematic.

The notion that phonological properties interact with the syntactic environment in which forms occur is quite a familiar one, especially in the description of accent and intonation (see *Syntax-Phonology Interface*). Word formation, too, may depend in some instances on the assignment by phonological rule of phonological properties (see *Morphology in Linguistics*) in a way that contradicts the assumption that phonology applies strictly to the output of this part of the grammar.

The most extensively elaborated picture of how phonology interacts with the rest of grammar is presented by the theory of Lexical Phonology (see papers in Hargus and Kaisse 1993 for introduction and explication). Briefly, this picture distinguishes

between lexical and post-lexical regularities, with the former applying in a way that interacts with word-formation, and the latter applying to a representation in which fully formed words appear in their syntactic context. The lexical rules, in turn, may (depending on the language) be divided into two or more *strata*, for example, rules applying to *roots*, *stems*, or *words*. A process of word formation takes some lexical unit as its input and yields an output (affixed or otherwise altered in form), with this output then subject to appropriate phonological modification. The resultant representation may serve as the input to further *cycles* of word formation plus phonology, until a complete surface word is arrived at.

These units, assembled into larger syntactic constructions, are then subject to the post-lexical rules. While various forms of lexical phonology generally constitute the background assumption of much phonological discussion, the correctness of such a view of the overall architecture of grammar has come into question. In particular, the rise of constraint based theories implying a single stage in the conversion of underlying to surface form has appeared incompatible with the sequential, derivational character of lexical phonological description. Some researchers have sought to reconcile these two trends in phonological theory, while others have attempted to augment one or the other sub-theory in such a way as to include the results of the other.

2.5 Rules vs. Constraints in Phonological Description

Formulations of phonological regularities since the 1950s have drawn on the mechanisms of automata theory: standardly, these have been expressed as rewriting rules that map an input representation onto an output, one step at a time. Developments in the theory of computation, however, have given rise to an alternative possibility. Instead of converting inputs to outputs in several stages, with each step involving the imposition of a single regularity in the computation of a new representation, one might formulate all of the regularities as elements of a single system of constraints. If these constraints are ranked with respect to one another, it is possible to say that any particular constraint may be violated in the output, provided that such a violation is motivated by the need to avoid violating a more important (higher ranking) constraint. The resulting theory provides an architecture of grammar that is (at least apparently) very different from that which has dominated most of the literature in phonology. For example, the kinds of interaction among regularities treated above as matters of rule ordering can no longer be described in this way, since all of the constraints in the grammar apply (in principle) in a single, simultaneous block. Constraints can have a language-particular ranking among themselves, but this is a matter of priority, not logical

presupposition. Other differences have been alluded to in the discussion above.

Constraint based theories along the lines of Optimality Theory (Prince and Smolensky 1993) have been shown to have a number of significant advantages over rule-based accounts, and currently constitute the most active area of investigation in phonological theory. It remains to be seen, however, what character a comprehensive theory will have once the substantial body of results achieved within earlier, apparently incompatible frameworks has been incorporated comprehensively.

Phonology, Nonlinear

Nonlinear phonology is a loose collection of relatively recent theories that address various aspects of the sound structure of human languages. Traditional approaches to phonology are linear, which means that they represent each word as nothing more than a string of speech sounds (called segments). Each segment is a bundle of its phonetic attributes, called distinctive features, but no further structure is assumed. Nonlinear phonology posits a richer architecture: segments are organized into a hierarchy of constituents, such as the syllable, the stress foot, and so on; and distinctive features are liberated from the segmental feature-bundle, allowing them to have domains that are larger or smaller than a single segment. This article examines some of the consequences of this hypothesis, focusing on two particular implementations of it.

1. Historical Background

Before the mid-1970s, most research in phonological theory started from the assumption that segments are linked together like beads on a string (see *Phonology*). In this view, phonological representations are very similar to alphabetic writing, with exactly one symbol standing for each segment and with little or no structure beside the linear order of the segments in a word.

The best known theory of this general type is the one in Chomsky and Halle's (1968) *The Sound Pattern of English* (SPE). The SPE theory is rigorously and consistently linear: for example, syllables play no role at all, and constituents such as the word have only a derivative status. The only departure from the alphabetic model is that each segment is assumed to be a bundle of distinctive features standing for its various attributes (such as nasal, voiced, rounded lips, and so on).

During the 1940s, two important precursors to contemporary nonlinear phonology emerged independently in the work of J. R. Firth and Zellig Harris. They shared the idea that phonological properties could have domains larger than a single segment. For example, in the South American language Terena, the meaning of 'I' or 'my' is marked by nasalizing (indicated by a tilde) a sequence of segments beginning at the left edge of the word: *owoku* 'house', *ōwōngu* 'my house'; *arine* 'sickness', *āřinē* 'my sickness'. Firth or Harris would say that the domain of nasality in Terena is (approximately) the word. Their theories did not have much influence, though, and their work was largely neglected for several decades.

2. Nonlinear Phonology

In reaction to SPE's strongly segmental orientation, the mid-1970s saw a profusion of nonlinear ap-

proaches to phonological phenomena, supplying ideas and insights that continue to be studied in the present day. These models were developed to address empirical problems that had been disregarded or treated unsatisfactorily in SPE: tone, long distance assimilation processes, syllables, the typology of stress systems, and the interaction of phonology with morphology and syntax.

Two leading ideas have emerged. One is *autosegmentalism*, the notion that distinctive features, rather than segments, are the atoms of phonological representation. (This term was coined by John Goldsmith.) From an autosegmental perspective, a distinctive feature is not an attribute of a segment, as in SPE, but a free standing entity. This status allows the feature to act independently of its segmental host, approximately as in Firth's and Harris's theories. The other leading idea is the *prosodic hierarchy* (a phrase coined by Elisabeth Selkirk), which organizes segments into successively larger constituents such as the syllable or word. The prosodic constituents are analogous to the more familiar syntactic constituents such as sentence or noun phrase (see *Constituent Structure: Syntactic*), and, as in syntax, structural requirements imposed on the constituents are an important analytic tool.

Autosegmentalism and the prosodic hierarchy are complementary, not competing, hypotheses. As a matter of logic, they are not mutually exclusive, since autosegmentalism speaks to the nature of subsegmental units (distinctive features), while the prosodic hierarchy is a claim about how segments themselves are organized into larger groupings. They have also been applied to factual domains that are mostly distinct. Autosegmentalism helps to solve problems in tone and featural phonology, such as assimilation. The prosodic hierarchy is important in understanding the phonology of syllables, stress, words, and phrases.

Autosegmentalism and the prosodic hierarchy are, ultimately, claims about how language is represented in the human mind. Though they allow for a considerable range of variation between languages, they also have a core that is claimed to be universal. Hence, the main evidence for these theories comes from observations about phenomena that recur in many languages.

The rest of this article discusses the implementation of these two aspects of nonlinear phonology, the results and controversies that emerge from them, and their present and future prospects.

3. Autosegmental Phonology

The following example illustrates one of the key arguments for autosegmentalism. Some speakers of the Bantu language Sanga use a secret language (analogous to pig Latin in English) called Kinshingelo. Words in this secret language are formed by sys-

tematically permuting the segments of Sanga words, as in the following example:

Sanga
báá.kó.lwèé bàà.dyáá má.tá.bá áá.ŋkáá.mbò
Kinshingelo
báá.lwé.kòó dyàà.báá má.bá.tá áá.mbòó.ŋká
Gloss

'The birds are eating my grandfather's corn.'

The accents mark tones: acute *ó* is high and grave *ò* is low. Double vowels are long, so *áá* stands for a long *a* vowel with a rising (i.e., low–high) tone. For expository convenience, syllable divisions have been indicated with a full stop.

A Kinshingelo word is formed by swapping the last two syllables of each Sanga word. But not precisely: the segments themselves are swapped, but their tones and length are not. Speakers of Sanga unconsciously regard *áá* as somehow divisible into three components: a part that describes the action of the tongue and lips in forming consonants and vowels, a part that describes the action of the larynx in controlling tone, and a part that describes the duration of the vowel. A useful analogy is an orchestral score, which contains distinct but coordinated instructions for many, different instruments. This is the central insight of autosegmental phonology: speech sounds consist of independent components which are coordinated in time.

Tone is the premier example of an independent component of speech, and in fact autosegmental phonology was first developed to deal with tone. Some other consequences of autosegmentalism for the analysis of tone include:

(a) *Persistence under deletion*. When a vowel deletes, its tone may remain and attach itself to some nearby vowel.

(b) *Floating tones*. When a vowel deletes, its tone may remain and express itself indirectly, by affecting following tones.

(c) *Toneless syllables*. Some syllables have no tonal specification at all. Their pitch is determined by linear interpolation between syllables that have tones.

(d) *Tone shift*. In the Bantu language Kikuyu, every tone shifts exactly one syllable to the right, domino fashion, so /tòmátómàyà/ becomes tòmátómàyà

(e) *Tone melodies*. In some languages, words are limited to a small set of fixed tone melodies, or tone melodies may mark certain morphological distinctions.

In sum, tones and segments may behave independently of one another. This is the expected result of the autosegmental hypothesis (see also *Suprasegmentals*).

Not long after it was developed, autosegmental phonology was applied to nontonal phenomena as well. The idea is that every distinctive feature—[nasal], [voiced], and so on—occupies its own separate autosegmental 'tier,' allowing it to function independently of segments or other features. The main focus of

**Figure 1**

Autosegmental representation of Warao *mōāũpu*

research in this area has been on two related problems: assimilation and harmony.

In assimilation, one segment (the target) takes on some of the features of another, nearby segment (the trigger). Harmony is a kind of long distance assimilation, where the triggering segment and its target are not necessarily adjacent. Here are some examples from the South American language Warao, and the North American language Chumash:

- (a) Warao /moaupu/ → *mōāũpu* 'give them to him'
- (b) Chumash /k-sunon-š/ → *kšunonš* 'I am obedient'

In Warao, the feature [nasal] assimilates, affecting a potentially unbounded sequence of vowels after a nasal consonant. In Chumash, the feature [anterior] assimilates, changing *s* to *š* (the initial consonant in *ship*) if followed anywhere in the word, at whatever distance, by another *š*.

Autosegmentalism contributes to the understanding of these processes in two ways. First, it provides a natural interpretation of assimilation. Because features and segments are independent, the domain of a feature can be larger than a single segment. Assimilation expands the domain of a feature from one segment to many. Second, autosegmentalism allows long distance harmony processes to be analyzed as local on the tier of the assimilating feature. These two key insights are usually expressed graphically, as in Fig. 1. The feature [nasal] is shown on its own autosegmental tier, separate from the rest of the segment. Temporal coordination between [nasal] and the rest of the segment is indicated by association lines. The solid association line is original, while the dotted association lines are the result of the process of assimilation. The effect of assimilation here is to expand the domain or scope of [nasal] to include the vowels *oau*.

The most radical autosegmental theory is one in which every distinctive feature is on a separate tier, with complete freedom to act independently of all other features. This view cannot be right, because there are strong functional associations among various subsets of the features. For example, the features that characterize states of the larynx have a considerable degree of cohesion in phonological systems, assimilating or neutralizing together.

Functional groupings of features are addressed in theories of feature geometry. (This term was proposed by G. N. Clements.) The idea is to posit a layer of representation between the segment and the features.

**Figure 2**

A model of feature geometry

Elements of this intermediate layer, called class nodes, are constituents corresponding to the observed functional groupings. A typical implementation, abstracting away from controversial details, appears in Fig. 2. The laryngeal features often act together in phonological processes, and so there is a constituent, the Laryngeal node, that unites them. Similarly, a single process will often affect the various features that distinguish *p* from *t* from *k*, and so there is a constituent, the Place node, to unite them as well. Feature geometry, like autosegmental phonology itself, is claimed to be universal. Research in this framework is oriented toward discovering a set of class nodes that will account for all (or at least all common) phonological processes in the world's languages.

4. The Prosodic Hierarchy

The term prosody is used by phonologists to refer to the durational, rhythmic, and phrasing aspects of speech. The study of prosody includes syllables, stress, restrictions on the size or shape of words, and many of the ways in which morphology or syntax can affect pronunciation (see *Word, Linguistics of; Linguistic Typology*).

A key insight into the nature of prosody is the idea of a small, universal set of prosodic categories arranged into a hierarchy (see Fig. 3). Certain additional assumptions give the hierarchy predictive value:

(a) *Grouping and layering*. Level *n* of the hierarchy imposes a grouping structure on the layer just below it, level *n* – 1.

(b) *Headedness*. Every constituent at level *n* designates a specific, most prominent constituent at level *n* – 1 as its head.

(c) *Structural requirements*. There are global and parochial conditions on the well-formedness of constituents. For example, languages frequently require that feet be binary, and there is also evidence of binarity conditions on other levels of the prosodic hierarchy. So, proceeding from the bottom of the hierarchy, a syllable is a grouping of segments; the head of the

Figure 3

A prosodic hierarchy model

syllable is the peak of acoustic energy, usually a vowel. A foot is a grouping of (usually two) syllables, one of which is more prominent than the other. The more prominent syllable is the locus of linguistic stress. A phonological word is a grouping of feet, one of which is also the most prominent (the locus of main stress). A phonological phrase is a grouping of phonological words that also includes a most prominent member, and so on.

Results of surprising subtlety and generality can be derived from these modest premises. For example, many languages set a lower bound on the size of the phonological word. The Australian language Diyari is typical in this respect: it has no monosyllabic words at all. This so-called minimal word requirement follows from joint action by three different constraints: layering (the phonological word dominates the foot in the prosodic hierarchy); headedness (every word must contain at least one foot, to serve as its head); and a structural requirement that feet be binary, since they are the basic units of stress rhythm. Comparable results can be found at other levels of the prosodic hierarchy.

5. Present and Future Prospects

Nonlinear phonology has been an active area of research since the late 1970s. The basic autosegmental hypothesis enjoys wide and perhaps universal acceptance. Various details are matters of debate, however:

- Do all features have the same autosegmental status as tone?
- Is feature geometry an appropriate model of featural organization?
- If so, exactly how are the features organized?
- Are (binary) features the appropriate units of subsegmental structure?

The prosodic hierarchy is somewhat more controversial. Although notions of constituency do play a

role in most theories of prosody, there are also models that are partly or entirely constituent-free.

In recent years, much research has focused on the ways in which Optimality Theory can illuminate topics in nonlinear phonology. A particularly productive line of investigation has been the study of constraints that align the edges of prosodic constituents with morphological or syntactic ones. These constraints relate the prosodic hierarchy to the hierarchy of grammatical constituents, offering a new perspective on the interface between phonology and grammar.

Photography as a Medium

For over a century and a half, photography has been the most popular and widespread means of making images. The first and primary tool of photography is the camera, and changes in the medium and its

applications are often attributed to technical developments in making, reproducing, and distributing photographs. Equally if not more significant, however, have been changes in the ways people think about photography, including ideas about what and how photographs represent, and the roles they have played in social, political, and economic life. This article examines developments and conflicts in the idea of photography within a historical framework of changing cultural practice.

1. Photography's Origins

The invention of perspective in the fifteenth century laid the foundation for the system of visual representation that became photographic. The camera obscura, used by scientists, artists, and magicians since the Renaissance, is the most important precursor to the camera. By the eighteenth century this device had evolved from a large clumsy apparatus for projecting an image onto a plane surface, to a more portable instrument, used for the curiosity and pleasure of looking at images of all sorts of objects and scenes projected by the lens.

A knowledge of light-sensitive materials was particularly available in Europe by the 1720s, and one of the riddles of photography is why nearly a hundred years passed before this knowledge was applied to fixing the camera obscura's image. Despite a broad fascination with display forms, such as the diorama, that created illusions of realistic representations of nature, the idea of the photograph as a permanent copy apparently did not exist. Suddenly, in the 1820s a range of experimenters began simultaneously to compete to be the first to successfully fix the photographic image; the desire to photograph had emerged.

Photography's invention is generally dated to 1839, when breakthroughs were announced nearly simultaneously in France and England. Louis Jacques Mandé Daguerre's induplicable monochrome on a silver-coated copper plate, and William Henry Fox Talbot's reversed image—the negative—were the first successfully publicized and patented processes. The daguerreotype enjoyed an immediate popularity, setting off a craze which by the end of the year the French press had named '*daguerreotypomanie*.' Talbot's calotype system, on the other hand, based on a negative image that could be used to print a potentially infinite number of positives in as many different sizes, laid the foundation for all subsequent developments in photography. The refinement and diffusion of these two systems, alongside many competitors, had an immediate impact on European social life and spread quickly to North America and colonial outposts.

Photographs appeared in many display forms, as cartes-de-visites and stereographs, in albums and as lantern slides, and photography surfaced as a theme in popular music, on the stage, and in artifacts ranging

from home furnishings to fashion accessories. Photography as an *idea* permeated mid-century European popular culture.

2. Early Applications of the Medium

At the same time that photographic tools and processes were being simplified, an agenda was being established for how the new medium was to be used. This included the people, places, and events represented in photographs and, equally important, who was taking the pictures and who were the intended viewers.

2.1 Photographs of People

Within months of Daguerre's announcement, professional portrait studios had sprung up in Paris, and soon studios were established in other major European cities, in New York, and in Washington. From 1860 onward, portraiture expanded to provincial towns, to less industrialized European countries, and to Australia, China, Japan, Mexico, and South America.

The photographic portrait represented a democratization of the painted portrait, and was commissioned first for private use within a family. The rising status of certain photographers led to commissions from men in public life whose positions required an official portrait. Most portraits of individuals followed the strict visual conventions of the painted portrait, a head-and-shoulders composition, with the sitter's head slightly turned to avoid a direct gaze into the camera. Portraits of family groups were common, and a custom quickly developed of photographically commemorating important events such as weddings and graduations. Photographs of deceased relatives, lying peacefully in their caskets, were also highly valued.

In the 1860s, studios began to turn out millions of inexpensive *carte-de-visites*, full- or bust-length portraits of workers, tradespeople, members of the bourgeoisie and aristocracy, native people of the colonies. These mass-produced images were often instrumental in establishing the status of a politician or celebrity, and both the French and British royal families permitted the sales of their images as *cartes*. Through its broad distribution, the *carte-de-visite* also contributed to forming Western ideals of feminine beauty and fashion, as well as ideas about people from the nonindustrialized parts of the world as exotic and other. The *carte* craze further generated a surrounding industry of albums and holders for cataloguing and exhibiting the growing image collections.

In 1888 George Eastman launched the first Kodak camera, with the slogan 'You push the button, we do the rest,' and immediately opened the practice of photography to a much broader segment of the

population. Studio portraiture declined as amateurs began to photograph family and friends. The repertoire of photographic events was also expanded as picture-taking became associated with holidays, family celebrations, and vacation trips. Photographic practice had entered the domestic domain, forming a bridge between personal memory and public history. A hundred years after the first Kodak camera, photography was fully integrated into family social life. In the mid-1980s, for example, over 90 percent of US families owned a still camera and amateurs were taking more than 11 billion photographs a year (Chalfen 1987). The majority of these pictures were of family members and friends and were rarely seen outside that social group. Nonprofessionals' private photography today accounts for the largest single application of the medium. Studies have shown that people attach enormous value to these images, and losing photographs of family and friends, for example, through fire or war, is often experienced as a greater tragedy than the loss of other material possessions.

2.2 Distant Worlds

The early years of photography coincided with the period of colonial expansion and exploration of newly won territory for the industrializing nations of Europe and North America. Wonders of nature, the dynamic new cityscape and its architecture, and the exotic cultures of distant lands held a fascination and attraction for many. The camera was an ideal tool for showing what was new or previously unknown to an audience eager to marvel over sights they could not see with their own eyes. Photography also opened up new territories for tourism by people who, having seen a place in pictures, now had the desire and means to experience it themselves. A new aesthetic of the landscape also stimulated tourism, as for example when photographs of the rocky Scandinavian coasts brought British and German tourists north in the 1870s (Rosenblum 1984, p. 112).

Photographs of popular European tourist sites, such as the city of Rome and its ruins, were marketed as stereographs. Distant lands of North Africa and the Near East became accessible to the armchair tourists of Europe as early as the 1850s through Francis Frith's photographs. Frith's *Egypt and Palestine Photographed and Described* (1858) was the first of 11 volumes and three sets of stereographs (Rosenblum 1984, p. 122). His work was motivated in part by a concern over growing French influence in the region, and must be seen in the broader context of British expansionist goals of the period. Local Egyptian photographers also opened studios and marketed their work to the growing European fascination with views of the ruins and landscape of the Near East. Similar patterns developed in India and parts of the Far East. By 1884, for example, several thousand native pho-

tographers were in business in China, serving both local clients and the Western trade.

In North America, photography was linked to Western expansion. Photographers accompanied survey teams in order to document areas for future mineral exploitation, rail routes, and civilian settlement, at the same time that they were contributing to the visual discourse of the American frontier and its native peoples. The natural wonders of the wilderness, including Niagara Falls, were immensely popular stereographic themes, used in lantern slide shows and collected in albums. This iconography and the photographers who produced it, such as Carleton Watkins and William Henry Jackson, established the grandeur of the mountain landscape as a symbol of transcendent idealism. Their work also contributed to lobbying efforts to establish a national park system in order to save the pristine wilderness from commercial exploitation by private interests.

Nor did the city escape the camera's gaze. In contrast to images of untouched wilderness and ancient unchanging ways of life, here the focus was on physical transformation. New transport systems, bridges, and buildings made possible by new technologies and materials were transforming the city into a modern metropolis. Urban expansion was a source of national pride, and both governments and private interests supported photographic documentation of the major cities of Europe and North America. Cityscapes in panorama format were especially popular, a parallel to the painted panoramas and dioramas that had emerged as mid-nineteenth century forms of entertainment.

Photography's prominent and various positions in the emergent discourse of modernity was never more evident than in the world expositions, the late-nineteenth century spectacles of science and marketing, combining knowledge and entertainment. Beginning with the Crystal Palace in London in 1851 and followed every few years in Britain, France, and the United States, these major events both symbolized and displayed industrial expansion, made possible by new technologies and materials. Displayed side by side with the symbols of modernity were the exotic products and peoples of the underdeveloped nations, the colonies. At this point in the medium's development, photography provided an unproblematic means of expanding knowledge of the visible world, and served 'the general urge in all industrialized societies to measure, describe, and picture the physical substances of all things on earth and in the heavens' (Rosenblum 1984, p. 140).

3. Concepts of the Image

Photography's popularity as a democratic form of self-documentation, intertwined with colonial interests and industrial expansion, point to the camera as a

tool that linked seeing and knowledge in new ways. Within the sciences, in the arts, and in social reform movements, distinct and often conflicting visual discourses have developed around the photograph as a source of insight and knowledge. We turn now to the ways of seeing with the camera that were generated within each of these broad fields.

3.1 Photography and Science

Within the discourses of science, photography was to be a witness to scientific observation with greater accuracy than the human eye was capable of. In medicine, photography provided close visual description of the human body, and was an aid in documentation and diagnosis of medical problems and also psychological reactions and mental aberrations. Examples are portrait photographer Professor John William Draper's book *Human Physiology* (1856), illustrated with woodcuts based on photographs and Dr. Hugh Welch Diamond, also known for his pictorial art photography, who documented women inmates of the Surrey County Asylum. Charles Darwin's *The Expression of Emotions in Man and Animals* (1872) was illustrated with photographs from a variety of sources. Microscope lenses were developed and the discovery of X-rays by Conrad Wilhelm Roentgen (the 1901 Nobel Prize recipient) led to their immediate use as camera images in medical diagnosis. Motion studies and stop-motion experimentation depended heavily on photographic documentation. Eadward Muybridge's 100,000 images analyzing movements involved in animal locomotion and a range of human activities (including walking, curtsying, and bricklaying) provided a new if contested way of seeing that also influenced the arts, in particular Cubist and Futurist painters.

Taxonomy was a unifying concept of the nineteenth century scientific paradigm, and studies of the human species were formed by the delineation and elaboration of physical and cultural distinctions. Anthropology became a dominant discourse of explanation, based on historical and biological notions of culture, and relying heavily on comparative taxonomic methods in order to systematically catalogue the world's peoples (Edwards 1997). Photography was central to the anthropometric systems developed to produce comparable data for analysis and classification. The system used by the distinguished British biologist Thomas H. Huxley for the Colonial Office, for example, involved posing individuals naked with a measuring rod in order to produce 'a systematic series of photographs of the various races of men comprehended within the British Empire' (cited in Edwards 1997, p. 56). These studies of human physiogony, used to expand evolutionary theory, contained a strong moral dimension, concerned with both creating and sustaining the complex system of social knowledge in which the images operated. Variations on the method were

applied in hospitals, prisons, and other institutions where photographs of inmates were used to establish and classify social types.

The 1870s and 1880s also brought about an awareness of the contributions photography could make to anthropological fieldwork, by Edward B. Tylor and others. Yet there are few examples of systematic photographic documentation in ethnographic field studies. Early photography of the ways of life of diverse folk groups was most often carried out by missionaries and educators or by artists working in the pictorial tradition. Edward Curtis, Adam Clark Vroman, Robert Flaherty, and Frances Flaherty documented native American tribal life in its positive aspects, romanticizing in particular the close relationship to nature. Nor was it uncommon for ethnographic photographs from the turn of the century of peasant customs made in a pictorialist style to be used to advance the cause of nationalism, as in several Eastern European countries. The most common reference to an ethnographic photography worth emulating is the classic study of *Balinese Character* (1942) by Margaret Mead and Gregory Bateson, as the 'first saturated photographic research in another culture' (Collier and Collier 1986, p. 12). Visual anthropology at mid-century was more closely associated with documentary film than with photography. Ethnographic photography survived as an *ideal*, however, despite the general absence of large-scale systematic studies. The British 'Mass-Observation' project in the mill towns of northern England in the 1930s, for example, was designed as an 'objective documentation' of working class life, in the manner of an anthropological study.

The archive has worked hand in hand with the scientific endeavors of accumulating and systematizing evidence. Seen as a repository of visual knowledge, the archive is related to the ideal of a comprehensive collection of images that together represent the whole (other examples being the family album or collection of *carte-de-visites*). The structure of the archive and its classification system was intended to mirror the physical and social world that the collection represented. Following Michel Foucault's groundbreaking archeology of the human sciences (1970), museums of natural and cultural history, as well as police, medical, and other archives, can no longer be seen as disinterested institutions that sustain and perpetuate value-free systems of knowledge, but reflect instead the structures of political and economic interests that gave rise to them. The photograph's evidentiary authority is thus inseparable from the archive as a repository of knowledge and power.

3.2 Photography and Art

Contrary to the idea of the photograph as an objective visual record, it has been argued that photography is inseparable from the Western pictorial tradition. Particularly in its relationship to landscape and nature,

photography employed a set of conventions and aesthetic standards theorized by the European concept of the 'picturesque.' Emulating themes from the fine arts, many early photographers developed techniques that undermined the sharp literalness of the lens in their aspirations to make images that were at once truthful, beautiful, and inspirational. Exhibiting esthetic photographs in an appropriate context was a paramount goal of the turn-of-the-century Secessionist movements in Europe and the United States, and was important to establishing photography's status as art. Pictorialism in photography was a synthesis of the realism of the camera image, with frequently formulaic romantic compositions of peasant or working class life.

A complex and uneasy relationship between photography and the fine arts has continued, even as the repertoire of art photography has expanded. This is generally beyond the scope of this article, apart from several developments relevant to photography's relationship to the social sciences. On the one hand, themes drawn from peasant and working class life as well as of non-Western people integrated scientific inquiry with romantic images of an exotic or primitive Other as legitimate subjects of photographic art. On the other hand, attempts in the 1920s to define and explore the characteristics which distinguish photography from other visual arts laid the foundation for a more radical 'straight' photography, called New Realism or *Neue Sachlichkeit* in Europe and North America. The nonmanipulated or spontaneous photograph became a means of exploring and exposing familiar subjects in new ways. These different schools and genres of art photography became more or less systematized as museums began to add photographs to their collections. The Museum of Modern Art in New York is a noteworthy example of a leading museum where a series of influential curators established a vocabulary of photographic practice based on the premises of modernism. By the 1940s, a photographic canon was in place, including a history of art photography with specific artists, works, and genres represented in the museum's collections (Newhall 1949). Of particular importance to the social sciences was the respect this canon established for the genre of documentary photography as a legitimate form of esthetic practice.

3.3 The Photographer as Engaged Observer

Parallel to their idealized representations of European peasants, from the 1850s onward artists began to be concerned with the social and ethical consequences of industrialization, preparing the way for documentary photography's role in social reform campaigns. 'Before' and 'after' images became a staple of reform photography in the 1890s, as evidence of the positive effect the reform school or institution had on its

residents. Photographs from the slums of New York (by Jacob Riis) and of child labor conditions (by Lewis Hine) were used to raise the fears and sway the consciences of politicians and a middle-class public. The photography of social reform was closely linked to new means of dissemination: the half-tone process for mass-producing photographs had been developed in the 1890s and a range of new periodicals arose in its wake.

Alongside the popular press' increased use of photographs after the turn of the century, social reform journals were among the first to recognize photography's ability to advocate a cause. Here the *American Charities and the Commons* is noteworthy. The *American Journal of Sociology* was also using photographs to illustrate articles, for example, on housing conditions. This visual material, often by women who held administrative positions in social action agencies, later declined under Albion Small's editorship, as the journal aligned itself with sociology's move to establish itself as a scientific discipline (Stasz 1979).

By the 1920s, documentary photography, as the genre came to be known, was recognized as an effective means of drawing attention to social issues. The best known example of such an effort was the photographers who worked for the US Farm Security Administration (FSA) under the leadership of Roy E. Stryker in the late 1930s, documenting the effects of the depression on rural Americans and the need for government aid. In other cases, photographers used the documentary form to draw attention to marginalized social groups, occasionally drawing on their own experience as members of the culture they documented. One of the clearest ideological expressions of photographers' identity was the Worker Photography movement, most active in Germany between World Wars I and II. The International Communist Party, convinced that photographs unavoidably reflect the class of the person holding the camera, mobilized workers in a variety of documentary projects and publications. In direct contradiction to a claim of impartiality, this photography based its authority on the photographer's membership in the group. It can thus be seen as a precursor to anthropology's interest in indigenous photographers' images as expressions of their specific cultural perspectives.

The authenticity of the documentary style was based on a complex set of factors. Seldom was the work based on a single photograph, but instead was built up through a series of images witnessing the photographer's proximity to the subject over an extended time. Despite many exceptions, the images also tend to follow a specific visual code. Straightforward photographs of people, taken in their everyday environment under available light conditions, are the most typical. If the subject appears to be aware of the camera, he or she is usually gazing directly into the lens. The photograph's claim to truth is based therefore on the

seemingly contradictory appeals of the photographer's simultaneous engagement with and objective distance from the subject.

4. Photography and Mass Society

Closely related to the ways photography has portrayed its subjects is the effect of images on those who see them, the audience. Photography was a mass medium almost from its inception, as the idea of the photograph and the ways it was marketed had a broad and immediate social and cultural impact. The 'very insatiability of the photographing eye' and the 'omnipresence of photographed images' position the medium in a vortex of complex moral, ethical, political, and esthetic issues. Sontag's influential book of essays *On Photography* (1973) brought many of these issues up for debate. Yet the exact nature of the photograph's appeal and its effect on its viewers has remained elusive. Despite extensive research on photography's impact on attitudes and behavior, results have been either inconclusive or too context-specific (regarding the viewer's age and background or the viewing context) to support any general conclusions. What is evident, instead, is a widespread belief in the photograph's influence which has in turn led to specific applications of the medium based on conceptions of the nature of photographic communication as a highly unstable synthesis of factual information and seductive attraction.

From the 1850s photographs began to be used alongside other illustrations in some magazines, and the widespread application of the half-tone process in the 1890s coincided with the emergence of new audiences in Europe and the United States. Photography was thought to appeal in particular to people who were either nonliterate or had not yet mastered the language of their new country. A new inexpensive illustrated press arose that used photography in often sensational ways, and photographs began to appear in advertising. Political campaigns made extensive use of photography from the 1920s onward, in documentary forms described above, but also in photomontage and posters. The reticence of many newspapers to make extensive use of photography (for example, the morning newspapers 'of record' in New York and London) is an exception which nevertheless rests on the same notion of the photograph's communicative power. The photograph, if seen as an unmediated copy of nature, does not require language or reason to be understood, but appeals instead directly to the emotions. Newspapers and other media that wished to base their appeal on rationality excluded photographs from their pages. Even if an image were manipulated through technical or other means, the message that the audience saw or 'received' was accepted as representing reality.

The model of mass communication that emerged first in the United States and dominated research for

several decades was based on the notion of communication as a successful 'transmission' of a message from an active and powerful source to a passive receiver. The origins of the model and the research it generated can also be traced to growing concern over the power of the media, particularly in the service of political propaganda and the rise of fascism in Europe after World War I. Although only sporadically applied in research on photography, the transmission model of communication served as the underlying framework of explanation of photography's influence on its audience. The power of images is assumed to be greater, for example on the relatively unformed psyches of children and youth. 'Moral panics' continue to pursue the image and its influences, giving rise to research on Hollywood films in the 1930s, on comic books in the 1940s, on television's effects on children in the 1950s and 1960s, and video games at the turn of the century.

Countering the transmission model of photography's influence on its audience is the perspective that considers photography as a cultural practice and phenomenon which participates in the construction of power and meaning through the mutual and intertextual establishment of social and political institutions and forms of visual expression. The cultural perspective views the audience not as passive receivers, but as members of a (sub)culture who employ cultural knowledge as they produce, consume, and interpret photographs. The cultural perspective does not deny the power of the media, but rather sets it in a historical, social, or political context, and examines how the media use photographs to address or position the viewer in specific relationships to media content. The perspective shifts the emphasis from an inquiry into photography's impact on individual or group attitudes and behavior to an examination of the ways photography is used in the construction of meaning, often focusing on social values and the use of stereotypes. The medium has been decisive, for example, in the production of visual representations of gender and gender relations, as revealed in Erving Goffman's study of advertising (1979). Other studies have demonstrated how media images of women not only establish standards of feminine beauty, but also link the image of the female body to products and services in a process of commodification that objectifies all women (cf. Williamson 1978, Irigaray 1985, Bordo 1993, Solomon-Godeau 1991). Other analyses have provided insights into the formation and perpetuation of stereotypes of race, in advertising but also in the news media, with groundbreaking work carried out at the Centre for Contemporary Cultural Studies in Britain in the 1970s.

Issues of media power and influence are also linked to photography through a growing concern over the image's role in surveillance. Cameras, in addition to their continually expanding position in private life, are used increasingly in both public and commercial

spaces for the ostensible purpose of increasing security and preventing crime. Yet the images taken by these cameras also raise issues of the photograph's potential for restricting, documenting, and controlling individual behavior. As technology extends the capacity to send images over global networks, the specter is raised of expanding spheres of media influence and control that transcend the nation state. At the same time, the interactive aspects of many contemporary media raise the possibility of individual and group autonomy from transnational media content, and the ability of the individual to form and reform images that are sent and received. The cultural impact of these relatively new image technologies is a current topic of debate, particularly with regard to the moral and ethical implications of their distribution and use.

5. *Technology and Revisions of Photographic Meaning*

A central question throughout photography's history is whether the meaning of the photograph is a function of the medium *per se* and its technical, chemical, and optical relationship to the subject in front of the camera, or is formed instead through the culture which surrounds it. Benjamin described how photographic reproduction and mass distribution irrevocably altered the individual's encounter with the original, following a more general argument developed within the Frankfurt School over the hegemonic power of cultural production in mass society. Yet it was not until the 1970s that a number of theorists began to address the specific problem of photographic meaning, particularly issues related to what and how the photograph represents. Roland Barthes (1977) used a semiotic analysis to unlock the problem of 'the photographic paradox': that is, the photograph represents an analogic reproduction of reality or a message without a code, and simultaneously a connotation or coded message, representing what society thinks about the subject. The major task of the denotative aspect of the image, according to Barthes, is to naturalize the cultural, that is, to transform cultural values into a message that can be 'read' as self-evident, as nature.

The deconstruction of the camera as a cultural artifact and of photography as deeply informed by culture continued on several parallel fronts. The model of the observer that dominates Western science, defined by the Cartesian perspectivalism and the direct gaze, is encoded in the optical system of the camera. The model thus defines a particular relationship between seeing and knowledge that privileges the authority of this gaze and its representations. This 'way of seeing' was critiqued most forcefully in relation to documentary photography for its dehistoricized view of marginalized social groups, a view that in turn established a visual code for representing the Other

(Bolton 1989). Because photography has been constructed as a predominantly male practice, reinforced by the observer's gaze as male, female also becomes Other. Extensions of this critique to the uses of photography in the social sciences have implicated anthropology in particular for constructing its subjects as visually exotic. Related to this phenomenon, as mentioned above, is the institutional gaze, embodied and perpetuated through the archive, the museum, or the press (Tagg 1988).

In the 1970s, anthropologists also began to criticize the use of film and photography in fieldwork. Instead of being informed by anthropological concepts, the Western anthropologist's visual records reflected 'his' own culture, coded through the practices of family photography. Within the subfields of visual anthropology and sociology in the United States and Britain and their influential journals, this insight was variously developed into a broader perspective on photography, film, and media in general as sources for studying the cultural values and perspectives of those who create the images. This in turn supported a shift from image analysis to the study of the social and cultural practices in which photography is embedded. This complemented the critique being directed at the field of anthropology as a whole for perpetuating its colonial heritage through techniques of 'writing culture' that represented its subjects as Other (Ruby 1982). Anthropology's continuing interest in the photography of indigenous peoples and other subcultural groups reflects on the one hand a recognition of photography as a significant source for cultural analysis and on the other, attempts by the field to integrate the anthropological subject's own understandings into research and reports. Current ethnographic studies of media practices frequently include investigations of how images are interpreted and used by ordinary people. The photographic practices of professionals has been largely neglected, however, apart from the many biographies of well-known photographers and analyses of their work.

Digital techniques of making, reproducing, and transmitting photographs have contributed to undermining the authority of the photograph as analog or direct copy of reality. In the mid-1980s, the digitized image was seen by many, particularly within the press, as a direct challenge to established beliefs about how the photograph represents. Gradually the technique has been integrated into professional and private practices of making and distributing images, stimulating the rise of new media networks. The immediacy of image transfer and the portability of the technology have vastly increased the number of photographs in circulation, including those depicting war and human suffering. Some analysts argue that this phenomenon results in 'compassion fatigue,' reducing the moral impact of the image (Moeller 1999). In the meantime, new applications of interactive image technologies are emerging in the arts, in youth culture, and in diasporic

communities. The digital transfer of images globally has given rise in some quarters to a utopian vision with the photograph as a cornerstone of a global visual culture. More realistic analyses point to the diversities of culture worldwide and the continued vast inequalities in access to these technologies as critical impediments to a hegemonic visual culture.

Photojournalism

Photojournalism emerged in two distinct phases: during the late nineteenth century with the use of photographic images in newspapers and magazines as a new form of covering the news, and during the 1920s when photojournalism matured with the aid of technological advancements and was recognized as a form of documentary expression in most parts of the world. Unlike the spread of printing—or television later—photojournalism as a professional practice appeared almost simultaneously throughout Europe, the United States, and elsewhere. Thus, by the mid-1920s photographic expansion in Japan included the use of Leica cameras and access to the visions of *Neue Sachlichkeit* and Bauhaus practices in Germany, while similar developments in China were also directed by Western influences, although (between 1966 and the 1980s) the Cultural Revolution slowed the spread of photojournalism.

The beginnings of photojournalism occurred in the middle of the nineteenth century: photographers documented the US American-Mexican war in the 1840s; James Robertson and Felice Beato (England) photographed uprisings in India and China in the 1850s and 1860s; while Roger Fenton (England) covered the Crimean war in 1855 and Francis Frith (England) visited the Nile in 1856. Mathew Brady (USA)—with the aid of Alexander Gardner and George N. Barnard, among others—produced Civil War images in the United States between 1862 and 1864, and Jimmy Hare (USA) began working as a staff photographer for the *Illustrated American* in 1889. He later traveled to Cuba and also photographed the Russo-Japanese War, the Mexican Revolution, the Balkan War, and World War I before his retirement in 1922. Frequently, travel photographers and those accompanying expeditions, also worked as photojournalists.

The rise of photojournalism parallels the technological, social, and economic developments of the times. Technological innovations included the perfection of printing techniques to reproduce photographic images (halftones): beginning with the *New York Daily Graphic* (USA), 1873, or *Le Journal Illustré* (France), 1886, although the US press did not use halftones regularly until 1897. Also important was the development of flexible, transparent film (George Eastman, 1889), and the invention of smaller cameras (Ermanox, Leica/Germany, 1925), faster films (35mm, Kodak/USA, 1923, reversible emulsion (AGFA/Germany, 1923), and the introduction of

electronic flash equipment (Vacu-Blitz/Germany, 1929; Sashalite/England, Photoflash Lamp/USA, 1930).

The growth of photojournalism was advanced by the expansion of the reading public—with the addition of the working class—accompanied by an increased availability of inexpensive newspapers and picture magazines. Also, the public desire to ‘see’ the world—fuelled by the popularity of the movies (and newsreels, in particular) especially during the 1920s—created new demands on print media to legitimize photojournalism as a professional practice. In addition, the role of photography in education and propaganda, particularly in the Soviet Union, and its use in authoritarian societies, like Hitler Germany, energized photojournalism and strengthened its commitment to the ideals of social or political revolutions while providing increased picture coverage of the respective societies. The rise of worker-photographers in the Soviet Union and Germany during the 1920s also extended the notion of photojournalism to include the contributions of the working class to a photographic surveillance of the social environment. However, in post-1949 China, the use of photographs by the press remained restricted until much later (e.g., the first national photojournalism contest was held in 1981).

Photojournalists of the modern era found increasing numbers of professional outlets with the rise of mass circulation picture magazines, among them: *Arbeiter-Illustrierte-Zeitung*, *Berliner Illustrierte Zeitung*, *Vu*, *Paris Match* (France), *La Vanguardia* (Spain), *Picture Post* (England), *Look*, *LIFE* (USA), *Ogonyok* and *USSR in Construction* (USSR), or *China Pictorial* (China). Although photo agencies had existed since the end of the nineteenth century (e.g., Bain News Service, 1895, Underwood & Underwood, 1901, International News Photos, 1909 all in the USA) and photographers had been employed in considerable numbers by the press since the beginning of the twentieth century, increasing demands for photographic coverage by a rising number of media clients since the 1920s resulted in the establishment of new picture agencies. Photographs became commodities, and photographic agencies with their own staffs and national or international visibility produced and disseminated single images and photo stories. Among these photo agencies were: Mauritius, Weltrundschau and Dephot (Germany), Keystone, Rapho (France), Soyuzfoto, Novosti Picture Agency (Soviet Union), Acme Newspictures, Black Star, Wide-World Photos (USA), Scala (Italy), Nippon-Kobo (Japan) or—after World War II—agencies like Magnum, Viva, Gama, and Sygma (France), Contact Press Images (USA), and—since 1949 in China—the Bureau of Photojournalism, a government agency, reorganized as the Department of Photojournalism in the New China News Agency in 1952.

Together with traditional news agencies like the Associated Press, USA, or Reuters, England, these

agencies became wholesale suppliers of visual material for the world press, working as commercial sources or cooperatives while setting the professional standards of modern-day picture coverage. They were aided by the development of wire transmission (invented in 1905 by Alfred Korn in Munich, Germany) in the early 1920s (London-New York over the Bartlane Cable system). The Associated Press New Photo Service began in 1927 and delivered photographs by train and plane; its Wirephoto network (1935) and the United Press Telephoto service (1936) helped increase the traffic in photographs, but made local editorial staffs less dependent on local photo coverage. At the end of World War II, the (New York) Times Photo service offered a worldwide news photographs service. The first satellite transmission of photographs in the United States occurred in 1960, followed by the launching in 1962 of the Telstar satellite for live transmission of pictures between Europe and the United States. Laserphoto was introduced by the Associated Press (USA) in 1977 and replaced by Photostream in 1991, an innovative transmission system that uses digital technology. The Associated Press (USA) had patented a portable digital image scanner in 1983 for the transmission of photographs from remote locations. Digital cameras appeared in 1988, and digital darkrooms in 1989 (*San Francisco Examiner*). The Associated Press (USA) began distributing news photographs via the World Wide Web in 1995.

Photo agencies also became depositories of visual representations of public life during most of the twentieth century (the Hulton Deutsch Collection (England) is one of the largest picture libraries in the world with over 15 million images; the Associated Press (USA) maintains an active picture archive with over 500,000 images, accessible over the Internet). The combined organizational network of photo agencies worldwide and their archival holdings constitutes a formidable, if not dominating cultural and commercial force in the process of visual representation. To a significant extent, journalism everywhere relies on the images that photo agencies supply.

By the end of the 1920s photojournalism was firmly established worldwide in the metropolitan press with the hiring of picture editors and the use of staff photographers in the editorial process. Smaller newspapers were considerably slower in creating staff positions for photographers. Over the years, the work of photojournalists has been preserved in the public and private archives of the press around the world. Among the most prolific photojournalists of modern times are Erich Salomon, Alfred Eisenstaedt, and Wolfgang Weber (Germany), Max Alpert, Arkady Shaikhet (Soviet Union), Eugene Smith, Margaret Bourke-White, Weegee, David Douglas Duncan, Mary Ellen Mark, Susan Meiselas (USA), Werner Bischof, René Burri (Switzerland), Robert Capa (Hungary), Ihei Kimura (Japan), Wu Yinbo, Zhang

Suicheng (China), Shomei Tomatsu (Japan), Peter Magubane (South Africa), Henri Cartier-Bresson, Martine Franck, Gilles Peress (France), Sebastião Salgado (Brazil), Bert Hardy, Don McCullin (England).

Photojournalism succeeded in making the world a knowable, visual experience and in creating a sense of familiarity with people and places. The presence of photojournalism in the public sphere has a profound effect on the public staging of politics. Photojournalism, by its very nature, generates attention, and because of its impact, raises issues of privacy, sensationalism, and manipulation in a marketplace that thrives on the exploitation of the image. Unlike others, photojournalists—to be effective—must seek the proximity of unfolding events, including the hazards of social unrest, revolution, or war. Consequently, they often risk their lives and sometimes pay the ultimate price in their pursuit of the perfect picture (by 1971, for instance, 25 of 35 non-Vietnamese journalists killed during the Vietnam war were photographers or cameramen).

The practice of photojournalism, beginning in the 1920s, led to an exploration of the documentary style and produced single and multiple images to convey the news. Photographs became a regular staple of newspapers and affected their make-up and design. When photographers thought editorially, the result was a new vocabulary of journalism. But, as Evans (1978/1997, p. 255) suggests, 'photography is not photojournalism'; instead, words are needed to supply more information than are conveyed by a photograph. Words help explain, confirm, and reinforce, they also place events in time and space. According to Hicks (1952, p. 5), 'the basic unit of photojournalism is one picture with words.' Photojournalism acknowledges the importance of words, either provided in the form of outlines or stories authored by the photographer or journalist-colleagues.

The picture story (or photo essay) constitutes the long form of photojournalism; its visual narrative typically focuses on a single subject and is the outcome of careful planning and extended professional commitment to a project. Ideally, the resulting presentation—not unlike an essay—consists of a flow of images, characterized by a strong opening, a descriptive middle passage, and a decisive ending. Pioneered first in the Soviet Union and Germany during the 1920s, the photo essay became a determining characteristic of *LIFE* magazine in the United States; it challenged the imagination of photographers and editors to produce a durable visual narrative that could rely on the popularity of story telling to satisfy reader interests. There is also an affinity between photojournalism and photographic fiction; for instance, photo-novelas as social reportage constitute a form of visual narrative, which has been explored since the 1970s (as literary photography or photographic writing) by contemporary photographers.

With the advent of television in the 1950s and the demise of the mass circulation picture magazine (particularly in the United States) during the 1960s, photojournalism survives in news magazines and the daily press, in particular, where it continues to help strengthen the visual culture of the late twentieth century (aided by the ease of offset printing which improved the reproduction quality of images). The introduction (since the 1930s) of color positive and negative films (with distinctive processes developed by Agfa, Cibachrome, Kodak, and Polaroid) and their increasing use by the press (since the 1960s), added a new dimension to photojournalism; it enhanced the documentary quality of images and contributed to their visual impact (*LIFE* magazine published the first color photographs in 1952). Although black-and-white photographs maintain their abstract, documentary quality (and are used for this purpose in modern advertising), the work of contemporary photojournalism relies almost exclusively on the production and circulation of color photographs.

A distinctively different form of photojournalism emerged with the demise of picture magazines in the United States and the rising popularity of the book as an alternative medium for the dissemination of visual expressions. The book celebrates authorial prerogative and individuality of form and style; it also offers opportunities for exercising creative freedom and extended personal constructions of particular aestheticized visions of the world that favor a humanistic approach to photography and avoid claims of objectivity. The resulting emergence of a new kind of photojournalism at the end of the twentieth century borrows freely from the tradition of street photography and photographers ranging from Robert Frank, William Klein, and Garry Winogrand (USA), to Henri Cartier-Bresson and Robert Doisneau (France), or Josef Koudelka (Czech Republic). The sustained, book-length visual argument can be powerful, but when photojournalism catered more exclusively to a privileged class of bourgeois readers, experts, and connoisseurs of fine photography, it crossed into the realm of art: single news photographs appeared on museum walls and became commodified objects in the commercialized sphere of art collection (especially since the mid-1970s when photographs began to be featured regularly in art galleries).

In an image conscious world photojournalism survives and its tradition is preserved and celebrated by institutions such as the International Center of Photography (USA), or the World Press Photo Foundation, organizations such as the National News Photographers Association (USA) and educational programs, such as the University of Missouri School of Journalism (USA), all of which stand for similar organizations and activities in a number of countries.

Phylogeny and Systematics

Systematics is the study of the relationships among organisms, whereas phylogenetics is the study of the evolutionary relationships among organisms. In that sense, phylogenetics is a subset of systematics. Historically, before evolution was accepted as the unifying principle in biology, phylogenetics did not exist *per se*. Instead, organisms were classified on the basis of their phenotypic similarity.

1. Defining the Questions

One of the main problems with using phenotypic similarity as a basis for classification is that organisms evolve to become adapted to the environments in which they live (their niches) so that phenotypic convergence is a fairly common occurrence. For the most part, the longer ago in time that two organisms shared their most recent common ancestor, the more phenotypically dissimilar they will have become. However, phenotypic convergence as a consequence of adaptive evolution, along with rapid divergence as organisms adapt to totally novel environments, means that any classification based on phenotypes inevitably confounds phylogenetic relationships and adaptive

evolution. Given the evolutionary lability of behavioral characteristics, analysis of the adaptive or functional significance of particular traits requires that the phylogenetic relationship is properly defined so that evolutionary changes in behavior can be mapped on to those in niche use.

The advent of cladism as a technique aimed at identifying phylogenetic groupings through phenotypic analysis was a notable first attempt to isolate phylogenetic groupings. Cladism, as initiated by Hennig (1966), is, however, based on a model of evolutionary change which excludes the possibility of phenotypic convergence because it assumes that the same character cannot evolve on more than one occasion and that once a character has evolved it cannot revert to its former state. More recently, the field of phylogenetic analysis has been revolutionized by the rapid production of gene sequence data. Realistic models of molecular evolution are incorporated into phylogenetic analyses of various regions of the genome to produce phylogenies (evolutionary trees) of ever-increasing accuracy. How those trees will be used to produce classifications is not clear.

At the moment, recognized groupings (genus, tribe, family, and so on) are being revised so that they describe monophyletic groups (containing all the contemporary descendants of a particular common ancestor). However, the nominal groupings involved differ according to historical precedence: systematists who originally produced the hierarchical classifications in use today ranged along an axis from lumpers to splitters. The former were less keen to classify species with a particular degree of morphological similarity into different higher level taxa than were the latter. As a consequence, even when species within the hierarchical groupings are rearranged to represent monophyletic groupings, the most recent common ancestor for all the species in a particular genus would have been earlier in some orders than the most recent common ancestor for two species separated at the family level in other orders.

The development of this article introduces natural groupings, explains how phylogenies are determined, and then shows how phylogenies can be used to understand the functional significance of behavioral differences among taxa.

2. Natural Groupings

It has always been clear to modern humans that there are natural groups of organisms: trees, birds, flowering plants, spiders, and tortoises would be cases in point. It has also been clear, at least in more recent times, that there is a natural hierarchy of groups: there are animals versus plants, but within animals there are vertebrates and invertebrates, and within vertebrates there are birds, reptiles, mammals, and amphibians. The embodiment of the hierarchical natural classification was produced by Linnaeus around 1800. No particular

mechanism was envisaged for why this natural hierarchical classification should exist, but one frequently stated reason for studying it was to provide insight into the mind of the creator. With the benefit of hindsight, insofar as classifications were based on functional similarity, what were recognized to be the same character could in fact have separate evolutionary origins.

The major sea change occurred in 1859 with the publication of Charles Darwin's *Origin of Species* in which he argued that life was created on one or few occasions and that subsequent speciation resulted in the natural hierarchy. Indeed, it is worth remembering that the only figure in the book is of an evolutionary tree. From that time on, with a few notable lapses, it has been accepted generally by working scientists that natural groupings are a consequence of evolution and that they should be monophyletic. In practice, however, it did not always turn out that way. For example, it is accepted that birds share a more recent common ancestor with crocodiles than either does with lizards. As a consequence, crocodiles should be classified with birds rather than with lizards. This means that the reptiles do not constitute a monophyletic group, but what is known as a paraphyletic group: a group made up of only those descendants of a common ancestor that resemble it (or each other) phenotypically.

Despite the acknowledged fact that the reptiles constitute a paraphyletic group which, if it were to be made monophyletic, should include the birds, there has been little serious effort on the part of biologists to execute this particular taxonomic revision. To do so, would in some sense apparently cost more effort than it is worth. Instead, reptiles without the birds are accepted as a paraphyletic natural group, while palaeontological and other evolutionary analyses should include birds within the group.

3. Identifying Phylogenetic Relationships

There have been many schools of systematics, and most are of merely historical rather than contemporary importance. The major division is into methods that analyze phenetic relationships vs. those that attempt to reconstruct phylogenetic relationships.

The development of phenetic methods became particularly popular in the 1960s and 1970s following the publication of Sokal and Sneath's (1963) book entitled *Principles of Numerical Taxonomy*. The book outlined apparently objective methods of character scoring and the production of phenograms (trees that summarized degrees of phenetic similarity), using the then newly and widely available computers. The fatal flaw to the whole enterprise was the absence of a model of phenetic evolution. There is an infinity of so-called clustering algorithms and distance methods, each of which is appropriate for a particular model of phenetic evolution. Unfortunately, there was no objective way

to decide which to use. It might be argued that the aim of numerical taxonomy or phenetics is not to determine evolutionary relationships but rather to describe phenetic similarity, but even then there is an infinite number of distance methods and clustering algorithms, with no principled method of deciding on appropriate ones for all circumstances. The exercise foundered.

The use of phylogenetic methods was given a major boost by Hennig's (1966) book *Phylogenetic Systematics*. Hennig realised that if the phylogeneticist was willing to make certain assumptions about character evolution, then phylogenetic trees could be constructed from data based on the distribution of character states among extant taxa. If every character evolved only once and evolutionary change was irreversible, then monophyletic groups could be defined on the basis of shared derived characters. Problems arose when different characters produced different answers so that one character placed a particular species in one group while another character placed it in a different group, which meant that at least one character did not evolve according to Hennigian principles. Common sense often prevailed among cladists to distinguish between, for example, characters that might have evolved once and been lost versus those that evolved more than once. However, once cladists began to entertain the possibility that there are different models of evolution for different characters, then the advent of a model-based statistical approach to phylogenetic reconstruction became inevitable. The problem recurs, just as it did with numerical taxonomy, that for phenetic evolution there is frequently no principled way to distinguish among alternative models of evolution.

In the years immediately before genes were sequenced at such low cost and with such speed, an informative stepping stone between phenetic and phylogenetic analysis occurred with the advent of DNA-DNA hybridization technology. The method was developed and widely applied by C.G. Sibley and co-workers. Radioactively labeled DNA strands about 500 nucleotides long from a focal species were hybridized with similar strands from a number of phylogenetic relatives. The rate of dissociation of these duplexes provided a measure of genetic similarity between the sequences, thereby excluding purely morphological convergence as a factor producing errors in phylogenetic tree reconstruction. Several surprises emerged. For example, among the birds, Australian passerines seemed to be more closely related to each other than they are to passerines from other continents, thus suggesting that previous classifications based on morphological comparisons had failed to detect considerable convergent morphological evolution. Sibley and Ahlquist obtained representative samples of many thousands of bird species, representing the large majority of tribes. They then subjected the data to DNA-DNA hybridization analysis

to produce an estimated phylogeny of the birds based simply on the rate of dissociation of DNA–DNA hybrid duplexes. That phylogeny was used by Sibley and Monroe (1990) to produce a classification of birds: categories of rates of duplex dissociation were arbitrarily defined that were associated with each particular taxonomic status. Despite the various analytical difficulties of their method, and the arbitrary nature of their classification, their procedure was claimed to be both objective and repeatable. As a first attempt at a full phylogenetic classification for a major taxon, it has probably yet to be improved upon. However, while most of the major revised phylogenetic relationships that Sibley and co-workers revealed have remained intact, more appropriate methods for phylogenetic reconstruction from gene sequence data are now available.

DNA–DNA hybridization methods provide just one measure of the distance separating a pair of sampled individuals. That distance depends on the genetic similarity between those individuals in terms of base sequences. However, the same distance measure can be achieved in many different ways: if there are 20 base differences between individuals 1 and 2, and there are 20 base differences between individuals 2 and 3, that does not tell us how many differences there are between 1 and 3—just that there are between 0 and 40. All pairwise DNA–DNA hybridizations would need to be completed, even if we were accepting that DNA diverged at a metronomic rate through evolutionary time.

The production of vast amounts of gene sequence data means that every base pair becomes a character. Once we have a base sequence from a particular gene of a particular individual, it can be compared with that for every other individual for which we have equivalent data. This allows phylogenetic reconstruction using discrete rather than distance measures. What is more, we can describe models of molecular evolution with reasonable accuracy: we may know the relative substitution rates of the first, second and third base pairs, and we often have a good idea of transition to transversion ratios (the frequency with which a substitution is between purine and purine or between pyrimidines, vs. between purine and pyrimidine). We also know that some base substitutions are effectively neutral because they result in the same amino acid being coded for at the base-substituted triplet.

Before mentioning the most commonly used methods for discrete data, it should be pointed out that distance measures can be used and are used with gene sequence data. The methods differ in whether they assume branch lengths from the root to the tips of the tree are all equal and adjust the data accordingly (e.g., unweighted group pair method with arithmetic means: UPGMA) or whether they allow different rates of evolution in different parts of the tree (e.g., the neighbor joining method which often gives a good approximation to the minimum evolution tree). De-

Figure 1

A phylogenetic tree that is likely to produce data that will cause parsimony or compatibility methods to give misleading results. The correct tree is shown, with p and q being probabilities of character state change along the different branches of the tree. The wrong tree is likely to be determined when p is much larger than q because then B and C are likely to be more similar than are C and D (after Felsenstein 1978, 1983)

spite the fact that information is lost (the evolution of individual base sites cannot be traced down the tree), there is also the problem that approximations are made which often result in biologically impossible branch lengths being reconstructed (see Page and Holmes 1998).

The two most common model-based discrete methods of model based phylogenetic tree reconstruction from gene sequence data involve parsimony and maximum likelihood.

Parsimony was introduced as the so-called minimum evolution distance method by Cavalli-Sforza and Edwards (1967) as a computationally rapid route for approximating maximum likelihood trees. However, as a discrete method for finding the shortest tree, it is possible to adapt strict parsimony and weight the changes in appropriate ways (e.g., a transition might be four times as frequent as a transversion) and determine that tree with the smallest total of weighted steps. There are several problems with parsimony as a procedure. The first is philosophical—parsimony is a minimum criterion by definition and it may be argued that there is no minimum principle to evolution. The second major problem is that of 'long branch attraction' (see Fig. 1). Despite these disadvantages, parsimony remains a commonly-used procedure because of its computational speed.

Maximum likelihood is a very powerful tool in phylogeny reconstruction. The method asks which phylogenetic tree is the most likely one to have given rise to the set of gene sequences that we observe in our sample from the present day, given our specified model of gene sequence evolution. Indeed, it can go further and be used to estimate the most likely parameter estimates of our evolutionary model. The likelihood

approach is increasingly commonly used for the reconstruction of molecular phylogenies, and as computers get ever faster and more powerful, it will probably become the approach of first choice.

4. Using Phylogenetic Relationships to Analyze Behavior

When behavior is mapped on to phylogenetic tree structure, at least four types of informative analysis become possible. First, behavior itself may be seen to be responsible for phylogenetic tree structure. For example, species with particular modes of behavior may be more likely to divide into new species than others. Second, by mapping behavioral characteristics on to phylogenies, it is possible to determine which traits are ancestral and which are derived, and to determine which traits have changed most frequently over evolutionary time. Third, behavioral characteristics do not evolve independently of each other or of habitat use. If we are to understand why character covariation occurs, then phylogenetic tree structure must usually be an integral part of the necessary analysis. Fourth, adaptive radiations, such as Darwin's Galapagos finches, are well known but when we map behavior on to tree structure, it sometimes becomes apparent that independent adaptive radiations have remarkably similar structures—when the tape of life is replayed, similar arrays of diversity result. In this section, examples of each of these four types of phylogenetically-based behavioral analysis are described.

4.1 Behavior and Speciation

When behavioral traits are mapped on to phylogenies, it is sometimes possible to identify so-called 'key innovations' which appear to have resulted in high rates of speciation. For example, cichlid fishes are very speciose and their radiations seem to have coincided with a change in position of a particular muscle attachment which allowed the pharyngeal bones to manipulate individual prey items while still holding them. This released other areas of the jaw, which had been used for manipulating prey, to evolve for other functions. The cichlid radiations in African lakes are indeed characterized by a remarkable variety of feeding mechanisms. However, a problem with this explanation is that there may be other unrecognized characteristics unique to cichlid fishes that may also contribute to their explosive radiations.

A more convincing demonstration of key innovations resulting in increased rates of speciation is when the same innovation appears independently in different parts of the phylogenetic tree, and is statistically associated across a number of cases with an increased rate of speciation. One of the best examples of a repeatedly evolved such innovation is the ability

of insects to feed on vascular plants, known as phytophagy. There is a wide variety of vascular plants, and whenever phytophagy evolved, there are likely to have been many vacant niches to speciate into. Mitter et al. (1988) identified 13 nodes in a phylogenetic tree of insects where all the descendant species from one branch are phytophagous, whereas all those down the other branch are not. In 11 of 13 cases there were more extant species descended from the phytophagous branch than the nonphytophagous branch, and in each of those 11 cases there were more than twice as many phytophagous than nonphytophagous species.

A final example of behavioral changes apparently causing differences in rates of speciation comes from an original suggestion made by Darwin (1871). It is known that the females of some bird species actively choose their mate on the basis of phenotype. Darwin suggested that, when populations separate, the precise criteria for mate choice might alter so that if those separated populations came back together, mate choice would have promoted speciation. The most obvious criterion for determining whether females choose their mates by phenotype is whether males differ from females in physical appearance. When passerine birds are scored as sexually dichromatic or not, then it turns out that the repeated evolution of sexual dichromatism tends to be associated with subsequently higher rates of speciation (Barracough et al. 1995). It had taken more than 100 years before the phylogeny became available so that Darwin's theory could be tested.

4.2 Character Evolution

Mapping character evolution on to phylogenetic trees can be used to test ideas about how and why characters evolve. In order to carry out this process, it is necessary to have a phylogenetic tree showing the relationships among contemporary species, character states for each species, and a model for character evolution. Since the appropriate model for the evolution of most characters is poorly understood, ancestral character states usually are inferred from either a parsimony or other appropriate minimum evolution criterion.

Gittleman (1981) set out to test the idea that when patterns of parental care evolved among fishes, transitions were gradual and did not involve change by more than one parent. Twenty-one transitions were identified using parsimony on the phylogenetic tree, all of which were between biparental and maternal care, biparental and paternal care, no care and paternal care, and no care and maternal care. No cases involved the double transitions between no care and biparental care or paternal care and maternal care, a statistically significant deficiency if all transitions were equally likely.

A more thorough and quantitative analysis of historical patterns in parental care, this time among shorebirds, was reported by Székely and Reynolds

Figure 2

Comparative method of independent contrasts. Comparisons d1, d2, and d3 are independent of each other under a Brownian motion model of evolution for characters X and Y. If the two characters have shown uncorrelated evolution, values of the contrasts for one character will not be correlated with those for the other character

(1995). Again they used parsimony for ancestral character state reconstruction, but in this taxon they found that there had been an overall evolutionary reduction in paternal care, which was sometimes but not always compensated for by an increase in maternal care. The authors argued that this is a response to selection for males to partake in extra-pair matings or even to maintain multiple pair bonds.

How rapidly does behavior evolve in comparison with, say morphology and life history? Haldane (1949) suggested that one appropriate measure of evolution change was the 'darwin': a change of one logarithmic unit per million years. Gittleman et al. (1996) mapped the evolutionary change of two behaviors (group size, home range size), two life history characters (gestation length, birth weight), and two morphological characters (adult brain weight, adult body weight) using data for extant mammal species from eight taxa for which

there were reasonable phylogenies. The behaviors were more labile than the morphological characters, which were more labile than the life history characters. Such analyses may well identify characters which, for whatever reason, are the most evolutionarily constrained, leaving others more free to change.

4.3 Correlated Character Evolution

Bringing order to organic diversity is made simpler by two organizing principles: close relatives are more similar to each other than are distant relatives, and organisms share adaptations to common environments. As we have seen when attempting to reconstruct phylogenetic trees, it can be important to distinguish between these two reasons for similarity. However, the two principles cannot necessarily be

separated: because close relatives are often adapted to very similar ecological niches, they also share many adaptations in common, whether those adaptations were inherited from a common ancestor or not. If we wish to understand the extent to which similar adaptations are likely to arise in similar circumstances, it is nevertheless important to factor out identity by common descent. What is more, because close relatives share characters which may not be functionally related to each other (e.g., mammals have hair and give birth to live young, whereas birds have feathers and lay eggs), treating species values as independent points in a statistical analysis can result in functionally meaningless significant associations between characters as a consequence of pseudo-replication.

4.3.1 Independent contrast analysis. In order to tackle this problem, Felsenstein (1985) devised a method which traced the change in two or more characters on a phylogenetic tree, and defined for each character equivalent evolutionary independent contrasts which could be used for data analysis. Given character states for contemporary species, ancestral character states had to be inferred from a specified model of evolutionary change. Felsenstein used a Brownian motion model of change to estimate ancestral character states. In essence, all change that occurred between sister taxa evolved independently of change between other sister taxa. The consequence is that differences between the actual or estimated character states for sister taxa are used as the independent contrasts, which are standardized by branch lengths (variances of contrasts are larger when the time separating taxa has been longer). The direction of comparison is arbitrary, though it is conventional to order the taxa so that all contrasts for the independent variable are positive (or zero). The contrasts for the dependent variable(s) then use the same order of taxa and can take both positive and negative values. The contrasts for the dependent variable(s) are then regressed on those for the independent variables, and conventional statistical techniques (correlation or regression) are used to test for correlated evolutionary change. The null hypothesis is that change is uncorrelated, and significant departures from the null hypothesis can indicate either positive or negatively correlated character change. A hypothetical example is worked through in Fig. 2.

Although independent contrast analysis is widely used, statistical conclusions can, in fact, change when different models of character change are entertained. For example, Harvey and Purvis (1991) report a study of the evolutionary relationship between a measure of running activity and relative foreleg length (foreleg length corrected for body size) in a group of *Anolis* lizards. Three models of evolutionary change were considered (Brownian motion, punctuation, and minimum evolution), only the first of which produced a

significant relationship between contrasts for the two variables being studied ($p < 0.025$ compared with $p > 0.10$ for the other two models). Fortunately, diagnostics are available to test whether the assumptions of Brownian motion character evolution have been approximately met, given data for a set of contemporary species and a well-resolved phylogeny (Garland et al. 1992). However, when the hypothesis of Brownian motion character evolution is rejected, there remains a paucity of statistically powerful comparative methods.

4.3.2 Sister taxon comparisons. When a phylogeny is available, but there is no obvious model of character evolution, then the technique of sister taxon comparison can prove very useful. The idea is to compare pairs of contemporary species, chosen such that each 'sister pair' shares a more recent common ancestor than either member does with any member of any other pair. The result is that the difference between each pair of sister species has evolved independently of the difference between any other pair, and ancestral character states do not need to be estimated. The loss of assumptions results in fewer possible comparisons: if there are n contemporary species in a sample, so long as the phylogeny is bifurcating, then there are $n - 1$ possible independent comparisons, but at most only $n/2$ sister comparisons.

Møller and Birkhead (1992) have championed the use of sister taxon comparisons, and illustrated their use by testing the idea that high copulation rates among birds are a 'paternity insurance' mechanism. First, they asked whether rates of extra-pair copulation increased with local population density, which they did in all eight possible comparisons, which is a highly significant result (n.b. 15 potential comparisons are possible with 16 taxa when ancestral states are considered). Second, they asked whether birds living in colonies had higher rates of intra-pair copulations, which they did in 12 of 13 comparisons.

4.4 Parallel Structure of Independent Radiations

When a species invades a completely new habitat with unoccupied niches, there is the potential for an adaptive radiation to ensue. But how deterministic is evolution? Stephen Jay Gould suggested that contingency was such an important factor that, if we replayed the tape of life, we should invariably get different outcomes. That is, of course, true *sensu stricto*. However, early comparisons such as that between the placental and marsupial mammal radiations, and the very fact of evolutionary convergence, means that it is not the whole story. Recently, a number of case studies suggest a remarkable degree of similarity when the opportunity for similar radiations has been presented.

Anolis lizards in the Caribbean have invaded many small and a few large islands. On the very smallest islands, there tends to be one intermediate-sized species, but as island size increases large and small forms can coexist. Each of the largest islands supports an independently evolved *Anolis* radiation, with about seven different species occupying a variety of well-defined ecological niches. To the casual human observer there has been remarkable convergence, for example, the species living on twigs from different islands are well-nigh indistinguishable. Natural selection has led to the evolution of the same so-called ecomorphs evolving on different islands. The twig ecomorphs have a morphology that is adapted to the niche in which they live. Other ecomorphs live in the crowns of trees, on the trunks, on the ground, and so on.

While it may be easy to fool a casual human observer, would the same independently evolved ecomorphs be able to fool each other? That experiment has not been performed on *Anolis* lizards, but it has in a simpler system involving stickleback ecomorphs. At the end of the Pleistocene, after the glaciers had retreated from British Columbia, a marine stickleback invaded a number of freshwater lakes. In those lakes, parallel speciation occurred: a large benthic ecomorph evolved which feeds on invertebrates from the bottom of the lake, together with a smaller limnetic ecomorph which darts around in the open water living off plankton. There is strong assortative mating such that the benthic and limnetic ecomorphs will only mate with their own type in the wild, and have become true species. But would opposite sex individuals of the same independently evolved ecomorph from different lakes accept each other as mates? The answer is yes, in the laboratory. Rundle et al. (2000) took limnetic and benthic species from three separate lakes. Over 750 mating trials were set up in which individual females were presented with single males of the same or the alternative ecomorph, from the same or a different lake. Females were far more likely to spawn with a male of the same ecomorph as themselves, in which case it mattered not at all whether the male was from the same or a different lake.

Physical Activity and Health

The past three decades have witnessed a burgeoning of research examining the impact of physical activity on physical and mental health. This research has conceptualized physical activity as both a physiological and a psychological phenomenon. From the physiological perspective, physical activity is usually defined

as any force exerted by skeletal muscles that results in energy expenditure above the resting level. From a psychological perspective, physical activity is viewed as a behavior performed in specific social settings and controlled by motivational and volitional factors. Both perspectives complement one another, and they apply to different research questions. This article summarizes findings that refer to physiological as well as psychological aspects of the relationship between physical activity and health.

1. The Effects of Physical Activity on Physical Health

1.1 Overall Mortality

Epidemiological studies suggest that persons with moderate to high levels of regular physical activity or cardiorespiratory fitness have lower mortality rates than persons who are inactive or have low fitness levels (e.g., Sherman et al. 1999). This is supported by longitudinal research examining how changes in the level of cardiorespiratory fitness may affect subsequent mortality risks. For example, in a study by Blair et al. (1995), healthy men with an initially low level of cardiorespiratory fitness participated in two exercise tests about five years apart. Five years after the second exercise test, men in the bottom fifth of the initial fitness distribution who improved their fitness to at least a moderate level had a 44 percent lower mortality rate than men who remained in the bottom fifth. Similar results had already been found by Paffenbarger et al. (1993) in a cohort of initially sedentary Harvard alumni. Those men who started and maintained moderately intense activities extended their longevity on average by 0.72 years.

1.2 Cardiovascular Diseases (CVD)

Cardiovascular diseases, in particular coronary heart disease and stroke, are major causes of death, disability, and health care expenditures in Western societies. There is clear evidence that, within populations, the incidence of CVD is inversely related to habitual physical activity levels (Bauman and Owen 1999). Some of the studies in this field demonstrated a dose-response gradient between level of physical activity and risk of CVD outcome. Dose-response relationships were also found in those investigations in which measures of cardiovascular fitness, instead of physical activity estimates, were related to CVD mortality.

1.2.1 Coronary heart disease (CHD). Since 1953, about 40 studies analyzing the association between physical activity and risk of (CHD) have been pub-

lished. The first study in this field was conducted by Morris et al. (1953), who examined 31,000 employees of the London Transport Executive. A comparison between bus drivers and bus conductors revealed that physically active conductors clearly had a lower risk of a 'first coronary episode' than sedentary drivers. Classifying physically active and inactive people according to job title or occupational activity is typical for studies published before 1978. In the following years, level of physical activity was defined mostly by self-report measures of leisure-time activity or by indices that combined levels of occupational and leisure-time activities. More recent investigations have also emphasized the necessity to control for potentially confounding variables (e.g., age, sex, functional status) and to adjust for factors that are considered causal links between physical activity and CHD, such as serum cholesterol, blood pressure, diabetes, or body mass index.

Reviews of relevant literature have concluded consistently that physical activity is strongly related to a reduced risk of CHD. Furthermore, there is evidence in recent studies that this relationship holds true for both men and women. For example, findings from a prospective study among 72,488 female nurses who were 40–65 years old at the onset of the study suggest that sedentary women who became active in middle adulthood or later had a lower risk of coronary diseases than their counterparts who remained sedentary. Relative to women who walked infrequently, those who walked at a brisk pace three or more hours per week had a multivariate relative risk of 0.65 for coronary events (Manson et al. 1999). Physical exertion may temporarily increase the likelihood of an acute coronary event among persons with advanced coronary atherosclerosis who are not used to regular exercise. Although this risk needs to be taken seriously, it does not affect the general fact that physical activity is associated with a substantially lower overall risk for CHD.

1.2.2 Stroke. Contrary to the results for CHD, epidemiological data do not unequivocally confirm a relationship between stroke and level of physical activity. Most investigations in this field were planned as population-based cohort studies with follow-up ranges of 5–26 years. Among those studies that were designed to detect possible dose-response effects, many did not find a clear linear association. Some studies even suggested a U-shaped relationship between physical activity level and risk of stroke. By trying to explain these contradictory findings, it was assumed that the two different types of stroke, namely ischemic stroke and hemorrhagic stroke, need to be regarded separately. Since both types have specific pathophysiologicals, it may be possible that physical activity affects them in different ways. In a study by Abbott et al. (1994), inactive men had a

higher risk of hemorrhagic stroke than active men, but there was no main effect on ischemic stroke. More research is needed to further clarify whether physical activity plays a protective role against stroke.

1.2.3 Biological mechanisms. Several biological mechanisms may be responsible for the beneficial effects of physical activity on cardiovascular risks. These mechanisms involve the impact on blood pressure, atherosclerosis, plasma lipid/lipoprotein profile, availability of oxygenated blood for heart muscle needs (ischemia), thrombosis, heart rhythm disturbances, overweight, and healthier distribution of body fat.

1.3 Cancer

Cancer is one of the leading causes of death in industrialized countries. It is predicted that this proportion will increase in the next few years. Numerous studies have examined the role of physical activity in the prevention of cancer.

1.3.1 Colon cancer. Systematic literature analyses reveal that colon cancer is probably the most often-studied cancer in the field of physical exercise epidemiology. In 1996, a total of 29 studies on colon cancer were published (DHHS 1996). Of these, 18 studies considered only occupational physical activity, and 11 examined leisure-time or total physical activity. The results of the 18 studies using a measure of occupational physical activity draw a rather consistent picture: 14 studies found a significant inverse relationship between level of activity and risk of colon cancer; in four studies no such associations were observed. The 11 studies that referred to measures of leisure-time or total physical activity provided a similar pattern: eight reported an inverse association between level of physical activity and risk of colon cancer, while in three studies this was not the case.

In these studies, the level of physical activity during early adulthood was used as an effector variable. It is possible that this life period is too early to find an effect on colon cancer incidence in late adulthood. In most studies that controlled for potentially confounding dietary factors, the relationship between physical activity and risk of colon cancer remained significant. Taken together, the findings strongly suggest a significant association between level of physical activity and the occurrence of colon cancer.

1.3.2 Breast cancer. The report of the Surgeon General of 1996 reviews the results of 13 studies that examined the effects of habitual physical activity on risk of breast cancer (DHHS 1996). Of the 13 studies, four referred only to occupational physical activity;

the remaining nine studies used a leisure-time or total physical activity estimate. Of the four studies that focused on occupational physical activity, two found a significant inverse relationship between physical activity and breast cancer, but the other two did not. The nine studies considering leisure-time or total activity provide a contradictory picture: two studies found a significant inverse association, two reported a nonsignificant inverse association, three others could not observe any relationship, and the remaining two identified direct associations (i.e., the more active the person was, the higher the risk of cancer). Thus, there is only limited evidence for a protective effect of physical activity against the risk of breast cancer.

1.3.3 Conclusion. Epidemiological studies have also examined the relationship between physical activity and other cancers, such as prostate, testicular, ovarian, and endometrial cancer. Firm conclusions regarding these diseases cannot be drawn because data are often very limited or are inconsistent. The only clear association in this area seems to be the one between level of physical activity and the likelihood of developing colon cancer. To explain this finding, it has been assumed that physical activity reduces gastrointestinal transit time and thus diminishes the contact duration between the colon mucosa and potential carcinogens in the fecal stream.

1.4 Further Chronic Diseases

Level of physical activity has been related to further chronic diseases and conditions, in particular to diabetes, arthritis, osteoporosis, and obesity. Several prospective cohort studies lend strong support to the hypothesis that regular physical activity offers protection against the risk of noninsulin-dependent diabetes mellitus. Whether or not physical activity may prevent the development of osteoarthritis is still unknown. In postmenopausal women, physical exercise may impede the rapid decline in bone mass, thus protecting against osteoporosis, but this effect has not yet been unequivocally established. Reducing obesity by increased physical activity alone is a relatively slow process. Physical activity programs in combination with strategies of dietary management seem to be more effective in this regard.

2. The Effects of Physical Activity on Mental Health

There is a large amount of literature dealing with the psychological effects of physical activity. Numerous reviews and meta-analyses have dealt with this literature (Fox 1999, Morgan 1997). In studies examining the effects of physical activity on mental health, the most frequently observed outcomes include depres-

sion, anxiety, mood, self-esteem, self-efficacy, perceived stress, and cognitive functioning. On the other hand, the role of physical activity in the development and treatment of psychiatric disorders such as schizophrenia, dementia, personality disorders, or eating disorders has only seldom been investigated. The following section focuses on the association of physical activity with depression and anxiety (see *Depression, Hopelessness, Optimism, and Health*).

2.1 Depression

Research using correlational designs suggests a substantial relationship between physical activity and reduced symptoms of depression in men and women (Morgan 1997). In summarizing the existing literature, it was concluded that physically inactive persons are twice as likely to have symptoms of depression than their physically active counterparts. The association between level of physical activity and depression has been found in the general population as well as in clinical subpopulations (Fox 1999).

Correlational studies are often based on cross-sectional data, leaving the question unanswered whether physical activity has an effect on depression, or whether persons with good mental health are simply more likely to be active. In an attempt to resolve this problem of causality, cohort studies have been conducted in which the relationship between physical activity and depressive symptoms were examined in a longitudinal perspective. One of these cohort studies was conducted by Paffenbarger et al. (1994), who revealed that level of physical exercise reported at an initial interview was predictive of physician-diagnosed depression about 25 years later. In this investigation with 10,201 participants, the relative risk of depressive symptoms was 27 percent lower for men who had reported spending more than 3 hours of sports activities each week than for men who had reported no such activities. However, in other population studies, the level of physical exercise at baseline was not a risk factor for incidence of depressive symptoms years later (Weyerer 1992). Thus, the empirical evidence from cohort studies is still limited and inconsistent.

Another approach to resolve the problem of causality is intervention studies conducted in community or laboratory settings (Morgan 1997). A classical and often-cited work in this field is the experimental study by McCann and Holmes (1984). Altogether, 43 women students who scored higher than the cut-off point on the Beck Depression Inventory were randomly allocated to one of three groups: (a) aerobic exercise group, (b) placebo group, and (c) no treatment group. After five weeks, the aerobic exercise group showed a significant reduction in depressive symptoms compared with the two other groups, supporting the hypothesis that increased physical activity resulted in a reduction in depression. A more recent experimental study by King et al. (1993) demonstrated that greater

exercise participation was significantly related to fewer depressive symptoms, independent of changes in physical fitness or body weight. Other intervention studies have shown that the antidepressant effect of physical activity may be greatest in those with higher levels of initial depressive symptoms (Brown et al. 1995), suggesting that the psychological benefits of exercise are likely to be different for different people.

Several biological and psychosocial mechanisms have been proposed in order to explain the antidepressant effects of physical activity. In particular, it has been hypothesized that physical activity may induce changes in brain neuroreceptor concentrations of monoamines (norepinephrine, dopamine, or serotonin) or endogenous opiates (endorphins and enkephalins), which in turn are responsible for changes in the affective level (Morgan 1997). However, the observed depression-reducing effects of physical exercise may also be mediated by psychological factors such as exercise-induced feelings of mastery and self-efficacy, or by positive social and emotional experiences in the sport context.

2.2 Anxiety

Research has also suggested that physical activity may be linked to a reduction in anxiety. The psychological assessment of anxiety usually includes state and trait measures. State measures refer to the actual feeling of anxiety, whereas trait measures evaluate the stable personality characteristic of anxiety. In physical exercise research, state measures have been used mainly in pre-post-designs of intervention studies to explore whether a specific activity episode may have triggered changes in currently experienced anxiety. Results are relatively unequivocal in this respect. Immediately after a session of physical activity, most people report an improvement in mood, including a reduction in level of state anxiety (Berger and Owen 1998). However, this decrease in anxiety may persist for only 2–6 hours following the activity episode (Morgan 1997). In order to continuously profit from the anxiety-reducing effects of physical activity, it is obviously necessary to engage in physical activity on a daily basis. There is no clear evidence that regular physical exercise may have a general impact on trait anxiety (Schlicht 1994).

2.3 Further Psychological Effects

Physical activity has been considered to be a stress buffer in critical life situations (Fuchs and Hahn 1992). This has been explained by two different processes: physical exercise may affect the transactional stress-coping process, either by influencing an individual's appraisal of the potentially stressful situation, or acting as an emotion-focused coping strategy. However, empirical evidence supporting the stress-buffering role of physical activity is still very limited.

Another psychological construct often linked to physical exercise is self-esteem. In his review, McAuley (1994) concluded that the positive association between physical activity and self-esteem is observed both as an enduring consequence of habitual exercise training and as an immediate, short-term effect of single exercise episodes. Finally, several studies suggest that there is a direct relationship between level of physical activity and measures of cognitive performance, such as reaction time, nonverbal reasoning, and memory.

3. Conclusions

There is clear evidence that physical activity is significantly associated with reduced risk of all-cause mortality, all cardiovascular diseases combined, CHD, hypertension, colon cancer, and non-insulin dependent diabetes mellitus. Findings also strongly suggest that regular physical activity may reduce the risk of developing obesity, osteoporosis, depression, and state anxiety. However, effects on psychological factors such as cognitive functioning, self-esteem, body image, self-efficacy, control beliefs, or optimism are less clearly documented. Future research should focus on these emotional and cognitive factors that may be mediators in the relationship between physical activity and mental health. Based on data from epidemiological studies, it has been concluded that physical activity that increases the weekly energy expenditure by about 1,000 kcal (equivalent to about 90 minutes of running or 120 minutes of jogging) may be associated with substantial physical health benefits (DHHS 1996). But how much physical activity is needed to improve or maintain psychological well-being? Probably the mental health benefits of physical exercise are not only a matter of expended kilocalories (if at all), but also of exercise-related social interactions and emotional experiences. Clarifying the mechanisms by which physical activity may affect mental health dimensions is a challenge to sport and health psychology in the coming years.

Physical Activity and Health Promotion

Physical as well as mental health are stabilized and promoted by regular physical activity. The shortness of this article forces us to examine its health-promoting effects only in brief. The main reflections will conc-

entrates on two subjects: health promotion as a science-based theory to change health damaging behavior and the phenomenon that people of Western societies lead a sedentary lifestyle despite the evident benefits of activeness.

1. *Physical Activity and Health*

Disease prevention by regular physical activity has become more and more important. Its significance has been shown in various studies. Epidemiological and naturalistic as well as experimental studies demonstrate the risk-reducing and health-enhancing effects of regular physical activity. In particular, aerobic training seems to be effective in preventing cardiovascular diseases. The psychological benefits of physical activities are decreasing negative emotional states (e.g., anxiety) and increasing positive emotional states (e.g., vigor).

Whereas the effect of exercise on physical health can be explained by adaptation processes of the metabolic and cardiovascular system, the effects on mental health remain unexplained. Different kinds of hypotheses assume physiological (e.g., thermoregulation, endorphins), psychological (e.g., attention distraction, states of *flow*), or rather unspecific mechanisms (e.g., effort justification). Further research is needed to enlighten these mechanisms. However, it can be stated that physical exercise is an appropriate means for health promotion in most cases.

2. *Physical Activity and Health Promotion: Two Complementary Strategies*

Health promotion is a scientific conception to help people change their lifestyles towards a state of optimal health. Recently published theories conceive health and disease as independent dimensions. In view of such a concept, reducing cardiovascular risk by regular exercise does not lead intentionally, at the same time, to optimal physical, mental, and social wellbeing. The strategy of health promotion therefore has been extended in the past decades. Whereas in the 1980s health promotion was defined as a disease preventing strategy, it has been supplemented by a setting-based lifestyle strategy in the 1990s. Health promotion today focuses on disease prevention and health enhancement, while also aiming at changing behavior and improving the living conditions of social groups and individuals.

2.1 *Physical Activity and Health Promotion: The Behavior-oriented Strategy*

When focusing on personal behavior change without considering the environmental conditions, health pro-

motion seems to have rather limited success. About 50 percent of the population in the USA do not adopt regular exercise and 25 percent are not active at all (USCDCP 1994). Those who begin an exercise program often fail to adhere to it. Most of them relapse to inactivity after the first six months (Marcus et al. 2000). Previous preventive interventions have often used threatening contents to convince people to give up inactivity (e.g., threat of coronary artery disease).

When reviewing the literature on fear communication Leventhal (1970) described how threatening intervention practices are often provoking a negative relationship between fear and persuasion. So there is no linear relationship between threat and motivation to quit health-damaging behavior. One cause of this paradoxical effect is well documented in social psychology literature as the phenomenon of reactance (a reaction to feel a restricted liberty of behavior).

In the last decade of the twentieth century Health Psychology applies theoretical models (see *Health Behavior: Psychosocial Theories*) which define the cognitive determinants of health behavior (continuum theories) and construe behavior change as a stepwise process (stage theories). Current continuum theories are the Health-Belief-Model, the Protection-Motivation-Theory, the Theory-of-Planned-Behavior and the Subjective-Expected-Utility-Theory (see *Health Behavior: Psychosocial Theories*). Empirical tests verify at least four variables as predictive for health behavior in general (see *Health Behaviors*). A behavioral change is probable on condition that a person perceives health hazards as being likely (vulnerability) and severe (severity), and on the condition that this person is supplied with disease preventing alternatives (outcome expectancies), and has enough personal efficacy (self-efficacy) to change a risky lifestyle.

With regard to physical exercise, perceived behavior control, positive outcome expectancies, social support and severity, as well as vulnerability, define valid and reliable sociocognitive predictors determining adoption to exercise for men and women in different ways (Sallis et al. 1992). In contrast, knowledge about intervention strategies that try to foster exercise adherence or maintenance to physical activity, is at an early stage (Marcus et al. 2000).

Valid social and demographic predictors of health-related activities are mainly age, gender, neighborhood environment, school attainment, ethnicity, and income aside from sociocognitive variables. This means that women, elderly people, people with a lower education, low income, ethnic minorities, and persons living in an area with low recreational potential, are little active in sports.

Moreover health-related behavior (including health damaging activities) has proved to be quite stable (Sutton 1994). It is obvious that inactive people are not aware of the risks of leading a sedentary lifestyle. Continuum theories are scarcely suited to explain

changes from the sedentary-oriented stage to that of readiness for physical activity.

Stage theories (Transtheoretical-Model, Precaution-Adoption-Process) seem rather adequate to deal with this phenomenon (Weinstein et al. 1998). They postulate distinguishable stages in which varying processes pass, leading to different levels of change: for example, precontemplation, contemplation, active change, maintenance, and perhaps relapse. Adoption of exercise has been investigated by various authors, most of them using a cross-sectional comparison of people believed to be in different stages (e.g., Prochaska 1994). The results indicate an increase in the perceived benefits of exercise from a pre- to a postdecisional stage. More experimental and longitudinal research is needed to clarify the conditions under which people change from a sedentary to an active lifestyle.

2.2 Physical Activity and Health Promotion: The New-Public-Health Approach

Many health problems and severe diseases in modern societies are surely caused by overeating, alcohol consumption, drug abuse, and a sedentary lifestyle. Therefore, the question of how to change health-damaging lifestyles still remains important. The models and theories mentioned above help to develop efficient intervention strategies.

Physical activity is part of a health-enhancing lifestyle. The achievement of physical activity goes beyond reducing the risk of cardiovascular diseases. Contributing to social integration gives the feeling of internal control and—especially with young people—provides the conditions for learning adequate, rule-based social behavior (see Danish et al. 1996). Exercising in groups seems to promote the learning of suitable skills to mobilize social networks.

British studies especially, however (see Blaxter 1990), substantiate that particularly middle- and upper-class members of modern societies cling to a health-enhancing lifestyle. Body image and its relevance to physical activity is now a subject of growing importance for those with a modern, middle-class lifestyle. As can be suspected, inequalities in exercise engagement are not only caused by personal income, though this is a premise for taking part in physical activities such as aerobics, calisthenics, and power training in fitness studios. Causes may be found more likely in the 'social environment' of persons. Social environment construes informal as well as formal rules and norms and it provokes attitudes and values, feelings, thoughts, and actions, which then determine the actual position of a person in a given setting (e.g., workplace, school, family). From this point-of-view a certain health-damaging behavior (e.g., inactivity) may be functional in so far as it demonstrates identity with a defined social group or class. Empirical facts show that lower-class people share a mechanistic view

of the body. In general they do not expect to have personal influence on health and wellbeing. The consistent epidemiological results from USDCDP (1994) that are mentioned above, demonstrate that less physical activity participation correlates with lower educational attainment, lower income, minority status, old age, and being overweight. These factors seem to be significant barriers to exercise.

Interventions merely focusing on health-damaging behavior run the risk of ignoring the constraints and barriers of behavior change. They are liable to lead towards 'healthism.' They are likely to provoke moralistic attitudes such as blaming the victim (see Diekstra and Jansen 1990). Health promotion in the sense of New Public Health is a crossdisciplinary science that avoids such misinterpretation by preferring an ecological perspective. The *Ottawa Charter for Health Promotion* of the WHO pleads for an enlargement in the paradigm of the intervention process. Health promotion in this sense considers both personal behavior and personal environment. It includes disease prevention as well as health enhancement. Thus health promotion has the chance to look for daily life resources which are health enhancing. Those resources are, among other things, sufficient income, adequate command of work, ability to cope with daily hassles and daily uplifts, social integration and social support, self-esteem, and the feeling of internal control (Diekstra and Jansen 1990). As already mentioned, exercising in groups can contribute to the strengthening of these resources; therefore all social groups should have the opportunity to profit from these resources as well.

King et al. (1997) show that participation in an exercise program depends on its demands and type. They compared two groups of women—those who had less than 12 years of education with those who had more than 12 years. The Stanford-Sunnyvale Health-Improvement Project (SSHIP) found that the less-educated group, which was given an adequate home-based exercise program, had relatively high rates of long-term exercise adherence (two years). So, if matched to the right program, subgroups of lower classes have the chance to do quite well. Studies like the SSHIP will help to identify those variables, which can provide information on when and why people become more or less active over the course of time.

3. Conclusions

Physical activity is an appropriate means of enhancing physical as well as psychological wellbeing. Despite the growing evidence of the health benefits of regular physical activity, about 50 percent of adult people remain sedentary, especially those in lower socioeconomic status groups. Research in Health Psychology as well as in New Public Health is challenged to clarify those conditions and program parameters which are appropriate to enhance the motivation to

exercise and which bind people together in long-term regular exercise programs.

Physical Sciences: History and Sociology

The twentieth century was the century of the physical sciences. Immensely successful at making sense of the material world, they are also deeply embedded in the social fabric, and have become associated with technological development, economic well-being, and

national security and prestige. The physical sciences have also provided the knowledge required to produce a vast array of weapons and weapons systems. Their history and sociology are contested terrains, in which the issues at stake are commensurate with the ambiguity of their social role.

1. Object

The physical sciences as a coherent body of practices emerged in Western Europe in the seventeenth century (Dijksterhuis 1986/1950, Shapin 1996). At the time they encompassed the fields of physics, astronomy, and mechanics. They were at the core of a radical epistemological and social project which defined nature in mechanistic terms and as subject to law-like and predictable behavior. Their aim has been to understand but also to exploit and to manipulate their objects. Their means has been a combination of ‘reason’ and ‘experience,’ both of which had to respect locally defined and shared canons of good practice. Their practitioners mobilized mathematical tools and capitalized on the rigor of mathematical demonstrations to consolidate the logical force of their truth claims. They extended the reach of the human senses by building and using increasingly complex and powerful instruments which allowed for the controlled exploration of the properties and processes of matter.

2. Scope

The scope of the physical sciences has constantly evolved to include fields as diverse as chemistry, electricity, optics, and the study of solids. Beginning in the late nineteenth century, their potential for not simply understanding but also manipulating the material world led to their institutionalization, and the formalization of their links with the state, philanthropic foundations, and large corporations. Patrons and philosophers alike were impressed by their intellectual and pragmatic success, as revealed by the panoply of technologies which they spawned and on which millions of people depended for their well-being. Characterized as a set of techniques and practices, they were seen as a model to be emulated and reproduced. Traditional forms of knowledge were appropriated and subjected to their methods. Parts of the life sciences and the human and social sciences were colonized. Existing disciplinary boundaries were dissolved and new specialisms and fields emerged in the spaces thus created (Krige and Pestre 1997).

Consider the relationship between mathematics and the physical sciences. For Galileo and those who shared his intellectual project in the seventeenth and eighteenth centuries, the ‘book of nature’ was written in mathematical symbols and the laws governing its behavior could be expressed in mathematical form. This local unity between the physical sciences and mathematics persisted in the majestic constructions of

a Newton or a Laplace (Koyré 1985). Later, however, some mathematicians began to detach their objects from the empirical and the experimental (Bottazini and Dahan 2001). Particularly in Germany they reverted to a 'pure' mathematics in opposition to, and to defend themselves against, the rising intellectual and institutional importance of a mathematically informed theoretical physics which was based on, and guided, experimental work. It was this theoretical physics which transformed our conception of the structure and properties of matter in the late nineteenth and early twentieth centuries, combining theoretical analysis with philosophical reflection.

The exigencies of World War II swept aside these cultural norms and intellectual methods. A new kind of physics emerged, motivated by a pragmatic demand to get numbers out and to solve problems efficiently using an evolving toolkit of mathematical techniques. This problem-oriented rather than discipline-based approach persisted in the postwar era. It was entrenched through summer schools and conferences, and by interdisciplinary teamwork in universities and corporations, frequently undertaken with the needs of the military and the Cold War in mind. Pure mathematics continued with a life of its own, dedicated to abstraction, and often pursued with idiosyncratic brilliance in schools like the Bourbaki group in France. Its members saw themselves as the priests of high culture and disdained the vulgar materialism of those 'mathematicians' whose work was enmeshed with the empirical and the experimental.

Proponents of the physical sciences, actively encouraged by patrons, have repeatedly sought to colonize neighboring fields, redefining their objects so as to impose their methods and practices on them. The molecularization of biology is a case in point (Abir-Am 1982, Kay 1996). In the 1930s, officers of the Rockefeller Foundation, believing that the study of life needed to be purged of what they saw as its metaphysical content, actively promoted the migration of concepts and of instruments and techniques developed in the physical sciences, along with their practitioners, into biological research. The study of macromolecules of biological origin in the 1930s, and the unraveling of the molecular structure of DNA in the 1950s consolidated this reductionist project and contributed to the emergence of a new discipline, molecular biology. It was articulated around the concept of information, made use of instruments like x-ray crystallographs and electron microscopes, and benefited from an interdisciplinary symbiosis between physicists and researchers in the life sciences.

3. Practices

The physical sciences have always been enmeshed in complex matrices with other sciences, technology, and various social actors. This process was accelerated and consolidated in World War II. The development of

radar, nuclear bombs, and long-range rockets mobilized physicists at the core of interdisciplinary teams which brought together, in addition, material scientists, chemists, mathematicians, and engineers in vast techno-scientific systems. These systems were shaped by the military and demanded unquestioning political and financial support from the state and the resources of major corporations. They also required the collaboration of hundreds and thousands of 'non-scientific' men and women who were mobilized for the war effort, either voluntarily (as in the case of women who worked around the clock in radar stations equipped to detect enemy submarines off the South African coast) or under conditions of appalling cruelty (as in the forced labor camps which built V2 rockets for the Nazi regime in the 1940s).

World War II institutionalized the hierarchical and planned organization of research in large interdisciplinary teams centered around a project or a problem (Galison 1997, Galison and Hevly 1992). The practice of some of the physical sciences after the war, notably in high-energy physics, reproduced and exemplified many of these features. It has come to be taken as the paradigmatic 'big science.' Particle physics brings together hundreds of researchers from many different institutions around major accelerators and the detectors used to explore the collision processes produced in them. It is patronized by the state as an icon of prestige and a training ground for some of the most brilliant members of a strategic elite. It relies on advanced sectors of industry for the development and supply of sophisticated technologies (in areas like high vacuum, electronics, and superconductivity).

This change of scale has demanded that physicists become adept at a variety of skills and bow to constraints imposed by various regimes. The size of the equipment built and used and the numbers who work with it, the danger of explosion with the cryogenic detectors (bubble chambers) deployed above all in the late 1950s and 1960s, and the competing demands for opportunities to perform experiments have all transformed the material culture of physics. For leaders in the field, being a physicist does not simply mean pursuing one's specialty in a multidisciplinary team. It means being adept at fundraising, at project management, and at dealing with industry. It also requires that one accepts the bureaucratization of experimental work. Committees set research priorities and allocate beam time and floor space. The laboratory directorate imposes policies intended to protect the interests of the research community which depends on the facility it manages, and of the government or organization which funds it.

4. Instruments

Instruments lie at the core of the physical sciences. They are the essential means to the production and certification of knowledge. They are also complex and

capricious (Collins 1992, Latour 1987, Shapin and Shaffer 1985). One has to be trained to use them, learning how to control their irregularities and to make sense of their output. The results obtained, and the truth-claims made, are impregnated with the vagaries of the instruments and the tacit, hands-on knowledge and experience of those who used them. Replication, preferably by others elsewhere with an instrument which is 'similar in the relevant respects,' is the ideal and idealized strategy used to transform these local truth-claims into universal truths which tell us something about the structure of the world. Such similarity is contestable, and often contested. It also presupposes not only agreed protocols of experimental manipulation but also a level of technological development congenial to the construction of standardized, precision instruments. This level was not reached in Europe until the nineteenth century. Instrument-makers, be they gifted craftsmen with tiny workshops in the streets of London or Paris a century or two ago, specialized firms developing and marketing standardized laboratory tools, or giant industries supplying heavy equipment, thus provide the essential technical and technological infrastructure demanded by the physical sciences.

The production of standardized instruments requires the integration of theories of how the instrument works into its design. Simple theories of optics were embedded in the telescopes, microscopes, and binoculars produced by the vast eyeglass industry built up by Zeiss at the end of the nineteenth century. Scientists themselves have played an active role in developing theoretically based instruments dedicated to their research agendas. Marie Curie not only amassed radium in order to pursue her research, she also promoted and financially backed the construction of measuring instruments which she could use to establish and impose standards for radioactivity (Boudia and Roqué 1997). Ernest Lawrence built his laboratory and his reputation on the construction of ever-more powerful particle accelerators based on a theoretical understanding of the behavior of charged particles in electromagnetic fields (Heilbron and Seidel 1989). Standardized, these instruments were promoted as tools to cure cancer, were used to manufacture enriched uranium for the Manhattan project during World War II, and were advocated as particle beam weapons during the Cold War. Felix Bloch's recondite research into the magnetic properties of the nucleus, for which he shared a Nobel prize for physics in 1952, suggested a new and sensitive technique for identifying the components of compound mixtures. Working along with his graduate students at Stanford University and the local firm Varian Associates, which specialized in resonance techniques, his nuclear magnetic resonance instrument became a standard tool for chemical analysis in the 1960s.

Instruments can inspire awe, and nowhere more than in the physical sciences where their complexity

and size have often been exploited to legitimate the practices in which they are embedded and to increase the social weight of those who build them and demonstrate their powers. The sixteenth-century clock in Strasbourg cathedral was a masterpiece of craftsmanship. It was also a material illustration that the mechanical view of nature, congenial to and promoted by the partisans of the 'new philosophy,' was a feasible alternative to the dominant conception which took the natural world to be throbbing with life, intelligence, and purpose. The spectacular discharges sparked by Ruhmkorff coils in public arenas in the late nineteenth century thrilled a populace fascinated by an electricity which was replete with associations to medicine, spiritualism, and technological application. Giant particle accelerators and detectors (and telescopes), regularly put on display to impress the general public, promote and seek to justify the enormous cost of these recondite fields of research. Their size and power are limited only by technological feasibility, financial constraints and, today, political will. Each successive generation of instruments is reputedly bigger and better than its predecessors, as measured in easily understood, readily quantified units of energy (or resolving power). Each demonstrates scientific and technological leadership, inflates national pride, and fuels international rivalry.

5. Patronage

Patronage has made possible the emergence, consolidation, and then vast expansion of the sphere of influence of the physical sciences, notably that which has occurred over the past 150 years. Patronage by kings, emperors, the military, national governments, and private foundations has created the social niches and institutions and supplied the financial resources the practitioners of the physical sciences have needed to promote their projects. In return they have held out the promise that the knowledge they produced would improve not only understanding, but also, through that, the prestige and power of those who supported them.

Accommodation and compromise has usually characterized the relationship between practitioner and patron (Mukerji 1990, Price 1965). Both partners have fashioned identities and ideologies, and negotiated boundaries of power and autonomy, compatible with their mutual dependence on each other. Exceptionally that dependence has been denied, or subjugated to other dominant ideologies, as in the grotesque persecution of Jewish scientists by the Nazi regime in Germany in the 1930s. More usually pragmatism prevails, as in the unseemly race between the allies to secure the services of the scientists and engineers who had developed missiles used by that selfsame regime to bombard major European cities. The pragmatism of

patrons is matched by that of those whom they support; practitioners of the physical sciences have shown themselves remarkably adept at establishing a *modus vivendi* with whatever political regime provides them with the institutional and financial resources they need to pursue their work. The 'universalism' and internationalism of science so actively promoted in the twentieth century has gone along with the depoliticization of the community and the propagation of an ideology which has decoupled scientists as producers from their patrons as users of the knowledge which they have, in fact, co-produced.

The increasingly costly and complex equipment demanded by the physical sciences has led governments, above all in Western Europe, to pool resources and to fund collectively international laboratories and organizations (Krige and Guzzetti 1997). These collaborative initiatives have generally been restricted to basic research in domains of little direct strategic importance (like high-energy physics, nuclear fusion and space science, and also molecular biology). Even here the loss of sovereignty involved can be a disincentive to the participating governments. They drain resources from national programs and shift the locus of policy to an arena in which practitioners and patrons are locked into scientific, technical, financial, and political decision-making processes over which they have limited control. Indeed, the stability of intergovernmental schemes in the physical sciences depends on practitioners successfully persuading national authorities of the scientific and technical need for the laboratory and its equipment and on patrons defining the collaborative venture as an instrument of foreign policy. This has been particularly valuable for some domains of the physical sciences in the aftermath of the Cold War. With their field no longer perceived as an icon of national prestige and global power, nuclear physicists in the United States and even more dramatically in the ex-Soviet Union have seen support for their research falter, and have had to put their skills at the disposal of new and sometimes exotic patrons (like Wall Street brokers and investment banks). Their colleagues in Western Europe, by contrast, have continued to benefit from governments' use of their science as a tool to extend the 'European family' of nations to include many from the former Soviet bloc.

6. Historiography

Currently there are, broadly speaking, two ways of writing the history of the physical sciences (Golinski 1998). One approach focuses on product. It takes the output of research as an unproblematic corpus of established truths about the world. It is progressivist, and draws attention to scientific achievements and the logical, unidirectional connections between them. It is coupled with a sociology which defines scientific know-

ledge as comprising verified truths which are independent of social determination, and a corresponding view of the scientist as the member of a self-regulating community searching for objective knowledge.

The other approach focuses on process and practice. Inspired by sociological and anthropological arguments which insist that truth-claims are underdetermined by empirical evidence, it problematizes the products of research. It explores the social practices whereby consensus is forged among scientists, the processes whereby knowledge is legitimated in different times and places, and how it is reconfigured as it circulates among various groups of social actors. If for the former approach truth is simply a relationship between statements and the world, for the latter it is also a social accomplishment.

Each of these approaches emerged in a specific sociohistorical context and was shaped by a corresponding concept of science and the social role of its history. The focus on product was intended to celebrate science and scientists as the bearers of Reason and Truth, progressive forces opposing 'irrational' political ideologies which sought to impede their development and impose constraints on their field of action. The focus on process is a *fin de siècle* reaction to the success of that project. It seeks to puncture the pretensions of a science and of scientists whose cognitive authority and social power is immense, at least as far the physical sciences are concerned in some advanced industrialized countries. By insisting that social processes are central to the production of knowledge, it seeks to tie truth claims to the local contexts in which they emerge and are contested, and to draw attention to the uncertainty, ambiguity, and messiness which pervades scientific practice at the research frontier.

Each of these approaches has its associated political agendas and neither can lay claim to universal applicability. The former serves to defend the scientific approach wherever the appeal to empirical evidence and rational argument is threatened by institutionalized intolerance, and where science and technology have not yet been bent to alleviate poverty and suffering. The latter seeks to demythologize science and scientists wherever they have become entrenched and empowered in social structures, questioning the uncritical acceptance of science as a force for progress and of scientists as experts whose truth-claims and whose power lie beyond democratic debate and control.

Physicalism and Alternatives

Physicalism is the thesis that all there really is is whatever there has to be given the way reality is physically. Thus, if physicalism is true and there really are people, shopping malls, cities, and countries, then, given the way reality is physically, there have to be people, shopping malls, cities, and countries. The

alternatives to physicalism imply that there are actual phenomena in addition to whatever phenomena there have to be given the way reality is physically. Substance dualism is an alternative that maintains that there are actual substances—for example, immaterial souls, or entelechies, or disembodied spirits—that need not exist given the way reality is physically. Property dualism, another alternative to physicalism, maintains that there are properties—for example, irreducible mental properties or irreducible moral properties—whose actual pattern of distribution need not occur given the way reality is physically. Physicalism is a controversial thesis. Even if it is true, it might have been false; one or more of the alternative views might have been true instead. The debate over whether physicalism or one of its alternatives is true is thus an empirical debate.

1. Physicalism

1.1 Formulating Physicalism

So-called type physicalism is the doctrine that every type or kind of thing is physical. Physicalists need not be committed to type physicalism. Many physicalists allow that some kinds of things are such that is logically possible for them to have instances in, for instance, a spiritual realm that is wholly devoid of matter. For example, it seems logically possible for certain kinds of social institutions and social contracts to have instances in such a spiritual realm. Physicalists insist only that in reality, that is, in the world as it actually is (i.e., in the actual world), any instance of any kind of thing, including any kind of social institution or social contract, is at some level of composition, wholly composed of physical entities (Hellman and Thompson 1975).

Given that being wholly composed of physical entities suffices for being physical, physicalism implies token physicalism for objects, the thesis that every object that is physical. Physicalism is not, however, equivalent to this thesis. One reason is that even if every object is physical, it might be an accident that this is so, for there might be laws of nature according to which, were certain physical conditions to obtain, wholly disembodied spirits would come into existence. That is, the laws of nature might be such that a certain brew of physical ingredients would bring into existence wholly disembodied spirits, even though, by chance, the physical ingredients in question have never come together into that brew (Witmer 1997). Since physicalists deny that there are such laws it is too weak to formulate physicalism as token physicalism for objects. Another reason it is too weak is that token physicalism for objects is compatible with there being properties whose actual patterns of distribution over objects fail to be determined by physical laws and the pattern of distribution of physical properties, and,

according to physicalists, the pattern of distribution of every property is so determined.

It would be too strong, however, to formulate physicalism in a way that implies that all properties are physical properties, for physicalists typically allow that there are functional properties. A functional property is a second-order property: it is the property of having some property or other that occupies a certain lawful or counterfactual role (Putnam 1967, Block 1994). Functional properties are realized by the first-order properties that occupy the roles in question. (A functional property may be multiply realizable in that there may be more than one first-order property that can occupy the relevant role.) Many functional properties are such that it is logically possible for them to be realized by nonphysical properties, which is why they themselves do not count as physical properties. Physicalists claim, however, that physical laws and physical conditions determine what functional properties there actually are, and that, in actuality, functional properties are ultimately realizable only by physical properties. And they claim further that physical laws and physical states and events determine the occurrence of every state or event that is an instance of a functional property. Since nonphysical properties and kinds may be cited in laws of the special sciences, it would also be too strong to formulate physicalism in a way that implies that all laws are physical laws. Physicalists maintain only that all fundamental laws are physical laws, that nonphysical laws are determined by physical laws and physical conditions.

Still, physicalism is first and foremost a thesis about what there actually is. It is the thesis that all there actually is is whatever there has to be given the way the actual world is in every physical respect—in respect of what physical objects there are, what physical properties they have, what physical relations they bear to other physical objects, what physical laws govern their behavior, etc. Physicalism can allow that there are actual nonphysical kinds of objects, nonphysical properties, relations, laws, etc., provided that they must exist, given the way the actual world is physically. What physicalism disallows is that the actual world contains anything that is unnecessary for it to be exactly as it is physically.

Call any possible world (i.e., any way the world might be) that is exactly like the actual world in every physical respect, a physical duplicate of the actual world. It is, of course, trivial that the actual world is a physical duplicate of itself. Call any possible world that is a physical duplicate of the actual world and that contains nothing other than what is required to be a physical duplicate of the actual world, a minimal physical duplicate of it. It is by no means trivial that the actual world is a minimal physical duplicate of itself. For this claim has, for instance, the consequence that there are actually people, shopping malls, cities, and countries only if there have to be people, shopping malls, cities, and countries in order for the actual

world to be a physical duplicate of itself. Physicalism is equivalent to the controversial thesis that the actual world is a minimal physical duplicate of itself.

Call any possible world that is exactly like the actual world in every respect whatsoever, physical or otherwise, a duplicate simpliciter of it. A possible world could be a physical duplicate of the actual world without being a duplicate simpliciter of it. For there is nothing about the way the actual world is in physical respects that excludes there being, say, a realm of disembodied spirits, provided that this spiritual realm exerts no causal influence on the physical. Physicalism, however, disallows that there are such ‘extra entities’ in the actual world. Physicalism is equivalent to the following thesis: any minimal physical duplicate of the actual world is a duplicate simpliciter of the actual world (Jackson 1998). That is to say, all that there actually is is whatever there has to be given the way the actual world is physically if and only if any minimal physical duplicate of the actual world is a duplicate simpliciter of it.

The idea that any minimal physical duplicate of the actual world is a duplicate simpliciter of it can be vividly illustrated by a creation myth. Suppose that Mother Nature wanted to create an exact duplicate of the actual world. According to physicalism, then, all that She would have to do is create an exact physical duplicate of the actual world—a world exactly like it in every physical respect. Her work would then be done. She would have thereby created a world exactly like the actual world in every respect whatsoever.

1.2 The Term ‘Physical’

What is meant by ‘physical’ in the phrase ‘the way the actual world is in every physical respect’? The relevant notion of physicality is tied to physics. There is, however, a dilemma that any attempt to state the tie must face (Hempel 1969, Crane and Mellor 1990). The dilemma can be formulated thus: if by ‘the way the actual world is in every physical respect’ is meant the way current physics says the world is (in respect of what objects there are, what properties they have, etc.), then physicalism is no doubt false, for current physics is no doubt false. On the other hand, if by ‘the way the actual world is in every physical respect’ is meant the way the true, complete physics would say the world is, then physicalism is either trivially true or too obscure to be a subject of rational assessment.

While current physics is a vast improvement over any previous physics, it is, nonetheless, no doubt false. The first horn of the dilemma should thus be avoided. What, then, of the second horn? If the second horn were embraced, then it would be trivially true that the way the world is in every physical respect is the way the true, completed physics would say that it is, for the claim would be true by definition. It would not follow, however, that physicalism is true by definition,

or even that it is trivially true. For were 'the way the actual world is in every physical respect' to be understood in this way, then physicalism would be the thesis that all that there actually is is whatever there has to be for the actual world to be the way the true, complete physics says that it is. That thesis is by no means trivial. The true, complete physics would not, for instance, postulate a spiritual realm that is causally isolated from the realm governed by its laws. (Even if, contra physicalism, the true, complete theory of the actual world would postulate such realm, the part that counts as physics would not.) Yet it is by no means trivially true that there is no such realm.

Still physicalists do not maintain that 'the way the actual world is in every physical respect' means the way the true, complete physics would say the world is. For the true, complete physics might postulate phenomena that physicalists deny actually exist. Mechanics, the theory of motion, is a central branch of physics. A true, complete physics would thus include a true, complete mechanics. A true, complete mechanics would take into account all of the fundamental causes of motion. Suppose, then, that the actual world contains Cartesian minds, substances that are not extended in space, but that occupy intrinsic, conscious states that exert a fundamental causal influence on the motions of particles in the brains of human beings, and, thereby, a fundamental causal influence on the behavior of human beings. If so, then the true, complete physics would be a Cartesian-like physics in that it would postulate Cartesian minds. But were this the case, physicalist would regard physicalism as false. It may well seem preposterous that the true, complete physics is a Cartesian-like physics. Current physics is surely not that badly wrong. The point, however, is that it is not true by definition that the true, complete physics is not a Cartesian-like physics.

Physicalists indeed claim that the way the actual world is in every physical respect is the way the true, complete physics would say that it is. But this is not intended to be true by definition. Physicalists make the claim because they are betting that the true, complete physics will share certain features with current physics (Pettit 1993). Call any theory of physics that is an improvement over current physics and that retains the features in question (whatever they are), a successor physics to current physics. The physicalist is betting that the true, complete physics will be a successor physics to current physics. By 'the way the actual world is in every physical respect' physicalists mean the way that the true, complete successor physics to current physics says the world is. And thus physicalism is the thesis that all there actually is is whatever that has to be given the way the true, complete successor physics to current physics says that the actual world is. To steer a course between the horns of the dilemma, physicalists must identify the features that a theory of physics must share with current physics to count as a successor to it.

The place to look to discern the features in question is at the advances in physics and the special sciences of chemistry and biology that physicalists maintain lend support to physicalism. At the start of the twentieth century, not all chemical theorists accepted atomism, and even some atomists speculated that the explanation of chemical bonding might have to invoke fundamental chemical forces. By the middle of the first decade, however, Einstein's work on Brownian motion convinced the entire community of chemical theorists of the truth of atomism. Then, after two decades of work on the structure of the atom, quantum mechanics was proposed. Quantum mechanics provides a reductive explanation of chemical bonding that invokes no forces or energies other than those at work below the level of composition of the atom. For a time after the advent of quantum mechanics, there remained speculation that there may be a fundamental, emergent force at work in living organism, a vital *élan*; but with the advances of molecular biology, such as the discovery of DNA, this idea was abandoned. On the evidence, living things are wholly composed of subatomic entities (such as electrons, quarks, etc.), entities whose behavior is determined by forces and energies exerted below the level of the atom. Biological processes are wholly implemented by chemical processes, which, in turn, are wholly implemented by quantum mechanical ones (McLaughlin 1999a).

Physicalists are not committed to the truth of the whole of current physics, or even to the truth of quantum mechanics. They are, however, betting that the true, complete physics will share the following features with current physics: (a) every entity postulated by the theory will either be subatomic or, at some level of composition, wholly made up of subatomic entities; and (b) the theory will postulate no fundamental forces or energies that are not exerted below the level of the atom. Many physicalists hold that to count as a successor to current physics a physics must retain features (a) and (b). These physicalists allow for the discovery of new objects, properties, forces, fields, and laws, provided that these discoveries are consistent with (a) and (b). They maintain only that the true, complete physics will retain features (a) and (b).

Some physicalists, however, hold a more relaxed view of what features a theory of physics would have to have to be a successor to current physics. Some allow that a fundamentally new kind of macroscopic matter could be discovered that is not composed of subatomic entities, so long as all living things and everything with mental capacities is wholly composed of subatomic entities. Moreover, some physicalists allow for the discovery of emergent forces at work in living things and beings with mental capacities, so long as the forces in question are generated by spatio-temporal configurations of subatomic entities. It is logically possible that when atoms becomes so configured as to compose a cell or so configured as to compose a human brain in a certain of neural state, a

fundamental force comes into play that is not exerted by matter at lower levels of complexity. Such emergent forces would exert a fundamental 'downward' influence on the behavior of particles (Broad 1925, McLaughlin 1999a). They are ruled out by condition (b). But some physicalists allow that a successor physics to current physics could countenance such emergent forces since they would be generated by spatio-temporal configurations of atoms, and so not, for instance, by states of an entelechy or by ontologically fundamental acts of will.

Stronger and weaker notions of what counts as a successor physics to current physics can thus be distinguished, and with them stronger and weaker versions of physicalism. But even the weakest notion(s) of what counts as a successor physics to current physics would, for instance, exclude a Cartesian-like physics from so counting. The notions of a successor physics to current physics that are invoked to characterize versions of physicalism are vague since it is, for instance, somewhat vague what counts as physics. But they are not so obscure as to render any of the varieties of physicalism outside the realm of rational assessment. (The differences between the stronger and weaker versions of physicalism will not matter for what remains, and so will be ignored.)

Physicalism implies that there is a true, complete successor physics to current physics, but it is not equivalent to that claim. Nonphysicalists can accept that there is a true, complete successor physics to current physics, in even the strongest sense. Indeed, nonphysicalists can even allow that current physics may be true. For physicalism says more than that the actual world is the way that the true, complete successor physics to current physics says that it is. Physicalism is the thesis that all there actually is is whatever there has to be given the way that the true, complete successor physics to current physics says that the world is. It is this claim that nonphysicalists deny.

2. *Whether Physicalism or One of Its Alternatives*

2.1 *The Causal Priority of the Physical*

Physicalism is defended both by appeal to empirical evidence and by appeal to supraempirical considerations of overall coherence and theoretical simplicity.

Physicalists claim that physical determination is true: the objective probability of any physical event or state is wholly determined by prior physical events and states. Thus, the objective probability of the physical movements of any living organism or sentient creature, and any movement of any of its physical parts, will be wholly determined by prior physical events (perhaps those occurring on some cross-section of the backward light-cone of the physical movements in question). Thus, given physical determination, if there are actual

nonphysical states or events, then either (a) they do not causally interact with physical occurrences at all, or (b) they causally interact with physical occurrences, but not by means of any underlying causal chain of physical occurrences, or else (c) they causally interact with physical occurrences derivatively, that is, by means of some underlying chain of physical occurrences (McLaughlin 1994).

Physicalists appeal to supraempirical considerations of overall coherence and theoretical simplicity to rule out alternatives (a) and (b). In response to (a), they maintain that there is no need to postulate states or events that have no physical effects in order to explain anything that requires explanation. In response to (b), they maintain that since physical determination is true, this possibility would involve a bizarre kind of autonomous causal overdetermination of the physical by the nonphysical that can be ruled out on grounds of theoretical simplicity, and not at the expense of overall coherence (Witmer 1997). Finally, in response to (c), some physicalists argue that only physical events causally interact with physical events. However, some physicalists allow that there are nonphysical events that causally interact with physical events in a derivative way, by means of underlying causal chains of physical occurrences. For they maintain that the nature of the underlying relationship is such that in any minimal physical duplicate of the actual world, the physical occurrences in that world will underlie exactly the same sorts of nonphysical occurrences that their physical counterparts underlie in the actual world, and, so, that (c) is compatible with physicalism.

Few philosophers now challenge physical causal determination, most accept the thesis on the evidence. To answer supraempirical considerations for physicalism, nonphysicalists typically argue that there are reasons to accept that there are certain actual phenomena not countenanced by physicalism, and that those reasons outweigh the consideration that the phenomena would be either epiphenomena or autonomous overdeterminers of certain physical occurrences.

2.2 *Elimination or Entailment?*

According to physicalists, all that there actually is is whatever there has to be given the way the actual world is physically. When it is claimed that a certain phenomenon actually exists that is not required for the actual world to be exactly as it is physically, physicalists have two options. They can argue that there is no phenomenon of the sort in question, and thus be eliminativists or irrealists about it. (All physicalists are eliminativists about disembodied spirits, for instance.) Or they can argue that, despite first appearances, the phenomenon in question must exist given the way the actual world is physically.

The debate between physicalists and nonphysicalists is mainly centered on the mental and on phenomena

logically dependent on the mental. Some physicalists are eliminativists about the mental, or at least about the mental as conceived by folk or commonsense psychology (Churchland 1978, Stich 1999). But most physicalists are realists about the mental, and many are realists about the moral also, and attempt to explain moral properties reductively, in part, by appeal to mental properties.

Physicalists argue that a phenomenon must exist given the way the actual world is physically by arguing that it is plausible that its existence is entailed by the totality of physical facts (Jackson 1998). The totality of physical facts includes all particular physical facts and all general ones, including all nomological ones, and includes as well a 'that's all' physical fact, a fact to the effect that the physical facts in question are all the physical facts.

Given physicalism, the totality of physical facts, in conjunction with the contingent thesis of physicalism, entails all of the facts. Thus, if, for example, it is a fact that a certain property has a certain worldwide pattern of distribution, then the totality of physical facts in conjunction with the thesis of physicalism will imply that the property has that worldwide pattern of distribution. The totality of physical facts will, of course, imply facts about the actual worldwide pattern of distribution of physical properties. The totality of physical facts, in conjunction with the assumption of physicalism, will imply facts about the actual worldwide pattern of distribution of functional properties and any properties metaphysically necessitated by physical properties, and will imply as well that no other sorts of properties are actually possessed by anything.

One way to establish that mental facts are entailed by the totality of physical facts and the truth of physicalism alone is by showing that the relevant mental concepts are definable in terms of physical and topic-neutral concepts (Smart 1959). (Topic-neutral concepts are neither physical nor mental concepts; they include the concept of a part, the concept of causation, and logical concepts such as the concept of conjunction, the concept of negation, and the concept of universal quantification.) Both analytical behaviorism and analytical functionalism entail that there are such definitions. According to analytical behaviorism, mental concepts can be defined in terms of concepts of dispositions to peripheral behavior (Byrne 1994). According to analytical functionalism, mental concepts can be defined more broadly in terms of macro-physical and topic-neutral concepts (Armstrong 1968, Block 1994, Lycan 1994).

Analytical behaviorism is widely regarded as a failed project. It is now generally acknowledged that no mental concept can be defined in terms of concepts of dispositions to peripheral behavior. Analytical functionalism continues to have proponents (Lewis 1994), but it is controversial whether it is true of any mental concept. Analytical functionalism is most plausible for

intentional concepts such as the concepts of belief, desire, intention, and the like, since these concepts are, arguably, dispositional concepts. But it is especially controversial whether analytical functionalism is true of sensory (or phenomenal) concepts such as the concept of the felt quality of pain (Block 1995, Chalmers 1996). Many philosophers, both physicalists and nonphysicalists, claim that sensory concepts fail to have *a priori* functional analyses of any sort. They maintain that there is an explanatory gap between sensory concepts and physical and topic neutral concepts in that sensory concepts are neither definable in terms of such concepts nor are their references fixed by associated physical and topic neutral concepts (Levine 1983).

Scientific functionalism and type materialism are physicalist alternatives to these *a priori* approaches to explaining how mental facts are entailed by the totality of physical facts and the assumption of physicalism. To focus for illustration on the case of pain, scientific functionalism maintains that pain is identical with a type of functional state (and, so, a type of second-order state), albeit the identity is knowable only *a posteriori* (Loar 1997). Type materialism maintains that pain is identical with a type of abstract neurobiological state, and that the identity is knowable only *a posteriori* (Hill 1991). As Saul Kripke (1980) has demonstrated, identity statements in which the identity sign is flanked by rigid designators (terms that have the same reference in any world in which they refer) are either necessarily true or necessarily false, even if only *a posteriori*. 'Pain' is a rigid designator; it is the name of a certain kind of sensation. Statements asserting that pain is identical with a certain type of functional state or ones asserting that pain is identical with a certain type of neurobiological state will be necessarily true, if true at all. Given the necessity of identity, if pain is identical with either a type of functional state or a type of macrophysical state, then facts about the pattern of realization of the functional state or macrophysical state in question will imply facts about the pattern of realization of pain. Thus if, for instance, pain = neurobiological state *N*, then facts about the worldwide distribution of *N*-states will entail facts about the worldwide distribution of pain (and conversely). According to type materialists, the entailments will be only *a posteriori*. Scientific functionalists make an analogous claim of *a posteriori* entailment.

Some philosophers argue that physicalism must be committed to the *a priori* entailment of all the facts (save indexical ones such as, e.g., I = Brian McLaughlin) from the totality of physical facts and the assumption of physicalism, on pain of being committed to an unacceptable view of necessity and/or an unacceptable view of conceptual reference (Chalmers 1996, Jackson 1998). Also, some of these philosophers argue that since facts about sensory consciousness will not be *a priori* entailed by the

totality of physical facts and the assumption of physicalism, physicalism is false. Scientific functionalists and type materialists agree that facts about sensory consciousness are not so *a priori* entailed, but they reject the claim that the entailments must be *a priori*. They argue that while sensory concepts are not *a priori* linked to physical or functional concepts, and so do not admit of *a priori* functional analyses of any sort, sensory concepts nonetheless apply solely in virtue of the physical or functional properties to which they refer. Suffice it to note that this dispute turns on unresolved issues about the nature of necessity and the nature of conceptual reference.

B. P. McLaughlin

Piaget, Jean (1896–1980)

A most productive scholar in the area of children's intellectual development, Jean Piaget was primarily interested in epistemology or theory of knowledge. His genetic psychology (psychology of the genesis of thought) was intended to provide a scientific basis for epistemology, with the main concern to explain how knowledge can become more rigorous and more objective. Piaget's psychological explanations were inspired by several scientific disciplines and beside his studies in psychology and epistemology he published in other fields such as biology, logic, and sociology. His work derived from evolutionist approaches rooted in the nineteenth century yet it is still in line with scientific trends at the end of the twentieth century.

The core of Piaget's theory is the conception of mind as an active system which, like an organism,

assimilates external data into its structures and can adjust to these data. Special emphasis, in the knowledge process, is placed on the subject's activity and the structures through which he or she perceives and understands things. Thus, the development of knowledge is viewed as the construction of new structures (rather than the accumulation of new information) triggered and guided by internal processes during the subject's encounter with reality. Each new stage in this process opens up new possibilities. In this interactionist conception, structures are neither predetermined nor found in the environment and there are striking similarities between biological evolution, cognitive development in children, and the development of scientific thought.

1. Seven Decades of Scientific Productivity

1.1 Childhood and Adolescence (1896–1918)

Jean Piaget was born in Neuchâtel, a small city of Switzerland, on August 9, 1896. He was the son of an historian and professor of medieval literature at the university. Of his mother, he wrote in his autobiography that she was an intelligent and energetic woman, whose psychological imbalance created problems in the family. At the age of 11 years, Jean Piaget started classifying and collecting mollusks with the help of the director of the natural history museum of his hometown. In his teens, he was already an acknowledged specialist in the field and started publishing papers in scientific journals (as of 1911). This activity led him to decide to study natural sciences at the university between 1915 and 1918. At the same time, as of the age of 16 he became passionately interested in philosophy, and particularly in the theory of knowledge or epistemology. He soon decided to devote his life to the elaboration of a biological theory of knowledge, whose goal would be to explain the evolution of ideas both in individuals and in the scientific community. This project was influenced by evolutionary approaches in the field of biology (Lamarck, Darwin) and in philosophical works on issues of intelligence (Spencer, Le Dantec, Bergson). In the following years, Piaget's professor of philosophy A. Reymond convinced him of the importance of a rationalist approach making use of logic and mathematics.

In 1918 Piaget published a philosophical and autobiographical novel (*Recherche*) describing the crisis he had gone through because of the conflict he felt between religion and science, or, in other words, between value and rationality. Eventually, the search for truth, which is the goal of science, became the most important value for Piaget. *Recherche* also contained the outline of a theory of the evolution of living and cognitive organizations based on the idea of improving

forms of equilibrium between the whole and its parts. Piaget's twofold interest on the one hand in biology and the associated problems of the organization and evolution of living beings, and on the other hand in epistemology and related issues concerning the validity of knowledge and its development, forms the basis of all his work.

1.2 Complementary Studies (1918–1921)

Piaget was convinced that a theory of knowledge should be validated by psychological research, and decided to get training in scientific psychology as soon as he graduated from university with his Ph.D. thesis on mollusks in 1918. He then spent a term in Zurich, attending courses in psychopathology—where he encountered psychoanalysis—and in experimental psychology. He then studied in Paris from 1919 to 1921, where he attended lectures in psychology (specifically by Janet), philosophy (with Lalande), and history of science (by Brunschvicg who had great influence on Piaget's ideas). Courses in psychopathology provided him with a clinical interview method, which he soon used in his discussions with children. In effect, in parallel with his studies, he worked in the laboratory of Binet and Simon, standardizing intelligence tests for children. Piaget was fascinated by the reasoning of the children who did not yet answer 'correctly,' and he discovered that the study of children's thinking could be a means to validate a theory of knowledge. This program, which was to be the main focus of his work for 60 years, was very similar to the program designed by James Mark Baldwin (1861–1934), from whom Piaget borrowed several concepts and the expression 'genetic psychology.'

1.3 The Early Psychological Research (1921–1929)

In 1921, Claparède offered a position in his Institute for educational sciences (known as the Jean-Jacques Rousseau Institute) in Geneva to Piaget, who was to conduct most of his professional life in this institution. What he found there were stimulating intellectual atmosphere and students willing to assist him in his work. Together with them the young researcher started a series of studies of children's reasoning and soon published his first books: *The Language and Thought of the Child* (1923); *Judgment and Reasoning* (1924); *The Child's Conception of the World* (1926); *The Child's Conception of Physical Causality* (1927) (the titles given here and in the remainder of this text are the English translations of the French originals; the years are those of the original publications). The striking facts he discovered about the use of language, the non-differentiation of concepts and the explanations of physical phenomena in children, as well as the detailed

analyses and the synthetic categorization of these behaviors, brought Piaget almost immediate international fame. These studies showed that young children's thinking is structurally and functionally different from that of older children and adults. Young children lack a true logic of classes and relations, they have difficulties viewing reality from an objective viewpoint, and they lack moral norms, which command compliance on the basis of a feeling of necessity. Children's thinking tends to be egocentric, that is, they have difficulties in looking at things in perspective. In these early works, the passage from egocentric thought to a logical and more objective form of thinking was explained by a social factor: cooperation, or exchange between individuals who consider themselves as equals.

During this period, Piaget was involved in many activities beside his research. He taught child psychology at the J.-J. Rousseau Institute, philosophy and history of science at the University of Neuchâtel (1925–1929), was for a few months psychoanalyzed by Sabina Spielrein, a pupil of Freud, and continued to study the evolution of mollusks. In 1923 he married a student at the Geneva Institute. Piaget and his wife Valentine spent much time minutely observing their three children who were born between 1925 and 1931. These observations were the basis of several books published in the following years.

1.4 Administrative Responsibilities, Professorship and New Directions of Research (the 1930s)

In 1929, Piaget was appointed professor of history of science at the University of Geneva, where he subsequently became professor of sociology (1939) and of experimental psychology (after the death of Claparède, 1940). He also played an important administrative role at the J.-J. Rousseau Institute as associate director (1929), then as co-director (since 1932), reorganizing the Institute and establishing links between the Institute and the University. At the same time, and until the 1960s, he was director of the *Bureau International de l'éducation* and managed to convince the governments of many countries to join that organization.

Piaget's most important activities continued to be research and writing. During these years, he accumulated data on children's reasoning. However, apart from his book on moral judgment (1932)—simultaneously in French and in English—which was the sequel to the psychology books published in the 1920s, his major publications dealt with infant cognitive development. The choice of this topic stemmed from Piaget's conviction that logic has its roots in actions and also from his deep interest in the issue of the origins of knowledge. *The Origins of Intelligence* (1936) and *The Child's Construction of Reality* (1937) con-

tained extremely original observations and explanations of infant behaviors, and departed radically from Piaget's earlier writings as far as the explanatory model was concerned. Piaget discovered behaviors that had previously been overlooked, for example, the failure of babies younger than 9 months of age to look for an object hidden in front of them. Replications of these observations and experiments many years later around the world have confirmed these findings that had resulted from the observation of his three children.

In view of theory building, Piaget analyzed the elements of knowledge, the 'schemes' of actions, which become more differentiated and coordinated as development progresses. They evolve into increasingly complex and better-adapted forms of behavior, from automatic 'reflexes' to intelligent activities. This development is a special case of the relationship between the organism and the environment, in other words of biological adaptation. It results from the interaction between the subject of knowledge, who assimilates reality to his or her structures, and the object of knowledge, which may elicit an accommodation of these structures. Cognitive development is viewed as an evolving equilibrium between assimilation and accommodation. In *The Child's Construction of Reality* (1937), Piaget studied the growth of the practical knowledge of object permanence, space, time, and causality in infants. He introduced a new and abstract explanatory notion: the mathematical concept of 'group,' which several authors in the social sciences considered as an interesting model at the time. Piaget applied it to the organization of spatial knowledge in infants and was convinced that it could be used to explain the logic of school-age children. To this end, from 1937 onwards, he worked for three years on this model, expressing it in algebraic formulae.

Although Piaget was now a famous author who had received an honorary degree from Harvard University in 1936, his two books on infant cognition were not translated in English until the 1950s. They contained too many abstract considerations and microanalyses and were definitely ahead of their time. A third book, also based on the observation of Piaget's own children, was written during this period and published later: *Play, Dream and Imitation* (1945). It dealt with imitation in infants and the origins of symbolic thought in young children. Intellectual activity as well as play and imitation were defined in terms of equilibrium or disequilibrium between assimilation and accommodation.

1.5 The Mature Years: The Advent of Structural Analysis (1940s)

During this and the following period, Jean Piaget was prodigiously productive, thanks to a strict and very

regular work regime. In the mornings he would teach, discuss research with his large team of co-workers, and perform his administrative duties. Piaget would then spend the rest of the day mostly by himself. In the early afternoon, while thinking about the topics of his current writing, he would stroll or ride a bicycle in the countryside near Geneva. During the rest of the afternoon he would write, which was the best way for him to elaborate his ideas. Even when traveling or attending conferences he would not let a day go by without writing a few pages. Although he loved classical music he almost never went out in the evenings to movies, theaters or concerts. Both in summer and in winter, his love of nature led him to repeated sojourns in the mountains of the Valais, where he both hiked and worked.

The logical model of ‘grouping’ of mental operations, which he had recently developed, and which accounted for the organization of inferences in overall structures, inspired much research and writing. It permitted Piaget not only to describe the limitations of young children’s reasoning as he had done in his first books, but also to explain the sudden, stable, and rather generalized intellectual progress due to the advent of the elementary logic, of ‘concrete operations’. Between 1941 and 1948, his work resulted in six books: *The Child’s Construction of Quantities* (with B. Inhelder, 1941), *The Child’s Conception of Number* (with A. Szeminska, 1941), *The Child’s Conception of Time* (1946), *The Child’s Conception of Movement and Speed* (1946), *The Child’s Conception of Geometry* (with B. Inhelder and A. Szeminska, 1948), *The Child’s Conception of Space* (with B. Inhelder, 1948). These books study the elementary mastery of basic scientific concepts. This mastery, which usually emerges between the ages of 6 and 8 or 9 years, was explained in terms of the underlying ‘grouping’ structures that organize mental operations. This type of structure entails the reversibility of thinking, for Piaget an essential feature of natural logic. In contrast, younger children think that the number of a set of objects or the quantity of a substance change when spatial transformations occur, and that the duration of a movement corresponds to the distance covered, without taking into account the relative speed of the moving objects. These young children have difficulties comparing the number of elements in a subclass with the number in the superordinate class. As to space, geometrical capacities like inverting a spatial order, constructing a straight line with vertical sticks using a sighting method, and drawing the horizontal line of the water level in a tilted glass also usually emerge after the age of 7 years. The basic concept studied in each book was analyzed and defined in the light of children’s answers. For example, number was analyzed in terms of a synthesis between logical classification (class inclusion) and the seriation of asymmetrical relations (ordering by increasing or decreasing size); time was defined as the coordination of movements,

in which the ability to consider speed played a fundamental role, and so forth.

Piaget also published a *Treaty of Logic* (1949) and with his co-workers he studied perception in children in the laboratory of experimental psychology. These studies, which attracted Piaget’s attention to the phenomenon of regulation, were to provide the subject matter of a much later book. The same holds true for the papers in sociology which were published during this decade and collected in a book called *Sociological Studies* in 1965.

The second World War rendered contact with foreign colleagues difficult, but Piaget was invited in 1942 to give a series of lectures in Paris at the ‘*Collège de France*’ (published in *The Psychology of Intelligence*, 1946). The abstract nature of his explanations struck many listeners as much as the brilliant analyses inspired by various scientific disciplines. After the war, UNESCO entrusted Piaget with several missions.

1.6 Achieving the Ultimate Goal of his Work: The Elaboration of a Genetic Epistemology (1950s)

In the 1950s, while continuing his work in genetic psychology with the help of his co-workers, Piaget devoted much of his effort to the foundation of a genetic epistemology, i.e., the study of the basic concepts and processes of the development of scientific knowledge. This used to be a topic of philosophical study but now became an object of scientific analysis. Actually, Piaget had indeed pursued epistemological issues throughout his entire previous work while ostentatiously focusing on the explanation of children’s thinking. Now he wished to discuss questions of knowledge *per se* as they were raised in the sciences (but continued to use the study of children’s cognitive development for this purpose). In 1950, Piaget published three volumes of an *Introduction to Genetic Epistemology*. The book begins with a general introduction defining genetic epistemology and its method and stating the main issues. Piaget develops an idea he had already expressed in earlier writings, that of a ‘circle of sciences’: physical reality is explained by mathematics, mathematics is the product of mind, which is a result of biological evolution, and organisms are closely connected with physical reality. The book deals in great detail with the epistemology of mathematics and physics, and in lesser detail with the epistemology of biology and the social sciences.

To make progress in the domain of genetic epistemology, Piaget founded the International Center for Genetic Epistemology, which was a working group comprising researchers in psychology and scientists from various disciplines (mathematics, physics, logic, etc.). The Center was launched in 1955 after obtaining, with difficulty, the necessary funding. A new series of books, which contained the results of the studies

conducted at the Center for genetic epistemology, appeared from 1957 onwards. About 40 volumes were published in the series until the death of Piaget in 1980.

During the 1950s, when Piaget held a position as professor at the University of Paris (1952–1963), his psychological research in Geneva continued to progress and resulted in three books with B. Inhelder: *The Development of Elementary Logical Structures* (1959), a sequel to the studies of concrete operations; *The Origin of the Idea of Chance* (1951) and *The Growth of Logical Thinking from Childhood to Adolescence* (1955). The latter book provided a new description and definition of the highest stage of logical development: the formal operational stage achieved between the ages of 12 and 15 years. The formal model of the INRC group, derived from Klein's mathematical group, provided an account of the new possibilities of reasoning which were available to adolescents. It involved a greater number of combinations of operations than the grouping structures (in particular a 'double reversibility' of thought). Moreover, the experiments by Inhelder showed how the understanding of physical phenomena developed in children and how, through the use of an adequate interview procedure, adolescents could rediscover fundamental scientific laws on their own.

1.7 The Last Two Decades (1960 To 1980): The Pinnacle of Fame

Only in the late 1950s was Piaget's work rediscovered by English and American psychologists, although he already had been a most respected professor and researcher in the French-speaking countries, and a well-known author in many other countries. During the following two decades he was among the most cited psychologists and best known scientists in the world. Most of his books were translated from French into foreign languages (a total of 24 different languages). From the end of the 1950s onwards, he received an increasing number of honorary degrees each year. When he died, he had received over 30 honorary degrees and several prestigious awards. However, these honors and the travels they involved did not prevent Piaget from continuing his work.

Until the beginning of the 1970s, studies of genetic epistemology mainly focused on problems related to logic, language, space, time, and causality. The latter topic—strangely neglected for several decades—proved difficult to study and remained on the program of the Center for Genetic Epistemology for several years in succession. On the whole, these books, while discussing issues specific to each science (e.g., the relative importance of time and speed in judgments about duration, or the possibility of geometrical intuition) validated the constructivist conception of Piaget's epistemology. Effective forms of knowledge are neither innate nor drawn from the observation of

the environment. They derive from the interaction of active individuals with their environment. A consequence of this position (summarized in the short book *Genetic Epistemology*, 1970) is that the rate of intellectual development can be only moderately accelerated by education. The goal of education, according to the few texts devoted by Piaget to this topic (for example a long article in 1965) is to favor children's intellectual activity and their discovery of relationships and abstract concepts.

During the 1960s Piaget returned to his earliest field of interest: biology. He published a paper on the evolution of mollusks and about the reproduction of the 'sedum' plants, which he grew in his garden and observed carefully. In his book *Biology and Knowledge* (1967) he developed his ideas on biology and the parallel between biological and cognitive development. Simultaneously, he published three books on psychology. They dealt with the 'figurative' aspects of knowledge, whose function is to provide a kind of copy of things: *The Mechanisms of Perception* (1961), *The Child's Mental Imagery* (1966), and *Memory and Intelligence* (1968). These books showed that figurative aspects are progressively subordinated to the subject's operations: some optical illusions decrease with perceptual activity, and with the advent of logical thinking (concrete operations), mental images can adequately represent transformations, while memory of organized material improves. Intelligence is not captured by representation, i.e., a system of images or linguistic symbols; rather intelligence consists in operating on elements of reality or symbols and thus transforming them.

In the 1970s, after Piaget's retirement as professor at the University of Geneva (1971), he continued his work with a large team of researchers at the Center for Genetic Epistemology. Most of his publications dealt with processes of cognitive development. For over 20 years, his main aim had been to demonstrate that efficient forms of knowledge result from structures that organize mental operations, and that these structures, which become increasingly complex over time, are rooted in biological organization. The time had come to deal with the processes involved in the construction of these structures, a topic that Piaget had neglected since the 1930s, except for a few epistemological papers written in the 1950s. During the last decade of his life, between the ages of 75 and 84 years, Piaget developed concepts that had been introduced earlier but needed fuller consideration and a precise definition: equilibration, reflexive abstraction, generalization, the opening up of new possibilities, and so on. These concepts are highly interesting and very original ideas, difficult to operationalize, but with deep and general explanatory value. Unfortunately, Piaget was so eager to continue his work that he changed the focus of his research and his writing nearly every year, although these complex concepts would deserve more sustained treatment.

Reflexive abstraction is the process through which something new is abstracted from experience. What is abstracted is not a property of the external world, but derives from the organization of the subject's actions or operations. Equilibration is a self-regulation process, which is specific to living organizations. At the cognitive level, it is a reaction to an intellectual perturbation (such as a contradiction) which regulates the cognitive system and, in an attempt to compensate the perturbation, creates improved forms of knowledge. For his eightieth birthday in 1976, a kind of dissertation defense was organized: Piaget defended the theses developed in *The Equilibration of Cognitive Structures* (1975) before a 'jury' composed of famous scientists who represented different disciplines. In this last period, Piaget's work also dealt with the grasp of consciousness, contradiction, and dialectics. He explored the relevance to the explanation of cognition of the mathematical concept of morphism and of the idea of logic of meaning. The last work was conducted in collaboration with R. Garcia who was also co-author of *Psychogenesis and History of Science* (published posthumously in 1983). Piaget also dealt with problems of biology. His post-Lamarckian ideas attributed some importance to aspects of experience in the evolution of species (for example in *Behavior, a Motor of Evolution*, 1976).

1.8 Factors of Scientific Creativity

Piaget died on September 16, 1980, leaving behind a life's work of unusual scope, in terms of depth, originality, interdisciplinary relevance, and volume. The explanation of his exceptional scientific productivity is not only the conjunction of a brilliant mind with a great capacity for work, but also the stimulation of reflection by the results of constantly renewed research. It was also due to Piaget's sociability, which enabled him to easily convince others to work with him; and to a strong sense of a mission to which everything else was subordinate. According to Piaget, having a theory to contradict was a powerful stimulus. The dominant empiricist conceptions in psychology—neo-associationism—and logical positivism in philosophy played this role well into the 1960s. Since the mid-1960s, Piaget was busy developing arguments against the relatively widespread idea, prevalent since Chomsky published his work, that important aspects of knowledge are innate.

2. The Importance of Piaget's Work for the Social Sciences

Piaget's theory is exceptionally comprehensive, as it gives a detailed account of cognition from birth to adolescence, and also deals with scientific knowledge

in adults. It contains an incredible wealth of experimental data covering these periods in life, especially the age range from 5 to 9 years. It deals with fundamental problems often ignored in other psychological theories, such as the relationship between biological activity and cognition, the relative role of the subject and the environment, and the connections between different aspects of cognition such as perception, reasoning, and memory. In some respects Piaget's work was ahead of its time and it could therefore easily establish connections with emerging disciplines such as cybernetics (since the mid-1940s) and, later, artificial intelligence. The concepts of self-regulated systems and of feedback specific to cybernetics were involved, less explicitly, in the Piagetian ideas of reversible structures (present in his work at least since 1937) and of the regulation of cognitive activities (frequently referred to by him in the early 1940s). The artificial intelligence programs which expressed in symbolic language the expertise involved in the mastery of a task bear some resemblance to the Piagetian concept of repeatable action schemes and recall Piaget's attempts to formalize mental structures. Moreover, the multidisciplinary approach known as cognitive science, which emerged in the 1980s, is completely in line with Piaget's approach, with its links between biology, psychology, logic, and physics.

One aspect of Piaget's work, genetic epistemology, which is focused on scientific knowledge as investigated through studies of children, has had little impact outside of Geneva. By contrast, Piaget's psychological work has definitely influenced subsequent orientations and research in the social sciences.

Since the 1920s, Piaget's findings about the reasoning of children had considerable influence on child psychology. The influence was strong in the 1960s and 1970s, in particular regarding the four successive stages of cognitive development, (sensorimotor, pre-operational, concrete operational, and formal operational). In fact, Piaget's idea was not to define general stages of child development, but necessary steps in the integration of new forms of knowledge. His detailed findings concerning the emergence of new capacities, such as the search for hidden objects in babies, conservation of quantity in school-age children, and combinatory operations in adolescents remain useful landmarks of psychological development although they cannot be used as psychometric tests. During the same two decades, various experiments in education were directly inspired by aspects of the theory, namely the role of the child's activity and the importance attributed to general structuring abilities rather than specific learning. However, mainstream psychology and education, especially in English-speaking countries, often remained impervious to Piaget's influence, except for the growth of cognitive developmental psychology.

Cognitive developmental psychology became a productive subdiscipline of psychology, especially since

the beginning of the 1970s. Practically every developmental psychologist in the world at that time had at least some knowledge of Piaget's work and the very idea of studying cognitive development using a cross-sectional method was inspired by the work previously undertaken in Geneva. Piaget's writing often played the same role of a 'theory to contradict' that associationism or nativist conceptions had played for Piaget. Many authors in developmental psychology launched their careers by conducting experiments that were designed to prove Piaget wrong. Because his constructivist conceptions grant a limited role to social influence, and in particular to education, they were unacceptable to many. Much research has been performed especially in the USA to show that cognitive competencies existed in children well before the ages indicated by Piaget. In order to demonstrate this, the problems presented to the children were modified and compared to those presented by Piaget himself. The race for early competencies in the 1980s and 1990s gave rise to the idea that many cognitive capacities were innate. In the end, Piaget's conceptions were not followed, but thanks to his work a whole field of psychology developed.

Piaget's work paved the way for the cognitivist revolution in psychology, from the mid-1960s onwards. Psychologists had become interested in mental states, a taboo for many decades due to the predominant behaviorist conception. The new generation of psychologists could read in Piaget's work detailed studies of mental states that had been conducted over a period of several decades.

At the end of the twentieth century, Piaget's theory had indirect descendants in the fields of child psychology, cognitive science, and developmental psychology. Ideas of specialists in educational science are more directly inspired by Piaget's work, especially in French-speaking countries and in Latin America. Studies in moral development also derive directly from Piaget's research in this field. More generally, constructivist approaches which attribute importance to the activity of the subject, in applied psychology as well as in other disciplines, usually refer, albeit vaguely at times, to the work of the Swiss psychologist and epistemologist.

Piaget's Theory of Child Development

Jean Piaget's (1896–1980) theory counts as one of the most influential and enduring theories of cognitive development, and is firmly grounded in biology and epistemology. Although the focus of this entry is on the child developmental aspect of his work, it is therefore important to review some of the key epistemological concepts that Piaget adopted. Unsolved issues as well as present and future developments of Piaget's theory are also briefly reviewed.

1. The Epistemology of Piaget

Piaget, who trained as a biologist, had as a primary objective to understand the development of knowledge in the human species, rather than to understand why and how children develop. His first originality was to address philosophical questions (such as the origin or the development of knowledge) by empirical means, in particular by relying on the study of child development (supposed to be, at the beginning of his career, a mere 'detour' of some years). He established the discipline of *genetic epistemology* (the term 'genetic' referring to the concept of genesis or evolution, as proposed by Baldwin), with the aim 'to study the roots of the various sorts of knowledge from their most elementary forms on and to follow their development in ulterior levels including scientific thinking,' and by grounding it in both historico-critical and psychogenetic approaches. Piaget's epistemology is constructivist, in the sense that knowledge is neither a mere reflection of the external world (realism), nor a projection of pre-existing structures of the mind (nativism), and the origins of knowledge are to be found in the practical and cognitive activity of the subject. Piaget's epistemology is also fundamentally interdisciplinary.

His primary hypothesis was that intelligence is a form of biological adaptation (e.g., Piaget 1967), that is, intellectual or cognitive behaviors are the products of an organism, in interaction with its environment, and the end point of biological evolution. This is not to say that psychological phenomena can be reduced to biological ones, as Piaget always opposed biological reductionism; intelligence is an organizing activity whose functioning transcends biological organization, by elaborating new structures. The main characteristic common to knowledge and to living organisms is their adaptive character. *Adaptation* itself, whether biological or cognitive, relies on two mechanisms, defined very early in Piaget's work, namely *assimilation* (incorporation of new information into an existing system) and *accommodation* (modification of existing schemes or structures by newly assimilated elements, so as to respond to the demands of the environment). By so doing, actions and operations become coordinated with one another; such coordinations define a new entity, which in turn constitutes a new object for

thought and action. This is the process that Piaget labeled *equilibration*. Contrarily to frequent, but too simplistic interpretations, equilibration does not correspond to a stable (even if only temporary) state of equilibrium, but is the process of coordination in itself.

As a consequence of the functional continuity that Piaget postulated between biological and psychological entities, a given level of knowledge is always considered to result from a reorganization of the preceding one. Reconstruction means more than a mere addition of elements of a lower type in order to attain a higher level, but implies a total reorganization and a change in scale. One direct consequence of a constructivist perspective is that an epistemologist or a psychologist studying any level of development will ask what characterized the preceding level and will stress developmental progression towards higher levels. An essential mechanism for this reconstruction is *reflecting abstraction*, that is, a process by which the subject extracts characteristics or coordinations from actions or operations; it is called 'reflecting' both because it consists of a mental reorganization and because it implies a reflection or a transfer onto a higher level of what was established at a lower level. Reflecting abstraction is contrasted with empirical or simple abstraction, which bears mainly on observable characteristics of objects or classes of objects.

2. The Psychology of Jean Piaget

Piaget's psychology of intelligence is the most universally known part of his work, even though he himself did not consider it the main part (e.g., Piaget 1947, 1970, Piaget and Inhelder 1966). His theory transformed the field of developmental psychology by providing it with a new vision of the development of the child, to the extent that almost every developmental study has some connection with a question Piaget raised. Intelligence is defined as the most general form of coordination of the actions and operations that characterize the various developmental levels, and not as a mental faculty or an entity in itself; it develops through a succession of general stages, defined by overall structures ('*structures d'ensemble*'). Piaget was not interested in individual or task-specific performances, but in the generic behavior of subjects in classes of situations.

The successive stages or levels are general structures, which appear in a fixed order of succession, but are not necessarily tied to a given age, and which are such that a given structure n integrates, as a substructure, the preceding structure $n-1$. The number of stages defined in Piaget's publications varied from three to five. Most often, he referred to four stages: (i) the *sensorimotor stage* (approximately the first two years), itself consisting of six substages, or three periods, in which practical *schemes* develop, among which is the scheme of object permanence (operationalized by the

study of the search for hidden objects), one of the most studied domains in present day infancy research; (ii) the *preoperational stage* from approximately 2 to 6 years of age, also labeled representative (prerelational and intuitive, or prelogical) period, made possible by the emergence and the development of the *symbolic function*; (iii) the *concrete operational stage* (7 to 12 years) during which invariants (conservation), logical classes and relations, the concept of number, as well as different concepts of space develop, all of which are marked by reversibility; and (iv) the *formal operational stage*, during which adolescents develop hypothetico-deductive reasoning (i.e., beyond concrete objects and actions), and experimental schemata. Piaget used abstract algebra to formalize the underlying structures: a group of displacements for the sensorimotor stage, groupings for the concrete operational stage, and a group of four operations (INRC group) for the formal operational stage. He also attempted to formalize the pre-operational stage by means of the logic of functions. Other cognitive activities such as mental imagery, perception, memory, and language were always dealt with by Piaget in relation to the development of operational structures. They were termed 'figurative' because they attempt to represent reality as it appears. Figurative activities are contrasted with (and subordinated to) 'operative' activities which attempt to transform reality (e.g., Piaget and Inhelder 1966b).

Although Piaget grew less and less interested in the description of these general stages, this is probably the feature of his theory that has been most often retained and criticized. In particular, the generality of the stages was questioned by the existence of '*decalages*,' that is, temporal lags between acquisition of concepts supposed to pertain to the same level. Readers of Piaget have often overestimated the necessity of synchronism in acquisitions across situations as implied by the theory. It should be stressed that Piaget did not postulate that the generality of structures meant strict synchronism, even though some of his writings were admittedly ambiguous with respect to this issue (e.g., Chapman 1988).

3. Factors of Development

Piaget described four factors of development: (i) organic growth, and maturation of the nervous and endocrine systems; (ii) experience, which Piaget further decomposed into a factor of physical experience (actions exerted upon objects in order to extract their properties by simple abstraction) and a factor of logico-mathematical experience (extraction of knowledge by reflecting upon actions, whether effective or mental); (iii) social interactions and transmission; and (iv) equilibration. This last factor was undoubtedly the most important for Piaget; whereas he often paid little

more than lip-service to the first three factors, he spent considerable time in demonstrating the necessity of equilibration, which he considered to account for the 'vection' or direction of development (Piaget 1975). Majoring equilibration ('*équilibration majorante*') is seen as the causal mechanism underlying the progression of cognitive development. It is a dynamic sequence of states of disequilibrium–equilibrium and embodies the organism's strive toward a more general equilibrium. Equilibration is the only mechanism, according to Piaget, that can account for the emergence of novel behavior, even though more recent work has disputed the idea that Piaget's theory can really account for the emergence of novel behaviors. Cognitive structures are put into disequilibrium by perturbations which resist the assimilatory process and lead to errors or failures of action. Re-equilibration is made possible by regulations, which entail the modification of an action as a function of feedback regarding its previous outcomes, ultimately leading to compensatory reconstructions. Equilibration is thus necessary when contradictions and cognitive conflicts arise, hence the importance given by Piaget to cognitive conflict as a source of cognitive development.

4. Unsolved Issues in the Piagetian Theory

Piagetian theory has been subjected to numerous criticisms (probably proportional to his production) on the part of developmental psychologists, only some of which are summarized here; most critics addressed, however, only isolated elements of the theory or failed to take into account the fact that Piaget's project was essentially epistemological. First, numerous decalages, which could not be predicted by the theory, have been observed between concepts supposed to belong to the same structural level; between-task correlations are relatively low, implying that all tasks do not measure the same construct. This led a number of researchers to claim that development is domain specific. Moreover, the concept of overall logico-mathematical structure proved very difficult to operationalize. Second, Piaget's portrait of the child appeared too universal and focused on the subject, independently of his/her cultural environment. Third, the theory placed too much emphasis on the development of logico-mathematical thinking, as contrasted with other forms of thinking. Fourth, Piagetian theory did not provide sufficient information on learning mechanisms and on the effects of training. Consistent with his epistemological project, Piaget was indeed interested in demonstrating the commonalities, in terms of general mechanisms, between learning and development rather than in focusing on the specificities of learning. Linked to this is the difficulty for the Piagetian theory to account for the appearance of novel behaviors. Finally, like many other, general psychological

theories, Piaget did not take into consideration individual differences; however, it has been shown that the variability in performance, whether intra- or inter-individual, is much larger than could at first be suspected and constitutes a fundamental phenomenon rather than mere noise.

5. *The Heritage of Piaget*

Despite the criticisms addressed to the theory, Piaget's theory leaves an enormous heritage, some of which is no longer even acknowledged, because it has been incorporated into developmental psychology, almost as truisms. First, the constructivist view of development that Piaget defended is presently widely held by cognitive developmentalists, as well as by educational and cognitive psychologists. Likewise, the concepts of assimilation and accommodation, even though probably too general, are adopted by a large number of theoreticians. The view of children as active thinkers has also been generally adopted. Second, although there was a period in the 1960s and 1970s during which a large number of developmental researchers argued for domain specificity in development and against the existence of general stages, there is a growing consensus that the characterization of human cognitive development needs something more general than a long list of specific concepts, even if less general than the cognitive structures defined by Piaget. In any case, most developmentalists see the need for structural analyses that transcend any particular cognitive task. Similarly, the concept of scheme (defined as an invariant abstracted across several actions, to which new actions or objects can be assimilated and which allows for generalizations) has been retained and is close to other concepts such as schemas or scripts proposed in cognitive psychology. Third, although the construct of equilibration has been criticized for being too fuzzy, similar conceptualizations are now being proposed, whether by dynamic systems theoreticians, or by neo-Piagetians.

Last, but not least, Piaget contributed enormously to the research methods used in developmental psychology, even though he was criticized for not using a standard, quantifiable methodology. He pioneered the use of a clinical method (later to be called critical method), in which the researcher probes for the child's understanding through repeated questioning. Piaget insisted that the child's incorrect responses reflect a complex, underlying cognitive system, and should not be merely recorded as failures. Also, Piaget's work was and still is a source of very ingenious empirical techniques, in many different fields; Piagetian measures such as conservation, class inclusion, spatial representation, perspective taking, object permanence, moral judgment, transitive inference, and many others, have each produced countless studies by researchers around the world. Most of these tasks

were very productive, because they produced data that were both counterintuitive and generative of hypotheses about the way children think.

6. *Beyond Piaget's Theory*

As mentioned in the previous section, the Piagetian theory is still very active, not only in developmental psychology, but in neighboring fields too; many researchers around the world continue working with Piagetian tasks, even if they do not always acknowledge it, or even know it. Also from an empirical perspective, a flourishing new direction, which is very much in the spirit of Piaget's theory, is that of the 'theory of mind.' From a theoretical point of view, the core part of the theory has been retained while giving rise to new developments, as should be the case with any sound theory. Only some concepts were really abandoned, the best example of which is the logicization of overall structures. Without pretending to be exhaustive, two directions, at present, appear to be very close to Piaget's proposals, and promising for the future, namely the neo-Piagetian models, and the application of dynamic systems modeling to developmental psychology.

The objective of the *neo-Piagetian* models, initiated by Pascual-Leone and exemplified by scholars such as Robbie Case, Kurt Fischer, Graeme Halford, and Robert Siegler (e.g., Case 1992, Case and Edelstein 1993, Pascual-Leone 1987) was to provide a response to some of the questions left open in Piagetian theory, while preserving most of its core postulates. These models have in common the search for isomorphisms or invariants across different classes of situations. As a consequence, they have maintained or rehabilitated (after the emphasis on domain specificity mentioned above) the notion of general stage; however, the structuralist features are quite different from those postulated by Piaget. First, the hypothesis of a unique, general, logical structure underlying the organization of all behaviors at a given moment of development was abandoned, and replaced by more local ones, thereby granting more importance to context. Second, isomorphisms across domains are considered to result from common constraints or 'strictures' rather than from a common structure: general limits in processing resources or attentional capacity impose a ceiling on cognitive performances while allowing for situational and individual variability. Third, the importance given to context has as corollary a much stronger emphasis on task analysis, that is, on an analysis of the characteristics of external situations together with an analysis of the strategies that children adopt when confronted with these situations and of the processing load that these strategies entail. The challenge now is to understand under which conditions characteristic forms of reasoning are most likely to emerge, and why they do not despite the presence of sufficient general

resources. Fourth, some neo-Piagetians also assign a more fundamental status to individual differences; consequently, they claim that there may exist different developmental paths for different types of subjects. This implies that development is no longer led by a single, dominant general mechanism such as equilibration, but that several general mechanisms may interact to produce development, leading to a postulate of multidimensionality and multidirectionality in development (Reuchlin et al. 1990; Rieben et al. 1990). Such a postulate has long been adopted by lifespan developmentalists (e.g., Baltes et al. 1998), but took longer to be envisioned by child developmentalists.

A new, promising way of theorization is provided by nonlinear dynamic systems theories. Such models can be used to detect, and then model, developmental transitions, that is, changes from one stable mode to another one. The emphasis is on self-organization, which can be linked to Piaget's concept of equilibration. Although some scholars have begun to use nonlinear dynamics to build specific models of processes of development, particularly in the field of motor development or in conservation tasks (e.g., Thelen and Smith 1994, Van Geert 1994), these are only the preliminaries, and are still to be taken as metaphors; moreover, they require heavy methodological designs. Nevertheless, such attempts, which may help uncover discontinuities, i.e. stages, under what appears to be continuous change, could help bring explicit modeling into developmental psychology.

Piaget's Theory of Human Development and Education

1. Introduction

The life and work of Jean Piaget are one: his work was his life and his life inspired his work (Vonèche 2001). His theory of genetic epistemology (or experimental developmental theory of knowledge and knowledge acquisition) resulted in an immense *œuvre* of several thousand pages. All stemmed out of the encounter of his philosophical preoccupations as an adolescent about the validity of knowledge (scientific and religious essentially) when compared with his experience as a young natural historian.

As an amateur philosopher, in his teens, he had some deep religious preoccupations and wanted to reconcile science and faith into one unique form of knowledge. Religious knowledge was, in his mind, essentially subjective and emotional, whereas scientific

knowledge was objective and strictly cognitive. The obvious solution for the young Piaget was double. On the one hand, 'science cannot prescribe its premisses to value judgment ... [they] are given in immediate awareness and are undemonstrable' (Piaget 1915, p. 80). On the other hand, thinking is the essence of human existence in a very Cartesian (*cogito ergo sum*) way and in opposition both to, Kant's *a priori*ism on the one hand, and to, on the other hand, Brunschvig's idea of a radically contingent spiritual development over time in the history of human thought. Therefore, the solution of the problem of the origin and value of knowledge lies in a sort of experimental study of its evolution and metamorphoses over that special sort of time called ontogenesis. He considered this study as a sort of embryology of knowledge yielding the same results as biological embryology for the succession of living organisms and their hierarchical order. The stages of knowledge are equivalent to the biological scale of organisms.

2. Basic Theoretical Assumptions

Thus, knowledge is biological adaptation continued by different means. Whereas biological adaptation is made possible by specific organs performing specific functions and by specific species occupying specific ecological niches—thus essentially a mechanism of differentiation and speciation—things are quite different in the case of knowledge. In intelligent adaptation there is an ever increasing separation of form and content and cognitive processes exploit the organism as a whole and no longer specific parts of it.

What remains similar in biological and cognitive adaptation is the double process of assimilation and accommodation. Biological equilibrium is assured by metabolism, cognitive equilibrium by self-regulation. Cognitive self-regulation takes three different forms: rhythms, self-regulations, and mental operations. These three structures go from the simplest to the more complex and from the most external interface between organism and milieu to the most internal.

If rhythm is self-explanatory, the two forms of self-regulations: homeostasis and homeorhesis, are not. Homeostasis is the process by which any variation in one direction from the point of equilibrium is counter-balanced by a movement in the opposite direction. These movements existed in rhythm, but were successive. Now, they are simultaneous in homeostasis and form the components of a system. They limit each other by a reciprocal process of alternances. It is simply and purely a feed-back mechanism.

Homeostasis assures the stability of a given system or organism by keeping it in a stationary state in spite of perturbations. Homeorhesis is the same for evolutionary systems: instead of keeping the system stationary, it keeps the direction of evolution going, in spite of perturbations, on its path. It is a feed-forward

mechanism. What is common thus to regulations and rhythms is the central role of action. Every action in one direction is compensated by an action in the opposite direction, either successively or simultaneously.

An operation, for Piaget, is nothing more than an internalized action. For instance, an arithmetic operation is the action of reuniting two units: $2 + 2 = 4$. But an operation is a very remarkable action, because it is strictly reversible. Rhythmic actions are not reversible, they always take place in the oriented arrow of time. Regulations do not compensate each other totally; they always function by excess or default. They are not strictly additive and totally reversible. Operations are perfectly reversible: $4 - 2 = 2$ exactly. Such a perfection is mental, never physical.

The smart thing with Piaget's theory is that the same basic process covers the full range of adaptation from the simple metabolic assimilation of food to the most refined, abstract logico-mathematical operation. The process of transformation of rhythm into regulation and of regulation into operation is double: internalization, on the one hand, and reflexive abstraction, on the other.

But, if one thinks it over, internalization is a reflexive process and thus reflexive abstraction is enough. It is a reflection of a form on a higher level.

3. Cognitive Development

The process of knowledge is the same in the child and in the species. It goes, in both, from a state of dualism between the subject and the object to successive stages of differentiation and integration. The newborn baby does not distinguish self from world at first. Then the distinction is made by the baby only in the course of action. Piaget calls this period sensory-motor.

Its main features are the recognition that objects continue to exist when out of sight because they are part of a larger container called space, that they appear in time and present some relationship of causality, as far as reality is concerned, and that means and ends can be coordinated and differentiated, as far as intelligence is concerned. By reflexive abstraction, on its external immediate action, another level of equilibrium is reached by the growing child with the emergence of the semiotic function (language, symbolic play, imitation, representational drawing, dream). This new way of functioning makes present what is absent in reality. It paves the way for concepts, classes, relations, and number that will be attained in the next stage called concrete operational in which representational self-regulations become fully equilibrated into mental operations. In turn, concrete operations will be transformed into formal ones that are independent from their material support by means of a progressive dissociation between form and content until it is total and forms a complete logical system.

Thus the young adolescent is, by now, capable of hypothetico-deductive reasoning, of examining all the possibilities as well as the internal necessity and coherence of every single thought.

4. Piaget's Constructivism

The data collected by Piaget and the School of Geneva are world-famous. They have been criticized on many grounds, but always from a reductionist epistemological point of view, either nativism or environmentalism, whereas Piaget was constructivist. This constructivist perspective has been constantly misunderstood. It should be clear that such a structure as an operation with its internal logical necessity does not correspond either to a physiological apparatus or to a societal given. No mother, no teacher teaches a baby object permanence. Nevertheless all toddlers attain this concept-in-action. Conservation of matter, weight or volume is not taught in any school or home and nobody remembers having discovered it one morning. Nevertheless, it is reached without critical period. Nor drill.

Constructivism does not deny reality, contingency or stability of scientific knowledge as it is occasionally assumed. This assumption stems out of the confusion of Piagetian constructivism with a fairly recent trend in sociology of knowledge called the social construction of science.

Unlike sociological constructivism, Piaget recognizes the remarkable stability of scientific knowledge over time. He never denied, for instance, that the successive physical theories that have appeared since Newton or even Galileo were so stable that they encompassed superseded theories as special cases of their own theory. Piaget specifically showed the striking case for theory inclusion that Galileo's system formed for Newton's and Newton's for Einstein's. He made the same remark about modern theories of force interactions in contemporary physics.

As far as contingency is concerned, he accepted without any doubt that the advance of molecular biology was made possible by the concomittant and congruent development of computer technology allowing for long and complex computations required by molecular biological methods. Brunschvig's influence had been strong enough in that sense on the young Piaget as to remain with the old man.

Reality represents a greater difficulty, because there are different ways of approaching this concept. One can consider reality as the information given by the external world to which the human mind has to conform willy-nilly by registering it or dying. Or one can consider reality as what resists the *modus operandi* of the mind, in which case an object is what objects to the mind's demands and not a mere thing, outside there, imposing upon the mind.

Reality, for a constructivist, is a constant negotiation between the subject and the object in the course of their interaction. But, once again, the term interaction has a precise meaning for Piaget. Basically, interaction can be understood in three different ways. The first meaning is a mere relationship between two separate elements. For instance, in the case of a heated iron bar that is longer than a cold one, there is an interaction between length and temperature. The second meaning implies circularity in the relationship. For instance, the circularity between the scarcity of public transportation in the countryside which is due to the excess of private cars which, in turn, is caused by the lack of public transportation. The third and last meaning is Piagetian: it supposes the unseparability between reality and mental 'schèmes.' This means that a scientific fact does not exist independently from a scientific theory.

This is true for naive theories too. Before object permanence, it is pointless for a child to search for a disappeared object, since, in the infant's naive theory, the object has been reabsorbed by the environment until it comes back by magic and not by means of a complex logico-mathematical structure called the practical group of displacements.

Thus, Piagetian constructivism should not be confused with the social construction of reality. It is a theory that drives a middle course between the extremes of empiricism and rationalism in philosophy, Darwinism and creationism in biology, Durkheim and Tarde in sociology, behaviorism and Gestalt in psychology. In addition, Piaget thought he had empirically tested the validity of his position in the course of his studies of cognitive developmental as we shall see now.

5. Cognitive Development and Education

Essentially what Piaget observed is that intelligence evolves from states of lesser knowledge to higher ones and that cognition goes from simple to complex. But, if knowledge were learned, it would go at random from some patches of learning to others according to chancy encounters with the environment. On the other hand, if knowledge were the mere unfolding of innate potentialities, why should it go from simple to complex? There is no evolutionary nor social need for such a contrived process. Thus knowledge must be constructed step by step from direct action to internalized mental operations.

At every level of this construction corresponds a mode of equilibrium between self and reality that forms the structure of a stage that Piaget defines in logico-mathematical terms. The very existence of stages is, for Piaget, the evidence that knowledge is neither the mere unfolding of innate potentialities as in nativism nor simple registration of the features of the world as in environmentalistic and social learning theories, since the notion of stage implies a total

reorganization on a higher plane of what has been attained earlier at a lower level. This is mental construction.

Such a position involves also a choice of explanatory models that has been often misunderstood. Instead of choosing a physiological model of explanation for cognitive development such as maturation or brain states and transformation as do most psychologists, Piaget selected abstract models such as mathematical groups or equilibration theory to account for psychological processes such as adaptation. By so doing he conformed his explanation to his observation that intelligence is biological adaptation pursued by new and more potent means.

This carries an educational lesson. Teaching and learning which are essential to human development should be adjusted to the child's level of understanding so that any pedagogical incentive speaks to the child's condition at any given moment but also appeals to the next higher structure by calling attention on the contradictions and lacunae of the existing developmental level. This is no spontaneism. This is no drill learning nor socialization. This is cooperation (in the strong sense of a Piagetian operation) with the growing mind from the part of educators whose noble task is to co-construct knowledge with every new baby who comes to this world.

Pidgin and Creole Languages

1. Introduction

Most studies of pidgins and Creoles (PC) have focused on their origins, despite an undeniable increase during the 1990s in the number of works on structural features. Recently, some creolists have also addressed the question of whether, as a group, Creoles can be singled out as a structural type of languages. Space limitations make it impossible to discuss structural features in this essay, aside from the fact that there are no features that are peculiar to PCs, as explained in Sect. 2.

2. What are Pidgins and Creoles?

Strictly speaking, PCs are new language varieties, which developed out of contacts between colonial nonstandard varieties of a European language and several non-European languages around the Atlantic and in the Indian and Pacific Oceans during the seventeenth to nineteenth centuries. Pidgins typically emerged in trade colonies which developed around trade forts or along trade routes, such as on the coast of West Africa. They are reduced in structures and specialized in functions (typically trade), and initially they served as non-native *lingua francas* to users who preserved their native vernaculars for their day-to-day interactions. Some pidgins have expanded into regular vernaculars, especially in urban settings, and are called 'expanded pidgins.' Examples include *Bislama* and *Tok Pisin* (in Melanesia) and Nigerian and Cameroonian Pidgin English. Structurally, they are as complex as Creoles. The latter vernaculars developed in settlement colonies whose primary industry consisted of sugar cane plantations or rice fields, which employed massive non-European slave labor. Examples include Cape Verdean *Criolou* (lexified by Portuguese) and *Papiamentu* in the Netherlands Antilles (apparently—Portuguese-based but influenced by Spanish); Haitian, Mauritian, and Seychellois (lexified by French); Jamaican, Guyanese, and Hawaiian Creole, as well as Gullah in the USA (all lexified by English); and

Saramaccan and *Sranan* in Surinam (lexified by English, with the former heavily influenced by Portuguese and the latter by Dutch). Note that although Melanesian pidgins are associated with sugar cane plantations, they apparently originated in trade settings and were adopted on the plantations (Keesing 1988).

The terms *Creole* and *pidgin* have also been extended to some other varieties that developed during the same period out of contacts among primarily non-European languages. Examples include Delaware Pidgin, Chinook Jargon, and Mobilian in North America; Sango, (Kikongo-)Kituba, and Lingala in Central Africa, Kinubi in Southern Sudan and in Uganda; and Hiri Motu in Papua New Guinea (Holm 1989, Smith 1995). In the original, lay people's naming practice, the term *jargon* was an alternate to pidgin. However, some creolists claim that pidgins are more stable and jargons are an earlier stage in the 'life-cycle' that putatively progresses from Jargon, to Pidgin, to Creole, to Post-Creole by progressive structural expansion, stabilization, and closer approximations of the *lexifier*—the language which contributed the largest part of a Creole's lexicon.

Chaudenson (1992, p. 21) argues that Creoles developed by *basilectizing* away from the lexifier, i.e., acquiring a *basilect*, which is the variety the most different from the *acrolect*, the educated variety of the lexifier. Mufwene (2001) emphasizes that Creoles and pidgins developed in separate places, in which Europeans and non-Europeans interacted differently—sporadically in trade colonies (which produced pidgins) but regularly in the initial stages of settlement colonies (where Creoles developed). Moreover, the term *pidgin* was coined in 1807 (Baker and Mühlhäusler 1990), over two years after the term *Creole* was used in reference to a language variety. '*Pidgin English*,' apparently a distortion of '*business English*' developed in Canton, a geographical area where no large colonial plantation industry developed and no Creoles have been identified.

The term '*Creole*' was originally coined in Iberian colonies, apparently in the sixteenth century, in reference to nonindigenous people born in the American colonies. It was adopted in metropolitan Spanish, then in French and later in English by the early seventeenth century. By the second half of the same century, it was generalized to descendants of Africans or Europeans born in Romance colonies. Usage varied from one colony to another. The term was also used as an adjective to characterize plants, animals, and customs typical of the same colonies.

Creole may not have applied widely to language varieties until the late eighteenth century. Such usage may have been initiated by metropolitan Europeans to disfranchise particular colonial varieties of their languages. It is not clear how the term became associated only with vernaculars spoken primarily by descendants of non-Europeans. Nonetheless, several

speakers of Creoles (or pidgins) actually believe they speak dialects of their lexifiers.

Among the earliest claims that Creoles developed from pidgins is the following statement in Bloomfield (1933, p. 474): 'when the jargon [i.e., pidgin] has become the only language of the subject group, it is a creolized language.' Hall (1962) reinterpreted this, associating the vernacular function of Creoles with nativization. Thus, Creoles have been defined inaccurately as 'nativized pidgins,' i.e., pidgins that have acquired native speakers and have therefore expanded both their structures and functions and have stabilized. Hall then also introduced the pidgin-Creole 'life-cycle' to which DeCamp (1971) added a 'post-Creole' stage.

The first creolist to dispute this connection was Alleyne (1971). He argued that fossilized inflectional morphology in Haitian Creole (HC) and the like is evidence that Europeans did not communicate with the Africans in foreigner or baby talk, which would have fostered pidgins on the plantations. Chaudenson (1992, p. 21) argues that plantation communities were preceded by homesteads on which mesolectal approximations of European lexifiers, rather than pidgins, were spoken by earlier slaves. Like some economic historians, the socioeconomic history literature suggests that in North American colonies Creole Blacks spoke the lexifier fluently. In ads on runaway slaves in British North American colonies, bad English is typically associated with slaves imported as adults from Africa. Diachronic evidence of Creoles suggests that the basilects developed during the peak growth of plantations (in the eighteenth century for most colonies!), when infant mortality was high, life expectancy was short, the plantation populations increased primarily by massive importation of slave labor, and the proportion of fluent speakers of the earlier colonial varieties kept decreasing (Chaudenson 1992, p. 21, Mufwene 2001).

According to the life-cycle model, as a Creole continues to coexist with its lexifier, the latter exerted pressure on it to shed some of its 'Creole features.' This developmental hypothesis can be traced back to Schuchardt's (1914) explanation of why African-American English (AAE) is structurally closer to North American English than Saramaccan is to its lexifier: coexistence with it in North America and absence of such continued contact in Suriname. DeCamp (1971) and several creolists who followed suit (e.g., Rickford 1987) resurrected the position by invoking 'decreolization' ('loss of "Creole" features') to account for speech continua in Creole communities.

It is in this context that DeCamp (1971) coined the term 'post-Creole continuum,' which must be interpreted charitably. If a variety is Creole because of the particular sociohistorical ecology of its development, rather than because of its structural peculiarities, it cannot stop being a Creole even after some of the features have changed. Besides, basilectal and mesolectal features continue to coexist in these communi-

ties, suggesting that Creole has not died yet. Lalla and D'Costa (1990) present copious data against decreolization in Caribbean English Creoles.

Closely related to this issue is the common assumption that Creoles are separate languages from their lexifiers and ex-colonial varieties thereof spoken by descendants of Europeans. Thus, the nonstandard French varieties spoken in Quebec and Louisiana, as well as on the Caribbean islands of St. Barths and St. Thomas, are considered dialects of French rather than Creoles. Likewise New World nonstandard varieties of Spanish and Portuguese are not considered Creoles, despite structural similarities which they display with Creoles of the same lexifiers. Although not admitted in linguistics, the classification seems to have been associated generally with whether the majority in the largely proletarian communities speaking the new, colonial vernaculars is of European or of non-European descent. Otherwise, all colonial varieties of European languages are restructured and contact-based; the current classification of vernaculars into Creoles and non-Creoles remains question begging. The embarrassment stems largely from the absence of a yardstick for measuring structural divergence from the lexifier, especially when it is dubious that it was the same in every contact setting.

It has also been claimed that Creoles have more or less the same structural design (Bickerton 1984). This position is as disputable as the counterclaim that they are more similar in the sociohistorical ecologies of their developments, or even the more recent claim that there are Creole prototypes from which others deviate in various ways (McWhorter 1998). The very fact of resorting to a handful of prototypes for the general Creole structural category suggests that the vast majority of them do not share the putative set of defining features, hence that the features cannot be used to single them out as a unique type of language. On the other hand, variation in the structural features of Creoles (lexified by the same language) is correlated with variation in the linguistic and sociohistorical ecologies of their developments (Mufwene 2001). The notion of 'ecology' includes, among other things, the nature of the lexifier, structural features of the substrate languages, changes in the ethnolinguistic make-up of the populations that came in contact, the kinds of interactions between speakers of the lexifier and those of other languages, and rates and modes of population growth.

To date the best known Creoles have been lexified by English and French. Those of the Atlantic and Indian Ocean are, along with Hawaiian Creole, those that have informed most theorizing on the development of Creoles. While the terms 'Creole' and 'creolization' have often been applied uncritically to various contact-induced language varieties, several distinctions, which are not clearly articulated have also been proposed, for instance, between pidgin, Creole, koiné, semi-Creole, intertwined varieties,

foreign workers' varieties of European languages (e.g., *Gastarbeiter Deutsch*), and 'indigenized varieties' of European languages (e.g., Nigerian and Singaporean English). The denotations and importance of these terms deserve re-examining.

3. *The Development of Creoles*

The central question here is: how did Creoles develop? The following hypotheses are the major ones competing today: the substrate, the superstrate, and the universalist hypotheses.

Substratist positions are historically related to the 'baby talk hypothesis,' which I have traced back to nineteenth-century French creolists (e.g., Adam 1883). Putatively, the languages previously spoken by the Africans enslaved on New World and Indian Ocean plantations were the primary reason why the European lexifiers which they appropriated were restructured into Creoles. These French creolists assumed African languages to be 'primitive,' 'instinctive,' in 'natural' state, and simpler than the 'cultivated' European languages with which they came in contact. Creoles' systems were considered to be reflections of those non-European languages. The baby-talk connection is that, in order to be understood, the Europeans supposedly had to speak to the Africans like to babies, their interpretation of foreigner talk.

The revival of the substrate hypothesis (without its racist component) has been attributed to Sylvain (1936). Although she recognizes influence from French dialects, she argues that African linguistic influence, especially from the Ewe group of languages, is very significant in HC. Unfortunately, she states in the last sentence of her conclusions that this Creole is Ewe spoken with a French vocabulary. Over two decades later, Turner (1949) disputed American dialectologists' claim that there was virtually no trace of African languages in AAE and showed phonological and morphosyntactic similarities between Gullah and some West-African (especially Kwa) languages. He concluded that 'Gullah is indebted to African sources' (p. 254).

There are three main schools of the substrate hypothesis at the beginning of the twenty-first century. The first, led by Alleyne (1980) and Holm (1988) is closer to Turner's approach and is marked by what is also its main weakness: invocation of influence from diverse African languages without explaining what kinds of selection principles account for this seemingly random invocation of sources. This criticism is not *ipso facto* an invalidation of substrate of substrate influence; it is both a call for a more principled account and a reminder that the nature of such influence must be reassessed (Mufwene 2001).

The second school has been identified as the 'relexification hypothesis.' Its leading proponent Lefebvre (1998) argues that HC is a French relexifi-

cation of languages of the Ewe-Fon (or Fongbe) group. This account of the development of Creoles has been criticized for several basic shortcomings, including the following: (a) its 'comparative' approach has not taken into account several features that HC (also) shares with nonstandard varieties of French; (b) it downplays features which HC shares also with several other African languages which were represented in Haiti during the critical stages of its development; (c) it has not shown that the language appropriation strategies associated with relexification are typically used in naturalistic second language acquisition; and (d) it does not account for those cases where HC has selected structural options which are not consistent with those of Ewe-Fon. Moreover, relexificationists assume, disputably, that languages of the Ewe-Fon group are structurally identical and that no competition of influence was involved among them.

The least disputed version of the substrate hypothesis is Keesing's (1988), which shows that substrate languages may impose their structural features on a new, contact-induced variety if they are typologically homogeneous, with most of them sharing the relevant features. Thus Melanesian pidgins are like (most of) their substrates in having DUAL/PLURAL and INCLUSIVE/EXCLUSIVE distinctions and in having a transitive marker on the verb. Sankoff and Brown (1976) had shown similar influence with the bracketing of relative clauses with *ia*. However, the pidgins have not inherited all the peculiarities of Melanesian languages. For instance, they do not have their VSO major constituent order, nor do they have much of a numeral classifying system in the combination of *pela* with quantifiers. For an extensive discussion of substrate influence in Atlantic and Indian Ocean Creoles, see Muysken and Smith (1986) and Mufwene (1993).

Competing with the above genetic views has been the 'dialectologist,' or superstrate, hypothesis, according to which the primary, if not the exclusive, sources of Creoles' structural features are nonstandard varieties of their lexifiers. Speaking of AAE, Krapp (1924), for example, claimed that this variety was an archaic retention of the nonstandard speech of low-class Whites with whom the African slaves had been in contact. According to him, African substrate influence was limited to some isolated lexical items such as *goober* 'peanut,' *gumbo*, and *okra*. Since the late 1980s, Shana Poplack and her associates have shown that AAE shares many features with white nonstandard vernaculars in North America and England, thus it has not developed from an erstwhile Creole (see Poplack 1999 for a synthesis). Because some of the same features are also attested in Creoles, we come back to the question of whether most features of Creoles did not after all originate in their lexifiers.

Regarding French Creoles, the dialectologist position was first defended by Faine (1937), according to whom HC was essentially Norman French. This

position was later espoused by Hall (1958), who argues that 'the 'basic' relationship of Creole is with seventeenth-century French, with heavy carry-overs or survivals of African linguistic structure (on a more superficial structural level) from the previous language(s) of the earliest speakers of Negro Pidgin French; its 'lexical' relationship is with nineteenth- and twentieth-century French' (p. 372). Chaudenson (1992, p. 21) is more accommodating to substrate influence as a factor that accounts for the more extensive structural divergence of Creoles from their lexifiers compared with their non-Creole colonial kin.

The 'universalist hypotheses,' which stood as strong contenders in the 1980s and 1990s, have forerunners in the nineteenth century. For instance, Adolfo Coelho (1880–1886) partly anticipated Bickerton's (1984) 'language bioprogram hypothesis' in stating that Creoles' owe their origin to the operation of psychological or physiological laws that are the same everywhere, and not to the influence of the former languages of the people among whom these dialects are found. Bickerton pushed things further in claiming that children made Creoles by fixing the parameters of these new language varieties in the their unmarked, or default, settings as specified in Universal Grammar. To account for cross-Creole structural differences, Bickerton (1984, pp. 176–7) invokes a 'Pidginization Index' (PI) that includes the following factors: the proportion of the native to non-native speakers during the initial stages of colonization, the duration of the early stage, the rate of increase of the slave population after that initial stage, the kind of social contacts between the native speakers of the lexifier and the learners, and whether or not the contact between the two groups continued after the formation of the new language variety. Some nagging questions with Bickerton's position include the following: Is his intuitively sound PI consistent with his creolization qua abrupt pidgin-nativization hypothesis? Is the abrupt creolization hypothesis consistent with the social histories of the territories where classic Creoles developed? How can we explain similarities between abrupt Creoles and expanded pidgins when the stabilization and structural expansion of the latter is not necessarily associated with restructuring by children? Is there convincing evidence for assuming that adult speech is less controlled by Universal Grammar than child language is? How can we account for similarities between abrupt creolization and naturalistic second-language acquisition?

Not all creolists who have invoked universalist explanations have made children critical to the emergence of Creoles. For instance, Sankoff (1979) makes allowance for Universal Grammar to operate in adults, too.

Few creolists subscribe nowadays to one exclusive genetic account, as evidenced by the contributions to Mufwene (1993). The 'complementary hypothesis' (Corne 1999, Mufwene 2001) seems to be an adequate

alternative, provided we can articulate the ecological conditions under which the competing influences (between the substrate and superstrate languages, and within each group) may converge or prevail upon each other. This position was well anticipated by Schuchardt (1909, 1914) in his accounts of the genesis of *Lingua Franca* and of Saramaccan. More and more research is now underway uncovering the socio-historical conditions under which different Creoles have developed, for instance, Arends (1995), Chaudenson (1992, p. 21), Corne (1999), and Mufwene (2001).

Still, the future of research on the development of Creoles has some problems to overcome. So far knowledge of the nonstandard varieties of the lexifiers spoken by the European colonists remains limited. There are few comprehensive descriptions of Creoles' structures, which makes it difficult to determine globally how the competing influences interacted among them and how the features selected from diverse sources became integrated into new systems. Few structural facts have been correlated with the conclusions suggested by the sociohistorical backgrounds of individual Creoles. Other issues remain up in the air, for instance, regarding the markedness model that is the most adequate to account for the selection of features into Creoles' systems. For developmental issues on PCs, the following recently edited collections are good starting points: Muysken and Smith (1986), Mufwene (1993), and Arends et al. (1995). More specific issues may be checked in volumes of the Creole Language Library (John Benjamins) and of Amsterdam Creole Studies, in the *Journal of Pidgin and Creole Languages*, and in *Etudes Créoles*. Several issues of *Pacific Linguistics* also include publications on Melanesian Creoles.

4. *Creolistics and General Linguistics*

There is much more literature on the genesis, sociology, and morphosyntax of PCs than on their phonologies, semantics, and pragmatics. With the exception of time reference and nominal number, studies in semantics and pragmatics are scant. On the other hand, the development of quantitative sociolinguistics owes a lot to research on AAE since the mid-1960s (see, e.g., Labov 1972) and Caribbean English Creoles (e.g., Rickford 1987). Numerous publications in *American Speech*, *Language in Society*, and *Language Variation and Change* reflect this. There are also several surveys of creolistics. Holm (1988, 1989), Arends et al. (1995), and Mühlhäusler (1986, 1997), cited here, are just some of the references, which vary both in adequacy and in geographical areas of focus. It is hoped that, Corne (1999) is the beginning of a new trend of comparative studies of Creoles lexified by the same language.

Studies of structural aspects of Creoles have yet to inform general linguistics beyond the subject matters

of time reference and serial verb constructions. For instance, studies of *lectal continua* have had this potential, but little has been done by creolists to show how their findings may apply to other languages. The mixed nature of *mesolects*, those intermediate varieties combining features of both the *acrolect* and the *basilect* should have informed general linguistics against the fallacy of assuming monolithic grammatical systems. However, little has been done on the subject matter. Likewise, the debate on Creole genesis could have informed historical linguistics on the importance of varying external conditions to language change.

Although lack of consensus among creolists may be invoked as a general reason for this failure to influence general linguistics, alarming indifference from theoretical linguists, especially those engaged in theories of typology and universals, is a more important reason. Consensus cannot be expected of creolistics any more than of other subfields of linguistics or any other scientific discipline. However, in the broader context of language contact (including second-language acquisition), studies of especially Creole genesis have been inspiring. For instance, Thomason and Kaufman (1988) are cited widely in studies of indigenized English. Andersen (1983) was an important step to consolidate common interests between second-language acquisition and Creole genesis. More cross-fertilization might be expected between studies of Creole genesis and those of (child) language development (DeGraff 1999), as among diverse subfields of linguistics.

Pilgrimage

Pilgrimage involves the movement of a traveler or group of travelers away from home, usually with a specific, sacred goal in mind. In most cases, the term implies a journey to a place that has been sanctified by the presence or actions of a divinity or holy figure. Certain variations on this pattern are possible. Pilgrims sometimes wander continuously without a fixed destination, or the journey may be considered to occur in a purely metaphorical sense, involving spiritual development and transformation within the person. This article focuses, however, on the most common understanding of pilgrimage: literal movement across space that may also result in the crossing of conventional cultural, social, and religious boundaries.

1. Themes in the Study of Pilgrimage

Social scientific studies of pilgrimage were relatively sparse until the 1970s, although in the 1950s Eric Wolf had published a short but influential article on pilgrimage to the Virgin of Guadalupe in Mexico (Wolf 1958). Since the early 1970s, research has expanded and covered all of the world religions. Such academic engagement reflects a continuing and even increasing interest in pilgrimage that has become evident among participants who have better access than ever before to safe and effective modes of travel.

Many earlier studies adopted Durkheimian, functionalist perspectives in analyzing the significance and effects of pilgrimage. In other words, they interpreted the process of traveling to and gathering at a sacred place as providing ritualized opportunities for social unification and moral regeneration within populations that were normally widely dispersed. For instance,

Wolf (1958) argued that the shrine of the Virgin of Guadalupe in Mexico City represented a dominant symbol for the whole nation, condensing various historical, mythical, and cultural themes and focusing them on the activity of pilgrimage to a single place.

The most influential social scientific approach to the subject has come from the anthropologist Victor Turner (see, for instance, Turner and Turner 1978). He notes that, after an original founding event such as a vision, journey, or martyrdom, pilgrimages most frequently involve the gradual organization and routinization of the sacred journey. More speculatively, Turner argues that pilgrimage in the world religions shares certain characteristics with rites of passage in tribal societies. In both forms of ritual, the person is removed from the space and time of the everyday social environment and undergoes an emotionally and physically testing experience that can have lasting effects on perceptions of self-identity. Pilgrims thus enter the realm of what Turner calls social antistructure or *communitas*. He means by these terms that pilgrimage can involve the stripping away of everyday social statuses among participants, resulting in liberation from conformity to conventional norms and hierarchies. Pilgrims ideally cultivate direct and egalitarian bonds of comradeship during the temporary, set-apart time of their journey and dwelling at a shrine. *Communitas* therefore has the potential to contain an element of social critique since it puts the taken-for-granted quality of conventional institutions in question. Representatives of orthodoxy in many of the salvation religions often feel ambivalent towards pilgrimage and attempt either to suppress or control its tendencies to foment lay frustration with religious hierarchies.

Turner notes further that pilgrimage is frequently associated with images of death and rebirth, mirroring the symbolic destruction and reconstruction of the religious traveler's identity. For instance, many who go on the major pilgrimage (or *hajj*) to Mecca will choose to be buried in the white robes they wore on the pilgrimage. It is believed that these people will thus present themselves at the Last Judgment in the garb appropriate to a rejection of worldly, profane actions.

Turner's work has proved to be so significant partly because it appears to provide a vocabulary and theoretical framework that can be generalized and applied to varied cultural contexts. However, numerous subsequent works have criticized aspects of his thesis that pilgrimage is inherently antistructural in form and significance. Authors have pointed out that such a paradigm is possibly more reflective of a Christian ideal of human fellowship than of social and political realities in religious systems in general. Many examples of pilgrimage appear actually to reinforce situations of conflict between participants. For instance, Messerschmidt and Sharma (1981) examine Hindu pilgrimage in Nepal and find that caste and class divisions are not transcended through common

engagement in the ritual. They argue further that conventional Christian ideals of egalitarianism and homogeneity contradict certain Hindu assumptions concerning the inevitable persistence of religious hierarchy.

Powerful and widely cited criticisms of the Turnerian paradigm are contained in a book that is ostensibly devoted to studies of Christian pilgrimage but presents arguments that have much wider application. Eade and Sallnow (1991) characterize pilgrimage sites as ideal locations for contesting, rather than consolidating, the sacred among religious participants. As centers of power that can provide religious legitimation for political aspirations, shrines often present powerful incentives for a particular interest group to attempt to control the behavior and beliefs of religiously motivated visitors (the point is illustrated clearly by the politically charged and often violent history of Jerusalem). Pilgrimages, according to this view, provide the material and ideological focus for competing discourses and agendas, not only between sacred and secular authorities, but also between lay pilgrims and clerics, locals and incomers, members of different denominations, and so on. Sacred sites are described by Eade and Sallnow as the equivalent of empty symbolic vessels waiting to be filled by the possibly mutually contradictory assumptions of the various people who visit them. The authors also suggest that to regard pilgrimage as a unitary institution is highly problematic, even within a single religious system, since it can contain so many historically specific behaviors and meanings. They add, however, that Christian and perhaps other forms of pilgrimage can be conceptualized as involving a basic triad of 'person,' 'place,' and 'text.'

In fact, Turner did anticipate at least some of the later criticisms that have been leveled at his model of pilgrimage. He was aware of the potential for pilgrimage sites to be co-opted by political elites, the fragility of states of *communitas*, and the capacity of pilgrimage sites to encourage widely differing interpretations from pilgrims. However, the notion that pilgrimage should be seen as an arena for contestation as much as cooperation has proved popular in recent years. Its adoption by many scholars is not surprising since it resonates with contemporary social scientific perspectives that have been influenced by postmodern understandings of culture as unstable, fragmentary, and open to multiple appropriation.

A less controversial set of issues, discussed by Turner and others, is raised by the contention that pilgrimage can encourage participants to consider themselves part of translocal religious and cultural systems. Among Hindus, for instance, a sense of participation in a sacred geography that covers the whole of the Indian subcontinent can be cultivated by travel to shrines. Some devotees choose to circumambulate the entire country, visiting sacred spots along the way. Holy places themselves may be officially

or unofficially ranked in importance, thus constituting an internally heterogeneous but widely dispersed framework of sites. Among Christians, Jerusalem (located within 'the Holy Land' itself) has often been regarded as the pre-eminent location for pilgrimage, containing as it does so many sites associated with biblical events. It is followed in importance by other locations of transnational importance, such as Rome or Compostela, and then by pilgrimage locations that have significance in national or more narrowly defined regional contexts.

2. Methods of Study

Pilgrimage raises unusual problems in relation to conventional social scientific methodologies. Any given site is located within a much wider political, economic, and religious framework that must be taken into account in analysis. As a religious practice, pilgrimage has often complemented (and incorporated) other translocal activities like trade, tourism, and exploration. Pilgrims themselves may move across geographical, social, and religious boundaries, so that the scholar is faced with a diffuse and literally shifting object of study.

Various methods can be used to encapsulate the most important aspects of the phenomenon. Pilgrims can be followed as they journey to a shrine (Gold 1988, Frey 1998). More commonly, a single pilgrimage center or shrine is focused upon, and the activities of various pilgrim groups observed as they pass through the sacred center (Dubisch 1995). At a wider, macro level of analysis, whole systems of pilgrimage within a religious tradition may be studied (Turner and Turner 1978), or comparisons made between pilgrimage systems in the various world religions (Coleman and Elsner 1995).

The fact that pilgrimage sites tend to persist over time provides a good opportunity to combine historical with sociological interests (Turner and Turner 1978), and much work in this area demonstrates the ways in which a given site can retain its identity as a sacred place despite the fact that it is appropriated by different and sometimes competing religious systems over perhaps hundreds of years. Guadalupe, for instance, provides a good example of a shrine that has probable pre-Christian as well as Christian roots. The mixture of religious associations increases its significance as a site whose symbolism and mythology can be invoked in current debates concerning the relationship between precolonial, colonial, and post-colonial identities in Mexico.

3. Future Themes of Research

Pilgrimage has the potential to be at the center of much future research that could be of importance to the social sciences in general. As a social phenomenon,

it encourages the researcher to engage with some key theoretical debates in a variety of disciplines. The current popularity of pilgrimage as an activity raises the question of its significance for predictions of secularization and/or religious revitalization in various parts of the world. Some scholars have also speculated over the extent to which apparently secular activities such as going on holiday or visiting the graves of pop stars share the same structural features as pilgrimage. Certainly, it seems likely that tourism and pilgrimage will become increasingly intertwined in many cultural contexts in the future, given the popularity and flexibility of both activities. In addition, pilgrimage studies are relevant to ongoing discussions of the significance of processes of globalization in the modern world. Studies of sacralized forms of travel, involving the transference of people, ideas, and objects across national borders, can complement other research that is concerned to understand how social, cultural, and political units are being transformed by developments in technologies of mass travel and communication. Furthermore, in a world that is characterized by the displacement of populations from traditional homelands, pilgrimage may emerge as an increasingly important institutional means through which to unite diasporic communities. Tweed (1997) has recently argued, for instance, that pilgrimage allows Cuban exiles in Florida to map the landscape and history of their country of birth on to a new environment. Finally, pilgrimage provides many possible avenues of research in the light of increased social scientific interest in the body and embodiment, ranging from a focus on beliefs in miraculous healing to analysis of forms of movement associated with travel to and around sacred shrines.

Place in Geography

‘Place’ is vivid in experience, yet elusive as a concept. As a general term it embraces an aspect of the diversity of the world that is necessarily experienced though countless unique places. In spite of this ambiguity, ‘place’ in geography was considered for a long time to be more or less synonymous with ‘region’ or ‘settlement’ and so obvious that it needed no clarification. In the last half of the twentieth century this apparent obviousness has been brought into question as ideas about ‘place’ have been subjected to critical theoretical interpretation, and as changes in the character of actual ‘places’ have suppressed or distorted diversity. This article describes this sequence of change and the relationships between them.

1. ‘Place’ and ‘Places’

Aristotle, in his *Physics*, noted that ‘The question, What is Place?, presents many difficulties for analysis,’ then concluded that it refers to the precise dimensions of the space that contains something—‘place’ is a neutral container (McKeon 1941). This is a flexible but not very edifying definition since a container can range in scale from the space on my desk where I keep my dictionary, to Canary Wharf, to Paris, to Australia, to the earth as the place of humankind.

In contrast, Strabo (1917) wrote about 5 BC in the introduction to his *Geography* that ‘A knowledge of places is conducive of virtue.’ He believed that geographers, with their habits of travel and knowledge of the specific parts of the world, were qualified to distinguish good settings for human activity from bad ones, and by implication that content was more important than the container. The difficult question of ‘place’ faded into the background for almost 2,000 years, and, while it became acceptable to describe geography as ‘the study of places’ (Hartshorne 1959), this was left unexplained because ‘a place’ was apparently an unproblematic concept. The issue of scale was left, and remains, unresolved.

So ‘place’ has an enigmatic character, partly general and partly specific, midway between objective fact and subjective feeling. Entrikin (1991) calls this ‘the betweenness of place’ and proposes that it is best viewed from a point in the middle. From this perspective, ‘a place’ appears as a combination of objects and meanings that distinguishes somewhere from its surroundings, regardless of scale. For Walter (1988) it is

a ‘location of experience; the container of shapes, powers, feelings and meanings,’ and for Cresswell (1996) it is ‘a meaningful segment of space’ and a ‘container of social power’ (see *Geographic Thought, History of; Region: Geographical; Regional Identity; Scale in Geography*).

2. Experience and Sense of Place

In the 1960s a new theoretical and scientific approach to the spatial geometry of location, known as central place theory, served as a catalyst for more rigorous thinking about ‘place’ (see *Location Theory*). This approach considered towns and villages in terms of measurable properties and relative locations, and thus implicitly adopted an Aristotelian perspective that emptied places of content.

Geographers interested in specific places were dismayed by the aridity of central place theory but recognized that it was impossible to continue to use the concept of ‘place’ uncritically. Phenomenology was identified as a philosophical method that allows rigorous interpretations of place without denying diversity and meaning. The writings of M. Heidegger and M. Merleau-Ponty were used to argue that ideas of place are rooted in experiences of dwelling in specific places, and that these precede all abstractions about location, environment, or geography. Places are aspects of everyday experience, territories of symbols, memories, and associations; they are centers of being and belonging that connect people with their worlds.

Phenomenology discloses several elements of ‘place’ and place experience, including identity and sense of place, topophilia, and home. These insights have been absorbed into most subsequent discussions of place in geography, first in humanistic approaches and more recently in arguments which view place as a social construction (see *Humanistic Geography*).

2.1 Identity and Spirit of Place

Identity is what makes somewhere distinctive; it also suggests similarities, as when it is claimed that a particular fast-food restaurant is identical with one elsewhere. The term ‘identity of place,’ therefore, acknowledges that every place simultaneously differs from and has similarities with other places. This apparent contradiction requires clarification.

From an abstract perspective, it is possible to distinguish four essential components of place identity: location; an appearance of hills, rivers, buildings, and other objects; a community engaged in various social and economic activities; and a set of meanings and symbols. These are distinct and are not reducible one to the other (one cannot discuss location in terms of architecture, and so on), but these components are, in real places, always closely interwoven. Oaxaca in

southern Mexico is a colonial city that shares its architectural tradition and town plan with numerous cities in Latin America, and there is nothing unusual about its role as a center of regional government or its passion for fiestas. However, its location is unique, as are its elegant streets and buildings, and it seems unlikely that anywhere else has a annual festival—La Noche de los Rabanos—dedicated to carved radishes. In all places, even unremarkable ones such as new suburbs, some aspects are shared and others are distinctive, though the balance of these can vary widely. Even if appearance and activities are ordinary, meanings and symbols are always in some way distinctive.

Somewhere with exceptional place identity, like Oaxaca, is sometimes said to possess ‘spirit of place.’ This expression comes from the Latin *genius loci*, but the idea is derived from the ancient and widespread belief that certain places are inhabited by their own gods or spirits. In ancient Greece almost every hill-top, spring, grove, and outcrop of rock had its own guardian spirit; the Acropolis was the home of the goddess Athena. In this more secular age ‘spirit of place’ has lost its association with gods, and now refers to the immediately apparent yet rather elusive aesthetic quality of striking distinctiveness. Spirit of place is what makes particular places attractive and memorable.

2.2 Sense of Place

Sense of place is the capacity to recognize and respond to diverse identities of places. A place affects us directly through sight, smell, sound, and touch and sense of place is the synthetic faculty that combines these impressions with memory, imagination, and reason. (Note, however, that ‘sense of place’ is popularly and confusingly used to be synonymous with ‘spirit of place’; thus, it might be said that ‘Provence has a wonderful sense of place’).

Sense of place is not a uniformly shared and undifferentiated faculty. Many people are uninterested in places, some have an instrumental view of the world that regards places as resources to be exploited, while others are finely tuned to *genius loci* and place diversity. These variations have been clarified by making a distinction between an outsider’s sense of place, which looks at the world mostly in terms of objective qualities, and an insider’s sense of place, which seeks to grasp the distinctive properties of particular places in terms of their meanings for those who live and work in them. An outsider’s perspective pays scant attention to distinctiveness and is inclined to impose judgments on the basis of previously formed opinions; it is manifest, for example, in colonialism and in the propagation of placelessness (see Sect. 3.1). In contrast, an insider’s sense of place is responsive to the idiosyncracies of environment and culture. While

it comes with knowing and being known somewhere, and is most apparent in home places, it is also an ability that can be learned or enhanced by developing skills of careful observation and imagination.

2.3 Topophilia and Home

‘Topophilia’ lies at the intersection of spirit and sense of place. Literally it means ‘love of place,’ though Tuan (1974), who has given the term currency, defines it as ‘the affective bond between people and place or setting.’ There are, he suggests, ‘landscapes of persistent appeal,’ such as mountains and seashores, islands, carefully tended farms, and small towns. These are perceived through lenses of culture, familiarity, memories, even personal moods. Topophilia blends the inherent qualities of landscapes and places with the attitudes that different individuals bring to it. There are no fixed relationships in this. Sometimes a beautiful setting can be soured by ill-temper, yet at other times that same beauty may displace ill-temper.

Underlying an insider’s sense of place and topophilia is the notion and experience of ‘home.’ It is in ‘home’ where the significance of individual lives is most concentrated, where people feel they belong, where love of place is strongest. Home is a powerful emotional bond that can, for example, draw back refugees and those who have been uprooted in spite of the most adverse circumstances. Because of the intensity of these associations, in phenomenological interpretations ‘home’ is identified as the archetypal place.

2.4 Corrupted Sense of Place

Phenomenological interpretations mostly have been concerned with clarifying the subjectivity of place experience. In emphasizing roots and home they imply that ‘place’ and ‘sense of place’ are positive and provide the foundation for a deeply rooted yet balanced outlook on the world. This is not always the case. Harvey (1989) argues that consequences of a strong sense of place include sectarian politics and parochialism. This is apparent in local and neighborhood practices that resist anything which might upset racial homogeneity or promote social equity (see *Locational Conflict (NIMBY)*). There is a fine and unclear line between such intolerance and efforts to protect a place from massive redevelopment and equivalent changes that might destroy its identity, but when that line is crossed sense of place can be said to have become corrupted. A corrupted or poisoned sense of place selectively stresses local identity and home to the virtual exclusion of shared values (Relph 1997). It is always unpleasant, and at its worst, in xenophobia and ethnic cleansing, it can be brutally violent.

3. *Modernist and Postmodernist Changes in 'Places'*

At the beginning of the twentieth century most peoples' lives were, as they always had been, largely confined to within about one day's walk of where they lived. Nowhere was entirely isolated from outside contact, but with lack of mobility social changes dispersed slowly and usually adapted to specific contexts, so the local distinctiveness and geographical diversity were continually reinforced. This diversity was created under social and technological conditions dramatically different from those which now prevail. Since the mid-nineteenth century technologies of electronic communications and mass travel, coupled with rapid cultural and economic changes, have collapsed distance. The ways places are made, and the ways they are experienced, have both changed. Old places may be regarded with great affection, but they are historical fragments; geographies that are being made now consist mostly of placeless or arbitrarily fabricated settings.

3.1 *Placelessness*

Placelessness is the condition in which different places look much the same, and, more importantly, offer the same opportunities for experience. It is the erosion of geographical distinctiveness and diversity. Examples are legion: shopping centers, apartment buildings, airport terminals, expressways. Augé (1995) calls these 'nonplaces.' The new high-rise Okura Hotel in Kobe in Japan could equally well be in Houston or Mexico City and the adjacent shopping center is so dislocated from its context that much of it only has signs in English.

In part, placelessness is the expression of modernist styles of architecture and planning that were conceived in the 1920s to take advantage of new building materials of glass, steel, and concrete. These styles are functional, standardized, and international. They respond to the essential sameness of people everywhere and can be applied anywhere, regardless of climate or culture. Placelessness is also the child of transnational corporations and a global economy that strive to provide familiar goods and services to consumers in the most profitable and efficient way possible. Modernist design and corporate capitalism fit together well. The result is that the same products, the same companies, similar buildings, and similar landscapes can be found almost everywhere.

3.2 *Place Exploitation and Postmodernism*

Since about 1980 placelessness has developed a more subtle and complex character. As uniformity replaces diversity, distinctiveness becomes increasingly valuable and worth maintaining. Sometimes, as in heritage

preservation, the aim may be to protect intrinsic local identity, but the larger consequence has been to turn place identity into a commodity. Distinctiveness sells. In tourism, historical districts and unique landscape features are obviously attractive place qualities. Less obviously, in a global economy in which capital is mobile and businesses can locate anywhere with educated workers and reasonable land costs, a distinctive place identity can be decisive factor for a city trying to attract investment.

Once place identity is regarded as a commodity rather than an intrinsic property of somewhere, it can be exploited in many ways to promote tourism and attract other business. It can be selectively enhanced either by reconstructing destroyed buildings or historical districts, as in Place Royale in Quebec City, or by converting former industrial areas into festival markets of restaurants and galleries, as in Covent Garden in London. Links with celebrities or events, real or fictional, can promote marketability, so Atlanta is associated with *Gone with the Wind*; and Wigan has a Wigan Pier shopping center with an Orwell restaurant. If local identity is too bland elements of more distinctive places can be copied. Las Vegas, which excels in place plagiarism, has design fragments of Egypt, Italy, the tropics, New York, Ireland, and Japan in hotels and casinos on its main strip. More restrained copying is to be found in the restaurants, shopping centers, and entertainment districts of most cities, so gondolas ply the otherwise placeless waterfront in Toronto.

The exploitation and fabrication of place identity erodes distinctions between local history and contrived heritage, between fiction and reality, in order to allow capital to pursue its relentless aims. Harvey (1989) argues that these are processes of postmodernity. Their consequence is a placelessness achieved not through uniformity, but through what Sorkin (1992) calls 'ageographical variety.' Place identities have been uprooted, turned into transportable goods, and rearranged without regard for context.

4. *A Progressive or Critical Sense of Place*

These changes in the character of actual places raise questions about the notion of 'sense of place.' Phenomenological accounts imply that sense of place is constant across space and time and unaffected by electronic communications and increased travel. A different interpretation, based in critical social theory and political economy, proposes what Massey (1993) calls 'a progressive sense of place.' Instead of viewing places as bounded settings rooted in home and local traditions, a progressive sense of place looks outward from a specific geographical context to connections with wider processes. It sees each place as a unique point of interaction within networks of social and economic relations. From this perspective places appear as distinctive social spaces of inclusion or

exclusion, within a broad and changeable geographical context (Cresswell 1996).

A progressive or critical sense of place offers a possible foundation, that is neither nostalgic nor exclusionary, for understanding recent social and urban changes (Harvey 1996). It recognizes the global processes at work in place exploitation and, therefore, can provide insights into cultural 'displacements' and unanticipated juxtapositions of mosques, Chinatowns, and protestant churches that are the consequence of the intercontinental population movements of the last 50 years and which have turned many cities and towns into multicultural and multicentred places (see *Place, Power of*).

5. Place-making

As a concept, 'place' has evolved rapidly from a background, neutral term to one that is an important theoretical and empirical subject not only in geography, but for many of the social sciences (Walter 1988, Augé 1995, Casey 1997). A simultaneous, possibly coincidental shift from distinctiveness to placelessness and ageographical variety has occurred in the identity of actual 'places.' A repeated theme in recent discussions of these changes in 'place' and 'places,' regardless of discipline and regardless of whether the approach is theoretical, empirical, or phenomenological, is the need for individuals and local communities to be involved in making and maintaining their own places. Places have ceased to be objects for description and have come to be regarded as complex theoretical phenomena, as foundations for social resistance against remotely generated economic forces, and as centers of stability in world of change.

E. Relf

Place, Power of

The 'power of place' refers to the spatial form of landscapes, towns, and buildings as an important aspect of social and political life. The phrase is used in various contexts: analyzing social life in existing places, advocating the preservation of historic places, and formulating goals for the design of new places. As a phrase, 'power of place' combines the meanings of location, locale, and 'sense of place' (Agnew and Duncan 1989). It involves an approach to aesthetics drawn from work dealing with 'local distinctiveness' (Clifford and King 1990) in architecture, landscape architecture, cultural geography, and environmental psychology, with an approach to politics drawn from work on space in the social sciences (Hayden 1995). Its practical applications in urban planning include preservation and urban design.

1. Definitions of Place and Power

'Place' is one of the trickiest words in the English language. It carries the resonance of homestead, location, and open space in the city as well as a position in a social hierarchy. The authors of books on architecture, photography, cultural geography, poetry, and travel rely on 'sense of place' as an aesthetic concept but often settle for 'town character,' 'local distinctiveness,' or 'the personality of a location' as a way of defining it. In the nineteenth century and earlier, place also carried a sense of the right of a person to own a piece of land or to be a part of a social world, and in this older sense, place carries more political history with it. Phrases like 'knowing one's place' or 'a woman's place' still carry some territorial meanings and imply political power relationships (see *Community Power Structure*).

1.1 Place and Social Life

People experience places in ways that are critical to their well-being or distress. An individual's sense of place is both a biological response to the surrounding physical environment and a cultural creation. From childhood, humans come to know places through engaging all five senses: sight, sound, smell, taste, and touch. Research on perception shows the simultaneous engagement of several senses in orientation and wayfinding. Children show an interest in landmarks at three or earlier, and by age five or six can read aerial maps with great accuracy and confidence, as an example of the human ability to perceive and remember places (Tuan 1977).

As social relationships are intertwined with spatial perception, the subject of human attachments to places, as well as the ability to conceptualize places, is a fascinating one that defies simplistic research models in any field. Environmental psychologists define 'place attachment' as having social, material, and ideological dimensions (Altman and Low 1992). Some sociological studies of urban renewal, especially those which study the process of mourning for a lost neighborhood, have utilized attachment theory as well (Marris 1986). Many sociologists speak of 'locale' as part of fieldwork; anthropologists deal with the design of settlements and living space as part of the material culture of any group. Studies in the cognitive mapping of places often reveal the social dimensions of knowledge of the city. If place does provide an overload of possible meanings and methods of inquiry for the researcher, philosophers have argued that place's very same assault on all ways of knowing (sight, sound, smell, touch, and taste) make it powerful as a way of structuring social attachments and as a container of memory. Thus the concept of *lieux de memoire* (sites of memory, or places of memory) popularized by Pierre Nora in France, and expanded as processes of remembrance (Hayden 1998).

1.2 Place as Cultural Landscape

Cultural landscape studies, as geographer Carl Sauer and the 'Berkeley School' developed them from the 1940s on, focused on the evolution of places and included the 'combination of natural and man-made elements that comprises, at any given time, the essential character of a place' (see *Landscape Architecture*). Cultural landscape studies emphasized the connection of natural environments and built interventions. Yet cultural landscape methods for studying places, and people's shaping of them, tended to stress the physical and not the political dimensions of places, leaning to the study of rural, pre-industrial landscapes, vernacular house types, and patterns of cultivation, considering ecology but avoiding issues of political contestation. Among the noted essayists of this type was John Brinckerhoff Jackson (1997).

1.3 Places and Power Struggles

As the landscape is more densely inhabited, economic and social forces affecting it are more complex, change is rapid, layers proliferate, and often abrupt spatial discontinuities result. The shaping of urban places involves gaining political access to territory as well as owning, planning, designing, constructing, using, and demolishing various kinds of built space. One can't simply turn to work on location in economic geography (or any other kind of quantitative analysis) because there the human experience of place is an essential topic that is often lost. Rather, the cultural landscape model has been more firmly connected to urban sociology, anthropology, and political science, retaining the physical analysis necessary to convey the shape of urban places, while adding more focused analysis of social and economic contestation (Duncan and Ley 1993, Groth and Bressi 1997). Historians are also claiming this subject matter: 'The story of how different peoples have lived and used the natural world will become one of the most basic and fundamental narratives in all of history, without which no understanding of the past could be complete' (Cronon 1992).

It has often proved easier to study either the natural or the built components of an urban cultural landscape than to wrestle with the combination of the two, fusing analyses of place and power. For many environmental historians, the deployment of land and natural resources has been a central preoccupation. Urban historians have focused more on power struggles; architectural historians on styles and patterns of building. The phrase, 'power of place,' suggests that all three areas are intertwined in some of the spatial struggles of urban development. The aesthetic qualities of architecture or of the built environment cannot be divorced from those of the natural environment without strange dislocations of experience: expensive houses swathed in smog; skyscrapers built on unstable soils, freeways blocking river fronts.

1.4 Avoidance of 'Place'

In the last decades of the twentieth century, social scientists frequently avoided 'place' as a concept, and thus sidetracked the sensory, aesthetic, and environmental components of the urbanized world, in favor of more quantifiable research with fewer epistemological problems (Agnew and Duncan 1989). Melvin Webber used 'non-place urban realm' to refer to the decline of face-to-face activities and the rise of telephone and television. Some analysts have extended this by arguing for the importance of an increasingly 'placeless world' (Relph 1976) or 'non-places' (Augé 1995) dominated by 'organization space' (Easterling 1999). Others prefer to retain the concept of place, and critique unpleasant, unlivable places (Hayden 1995). A paved-over neighborhood, restructured as freeway

lanes, parking lots, and mall, should still be considered a place, if only to explain why the new space lacks the pedestrian scale, lively texture and local meanings of the older place.

2. *Connections between Place and Space*

Sociologists' analyses of the 'production of space' provide a framework that can be used to relate the 'power of place' to the political economy. Lefebvre (1991) argues that every society in history has shaped a distinctive social space that meets its intertwined requirements for economic production and social reproduction. In terms of production, this would be close to cultural geography in identifying spaces or landscapes shaped for mining, manufacturing, commerce, or real estate speculation. Most original is his analysis of the space of social reproduction, which ranges over different scales, including the space in and around the body (biological reproduction), the space of housing (the reproduction of the labor force), and the public space of the city (the reproduction of social relations). Here he links the physical to the social in decisive ways. Cultural critics praised Lefebvre: he 'called for a new kind of spatial imagination capable of confronting the past in a new way and reading its less tangible secrets off the template of its spatial structures—body, cosmos, city' (Jameson 1991). His analysis also fueled the 'non-place' debate: a quality of late capitalist space is the creation of many identical units—similar but not 'placeless' places—by the large commercial real estate market which has become, in itself, a distinguishing feature of the global economy.

The cultural costs in terms of identity, history, and meaning have also been weighed, and here the phrase 'power of place' is used again. In a world increasingly given over to global corporations and their large, box-like buildings unrelated to local landscapes, the importance of local places as icons of resistance increases. Place-based social movements may resist demolition, preserve historic places, or demand place-sensitive urban design and architecture.

3. *Place-based Social Movements*

One of the consistent ways to limit the economic and political rights of groups has been to constrain social life through limiting access to places. The interplay between the social and the spatial is constant. The women's rights movement of the late nineteenth and early twentieth centuries was a struggle against spatial segregation based on gender. Women were not allowed to walk freely in public, obtain education, or vote. So too, the civil rights movement of the 1960s emphasized overcoming spatial segregation. Jim Crow laws restricted the African American community: streets, neighborhoods, schools, colleges, hotels, stores, fire

stations, swimming pools, and cemeteries were all segregated. To understand the intersecting struggles of race, class, and gender, the spatial dimensions of traditional 'woman's sphere' would have to be studied in combination with the spatial limits imposed by race or class. In the twentieth century, urban renewal often attempted to target poor neighborhoods and those inhabited by people of color. Resistance to demolition was a place-based campaign.

3.1 *The Power of Place, Los Angeles*

In Los Angeles, The Power of Place, a non-profit corporation, was founded by urban historian and architect Dolores Hayden. Operating from 1984–91, it documented and interpreted the political dimensions of place as historical experience, with a special concern for gender, class, and ethnicity. One premise of this project was that architects, planners, and artists, as well as specialists in preservation, have an important role to play in making the entire city more comprehensible, and its history more visible, in the minds of citizens. The group traced an itinerary of work places in downtown connected to the growth of the city: citrus farms, flower farms, oil wells, garment factories, and other economic activities between 1780 and 1940. On this itinerary, buildings were preserved and interpreted, and new public art and open space designs were created (Hayden 1995). Similar projects were organized in London by a group called Common Ground (Clifford and King 1990) and continue to be developed in many other American cities.

3.2 *Civil Rights Museums*

It is possible to identify historic urban places which have special significance to certain populations fighting spatial segregation of different kinds: a church where major civil rights meetings were held; a local newspaper that crusaded for fair housing; the first place in a city where women tried to vote; the first place where new immigrants were allowed to own land; the first integrated primary school. The Women's Rights National Park in Seneca Falls, New York is one such museum. There are also sites of assassinations, lynchings, massacres, and riots. The motel where Martin Luther King was shot, the Lorraine Motel in Memphis, Tennessee, is now a national civil rights museum, but every city and town has similar landmarks where territorial struggles have been waged.

3.3 *The Lower East Side Tenement Museum*

Another kind of museum to exploit the power of place is the Lower East Side Tenement Museum in New York. Ordinary dwellings contain the physical evi-

dence necessary to analyze the material conditions of ordinary workers' lives in earlier times. Standing inside a tenement apartment—perhaps four hundred square feet of living space for an entire family, minimal plumbing, only one or two exterior windows—leaves a visitor gasping for air and looking for light. The claustrophobic experiences of immigrants living for decades in crowded, unhealthy space are conveyed by the building in a way that a text or a chart can never match. Because a tenement was typical of hundreds of thousands of tenements all over the city, its implications for the historic urban landscape are broad. One building tells the bitter story of thousands of developers and millions of tenants. When this museum was acquired by the National Trust for Historic Preservation in the late 1990s, it signaled new prestige for social history museums everywhere.

3.4 *Parades and the Power of Place*

Festivals and parades also help to define the power of place by staking out routes in the urban cultural landscape. They intermix vernacular arts traditions (in their costumes, floats, music, dance, and performance) with spatial history (sites where parades begin, march, and end). African American jazz funerals marching through the streets of New Orleans, Chinese New Year parades, saint's day processions in Irish American or Italian American Catholic communities, and graveyard ceremonies for the Day of the Dead in Mexican American communities are just a few examples. Political parades have been representing communities and their causes for a long time, from workers with the tools of their trades to suffragettes. Since the 1960s, civil rights marches in Southern cities, women's marches to 'Take Back the Night,' and Gay and Lesbian Pride Parades in major cities have also been part of campaigns to achieve greater political representation.

4. *The Power of Place—Applications in Urban Design*

Some recent books proclaim the imminent end of urban public places. Advances in computer technology have affected many parts of daily life and often dispersed neighborhood activities. 'Disneyfication' fills theme parks and casinos with entertainments built to resemble older towns. Shopping malls take up historicist built forms as well. The global migration of capital, and the resultant production of 'organization space' emphasizes freeway interchanges or airports as locational determinants, eroding the importance of older central cities. Virtual reality promises to simulate more and more spatial experiences.

Nevertheless, human beings still situate their lives and work in material spaces of different scales. There

are many signs that places are more important, and more contested, than ever. Numerous older cities and towns have been protected by a growing movement for historic preservation. New town design is frequently done in accordance with the architectural movement promoting pedestrian scale and known as the 'New Urbanism.' Similarly, planners involved with campaigns for 'smart growth' have been heartened to hear that most Americans ranked urban and suburban sprawl ('placelessness') as an important political issue in 2000.

Studies exploring the 'power of place' are rapidly increasing in academic research, although the authors are scattered in half a dozen fields—history, geography, architecture, urban planning, landscape architecture, art history, anthropology, sociology, and others. In the 1980s, 'place' was not quantitative enough for the mainstream of social science, or narrowly aesthetic enough for the mainstream of art history and design. At the start of the twenty-first century, scholarly work on the broad cultural and political importance of places is part of many interdisciplinary programs such as cultural studies or American studies, as well as all of the separate disciplines. Work on the 'power of place' also has much to offer citizens and local public officials. Scholars and practitioners take discussion of 'the power of place' and other public arts to public forums in cities and towns (Imagining America 2000). Understanding the creation of places as a social and political process can lead to new projects to extend public meaning in the urban cultural landscape.

Placebo Studies (Double-blind Studies)

The story of placebo and of the double-blind method is part of the greater saga of the randomized clinical trial. When regulatory agencies mandated in the 1960s and 1970s that clinical trials of new treatments conform to research methodology, including randomization, double-blind design, and placebo controls, they affirmed a shift that had taken place in American medicine. For four millennia, and well into the 1950s, medical practice had been governed by expert opinion, and treatment was mainly placebo, at worst 'filling the cemeteries' (Shapiro and Shapiro 1997).

In clinical trials, patients are the subjects of all treatment modes, including drugs, radiation, surgery, psychotherapy. This article describes how trials have been conducted and the results interpreted. Clinical trials are termed 'open label' when patients and researchers know that the active drug is being given; 'single-blind' when the patient does not know what he or she is receiving; and 'double-blind' when neither the patient nor the research team knows who is receiving what. 'Randomization' denotes the assignment of experimental subjects through a table of random numbers, dice, or other statistical tools. 'Placebo' was first defined for medical use in 1785 as a substance that was pharmacologically inert, given to reinforce a patient's expectation to get well. Glantz's definition of placebo terms the placebo effect 'a response at-

tributable to therapy *per se*, as opposed to the therapy's specific effects' (Glantz 1997). Current usage differentiates active placebo that has pharmacologic effect from inert placebo.

Thomas Kuhn, the historian of science, defines normal science as the prevalent system of beliefs and practice. He likens practitioners to chess players, who test alternative moves but do not challenge the rules of the game. The game is challenged through discovery or a new hypothesis. Practitioners of normal science combat the skeptics, solve the problem, postpone solution, or attempt to reconstruct the discussion from new fundamentals. Kuhn quotes Max Planck: 'A new scientific truth can often prevail only when its opponents die and the new generation grows up.'

Kuhn underlines that resistance to change evolves not from wrong-headedness but from the impossibility of measuring or comparing different standards. Scientists and laymen could not accept Einstein's theory of relativity that proposed that space was curved, because Newtonian physics had proven that space was flat, homogeneous, and unaffected by the presence of matter. In the 1960s and 1970s depression was thought to be caused by psychological factors until challenged by evidence that a functional deficit of neurotransmitters, norepinephrine, dopamine, or serotonin or abnormality of their receptors is the cause. While opposition to this remains, most researchers now are refining particulars of neurotransmitter metabolism.

The acceptance of the double-blind method and placebo controls are among the most important developments in science and illustrate how new discoveries drive new theories that are eventually accepted in place of incompatible, older theories.

1. History of Placebo

Placebo concept and the word derives from the Hebrew 'I will walk before,' interpreted to mean 'to please.' It gained a secular connotation in the fourteenth century, to become derisive meaning one who 'servily echoes another' (Shapiro and Shapiro 1997).

The first medical definition of placebo appeared in a medical dictionary in 1785. In the late eighteenth and early nineteenth century, it was defined as medication given to please. Eventually, it meant 'a common method or medicine' and referred to treatments as well as medicaments not yet classified as inert. References to placebo as medications were retained in the medical dictionaries until the 1950s.

The use of placebos as controls in clinical research emerged from their long history as therapeutic agents. For four millennia, medical practitioners utilized thousands of substances, 0.03 to 0.04 percent of which are pharmacologically active. These physicians did not discriminate among active and inactive concoctions, and it is not known whether active drugs were used in

effective doses. In the nineteenth and twentieth centuries, some physicians' rationalization for the use of placebo was mobilizing hope.

Efforts to introduce placebo controls into research designs had been confounded in the 1930s by the growing low esteem of placebo as treatment on the part of the medical establishment. But because of self-delusion or hypocrisy while placebos were considered quack treatments prescribed by quacks, most community physicians also used placebos. They gave vitamins without acknowledging their lack of activity for the conditions for which they were prescribed, for example. Jerome Frank, the American psychiatrist, has said that psychoanalysis might be the major placebo of the twentieth century.

Reformers from different generations concerned with the practices of their mainstream clinical colleagues advocated alertness to self-deception as to the efficacy of treatments. Roueché said that 'results from 10 well-controlled cases were superior to haphazard impressions from 1,000 cases' (Marks 1997).

2. Medical Theories

In primitive supernaturalism, illness was attributed to actions of the gods and treated with magic administered by shamans. Greek medicine combined rational and irrational explanations and treatments, using miracles, divine healing, and natural remedies. Dream interpretation was a precursor of the confession and psychotherapy. Galenic medicine of ancient Rome was predicated on Galen's principle of opposites: if a drug caused fever, it would cure chills. Galenic theories had an answer for every question and maintained a tenacious hold on medical practice well into the nineteenth century. For example, Galen had observed pus in wounds and erroneously concluded that it was essential to healing rather than a symptom and made no attempts to relieve it. Because of this belief, thousands died of infection.

Theriac, a concoction that was the mainstay of Galenic medicine, had between 33 to 100+ substances in it, eventually being prescribed as a remedy for almost every human ailment. Theriac contained opium, which alleviated pain but was addictive. The rest of the ingredients were mainly placebos; many were harmful.

The laying on of hands was a hallmark of Christianity's return to mystical explanations of illnesses. Charles II of England used therapeutic touch on almost 100,000 persons to cure scrofula, glandular tuberculosis. Skeptics attributed cures to effects of the imagination, incorrect diagnoses to start with, and spontaneous remissions. In the nineteenth century, Claude Bernard asserted that science had to be 'founded on observation and proved by experience.' He influenced the development of studies on pathology, physiology, and bacteriology, but pharmacology continued to lag behind. However, criticisms of

'normal' medicine and its treatments were voiced, notably by Oliver Wendel Holmes, who urged the retention only of quinine for malaria, mercury for syphilis, colchicum for gout, iodine for goiter, and ipecac for dysentery. If all medications 'could be sunk to the bottom of the sea, it would be all the better for mankind and all the worse for the fishes,' he said in 1860 in a much-quoted statement. Often paradigm shifts are spurred by knowledge acquired elsewhere.

Laboratory science was making major inroads by the end of the nineteenth and early twentieth century, when therapeutic chemical compounds began to be synthesized and replaced some of the naturally occurring medicaments. This was made possible by progress in laboratory sciences, biochemistry, physiology, genetics, and immunology, which are in turn based on chemistry and physics. Animal experiments where variables could be well controlled became standard.

While the concept of the scientific method was beginning to impact medicine in the nineteenth century, theories of therapeutics based on *a priori* reasoning, were still entertained. Homeopathy was a success because of placebo effects, but also due to its theoretical base that less is more. Miniscule dosing probably protected patients from ill affects of noxious substances dispensed in more robust doses by non-homeopathic physicians.

3. Beginnings of the Scientific Method

From antiquity, 'open label' experiments were conducted but results were explained by 'medical ideas (that) were speculative... and medical hypotheses that relied on a priori reasoning (Shapiro and Shapiro 1997). In the seventeenth century, Sir Kenneth Digby, an English Renaissance man, carried out a single blind experiment on a single patient. He attributed the positive results to the popular concept of sympathetic powder (Shapiro and Shapiro 1997).

In 1872, John Tyndall, an English physician, suggested that the community pray for from 3–5 years for patients ill with fatal diseases to see if differences emerged between them and others not prayed for. If or how the suggestion was carried out was not clear.

Towards the end of the seventeenth century through the early eighteenth century, some British physicians called for comparative trials using 'simple arithmetic,' i.e., 'open label' trials. These reformers were generally Scots, provincials, without access to established centers of medical influence and power, and thus, more open to new ideas. Harry M. Marks, the historian, warns that the historical record of the clinical trial is incomplete and informs that Western European and American scientists influenced each other. He points out that among medical reformers, two parallel viewpoints were emerging: medicine can be a science if it rigorously applies research that is

subsequently channeled into clinical practice, and clinical medicine can be as scientific as laboratory sciences if scientific methods are applied to judging medical treatment.

Marks further subdivides the history of the clinical trials in the US into organizational and methodological reform. The first Food and Drug Act was adopted in 1906. The American Medical Association Council on Pharmacy and Chemistry was established in 1912. The standards of the AMA Council on Pharmacy and Chemistry set by expert opinion were adopted in the Food and Drug Act of 1938.

In 1958, the AMA Council on drugs authorized the publication of a paper by Walter Modell and Raymond Houde and 'approved the use of the double-blind method, controlled comparisons, randomization, (and) statistics...' (Shapiro and Shapiro 1997). By 1970 the Food and Drug Administration was empowered to monitor the safety and effectiveness of new drugs based on adequate, well-controlled investigations using appropriate statistical methods, the result of the reforms in methodology that influenced organizational reform.

In the US, Marks credits successive generations of challengers to the methodological status quo, nineteenth-century therapeutic nihilists, and also followers of Claude Bernard's rational therapeutics that stressed knowledge of etiology before treatment. The therapeutic reformers of the twentieth century included Torald Sollmann, George H. Simmons, Thomas C. Chalmers, and Morris Fishbein. Simmons, editor of *Journal of the American Medical Association*, attacked manufacturers for flooding the market with exaggerated claims for unproven nostrums. Fishbein, another editor of *JAMA*, 'unrelentingly described the fads and follies of healing cults and medical follies' (Shapiro and Shapiro 1997). Chalmers urged in 1975 that the first patient put on any new drug be part of a clinical trial.

Charles S. Pierce and Joseph Jastrow are credited with the first use of randomization in 1885. Rivers in 1908 used the double-blind design and placebo (without using the terminology) in an experiment testing the influence of alcohol and other drugs on fatigue. He noted, 'The action of suggestion can never be excluded from any medical treatment' (Shapiro and Shapiro 1997). In 1917, John E. Coover first used the terms 'controlled experiment' and 'randomization' (Shapiro and Shapiro 1997), which only became standard through Sir Ronald Fisher's book, *The Design of Experiments* in 1935. The number of experimental studies increased steadily through the work of, among others, Louis Pasteur, Robert Koch, and Rudolph Virchow. Torald Sollmann, professor and chair of the Department of Pharmacology at the Medical School of Western Reserve University, headed for 55 years the AMA Council on Pharmacy and Chemistry. Sollmann urged that it was 'essential that clinical experimentation should follow the canons of other

scientific experimentation' (Shapiro and Shapiro 1997). He coined the term 'comparative method.' Publications of the Council made reference to 'the blind test' and published what was probably the first study of the 'double-blind procedure.' In 1930, Sollmann recommended the use of the 'blind test,' used the term 'placebo' for the first time in research, and dropped the term 'comparative method.' But his news had little impact on practice, and the AMA Council on Pharmacy and Chemistry continued to rely on reviews by its member experts rather than on controlled studies.

The experts were researchers of unquestionable skill and integrity, but they rarely had experimental data and focused on confronting the tactics of manufacturers, their aggressiveness and exaggeration of claims, and on manufacturer-supplied laboratory evidence. Their influence led to a 'seemingly deluded faith in experts,' from 1900–1930 i.e., themselves and colleagues of the same ilk (Marks 1997).

A major milestone was a single-blind study in 1932, when Harry Gold tested the use of xanthine against placebo (lactose) for cardiac pain. He realized that physicians were asking the patients leading questions and prejudicing answers, and thereafter, tried to blind the physicians, as well. In 1935, Hediger and Gold compared two forms of ether in a 'blind test' and legitimized the use of placebos. Kwit summarized their insights: 'Towards the end of the study we realized that the doctor must not know what he gives, the patient... what he receives, and the questioner must not know what was given' (Shapiro and Shapiro 1997).

Like Sollmann earlier, Gold in the 1930s failed to have an immediate effect on medical practice. However, throughout the next two decades, researchers flocked to work with him and the new methodology, and he supervised many double-blind, placebo controlled studies. In a 1950s interview with Shapiro, Gold said, 'The placebo and the double-blind were companions after our 1937 study.'

A 1948 joint study by the US Public Health Service and the British Research Council is generally considered the first clinical trial. It tested the effectiveness of streptomycin in the treatment of tuberculosis. Patient selection was randomized. Evaluators of the patient X-rays did not know which patients had received streptomycin and which placebo. The treatment was not blind, because streptomycin-treated patients received up to four injections per day. Since the controls were bed-rest only patients, it would have been unethical to subject them to injections of placebo.

4. New Paradigm I

It was not until the 1950s, when antibiotics were discovered and mechanisms of several metabolic diseases understood that modern medicine began, and

clinical research could continue to make inroads. Through the 1960s and 1970s, the scientific method superseded authority and tradition. Treatments had to show sensitivity, specificity, and predictability through statistically sound techniques, randomization, the double-blind method, and placebo controls.

Current clinical standards for research are reflected in the US Preventive Services Task Force recommendations for treatment. Guidelines of 1989 (revised 1996), rank in descending order of reliability and ascending order of bias and misinterpretation randomized controlled trials, nonrandomized controlled trials, cohort studies, case control studies, comparisons between times and places, uncontrolled experiments, descriptive studies, and expert opinion.

5. *New Paradigm II*

The new scientific canon of clinical research encountered challenges and doubts almost as soon as it became established. Questions of method were raised about blindability in double-blind studies, as well as the precise definition, activity, and validity of placebo. Critical voices questioned ethical aspects of clinical trials that deprived half the patients of a medication that might be effective. The ensuing debate polarized ethicists and physicians.

6. *Blindability*

Extensive reviews of blindability indicated that studies took its validity for granted. It was suspect in the few double-blind trials that tried to carry out such tests of validity. Basoglu, in review of the literature found that only three of 23 double-blind psychopharmacology studies maintained blindability in patients, physicians, and assessors. Side effects, explanations in informed consent forms, past experience with similar drugs, and improvement with the active drug but not placebo sabotaged blindability. In his own comparison study of blindability of alprazolam, an anti-anxiety agent, with behavior therapy for panic disorder, Basoglu found that patients, treating therapists, and assessors were able to guess correctly, to a statistically significant extent, the patient's category. Patients treated with the active drug were more accurate than those on placebo, and active drug accuracy was highest at late stage of therapy, when optimal dosing and maximal efficacy had presumably been achieved.

Morin et al. (1995), recognizing that judgments carried out at the end of a study as to what was drug, what placebo could be influenced by treatment response to active drug, compared Temazepam, a hypnotic, and an inactive placebo. They carried out three assessments over 8 weeks. All patients received cognitive or behavioral therapy. Both patient and physician groups showed a statistically significant

high degree of accuracy in guessing at 1 and 8 weeks with no better than chance guessing at week 4.

From these and other studies, it appeared that certainty ratings increased with time, that experienced patients showed greater accuracy in penetrating blinding, and that patients on active drugs guessed better than those on placebo. In summary, neither the patients nor the administering physicians were blinded to any significant degree.

7. *Placebo*

Harry Gold had accepted earlier twentieth-century definitions of placebo, such as Rivers' that placebo gives an inactive imitation of the substance being tested and Sollmann's that placebo furnishes the comparative check of the natural course of the disease, and did not explore the nature of placebo and placebo effects. Current theories on the nature of placebo and placebo effects include spontaneous remission due to biological diversity, conditioning, mobilization of endogenous endorphins, and the statistical phenomenon of regression to the mean. In 1955, H. K. Beecher calculated that 35.2 percent improvement in 15 clinical trials involving different diseases was due to placebo.

McDonald and Mazzuca (1983) concede the evidence that patients improve during placebo treatment, but point out that that is not proof that placebo treatment is the reason. The percentage of improvement observed in placebo treated patients is identical to that predicted from a statistical phenomenon known as regression to the mean where both objective and subjective measures of abnormality tend to improve and move towards the mean with successive measurements. McDonald and Mazzuca (1983) illustrate this in a review of 30 randomly selected placebo controlled clinical trials. Placebo effects and regression to the mean are both 'not uniform, constant, or predictable.' (Regression is by definition a random phenomenon.) McDonald and Mazzuca do not negate the usefulness of placebo. In comparisons of known drug with unknown, placebo controls can clarify ambiguous results. Placebo controls are also useful in conditions that fluctuate.

McDonald and Mazzuca note that placebo effects can be created through conditioning, citing the work of Stewart Wolf on the effects of conditioning and suggestion on measurable physiologic events in human beings.

8. *Placebo Amplification*

Richard Thomson believed that fewer studies would show a significant difference between placebo and drug if an active placebo were used as control. He reviewed 75 studies of tricyclic antidepressants com-

pared with active placebo (atropine) or with an inert placebo (lactose). Indeed, as postulated, antidepressant efficacy was ranked as superior in only one of the seven atropine/placebo studies available, while the tricyclic antidepressant was ranked superior in 43 of 68 studies controlled by an inert placebo. One explanation might be that atropine might have an antidepressant effect of its own. However, Thomson concluded that placebo amplification, a situation where physiological effects of taking a drug convince subjects already committed to treatment that the treatment is, in fact, effective, was the phenomenon being observed.

Roger P. Greenberg compared a tricyclic antidepressant with a new drug being tested, as well as an inactive placebo. He postulated that in a study focused on a new drug's effectiveness, there would be less interest in proving the efficacy of the older drug. Indeed, compared with claims in earlier literature, the older drug was much less effective.

Shapiro and Shapiro (1997) reviewed 27 studies of guessing of placebo and drug allocation and found that overall, both patients and physicians made correct identifications in 60 to 80 percent of tests. Eighty percent of drug guesses, but only 50 percent of placebo guesses were correct in their own study.

Fisher and Greenberg (1995) found in a review of world literature of studies of psychotropic drugs prior to 1993 that 'double-blind is vulnerable to penetration and hence, to bias,' placing all previous psychopharmacological research in question.

To try to rectify previous research on the efficacy of psychotropic drugs, Fisher and Greenberg suggest greater complexity in research design, the use of active placebo, various crossover designs, 'conventional drug' and 'drug disguised' groups, dose ranging, and the testing of drugs in opposing contexts, i.e., in an atmosphere of optimism or pessimism. They concede that current regulations preclude a drug disguise scheme for example, and agree that a completely foolproof design is not likely ever to be contrived. Personalities of patients and researchers were a factor in correct guessing of placebo or drug. While overall studies showed agreement among evaluators, rater differences were noted. Patient noncompliance was another confounding variable.

9. *Ethics*

As early as in the 1960s, ethical considerations about clinical trials involving randomization, double-blind methodology, and placebo controls were raised. Benevolent paternalism had been a prevalent ethical guideline since antiquity. At worst, it led to egregious exploitation of patients. In the late 1950s and 1960s, H. K. Beecher, in several watershed papers, cited instances of unethical and unscientific proceedings by

researchers. He recommended that patients must give 'informed consent.' The US Public Health Service responded by proposing the establishment of Institutional Review Boards. The National Institutes of Health mandated Internal Review Boards, and the Food and Drug Administration, published in 1970, rules for 'adequate and well controlled clinical evaluation' (Shapiro and Shapiro 1997).

Beecher's papers helped move medicine from its tradition of paternalism to informed consent and patient autonomy. However, many in the medical establishment complained that the patient-physician dyad was being fractured by a mass of lawyers, judges, journalists, philosophers, and legislators. And that inevitably, bureaucracy was stifling the practice of medicine.

Ethicists had entered discussions in the 1970s, questioning placebos, the double-blind procedure, and the randomized clinical trial. Sissela Bok and Beth Simmons took strong stands opposing the use of placebos without informed consent. Others considered the use of placebos to be unethical in practice but permissible in research, to the point of not informing subjects of the research design. Some proposed that it was unethical not to carry out a placebo controlled, double-blind study. Still others concluded that since placebos have shown positive therapeutic effects using a placebo as control does not deprive patients of all treatment.

Questions have also been raised about how informed is informed consent in general, and especially if the subjects are cognitively or psychologically impaired? Attempts to resolve some of the issues are also being made. Where an effective treatment exists but a new one is being tried, the potency of the established treatment, as well as the severity of the patient's condition, are considered. As part of the experimental design, patients are moved from experimental or placebo cohorts to conventional treatment if their conditions deteriorate.

In 1978, while the rest of the Western scientific community moved towards research criteria of randomization, double-blind, and placebo controls in clinical trials, Germany passed laws substituting proof of efficacy through clinical open trials or expert opinion as qualifications for acceptance and registration of drugs. Controlled studies were no longer considered as essential to proof of efficacy.

In the introduction to the Physician's Desk Reference for Herbal Medicines, the editors say that in the absence of the 'rigors of FDA review' of these preparations, the editors are basing their guidelines on 'the closest available analog to FDA approved labeling—the findings of the German Regulatory Authority's watchdog agency commonly called Commission E'...its conclusions represent the best expert consensus...'

Statisticians contend that uncontrolled studies tend to favor a positive outcome.

10. Summary

Scientific thinking, defined by uncertainty that drives observation, hypothesis formation, and further search, was a late arrival to medicine, which was still laboring under few restrictions, guided by elaborate theories, mysticism, superstition, tradition, and authority.

Scientific thinking met much resistance in the medical establishment, but open label clinical trials, clinical trials using placebo controls, and double-blind methods began and continued into the twentieth century. In the 1950s when it became possible for the first time to cure people, statisticians became essential partners in the research team (Glantz 1997). Methodological and ethical questions began to be raised in subsequent decades about contemporary scientific criteria. Patient activism had also contributed to the erosion of paternalism that afflicted research design, as well as clinical practice.

The future may render clinical trials obsolete. We may well have a database atlas of the brain and body that will enable the researchers to calculate and theorize about effects without the use of human subjects.

The reader is referred to Marks (1997) and Shapiro and Shapiro (1997) for more complete historical surveys, detail, and documentation.

Placebos, Use of: Ethical Aspects

A placebo is a therapy, or an intervention designed to simulate therapy, that has unspecified activity for the condition being treated. Placebo components exist in all treatments that produce an expectation of good effects, including competent and caring professional behavior of those delivering the therapy, and status or attractiveness of the institution. Placebos effectively relieve symptoms of most medical and psychological conditions. The underlying mechanisms are increasingly a topic of theory, speculation, and research. The ethics of using placebos depends on context, theory, and purpose. This article examines evolving theories and uses of placebos and associated ethical issues.

1. History

Before modern medicine, many substances thought to have curative powers, e.g., arsenic, produced feelings of wellness, before perhaps killing the patient. Such placebo effects, due to ignorance of the physician and patient, were primary active ingredients of ancient medical practice. By the mid-1800s, Koch, Pasteur, and others demonstrated that specific bacteria could cause specific diseases, giving rise to specific pharmacologic and surgical interventions replacing non-specific healing therapies. Placebo effects became 'nuisance variables' to be controlled for, and ethics considered when it was acceptable to use placebos instead of accepted treatment modes. Finally, placebo effects are being studied as interesting phenomena in their own right.

Their therapeutic value is increasingly recognized, and the ethics of failing to use placebos to produce beneficial results is being questioned. Today's profes-

sionals produce placebo effects unwittingly, incidentally, or deliberately in research and practice in many fields including medicine, psychotherapy, and teaching. Today's ideal professional would appropriately and deliberately combine the power of modern science and technology with the healing power of placebos. Unfortunately, impersonal cost-cutting programs may inadvertently eliminate such effective strategies.

2. Definitions and Uses

The ethics of placebo use depends on which definition or theory of placebos is employed.

2.1 The Pharmacological Paradigm

The term placebo, from Latin *placere*, 'to please,' was coined to mean a pharmacologically inert substance, e.g., a sugar tablet, deliberately disguised as medication. Thus defined, the placebo is used to satisfy complaining or malingering patients; placebo effectiveness was until recently considered proof of patient psychopathology or feigned illness. Today's physician still employs placebos when the requested medication is inappropriate, but to satisfy concerns about lying to patients, may use very weak medications rather than inert substances.

Research on new treatments may yield 'success' simply as placebo effects. To control for this 'noise' researchers randomly assign both subjects and researchers to placebo and therapy groups. Double blind designs are used because researcher belief also influences results. The therapy is deemed successful if it yields better results than the placebo. (Without a placebo group, recovery due to treatment could not be distinguished from recovery due to spontaneous natural healing, as well as from expectancy effects.) To satisfy ethical requirements, researchers:

- Inform subjects that they may receive placebos;

- Specify the chance of receiving a placebo;

- Use placebos only when genuinely uncertain about treatment effectiveness;

- When inert substances might do harm, compare experimental treatment to baseline clinical data or current effective treatment;

- Monitor subjects regularly for adverse effects and remove immediately from placebos if indicated;

- Provide the placebo group with effective therapy later;

- In double-blind studies, ensure that the code can be broken quickly to discover whether a placebo is causing a worsening condition;

- Do not use placebos with highly vulnerable populations;

- Use placebos resembling the active preparation so that patient and researcher cannot detect the difference.

Use of placebo control groups has, unfortunately, become such a hallmark of publishable research that placebo controls may be used when other approaches, e.g., comparison with current effective treatments, are as rigorous, often more appropriate, and put the subject's interests first. Placebo control groups in psychiatric research on such vulnerable populations as persons suffering severe depression or schizophrenia have come under considerable scrutiny. Full comprehension and consent of the patient and next-of-kin concerning the possible use of a placebo, and careful surveillance of the patient, are crucial to ethical use of placebos when suicide or other forms of harm are plausible risks.

The pharmacological paradigm ignores sociocultural and interpersonal variables, expectations, learning, neurophysiology, and real therapeutic value of placebos. The malingering patient notion implies personality or demographic characteristics of placebo responders, but such characteristics have not been found.

2.2 Remembered Wellness

Newer conceptions and uses of placebos are highlighted in Benson and Friedman's (1996) article. Under the right circumstances anyone might respond to a placebo. Placebos are not absence of treatment. What persons believe can diminish pain and objective symptoms of disease. The components of 'remembered wellness'—the patient's and physician's positive beliefs and expectations, and a good relationship between the two parties—are one of medicine's most powerful assets. Impersonal medical care and drug or surgical interventions are not effective in treating most diseases. Most visits to physicians stem from conditions related to stress and other psychosocial factors (Kroenke and Mangelsdorff 1989) which are responsive to placebo effects.

Such placebo effects based on 'remembered wellness,' accompanying standard therapies comprise effective care. For example, in an experiment using five standard therapies for angina pectoris, patients who believed in the therapy experienced about 80 percent relief from chest pain, reduced nitroglycerine usage, improved electrocardiogram, and increased exercise tolerance; skeptical patients experienced about half as much therapeutic benefit (Benson and McCallie 1977). In Canner (1980) among patients given placebos, less compliant patients had a 28 percent mortality rate after five years, while compliant patients had a 15 percent mortality rate.

Placebo use has evolved to entail warm, caring, sympathetic relationships that foster positive beliefs, combined with appropriate standard specific therapies. Thus defined, placebos are devoid of deception, and integral to quality of life, health, sound professional conduct, and empowerment and self-help.

Under this conceptualization, it is reductionist scientific medicine coupled with impersonal managed care that is ethically questionable.

3. Theories of Why Placebos Work

Three fundamental theories of placebo mechanisms are: conditioning (learning), hope and expectancy (cognition), and neurobiology (subjective experience). These three mechanisms are not mutually exclusive. Each provides ethical insights into placebo use.

3.1 Learning

Classical conditioning involves pairing an unconditioned stimulus (UCS), e.g., a charismatic, enthusiastic teacher who emphasizes the excitement and importance of a topic, with a neutral stimulus (a not-particularly exciting curriculum) which becomes the conditioned stimulus (CS) and evokes enthusiasm and dedication in the student. Pairing morphine (UCS) given to patients in great pain, causes the nurse and syringe to become conditioned stimuli (CS) for pain reduction. Placebo effects persist when only the CS is present and, following principles of partial reinforcement, continue undiminished if the UCS is reintroduced periodically, but eventually extinguish if the UCS is never reintroduced. For example, if a painkiller (UCS) having severe side-effects is interspersed with a placebo in an identical capsule (CS) and intermittent reintroduction of the UCS, the effect may be a continuously effective analgesic with diminished side-effects. There is a powerful relationship between magnitude of UCS and response to the CS. For example, a massive dose of morphine (UCS) will result in a massive placebo (CS) effect. These principles of conditioned analgesia have been found with animals as well as humans.

Ethics requires disclosure of use of conditioning; e.g., following explanation of learning theory, the doctor might state that the UCS would be intermittent and that the client's own relevant powers will serve to reduce pain. Conditioning produces expectancy, and memory of UCS effectiveness, as well as measurable neurological change.

3.2 Desire and Expectancy

Need or desire (e.g., for relief from pain) and expectation that a given therapy is effective will mediate placebo analgesia. These cognitive factors become associated with the CS and extend and support the role of learning. Authoritative professionals can create powerful hopes and expectations which can produce a placebo response without prior exposure to an objective UCS, though such exposure (combining conditioning with expectancy) increases expectancy.

Similarly, expectancy can result from learning about an agent's therapeutic value, especially when one strongly desires that effect. Thus, persons desperate for relief are highly vulnerable to quackery, fraud, superstition, or cults, which may produce significant temporary relief through placebo effects. Conversely, anything expected to cause distress, sickness, or death (e.g., feared surgery, awkward physicians, institutions with poor reputations) can have a *nocebo* effect (Hahn 1997). Culturally based expectations, and good or bad relevant prior information or experiences, as well as aspects of the current therapeutic situation will create expectations and have placebo or nocebo effects. Positive expectations result in far superior outcomes of standard medication, surgery, education, and other interventions. The ethical professional uses expectancy effects to good ends, not to deceive people.

3.3 Neurobiology

If placebo effects are solely products of imagination, the ethics of placebo use concerns fooling people. However, as scientists discover how subjective 'mind' acts on the physical body, the ethics of placebo use changes. The functioning of neurons is involved in mental representation (e.g., the self, an image); subjective experience (e.g., pain, feeling of wellness); and bodily change (e.g., hormone secretion, healing); and the neural network, itself, is an objective physical entity. Thus, for example, injury causes pain, morphine reduces that pain, and placebos also alter neural representation of the injury (pain) in proportion to the preceding amount of morphine. Research has demonstrated neural substrates of placebo effects, especially analgesic effects, and imaging technology holds promise of rapid advancement in this area (see Fields and Price 1997).

Neurological models of placebo effects provide a framework for research on the role of language, culture, and environmental context in helping to reduce stress and pain, reversing disease processes, and healing injury. Future discoveries in this domain may lead to rewriting the ethics of placebo use.

4. Summary

Placebos have evolved from deception, and 'noise' that researchers control for, to phenomena studied in their own right. Research has shown that what persons think can affect objective (structurally or functionally measurable) changes in physiological functioning. Further theory and methodological developments promise the possibility of effective self-administered placebos—a new kind of self-help, and of radically new ethical considerations regarding placebo use.

J. E. Sieber

Plagues and Diseases in History

Disease is the sting of death and death is the necessary victory of the grave. Disease is a mechanism of adaptation—that is, of attack, equilibrium, and defense—of the living being to its habitat. Human development and evolution, in its social, cultural, and ecological setting, give rise to alterations in the human organism, both in body and mind, against which it

must struggle. The evolution of the species, society, and culture takes place within a given environment and this environment may alter the pathological spectrum. If according to Bichat life is resistance to death, it may be said that life is resistance to disease. The human being seeks Hippocratic and Aristotelian equilibrium but, in doing so, he or she is frequently subjected to changes and movements that endanger this quest.

These changes, quite frequently depend on the human being, on his or her customs, social groupings, or on settlements that lead him or her to avoid malaria by settling in mosquito free zones or to control smallpox by vaccination. On other occasions, such changes do not depend on the human being but arise in the environment or within the diseases themselves that may appear or disappear of their own accord, as was the case with the 'English sweate.' On yet other occasions, these changes are merely due to cultural appreciations, such as is the case where certain sexual practices such as masturbation or homosexuality are stigmatized as diseases. On the other hand, disease is not always considered harmful: thus it may be considered a distinction of the gods, as was the case of epilepsy in the time of the classic authors. This same disease was associated with the devil by the Christians, and historically, it had always been a marked distinction of great personages from Caesar to Napoleon. Disease can also be considered a way towards perfection or transformation, leading to the creation of art or the salvation of the soul. It may also have political repercussions: it is claimed that George III's madness gave rise to problems for the British crown while Roosevelt's fragile health was considered to have placed him in a weak position in the Yalta negotiations. Socially, disease has sometimes been considered the stigma of groups or races. Medicine and politics have endeavored to preempt social changes by means of eugenics which began with recommendations or orders to avoid marriages entailing risks (real or imaginary) and went on to such processes as sterilization and abortion. Hereditary problems are thus intertwined with cultural, social, religious, and moral ones. In contrast with the stark determination of former times, there is today an attempt to draw new optimism from the possibilities of genetic modification. Although, in this latter respect, there is fear of a future where such a formidable force could rest in the hands of the rich and powerful. Thus, individual disease or illness is rooted in society, being tied up with the history of great endemics and epidemics.

1. Ancient and Middle Times

Paleopathology enables us to discover the high incidence of diseases in the early inhabitants of the

Earth, especially in the cases where such diseases left their mark on the bone. It is thus possible to detect remnants of tumors, infections, and osteoporosis as also traumatism, dental alterations, rheumatism, and osteopathy. From the first settlements in the Fertile Crescent, changes have taken place in the relationship of man and animals with their environment and it is possible to establish an extensive catalogue of diseases which largely subsist down to this very day. Particularly significant are the forms of settlement, the crops, and the contact of man with cattle, pets, and parasites. Thus in the fourth and third centuries BC, malaria had already set in the early civilizations in marshy areas where the water and the crops provided the conditions for the mosquito to infect man. Evidence for the existence of seasonal and intermittent fevers is already to be found in Chinese, Indian, Sumerian, Assyrian, Babylonian, and Egyptian cultures. The link between splenomegaly and fever is mentioned in the Papyrus of Ebers, dating from 1570 BC. The connection between fever and marshy areas appears in the Hippocratic text *On Airs, Waters and Places*. Deforestation, agriculture, temperature, and a greater population density, as well as military and commercial movements favor the spread of the disease. In the third century BC in Italy, the disease becomes acute and in the first century BC Varron coincides with Lucretius in pointing to small animals as the cause of the disease and recommended that these be either abandoned or sold and that people should dwell on high ground, this latter being traditional advice and here also defense reasons counted. The spread of malaria got worse in Rome owing to negligence and flooding and it reached its zenith at the time of the fall of the empire, a cataclysm to which it may have contributed.

The bubonic plague was endemic in the Near East in pre-Classical times, the buboes being described by Hippocrates. In 430 BC, Thucydides describes the plague of Athens in the war against Sparta, but it is doubtful that this case refers to the bubonic plague. The first reliable description of this disease is that given by Rufus of Ephesus in the first to the second century AD, in the epoch of Trajanus; and in the sixth century, the plague of Justinian initiates the descriptions of the first great epidemic cycles. Up until the Christian era, there is equilibrium between human beings, cities, and parasites but this equilibrium breaks down with the advent of the convoys that bring the two healthiest extremes into contact, namely, China and Rome. India and the Middle East continue to be dangerous and the situation at the extremes further deteriorates. Soldiers and merchants, animals and merchandise, slaves and prisoners all contribute to linking up the extremes of the known world. A consequence of this contact was the Antonine Plague in the second century. This plague was attributed to smallpox, something that had already existed as far back as the year 3000 BC, as certain mummies show.

In the Middle Ages, leprosy spread greatly. This biblical and present-day disease is accompanied by malignant connotations since dirtiness and overcrowding provided the conditions for the spread of the otherwise not extremely contagious *Mycobacterium leprae*. In this respect, the Route to Santiago de Compostella where pilgrims slept in groups and under conditions that left a lot to be desired provided a fertile ground for this disease. Another markedly religious character for the spread of the disease is to be found in the 'Sacred Fire,' 'St Anthony's Fire,' or ergotism, during which rye ergot was eaten. These diseases are linked to many others that owed their spread to squalor and poverty, for example, scabies and lice, consumption and fevers, anthrax and ophthalmia. In the Mediterranean bowl, malaria continued to be endemic with the population tending to resort to residing on the hills and mountains, far from marshy lands. The plague set in the incipient cities with the effects of rats and lice, making this disease an explicative example par excellence of epidemic history; see in this respect, Zinsser (1934). A second epidemic cycle commences with the Black Death in 1348. At this time, Venice establishes control over persons and ships. Commerce and the cities collapse and thus the hegemony of Castille over Aragon takes place, giving rise to the origin of the modern European Kingdoms and empires.

2. Modern Times

European expansion meant a sudden traffic of parasites towards the new worlds. The discovery of America, with its scattered population devoted to agriculture, where there were no dirty cities and where the inhabitants were devoid of immunity to the diseases of old Europe, produced an enormous demographic crisis. Certain diseases, such as smallpox ravaged the indigenous population, first in South and later in North America. Syphilis has supposedly come from America, brought back by the Spaniards and it caused havoc in Renaissance Europe. Sea voyages led to the development of scurvy, due to the lack of fresh foods. Other diseases also came from overseas, such as yellow fever, although it originated from Africa and later from the tropics, due to the commerce of slaves and merchandise. In the seventeenth century, it took root in Brazil and is still present today in the Amazon. Soon this disease spread to the Caribbean and throughout America, reaching New York and Boston and likewise Colombia, Ecuador, and Peru. It affected warm America and Europe, especially the Iberian Peninsula. Immunity and cut offs in commerce stalled the disease and today it remains endemic in tropical areas of America and Africa.

The plague arrested demographic growth in Europe since the enmity between states and trade impeded protection against the disease. The last plague of Marseille in 1720 and the relative peace of the

eighteenth century allowed all European nations to set up sea and land defenses with Austria becoming a solid bulwark in the face of the Ottoman Empire, thus sealing off all possible spread of the plague. Towards the middle of the eighteenth century, the third wave of the disease broke out and with the exception of Europe, it spread to all countries including Asia, Africa, and paradises like America and Australia, leaving remnants in those places. The eradication of the plague in Europe was a result of the advent of public hygiene, immunity to the disease, and the disappearance of rats and the old and dirty wooden buildings. The fire of London 'purified' the city, since the rebuilding was carried out in stone, eliminating animals and dirt.

The disappearance in Europe of the plague was followed by the appearance of cholera that had been endemic in India for 2000 years. This disease was described by Western travelers in the sixteenth century and its spread to Europe and America was a consequence of pilgrimages, trade, and a lack of cleanliness in water. A great pandemic broke out in 1817 and spread through Eastern Africa and Southern Asia and in a second wave it spread through Kabul and Persia reaching Russia and Poland in 1830. It then swept across Europe and had reached America by 1832. Over two centuries, terrible waves spread from the East and as late as the 1970s, the seventh outbreak of pandemic reached Europe. However, the timely and necessary cleansing of urban water supplies helped to stall its advance progressively. Nevertheless, as late as 1892, the free Hanseatic city of Hamburg suffered an outbreak of cholera epidemic while the neighboring Altona, governed by the new Prussian Reich, was able to avoid the disease, thanks to the successful filtering of its water. Cities and governments advanced in hygiene and they attempted to bring about healthier cities by means of appropriate public health measures.

Together with the major epidemics, death was continuously caused by two groups of endemic diseases. Two seasonal cycles of disease remained rooted into modern times: one in summer affecting children and due to enterocolitis, lactation problems, dysentery, and typhus, and another in winter affecting the old and due to typhus and pneumonia. The nineteenth century sees the beginning of the demographic revolution in Europe with a sharp decline in mortality, especially maternal and infant mortality. Diseases like diphtheria, chicken pox, scarlet fever, measles, and smallpox are combated with serum and later on with vaccination. Mother care also advanced both throughout pregnancy as also at childbirth and during lactation. Tertian fevers continue to be active and are combated in the Mediterranean area by clearing up the marshy areas, avoiding the mosquito by mechanical means, or by the use of cinchona bark (Peruvian bark), and later on of quinine.

The rise of great and industrial cities with low-grade outskirts and the emigration of peasants to the city

favoring the spread of maladies associated with poverty, squalor, lack of appropriate food, and exposure of people devoid of defenses. Some of the diseases are strictly occupational which is the case of miners and textile workers who were exposed to injury and to the industrial poisons that affected the proletariat. Other diseases are closely related to the harsh conditions of life with the spread of typhus and pulmonary diseases, especially tuberculosis, being due to this factor. Tuberculosis spread over the turn between the eighteenth and nineteenth centuries and while it was known as the disease in fashion, affecting notable and distinguished people, it struck the proletariat much more severely. Today, tuberculosis is again a serious threat. The same can be claimed regarding the enormous spread of syphilis as also with respect to drug abuse, beginning with alcohol and continuing with marijuana, cocaine, and morphine. At the middle of nineteenth century the opium trade was legalized in China, after the victory of the British army.

3. Contemporary Times

This last century marked the descent of the high mortality rates in countries that reached high standards of sanitary development, that is countries that invested in public health care, such as Britain or the USSR. Such advances have been due to public health services, hospitals, antibiotics, surgery, and vaccination and they have been reinforced by the developments in immunology, pharmacology, and biotechnology and with the promising future of improved genetic material. Smallpox is the first disease to be considered totally eradicated with only some samples of the virus being kept at a few laboratories for study purposes. But other viruses have taken its place. Thus the old influenza caused three heavy outbreaks of pandemic in 1918–9, 1957–8, and 1968: these were known respectively as the 'Spanish 'flu,' which originated in the USA, the 'Asian 'flu,' and the 'Hong Kong 'flu.' Poliomyelitis originated in the USA, affecting non-immune children and this disease has only been controlled in developed countries by means of vaccination. AIDS has meant a development in virus pathology and this disease has associations with the exploitation of poor countries, drug trading, and also an elite sector that has sprung rapid research in the field. The world commotion surrounding this disease has served both to reveal human altruism on the one hand, but, on the other, contempt towards those infected by the disease, since AIDS is becoming more and more the lot of the poor, such as large areas of Africa or southern Asia and of downcast or marginal groups such as the chronically ill, drug addicts, prostitutes, and homosexuals. Nevertheless, heterosexual transmission is advancing and is placing the future of all Africa in danger.

Forms of illness are changing. Development has managed to stamp out old forms of infectious morb-

idity. On the other hand, the increase in life expectation favors the development of Alzheimer and cancer. Cardiovascular accidents and traumatism, traffic and sports, factories and radiation are something that the twenty-first century will inherit. Ghettos and unemployment, and some of the old drugs such as heroin and tobacco or new synthetic ones are causing havoc even to the rich world. But in underdeveloped countries, the old morbidity continues to exist, giving rise to very low life expectation. Death is most rampant amid the least protected, especially women, children and the elderly, with the wars causing high death rates amongst men. Under such circumstances, diseases caused by deprivation and infection continue to be the most rampant.

Malaria has been eradicated from Europe thanks to drainage, improvements in crop cultivation, mechanical means, quinine, and insecticides. Today, faith is also placed on vaccination and the genetic modification of the mosquito. Yet malaria continues to be endemic in warm zones of America, Asia, and Africa. In the interwar years, the Rockefeller Foundation sponsored a campaign against the disease. In 1955, the World Health Assembly, meeting in Mexico, warned against the resistance of the mosquitoes to insecticides. Together with the WHO and the UNICEF, the US government was financing the eradication program of the Pan-American Health Organization. Today, an effort is being made to interest governments in this disease, a disease that represents a danger to 40 percent of the population. In Africa the situation is very serious due to the increase in agriculture and irrigation as well as emigration, the political and economic problems and the bad sanitary conditions following in the wake of housing expansion and deforestation. The WHO, through the 51st World Health Assembly of 1998, set up the program 'Roll Back Malaria' and, with aid from UNICEF and the World Bank, is endeavoring to bring about economic and sanitary improvements in developing countries.

Cholera continues to be endemic in Asia, between India and the Far East, and also in warm zones in America and Africa. *Yersinia* (or *Pasteurella*) *pestis*, discovered by Yersin and Kitasato, is still to be found throughout the world, except in Western Europe, carried by rodents, rabbits, and related species. Bacteria are carried by black and brown house rats, *Rattus rattus*: rat fleas are the arthropod vectors transmitting 'epizootic' plague to humans from rodent hosts, but transmission among humans is also possible. Short-term human immunity requires frequent vaccination. Almost forgotten in the civilized world, there is nevertheless always the possibility that the devil may once more send his rats to the old, rich cities.

Planetary Cartography

Planetary cartography is the making or study of maps of the planets, satellites, asteroids, and comet nuclei comprising our solar system. Maps of the Sun and other stars may be included for the sake of completeness, and future astronomers may prepare maps of planets orbiting other stars. The definition of 'map' is often biased towards modern terrestrial topographic maps, so for this article a broad definition is adopted similar to that of Harley and Woodward (1987): a map is a graphic representation designed to facilitate a spatial understanding of the object or region it represents. How many worlds have been mapped as of mid-1999? Several thousand maps of the Moon and Mars have been published, but maps of Pluto are limited to simple illustrations in journals. Asteroid 29 Amphitrite is portrayed in one simple sketch map, and the only published map of asteroid 1 Ceres is an illustration in a science fiction magazine. If Amphitrite is included but Ceres is not, 60 bodies in the solar system have been mapped in a scientific sense. When should a world be said to be mapped? It is accepted for this article that composites of multiple observations or images augmented with feature names or other in-

formation can be called maps, but not primary observational records (photographs or drawings).

The history of cartography can be portrayed as a linear evolution driven by successive developments in theory, technology and exploration, with modern scientific mapping as its zenith. Planetary cartography is particularly susceptible to this approach. Recent work (e.g., Harley and Woodward 1987) recognizes maps once dismissed as irrelevant and broadens the field to consider uses or aspects of maps overlooked in purely technical histories. Here both approaches are combined, useful references identified and areas indicated that will repay further study, for no comprehensive survey of this subject has yet been undertaken.

1. Background

The International Astronomical Union (IAU) oversees body and surface feature nomenclature, the definition of north and the locations of prime meridians, and publishes its decisions in its *Transactions*. Surface feature locations are determined by establishing a control network of points measured in multiple images of a world. Greeley and Batson (1990) summarize these technical issues. Many mapped bodies are near-spherical, but where they are not their shapes are estimated from stereoscopic images and the changing outlines of the object in views from different directions.

2. Pretelescopic Planetary Cartography

Markings on the Moon have always been visible, so representations of them are the earliest planetary maps. Drawings by Leonardo da Vinci dated about 1505 were long considered the oldest, but recently other ancient candidates have been suggested. Carvings at Knowth, Ireland (about 2800 BC) may represent the lunar markings, and one at the end of an interior passage might be illuminated at times by the rising Moon. The final form of Stonehenge, a circle containing a double horseshoe, may be a schematic map of the Moon akin to those at Knowth. Its solar alignment is most celebrated, but the full Moon occasionally rises on the monument's axis. Some Egyptian depictions of the sacred eye representing the Moon resemble the lunar markings. Plutarch gives several lunar place names. Some Arab world maps around AD 1100 resemble the lunar markings in reverse, recalling the ancient belief that the Moon is a mirror reflecting an image of the Earth. Van Eyck painted the Moon with markings in 1430, though they may be merely schematic. William Gilbert drew a lunar map with place names in about 1600, just before the invention of the telescope. Of uncertain age, not

ancient but probably drawing on a long tradition, are representations of the *maria* in native American art, including rock art in the Stein Valley, British Columbia and drawings of the Barasana culture, Colombia. The only other body which could be mapped without a telescope is the Sun, since sunspots had long been known in China, but no such map has ever been described.

3. Telescopic Planetary Cartography

Following the pioneering observations of Harriott and Galileo in 1609, lunar mapping advanced rapidly until the 1800s (Kopal and Carder 1974, Whitaker 1989). Successive cartographers sought mainly to improve accuracy and detail, since the Moon is unchanging. Riccioli's nomenclature became standard and was formalized by the IAU in the 1930s. Photographs eventually replaced more stylized drawings, culminating in several superb atlases produced under the direction of Gerard Kuiper (University of Arizona) at the dawn of the space age. Frequently overlooked in histories of lunar cartography are maps prepared by and for nonastronomers, such as Homann's 1720 map comparing the nomenclatures of Hevelius and Riccioli, and numerous small charts shown as insets in celestial or world maps from roughly 1650 to 1800. Some atlases of the 1800s also contain lunar maps. Though rarely more than poor copies of astronomers' map, they may have had a wider audience than their models. No systematic study of them has yet been made.

Other worlds were more difficult targets for telescopic observers (Greeley and Batson 1990). The first map of Venus, by Bianchini in 1728, misrepresented faint markings in the planet's opaque clouds as lands and seas. Similar maps were being drawn until the 1950s. Herschel first mapped Mars in 1783. Schiaparelli in 1877 measured feature locations for positional control, described the spurious 'canals' which influenced public opinion for decades, and introduced the modern feature nomenclature. The markings of Mars are variable, so maps are made whenever it is well placed for observation (Blunck 1982). Maps of Mercury, beginning with Schiaparelli's of 1889, were compromised by the assumption of an erroneous rotation period that was not corrected until the 1960s. Markings on the four largest satellites of Jupiter are at the limit of telescopic discernability, but a map was made by Douglass in 1897, and others followed in the 1900s. Ephemeral cloud features in Jupiter's atmosphere are plotted on what are essentially meteorological maps to monitor changes. Similarly, sunspots and other ephemeral features of the solar photosphere are mapped to record the Sun's changing appearance. These 10 bodies, excluding Earth, were all that had been mapped before the Space Age.

4. Space Age Planetary Cartography

Spacecraft have visited many worlds since 1959, and like terrestrial explorers these planetary missions generate many maps. Some are used for premission planning, some for operational use during the mission, and others provide a systematic record of discoveries made or activities undertaken. The subject has not yet been described in detail and will form fertile ground for future scholarship.

4.1 Cartography for Lunar Exploration

The Soviet probe Luna 3 photographed the Moon's far side for the first time in 1959. Later missions filled remaining gaps in coverage and revealed greater detail, permitting large scale mapping of some areas. Landing craft photographed their surroundings, which were mapped at large scales. The US Geological Survey (USGS), Army Map Service, and Aeronautical Chart and Information Center produced over 1,000 maps for the Apollo missions (Kopal and Carder 1974). Astronauts used maps for site selection, training, orbital navigation, and surface activities. In the Soviet Union, MIIGAiK and other agencies produced maps for their lunar missions, including robotic landers and rovers, but never undertook a systematic large-scale mapping program. Lunar mapping in both nations almost ceased in the mid-1970s, leaving a legacy of 1:250,000 and 1:1,000,000 scale maps as well as global and regional geological maps. Public interest in Apollo resulted in numerous popular maps, atlases, and globes in the 1960s, and for a time many general world atlases included a lunar chart. Most disappeared as interest in lunar exploration waned.

4.2 Cartography for Solar System Exploration

Following Apollo, robotic spacecraft travelled to other planets, all but Pluto having been visited by 1989. In the 1990s several asteroids were explored and other bodies were observed in greater detail. Almost every mission resulted in maps, from systematic geological and topographic mapping by USGS to large-scale charts of the immediate surroundings of landers on Venus or Mars. The Soviet Union attempted no systematic mapping, except at Venus, but its landers gave the only surface views of Venus yet obtained. Mapping by USGS up to about 1994 is summarized by Greeley and Batson (1990). Forty-two worlds had been mapped from planetary spacecraft data by 1999, 20 by USGS. One significant problem concerns small irregularly shaped bodies for which geodetic methods and map projections are still being developed. Many planetary maps since 1990 take the form of digital photomosaics and maps of radar reflectivity, elevation, etc. which may be distributed on CD-ROM or via the World Wide Web, reprojected to

any desired map projection and used in Geographic Information Systems. USGS has taken the lead in this, and many such products are now available for free download via NASA's Planetary Data System. The number of maps published on paper is declining, which will compromise historical studies. Public interest in Mars and the possibility of human expeditions before about 2020 led to the publication of several popular Mars maps in the late 1990s. These may be said to include maps of the Cydonia region of Mars illustrating unconventional concepts regarding the artificiality of features such as the famous 'face,' showing place names, alignments, and architectural or geological interpretations.

4.3 Telescopic Mapping in the Space Age

New instruments and techniques have enabled mapping of many worlds not visited by spacecraft, including Pluto and the asteroid 4 Vesta. Radar images of Earth-approaching asteroids have been used to derive shape models and maps, and comet nuclei have been mapped very tentatively by observing changing patterns of material ejected from their surfaces. These maps usually appear in scientific literature and are rarely seen by a nontechnical audience. Numerous stars should be included among the mapped celestial bodies, since methods have been devised for interpreting features in their spectra in ways that lead to simple maps of phenomena in their photospheres. Interferometers operating at visible wavelengths may eventually permit the mapping of surface features on planets orbiting nearby stars. Even in this solar system, the number of mapped worlds will exceed 100 not far into the twenty-first century.

5. Science Fiction Mapping

Some science fiction books and fan magazines contain maps reflecting both the stories themselves and contemporary knowledge of their settings. Like other popular maps they help shape public awareness of the planets. Post (1979) illustrates some examples, but the subject would repay greater attention. Here are considered only fictional maps of real worlds, Mars being the most prominent example. Fictional maps once showed canals and ruined cities, but now often identify lowlands which become seas on a future Mars made more earthlike by colonists. Notable among works illustrated in this way are the 'Barsroom' (Mars) novels of Edgar Rice Burroughs and magazines relating to his work, and the novels of Kim Stanley Robinson. A different class of planetary map has evolved to support role-playing games. These maps frequently include a mixture of fictional and real surface features, and have appeared in atlas and sheet map form as well as illustrations in game manuals.

6. Conclusion

Planetary cartography is a broad and rapidly evolving field with a long history. It has not yet been examined in its entirety. Maps record both the history of astronomy and space exploration and a much broader cultural response to those endeavours. A systematic effort to collect and describe this material is needed, including an attempt to preserve the increasing number of ephemeral maps on the Internet.

Planning, Administrative Organization of

This article is about the role of planning in organizations, with a focus on urban planning in local government. It takes the view that it is best to analyze the general before focusing on the particular. To this end, a generic model is outlined, which sets the stage for the later discussion. The article concludes with alternative strategy options for coping with some unique aspects of the urban planning situation.

1. The Nature of Organizations

1.1 Organizations and Management

A human organization is one form of an abstract concept called a system. A system is an assembly of parts that form a whole greater than the sum of the parts. Every system has some unifying principle or force that holds it together. In the case of a human organization, this unifying element is provided by the management of the organization. Management in general refers to those people in an organization who are authorized to give direction to the other members of the organization. Understanding management is the key to understanding any organization.

The field of management is large and complex, and many theories compete for attention. However, most theorists agree, that some structure of power is a necessary part of management. The wellsprings of human motivation remain somewhat mysterious, and often people will cooperate voluntarily without coercion, but some sort of power to influence behavior, either by promise of reward or threat of reprisal, seems essential to the success of any organization. Without it, managers cannot be sure their leadership will be followed.

The problem facing management is that members of organizations are self-conscious human beings with an innate desire for individual freedom and gain, and an innate dislike of restriction and loss. They naturally compete for power, and for the benefits in freedom and gain they believe come with it. Therefore, every time a human organization is formed, and a hierarchy of management power is set up, a field of competitive tension is automatically created, as surely as a magnet generates a field of electromagnetism.

1.2 Culture of Organizations

For the purpose of discussion, this field of tension will be called the 'culture' of the organization. Defined many ways by scholars, the term 'culture' is used here to refer to the degree to which the members of an organization are willing to vest power and authority in management. Three somewhat arbitrary positions along a spectrum make useful benchmarks: (a) a culture of 'consent;' (b) a culture of 'cooperation;' and (c) a culture of 'dissent.'

In (a), organization members are accustomed to accepting the centralization of power in a management hierarchy, and look to specific directions from management for guidance on a wide variety of operations. In (b), members are accustomed to working together creatively under minimum management guidance, except for specific directions on matters that most can agree require a higher vision. In (c), members are accustomed to questioning management directions of all kinds, and frequently tend to place a higher value on individual independence than on group cooperation.

Obviously, the more a culture is oriented towards dissent, the more complex is the management challenge. To understand how managers have dealt with this problem, it is useful to construct a simple model of a generic organization, and see how variations in its structure relate to differences in internal cultures and external conditions. The model presented here is based on four tasks that can be said to constitute the primary responsibilities of management.

1.3 Management Task 1: Mission

Mission is the management task of defining and communicating the basic purpose for the creation and

existence of the organization. Its role is to act as a symbol of values, an orientation for planning, and an inspiration for action.

1.4 Management Task 2: Structure

Structure is the management task of planning and implementing the form of the organization. In practice, this usually means dividing the constituent members into clusters, called administrative units, and assigning a manager to each cluster. The result is often portrayed as an 'organization chart,' a diagram showing the administrative units, with lines linking them vertically to either a single person (called here the 'executive,' or a small group (called here the 'board,' or to both, at the top of the chart. Together these two entities, plus their support staff, constitute the management 'apex.'

The vertical linkage always takes the shape of an upside down tree. This tree represents the way that all members of the organization relate to each other in terms of their authority, that is to say, their legitimate power to exercise control over subordinates. A hierarchy controlled by an apex is always necessary, because organizations need a way to reconcile disputes in a timely manner.

1.5 Management Task 3: Procedure

Procedure is the management task of planning and implementing the functions of the organization. In practice, it means controlling the behavior of individuals within the organization to ensure that plans are executed and products are produced efficiently and effectively.

Systems theory suggests that human organizations, like biological forms of life, can be described in terms of function, as linear process (with some internal feedback loops) from 'input' to 'throughput' to 'output,' and that its output can be divided into two components, one called 'product' one called 'waste.' This simple model is popular in the fields of economics and business management, where it provides a foundation for the idea of using product to measure the functional performance of organizations of all types.

1.6 Management Task 4: Product

Product is the task of designing the products that the organization creates and exports into its external environment. Product in this sense is an extension of the concept expressed in the term 'mission.' The products of an organization should represent a more focused and defined expression of the values and directions implicit in its mission statement.

The concept of product has come to play a critical role in analyzing and comparing the relative value of different organizations. Two criteria are used, one focused on the internal environment of the organization 'efficiency,' and the other on its external environment ('effectiveness'). Both criteria use the product as a surrogate by which to measure the organization as a whole. Efficiency is the ratio derived from dividing the product by the input. It is a quantitative measure. Effectiveness is the degree to which the product satisfies the mission of the organization with regard to its external environment. It is a qualitative measure.

2. Model of a Generic Organization

Summing up the key factors outlined in Sect. 1 a graphic model can be visualized. The structure of the organization is represented by a triangle, with its vertical axis reflecting the authority hierarchy of management. The procedure of the organization is represented by a horizontal line across the bottom of this triangle, reflecting the flow of work transactions through the organization from input to output. Operators comprise the bottom layer of the triangle, performing the actual transactions that create the product as it moves from input to output. They are supervised by managers in the upper layers of the triangle.

The mission and structure responsibilities of management fall along the vertical axis of the triangle, and the procedure and product tasks fall along its horizontal axis. Mission and structure, once established, are not often changed, whereas product and procedure must be changed frequently to keep the organization in balance with its changing external environment. Structure is a key factor influencing product and procedure. Three basic variations in structure design can be observed in practice, as follows.

2.1 Structure Alternative 1: The Divisional Model

In this model, the basic principle for clustering people together into administrative units is their degree of commonality with regard to technique, skill, knowledge, or activity. This creates a set of what may be called 'functional' divisions, each one centered on a different type of specialized operation. The effect of this model is to allow the apex to delegate authority over specialized operations to subordinate managers within the hierarchy, while still retaining strong direction over the design and production of the composite final product.

This model emphasizes quality of input, by setting up hierarchies of specialized knowledge and skill that can apply technology to improve the product. Power over all four management tasks is strongly concentrated at the apex. This model can be very efficient,

but depends on a culture of consent, fast internal communication linkages, and a comprehensible external environment. It can lose effectiveness whenever any of these supporting conditions break down.

2.2 *Structure Alternative 2: The Decentralized Model*

In this model, the basic principle for establishing administrative units is to include in each division all the special resources necessary to produce a complete particular product. This model creates a set of 'product' divisions that share all of the characteristics of the parent organization, with the exceptions that: (a) each division produces a different product; and (b) enough freedom is withheld by the Apex to ensure the health of the parent organization.

This model emphasizes quality of output, by setting up hierarchies of situational analysts who can adapt product designs to changing external situations. Power over product and its procedure is delegated by the apex, but control over mission and structure is retained. This model can be very effective in responding to local and rapidly changing product needs, but it depends on a culture of consent with regard to mission and structure, a greater aptitude for situational strategy by divisional leaders, and sufficient supplies of input resources to duplicate them across every product division. It can lose effectiveness whenever any of these supporting conditions breaks down.

2.3 *Management Structure 3: The Matrix Model*

In this model, the organization is divided into a set of 'functional' divisions as well as a set of 'product' divisions. The apex delegates control of both product and procedure, but avoids concentrating them entirely in the product divisions, by requiring them to share control of these tasks with the functional divisions through negotiated divisional agreements.

This model tries to achieve a balance between quality of input and quality of output, by delegating power in both directions. Power over mission and structure is retained at the apex. This model can be very effective in facing situations that call for the strengths of both the divisional model and the decentralized model. However, it heavily depends on a culture of cooperation in product and its procedure, and a culture of consent in mission and structure. Without managers and operators who value these cultures, this model can be difficult to sustain over long periods of time.

3. *The Place of Planning in the Generic Model*

3.1 *Planning vs. Implementation*

Planning is a process of choosing goals and ways to achieve them, 'before initiating action.' It is one of the

basic activities of the human mind. As long as the process of planning and the initiation of action constitute sequential events within a single human mind, there is no need to reflect on the relationship between the two events. However, as soon as the planning is performed by one person, and the action to approve and implement the planning by another, the question arises: How shall the two events be connected? How this question is answered is the key to the administrative organization of planning.

3.2 *The Generic Planning Process*

The process of planning for a client begins with 'analysis' and ends with 'synthesis.' As defined here, it involves six sequential actions, the first three of which are analytic, and second three of which are synthetic:

- (a) 'Survey' the nature of the current situation;
- (b) 'Forecast' trends, assuming no purposeful intervention by the client;
- (c) 'Compare' the trend scenario to the client's needs and desires;
- (d) 'Invent' possible alternative scenarios achievable through intervention;
- (e) 'Evaluate' the scenarios for feasibility and fitness;
- (f) 'Integrate' alternative scenario elements into one final version, 'the plan.'

The planner can adopt one of two modes while performing this process. All six steps can be performed by the planner alone, with only the sixth step, 'the plan,' passed on to the client. Call this the 'advocacy mode.' Or, the client, and other interested parties as well, can be invited to participate in some, or all, of the steps. Call this the 'participatory mode.'

3.3 *The Base Case: Planning and Implementation Combined*

The least political complications ensue when the divisional model is used in a consent culture, and planning is performed solely by the management apex. Military organizations typically use this model this way, largely because they face such threatening external environments that internal control and secrecy in planning become cardinal virtues.

Certain kinds of business organizations also use the model this way, especially those facing fierce competition analogous to the military situation. However, businesses in the modern world increasingly seem to find it more useful to foster a cooperation culture than a consent one, and, to that end, often shift to some form of the decentralized or matrix models.

Government organizations, by contrast, especially in democracies, increasingly find themselves facing cultures of dissent in the larger organizational unit (i.e., the nation or municipality) for which they function as management. Within individual govern-

ment agencies, however, management can often develop a culture consent or cooperation, because members of the agency voluntarily contract for employment knowing the management climate of the place.

In summary, evidence from the field suggests that the model to which management naturally gravitates is the divisional one, with the synthetic steps of the planning process performed directly by the apex, supported when necessary by a delegation of the analytic steps to a subsidiary unit without hierarchical authority. Some theorists suggest that this model represents the default mode to which all organizations tend to revert, especially when facing external pressures, such as strict performance evaluation, or strong technical competition at the output end, or just scarce resources at the input end.

3.4 Delegated Planning and the Administrative Planning Unit

When external conditions overburden the planning capacity of the apex in a divisional organization, the easiest approach is to expand total capacity by setting up an administrative planning unit (APU). This may be viewed as a lesser delegation of power than is involved in re-engineering the structure of the organization into a decentralized or matrix model, but it is a delegation of power nevertheless, and a power that is potentially very broad in scope. It is easy for other administrative units in the organization hierarchy to become nervous or hostile. Like management itself, every APU must work in a power struggle.

Since the apex usually wishes to retain direct control of the organization's mission and structure, the delegated planning responsibility usually only applies to product and/or its procedure. In manufacturing organizations the former is often called 'research and design,' and the latter 'quality control.' In either case, although the plans of the APU affect the entire organization, the APU's most important client, in terms of plan implementation, is always the Apex.

3.5 The APU in Decentralized and Matrix Models

In the decentralized and matrix models, the responsibility of planning for product and procedure is already delegated in large measure to the individual product divisions. If the apex wishes to exert control or influence over the product units in these divisions, it may set up an APU to fill some planning role that is intermediary between the mission and structure role of the apex and the product and procedure role of the divisions. When this happens, the APU role is typically

concentrated more on the analytic steps of the planning process than on the synthetic ones, or alternatively is focused on operational techniques for supporting a cooperation culture.

4. The Administrative Organization of Urban Planning

4.1 Urban Planning

Urban planning is a field and profession that arose after 1900, primarily in industrial nations. A search began to find methods to ameliorate the negative physical and social conditions of the industrial revolution, especially in urban areas. The concept arose that a good social reality needs the support of a good physical reality, and that the latter can be achieved by adopting a plan for the physical layout of the urban place. The idea was born that one of the major products of local government should be a spatial plan for the physical environment of its geographical area of jurisdiction.

In time, it became evident that a spatial plan by itself could not adequately deal with problems in the physical, social, and environmental systems of urban areas. Theorists concluded that other 'products' of local government (such as rules to regulate traffic, pollution, housing, and employment) were needed to supplement a spatial plan. Today, a wide typology of both spatial and operational plans are in use, as governments around the world seek to improve the form and function of their urban places for a wide variety of reasons. The challenge of getting such plans approved and implemented is made greater by one peculiar characteristic of urban planning that makes it qualitatively different from the kind of planning that all other types of human organizations engage in.

Two observations make the point. First, an organization's product is generally considered to be a creation that is extruded from the interior environment of the organization into its external environment. It is aimed at the exterior, not the interior, of the organization. Second, this product is much smaller in scale than its external environment, whether it be a battle plan for execution by a military organization, a computer or a software training program for sale by a business organization, or schools and police protection provided by a local government.

By contrast, the urban planning product is typically far larger in scale than these. More significantly, it is aimed, not externally, but internally—at the organization's own members. In fact, it is a plan to govern an important part of the lifestyle of the entire human society for which the government is the management. Because this plan is so sweeping in its internal effect, getting it approved and implemented is far more difficult than is the case for the typical

product plan in other organizations. It is more like the adoption of a labor-management agreement than the approval of a new automobile design.

4.2 Government Organizations

Other challenges to urban planning also arise because of the unique conditions under which government organizations must operate. These need some explanation. The mission of government organizations is generally to maintain a healthy and stable society. Typically, they consist of at least two tiers: national and local. National governments often face turbulent, complex, and hostile external environments, and tend to maintain a strong military function. For this and other reasons, most national governments seem to be organized structurally in the divisional model.

By contrast, local governments would seem to face less hostile challenges from their external environments, but, in fact, they must cope with some other conditions that are common to both national and local governments, and that may affect local governments more. The most significant of these are: (a) a limited managerial role within their organization (i.e., their constituency or society); (b) uncoordinated apex members; and (c) a culture of dissent. Together, these three conditions create a management situation of greater complexity than is the case for most nongovernmental organizations.

Regarding limits on governmental power, local governments are usually limited by statutes, in many more ways than is common for the management of nongovernmental organizations. This limitation of authority rests on a foundation of accepted social values, the most prominent of which are the importance given to protecting individual human rights (in democratic societies), and the importance given to protecting private economic markets (in capitalist societies).

Regarding uncoordinated apex members, democratic societies often create government structures that separate to various degrees the power of the board (the legislature) from the power of the executive (the president, governor, etc.), for the purpose of avoiding an excess concentration of power at the apex.

Regarding a culture of dissent, civil societies can often drift towards this end of the cultural spectrum for a variety of reasons, including problems created by the pace of technological change, or international relations, or changing human aspirations, or other sociological factors.

4.3 Urban Planning in Local Government

It is usual to find urban planning delegated to an APU, within a divisional local government structure. This APU inherits the same situational factors com-

mon to all APU's in divisional structures, but in addition, must deal with the unique conditions outlined above. In sum, the APU must find a way to get approval and implementation of its product in the face of: (a) the enormous social impact of its product; (b) a culture of dissent; (c) limited authority of government generally; (d) a fractured apex; and (e) competition for power with other units of government. What are some alternative approaches?

4.4 Strategies for Urban Planning APU's

The most direct approach of course, is to seek the approval of the apex, followed by the issuance of an apex command protocol throughout the organization. This approach has the merits of simplicity and efficiency, and can work well in situations where the scope of social change embraced by the plan is not too big, the cultural dissent level is not too high, the apex is not too uncoordinated, and the power struggle with other governmental units can be won. It fits well with the advocacy mode outlined earlier for the planning process method. Call this the 'apex approach' and the 'stability scenario.'

A second approach has better chances of success when the social change gets bigger, the dissent level gets higher, the apex is more uncoordinated, and the internal power struggle outcome is uncertain. In this approach, the APU needs to shift its planning process to the participatory mode, and reach out early in the process to seek the participation and counsel of all the key managers and operators within the government structure, as well as key movers and shakers within the general society. Call this the 'stakeholder approach' and the 'complexity scenario.'

A third approach may be necessary when the social change is very large, the dissent level is very high, the apex is seriously fractured, and the interagency power struggle is intense. In this approach, the APU expands the outreach scope of its participatory mode planning process to engage the support of as many individuals in the wider society as it can reach, on the theory that this third tier group may be persuaded to influence the stakeholders and the apex to approve and implement the plan produced by the APU. Call this the 'constituency approach' and the 'conflict scenario.'

4.5 Relationship of Organization to Strategy for Urban Planning APU's

Where the charter of the APU does not specify the structure of the unit, the unit's executive (usually called the planning director) can choose an organizational form. In small APU's in a stability scenario, the prevailing practice seems to mirror the tendency of other organizations to adopt the divisional form and use the advocacy mode. In a small

APU, the director is personally under a lot of external pressure, and, like a beleaguered military commander, may feel the need for internal secrecy and control, especially if the situational scenario shifts from stability to complexity or conflict.

In large APU's, especially within a complexity scenario, there are benefits to adopting the decentralized form and using the stakeholder approach, but they depend on developing an internal cooperation culture. By setting up different units to plan for subsections of the society, the scale of the planning product becomes more manageable. With responsibility for product delegated, the director is under less immediate political pressure. The weakness of this approach only surfaces when there are insufficient resources to supply all the divisions with adequate technical knowledge, and/or the need arises to make the divisional plans consistent with each other from a larger perspective.

Conflict scenarios present the most difficult situations to deal with, especially if the technical or consistency component of the plans is important. It is dangerous to use the constituency approach, because the APU may lose apex support if the elected officials feel threatened by this outreach into their electorate. However, if the director can build an internal culture of cooperation sufficient to support a matrix form, it is possible to blend a set of procedures and products adequate to the challenge, but, it is no sure thing. In the final analysis, urban planning is an art, not a science—in administrative organization as well as urban form.

Planning Ethics

Planning ethics refers to the integration of ideas from the fields of planning and moral philosophy, or ethics. As such, it covers a vast terrain of issues in planning theory and practice. Contrary to terms such as 'ethics in planning' or 'ethics of planning,' planning ethics does not privilege either planning or ethics; nor does it connote only a descriptive representation of values in planning. Instead, it is intended to depict the fact that planners and planning can benefit from incorporating ideas from moral philosophy into planning thought and professional endeavors. Further, ethics can also benefit by gaining insight as to how concepts in moral philosophy actually work in practice. Both disciplines may then be more effective in prescribing courses of action in human settlements (planning) and developing theoretical approaches of how persons ought to behave (ethics).

1. Ethical Content in Planning

Planning ethics may be divided according to several different analytic schemes. Wachs (1985) developed a particularly comprehensive and useful typology in this regard. As supplemented by Hendler (1995), it represents a way of discussing planning ethics with reference to five aspects of planning theory and practice. These attributes are: everyday behavior, plan making, administrative discretion, planning techniques, and normative planning theory. In each category are examples of descriptive analyses in which researchers describe and discuss the values planners actually have (e.g., Howe 1995, Gowdy and Hendler 1999) as well as normative analyses where planners advocate particular approaches to planning ethics (e.g., Beatley 1994, Harper and Stein 1993).

1.1 Everyday Behavior

Everyday behavior pertains to the fact that planners are, as persons or moral agents, subject to the same ethical guidelines as everyone else, although their professional status may give rise to particular rights

and responsibilities. Thus, planners may be judged according to the consequences of their actions (consequentialist ethics) or with reference to the inherent characteristics of the actions themselves (nonconsequentialist or deontological ethics). Consequentialist approaches to planning ethics include most prominently utilitarianism with its focus on creating the greatest amount of utility from either individual actions (act-utilitarianism) or actions arising from the application of ethical rules (rule-utilitarianism). Nonconsequentialist approaches, on the other hand, include Kantian ethics with its interest in the ethical treatment of persons as ends and not (only) means. While Kantian and utilitarian perspectives continue to attract much attention in philosophical and planning circles (e.g., Howe 1990, 1995), other consequential and nonconsequential ethical approaches have also proven attractive to planners and philosophers alike; these include, but are not limited to, communitarianism (e.g., Blanco 1995) which emphasizes community practices and virtues, environmental ethics (e.g., Beatley 1994, Jacobs 1995) which focuses on the relationships between and among humans and nonhuman components of our environments, and feminist ethics (e.g., Hendler 1994, Ritzdorf 1995) which attempts to incorporate into our considerations of moral issues the notions of care, trust, nurturing, and eradicating all forms of oppression. Communicative or discourse ethics (e.g., Benhabib 1992), too, has become an important part of contemporary ethical thinking and refers to procedural accounts of how one should make ethical decisions, with the presumption that, if one adheres to the rules guiding such a procedure, the outcome should, by definition, be good or right. This approach may be seen as underlying models of planning processes that emphasize consensus building and/or communicative rationality (e.g., Forester 1989).

Considerations of planners' everyday actions that are based on these sorts of ethical ideas include evaluations of behaviors corresponding to planners as professionals and nonprofessionals. Professionals are often seen as having added moral obligations in contrast to nonprofessionals, given their status in society. Doctors, lawyers, engineers, architects, and planners, among others, are trusted with going beyond motivations of profit and self-interest and focusing instead on the public interest. This status is accompanied by particular responsibilities for specialized knowledge not easily accessible to nonprofessionals, and self-regulation in the face of this specialization (Bickenbach and Hendler 1994). Specific behaviors addressed in this first category of planning ethics include, among others: avoiding conflict of interest; maintaining appropriate relationships with clients, employees, and colleagues; advertising one's services in certain manners; practicing within one's area and scope of competence; providing independent professional advice; and treating information appropriately

whether in terms of confidentiality or disclosure in reference to considerations of the public interest. Providing ethical guidance for planners facing decisions in these and related areas is central to this first aspect of planning ethics that focuses on everyday behavior.

1.2 Plan Making

Plan making is that part of planning having to do with the development, implementation, monitoring, and evaluation of plans, programs, and policies. Together, these sorts of normative statements have ethical implications in that certain amenities or disamenities are distributed or redistributed among citizens (and nonhuman components of our environments) in ways that benefit certain individuals or groups and impose costs on others. Assessing the implications of such decisions and actions pertains directly to the ethical theories and approaches listed above. Kantian-based ethics, for example, may be applied via a Rawlsian perspective in which resources are said to be distributed equally or, if inequity exists, so as to improve the situation of disadvantaged segments of the population in question. Examining the consequences of a planning document using a utilitarian calculus of costs and benefits is also common (see Sect. 1.4). Whichever ethical theory is used, however, is immaterial to the central idea that almost every decision made by planners potentially provides benefits and harms to individuals, groups, neighborhoods, or jurisdictions, and that this result has ethical implications associated with it. The importance of examining the (usually implicit) underlying assumptions and resulting implications of the ethical directions of plans, programs, and policies is the focus of this area of planning ethics.

1.3 Administrative Discretion

Administrative discretion refers to the ambiguity in planners' roles in their working environments. A number of roles have been proposed, ranging from advocate to technician to mediator to social learner (e.g., Gunton 1984). The fact that a planner's role is not discretely and concretely prescribed via the planner's professional organization and/or work environment means that considerable latitude may exist in the planner's determination of an appropriate or desirable way-of-being in professional planning work. Planners thus may exercise discretion in selecting for themselves a role (or roles) but this decision must be subject to ethical scrutiny. Whether, for instance, a planner may in fact explicitly advocate for a particular point of view is a controversial issue in this area of planning ethics. While, as suggested in the discussion of plan making above, any plan or program or policy does necessarily advocate for one course of action as opposed to

others, what and how such directions are advocated is sometimes seen as problematic within planning organizations.

In addition to choices among roles is the fact that administrative discretion highlights the issue of accountability in that planners are not elected officials and yet they may represent the interests of one group over another at any one point in time and in any given plan-making exercise. While such an affiliation may be couched in terms of the public interest, any value-laden connection between planning and developers on the one hand and environmentalists or social justice advocates on the other, for example, may be regarded as an improper exercise of the planner's discretion regarding that planner's role. Despite the fact that this representation of planning work is rooted in the largely outmoded conception of planning as value-free technical work, planners must acknowledge and address the fact that their discretion may be perceived as potentially troublesome.

1.4 Planning Techniques

Planning techniques are those methods or processes followed by planners in preparing or evaluating their plans, programs, and policies. Planners have a considerable array of analytic techniques at their disposal. Cost-benefit analysis, risk assessment, environmental assessment, program evaluation, participatory methods, and many others may be included in this regard. These techniques may aid a planner in deciding a course of action to follow or in assessing the effects of particular actions on different publics. Most of these techniques, and perhaps especially cost-benefit analysis, have been connected conceptually and methodologically to utilitarianism, as follows. First, utilitarianism relies upon the quantification of 'goods' and 'harms' so that both can be summed and compared. This is a starting point, too, for cost-benefit analysis in which costs and benefits are identified, measured, added, and contrasted in order to determine whether a course of action would result in more benefits than costs. Second, this sort of conclusion is clearly based on utilitarian thinking in which a maximum amount of good is sought.

The fact that planning techniques are linked to ethical theories is not particularly troubling. This kind of observation attests to the post-positivist world in which we find ourselves where the planner is not regarded as a value-free technician but as an individual who necessarily brings certain biases, values, and conceptual lenses to their work. Similar, then, to contemporary views of science, defining one's perspective and unearthing one's assumptions is an essential first step in doing research and in doing planning. While this approach to science and to planning continues to be debated, an issue arising

from the mere association of certain ethical approaches to certain planning techniques remains. This is the fact that techniques based on consequential or utilitarian thinking can be seen as over-represented in planning ethics in that methods based more on nonconsequential thinking do not have the prominence of their philosophical cousins. One branch of moral philosophy thus gets short shrift in helping planners to develop and evaluate plans—a branch that is generally regarded as just as viable and important as consequential approaches. Lake (1993) discusses one aspect of this phenomenon in the context of feminist ethics and techniques based on geographical information systems (GIS). He argues that the data-aggregation focus on GIS is incompatible with the focus on the 'concrete other' (Benhabib 1992) in feminism. The same could be said of other ethical theories that attempt to highlight individual experiences and inherent value (the 'right') as opposed to formulaic assessments of consequences (the 'good'). Uncovering assumptions and seeking a broader distribution of ethical underpinnings for planning techniques is of central importance to this area of planning ethics.

1.5 Normative Planning Theory

With its focus on the nature and intent of planning as a profession, as well as its scope or mandate, normative planning theory falls clearly within the realm of ethical analysis. What the planning profession *should* profess (Haworth 1984) is a question that demands this sort of scrutiny.

There have been many disparate suggestions regarding the ethical mandate of planning. Udy (1980) proposed that the four eternal values of goodness, beauty, truth, and love lay at the heart of planning and should be recognized as the normative direction for planning initiatives. Blanco (1995) developed an alternative list that included reason, community, environment, and democracy. Krumholz and others (e.g., Krumholz and Forester 1990) have written and practiced extensively in the area of equity planning, and Davidoff (1978, pp. 69–70) forcefully asserted that,

if a planner is not working directly for the objective of eradicating poverty and racial and sexual discrimination, then she or he is counterproductive. If the work is not specific in its redistributive aims, then it is at best inefficient. If the work is not aimed at redistribution, then a presumption stands that it is amoral. These are strong words. They must be. So long as poverty and racism exist in our society, there is an ethical imperative for a single direction in planning.

In the face of these conflicting sets of values, the field and profession of planning continue to have a normative nature that can only be called ambiguous. Each professional planning organization defines for itself its

central ethical values and then applies them in creating a regulatory structure for its practitioners. In contrast, then, to the fundamental pursuit of health in medicine and the quest for justice in law, planning cannot express its basic ethical norms as succinctly nor with as much certainty. Developing such a rubric or becoming more accepting of a diverse set of principles of moral guidance is a key part of this last aspect of planning ethics.

2. *Regulating Planning Ethics*

All of these ethical aspects of professional behavior are addressed in the codes of professions such as planning (see, e.g., Hendler 1990). Codes of conduct, especially, provide ethical guidance in the form of rules, sanctions, and encouragement towards, or away from, particular behaviors. Codes of ethics are more general and are usually seen as articulating a normative basis for the profession in the form of key values that are thought to be central to the professional community in question. In planning, these values often include environmental integrity, public participation, holistic decision making in terms of temporal, geographic, and disciplinary scope, and a respect for a social justice and a multitude of diversities. While not easily enforceable, codes of ethics provide for a unified voice of the moral intent of a profession and contribute to community building and identity formation within a profession such as planning.

Codes of conduct are used in assessing the behavior of individual professionals and, if necessary, imposing sanctions if the rules under scrutiny are found to have been violated. Suspension, financial penalty, expulsion, and education/counselling are examples of the kinds of sanctions levied by professional organizations. In that planners rarely have to be certified to practice their work, considerable debate is directed towards the licensing of planners and attendant issues regarding their discipline. While some planning institutes are content to regulate only their own members and show little concern for the behaviors of non-members, others have endeavored to expand their membership and refine the notion of planning so that only their members may refer to themselves as professional planners.

Together, codes of ethics and conduct may be seen as a bridge linking abstract moral theories and practical work such as planning in that the sorts of ethical issues discussed here are articulated precisely and resulting discussions may shed light on the implications of different ethical ideas 'on the ground.' As such, codes are growing and developing documents that have evolved significantly during the past two decades of planning ethics discussions. They themselves have also stimulated much in the way of discussion regarding the efficacy of the values they present as being good or right (e.g., Lucy 1988).

Through the processes employed in formulating a code and in subsequent discussions and revisions, planning ethics has enjoyed much in the way of constructive critique (e.g., Kaufman 1990).

Some planning organizations go beyond codes *per se* in educating their members about ethics and contributing to the interpretation of their codes by publishing ethical advisories that apply given sections of a code to a particular planning issue (e.g., AICP 1996). As the sophistication of planning ethics discourse increases, codes and planning practice can only be expected to benefit from an enhanced understanding of, and perhaps consensus about, the fundamental values that underlie planning activities.

3. *Planning Ethics in Theory, Practice, and Education*

Discussions of planning ethics have been most pervasive in planning theory where philosophical analyses of planning and planners are commonplace. It is here that arguments regarding the central tenets and values of planning have arisen, and varying normative models of planning have been developed. Planning practice, however, has only recently begun to emphasize planning ethics in the form of increasingly comprehensive and thoughtful professional codes, as well as enhanced disciplinary proceedings. Empirical analyses of planners' values and accompanying ethical approaches have assisted in our constructing snapshots of the moral terrain in which planners have placed themselves. While consensus is not apparent, certain loci of values around environmental integrity, social justice, and democratic decision making often emerge. In addition to such descriptive studies are normative assessments of planning activities that include both subfields of planning such as transportation, environment, education planning, waste management, etc. (e.g., Hendler 1995, Beatley 1994), as well as specific planning behaviors (e.g., Howe 1995).

Planning education, which usually has the intent of both training future professionals as well as being part of universities, where intellectual growth and development is a priority, has begun to 'mainstream' discussions of planning ethics in its curricula. Far from inculcating particular values, teaching about ethics in planning programs usually has the goal of helping students engage in rigorous ethical analysis as well as preparing them to practice in a profession which espouses certain principles. Thus, values are presented along with the means to examine them critically. This performs the dual function of satisfying planning institute expectations regarding the education of future professionals as well as the more academic intent of teaching students how to think clearly and coherently. Having the skill of developing and critiquing logical arguments helps students and professionals work through ethical dilemmas they will certainly

encounter in their employment and contribute to the increasingly sophisticated nature of planning ethics—theory, practice, and education.

4. Challenges in Planning Ethics

While the value-laden nature of planning endeavors is generally accepted, certain challenges and questions remain. Examples of these include the following. The similarities and differences between public and private planners continue to be analyzed in terms of their moral obligations. The fast-encroaching world of computer technologies and associated planning applications remains ill examined in terms of the fit of these technologies and the moral intentions of the planners and the planning profession they serve. As planning becomes broader substantively with focuses on land use planning but also on social planning, health planning, environmental planning, etc., it remains to be seen whether a single professional organization may be appropriate to govern planners' activities. Further, addressing planning issues in ways that not only accommodate but also celebrate racial, ethnic, sexual, and other forms of diversity continues to occupy the interests of many people who write about and practice planning. Current emphases on planning processes and public participation contribute to resolving such issues but do not address questions regarding such processes as issues of identity, representation, method, and practical considerations regarding the efficient use of planning resources. Empowerment, while often discussed in the context of planning theory, is seldom found in planning codes. Economic development, though central to the 1990s climate of planning, is not well represented in the ethical guidance supplied to planners. And so on. Clearly, planning will continue to have much to consider in the way of discussions regarding its ethical mandate and the methods to be employed in addressing the issues that arise within the context of its thought and practice.

As ethics has highlighted for planners the values in their work, and the need to address critically the values that lie at the base of their theories and their practices, so, too, has planning underscored the importance of discussing ethical issues with an eye to the application of any theoretical stance based in moral philosophy. Thus, planning ethics, as an interdisciplinary field of inquiry and one which does not rest on the laurels of either 'parent' discipline (i.e., planning or ethics), planning ethics promises to contribute to an especially critical and grounded approach to posing, and answering, the sorts of questions and challenges listed here.

Planning Issues and Sustainable Development

‘Sustainable development’ or ‘sustainability’ for short simply means that in a global context any economic or social development should improve and not harm the environment. This concept has developed from a global political process over the last three decades of the twentieth century into one that now touches every part of society. Sustainability has cut across all disciplines and professions, and has developed many complexities in relation to how people plan for their futures (Pezzoli 1997). Its application to planning is full of interest and controversy.

Town and regional planning has its origins firmly in a desire to improve the environment and create a better future. The visions of Ebenezer Howard, Patrick Geddes, and Lewis Mumford, for example, were all rooted in the need to make a greener city. Today there are many planners who use sustainability to rationalize why they are planning the way they do. This article will try to clarify the ways that sustainability is shaping how planning is done, as well as the differences in the ways that planners relate to sustainable development.

The issues relating to sustainability that appear to be uniting planners are:

- (a) How necessary it is to use holistic planning frameworks; and
- (b) How planning processes must start with community/civil society perspectives.

The issues which appear to divide planners are:

- (a) How planners view the size of cities; and
 - (b) How planners view density and car dependence.
- Some resolution will be attempted on these issues.

1. The Concept of Sustainability

Sustainable development was defined by the Brundtland Commission in 1987 after they were given the task of resolving the apparent global conflict between development and the environment (WCED 1987). They concluded that it is possible to develop the world in a way that improves the environment if:

- (a) High income nations see their responsibility to reduce their resource consumption with every new step in the development process;

- (b) Low income nations direct development to those who need it most as only then will population growth stabilize and misuse of natural resources begin to ease;

- (c) All nations need to see development as meeting community goals, thus development must be inherently a ‘bottom up’ process; and,

- (d) All professions and disciplines need to adjust to a more holistic, integrated approach if sustainability is to be converted into real change.

The thrust of this article is that, within the sustainable development framework of thinking, there are clear differences in what planners are suggesting sustainability means for cities. However, the overall situation cannot be seen as just a series of raging controversies, and indeed there are substantial areas of agreement.

2. The Agreements: Holistic Frameworks and New Planning Processes in the Age of Sustainability

Dyck (1998) suggests that sustainability is a concept which challenges prevailing planning theory because planning has emerged primarily from a modernist social context. In this perspective, modernism has associated growth or development with increased resource use, trickle-down economics, and ‘expert-oriented’ planning. Very few planners are, however, espousing a modernist view in the new millennium, and even the World Bank seems to agree with the basic conceptions of how sustainable development should now be viewed (Leitmann 1999). In particular, the areas of emerging agreement are the need for new, more holistic planning frameworks and community-sensitive planning processes.

2.1 Holistic Frameworks

The principles of sustainability outlined above can be applied to cities, though the guidance on how this can be done was not very clear in Agenda 21 and other UN documents. It is probably true to say that the major environmental battles of the past were fought outside cities, but that awareness of the need to come back to cities is now recognized universally by environmentalists, government, and industry (United Nations Center for Human Settlements 1996).

Anders (1991), in a global review of the sustainable cities movement, pointed out that ‘The sustainable cities movement seems united in its perception that the state of the environment demands action and that cities are an appropriate forum in which to act’ (p. 17).

One of the strongest themes running through the literature on urban sustainability is that, to solve problems, planners need to view the city as an *ecosystem*. As Tjallingii (1993, p. 7) puts it: ‘The city is

(now) conceived as a dynamic and complex ecosystem. This is not a metaphor, but a concept of a real city. The social, economic and cultural systems cannot escape the rules of abiotic and biotic nature. Guidelines for action will have to be geared to these rules.'

The city is an open ecosystem, having inputs of energy and materials. The main environmental problems (and economic costs) are related to sustaining the growth of these inputs, and managing the increased outputs. By looking at the city as a whole and by analyzing the pathways along which energy and materials (and pollution) move, it is possible to begin to conceive of management systems and technologies which allow for the reintegration of natural processes, increasing the efficiency of resource use, the recycling of wastes as valuable materials, and the conservation of (and even production of) energy.

There may be ongoing academic debate about what constitutes sustainability and how it applies to cities (Slocumbe 1993, Mitlin and Satterthwaite 1994), but what is clear is that many strategies and programs around the world have begun to apply such notions both for new development and for redevelopment of existing areas. Holistic frameworks such as the Extended Metabolism Model (Newman and Kenworthy 1999), the Ecological Footprint (Wackernagel and Rees 1996), and Local Environmental Action Planning (Leitmann 1999) are all emerging as new planning frameworks.

2.2 Planning Processes

One of the strengths of the sustainability concept is that it is not a set of regulations or even highly definitive principles. Its principles need to be examined by every local community to see how they can be applied to create better long-term futures for their children. Thus planners at the local level have often found something of the reality of sustainability through the use of Local Agenda 21 Plans which have emerged as a tool for planning since the Rio conference (ICLEI 1996, 1997, Selman 1996). Over 2,000 local governments have produced such plans. Others have adopted approaches based on sustainability indicators such as Sustainable Seattle (City of Seattle 1993) or the Local Environmental Action Plan (Leitmann 1999), and many are now using ICLEI's Cities for Climate Protection system as a guiding approach.

All these new processes stress that planning has moved beyond traditional approaches such as Impact Assessment or Strategic Planning based on trend projections and functional separation. They have in common a desire to plan from a community base, integrated with the goals of the market and other levels of government, including the new global agendas generated from Rio, Kyoto, and beyond.

The stories of hope emerging at a local level are rich and diverse when examined at the grass roots level

(e.g., Pathways to Sustainability Conference 1997, ICLEI 1997). The reason for this is probably that at the local level it is possible for government more easily to make the huge steps in integrating the environmental, economic, and social, in order to make policy developments that are sustainable. They are also closer to concerned people, and more distant from the single-issue powerful lobbies such as the fossil fuel and road lobbies, who are so obvious in shaping national priorities (Korten 1990, 1995).

2.3 The Disagreements: Application of Sustainability to City Size, Urban Form, and Transportation

The disagreements that are apparent among planners, who all profess to want more sustainable cities, are reducible to issues concerning urban form and transportation. They relate to the size of cities and to their density/car dependence.

3. City Size and Sustainability

Many planners subscribe to the view that, on environmental grounds (and other criteria), cities would be better if they were smaller (Troy 1996, Morris 1982). This is an old planning debate, for example, Fischer (1976) shows how optimum size cannot be found on any social or economic variable, but the debate has new currency in light of the current move to seek 'smart growth' and growth management. The desire to keep settlements small is seen by many to be a major part of what sustainability means.

The evidence from studies of settlements shows that as cities get larger they become more efficient in energy use per person and other critical sustainability variables (Newman and Kenworthy 1999, Naess 1993, Smith et al. 1998). This appears to be related to the economies of scale and density associated with bigger cities, which applies equally to technologies seen to be appropriate for sustainable development such as transit, recycling, or the new information industries. It does not mean, however, that larger cities do not reach capacity limits in terms of their airsheds and water systems. But it does mean that simple ideas of decanting people from big cities to smaller ones would not help to create a more sustainable global future.

The evidence suggests that smaller cities find the process of achieving efficiency in economic and resource terms harder than larger cities. The strong emotional appeal of 'smallness' to our age is not, however, without its basis. E. F. Schumacher's 'Small is Beautiful' approach, with its attack on modern gigantism, is still relevant as it suggests that all technology needs to be at an appropriate scale for the community that it is meant to be serving. Community-scale technology is emerging as communities begin to

assert their roles—whether the technology is in villages in the Third World or modern large cities (Korten 1990). The thrust of the New Urbanism and the ‘urban village’ movement is that communities need to be physically designed for and given infrastructure at the scale of the community, in cities both large and small (Calthorpe 1993).

3.1 Density and Car Dependence

In cities across the world the issue of urban sprawl is firmly on the agenda. Associated with it are the issues of density and levels of car dependence, and hence traffic. In the USA in 1998, 240 local governments had antisprawl initiatives on their ballots, and reductions in traffic had become a top priority across the country. However, debate among planners on these issues shows little sign of resolution.

The divide continues to widen between those advocating more compact cities and transit-oriented reurbanization (e.g., Cervero 1999, Whitelegg 1993, Roseland 1998, Newman and Kenworthy 1999, Calthorpe 1993, Elkin et al. 1991), and those advocating reduced densities and only technological changes to cars (e.g., Gordon and Richardson 1989, Troy 1996, Wachs and Crawford 1991, Johnson 1993). Another category of planners sit on the density/car dependence fence (e.g., Haughten and Hunter 1994), while others see the problems but tend to avoid the planning implications in low density, car-dependent planning (e.g., Leitmann 1999, World Bank 1996, Stren et al. 1992).

The data on density and car dependence is very clear. All cities appear to lie on the negative exponential curve of density and gasoline per capita (Newman and Kenworthy 1999). The same relationship is seen across cities, so that as density increases, per capita energy goes down, well beyond any income factors, for example, Manhattan uses 500 percent less energy per capita than the outer suburbs of New York. The mechanism is understood easily in terms of the relative ability to use different modes as distances between land uses spread out. It suggests that density is a powerful determinant of gasoline use, and hence if cities are to develop sustainably they should be facilitating reurbanization rather than new fringe development. Other planning studies have also shown over many decades the link between low urban density and a range of environmental problems (RERC 1974, Berry et al. 1974).

Despite this kind of evidence there is a long tradition of planners seeing density as a problem (Newman and Kenworthy 1989). Those planners advocating the benefits of sprawl who are associated with land or automobile lobbies can be discounted in debates about urban sustainability (STPP 1994). However, there are many environmental planners who also adopt the benefits of low-density planning (e.g., Gordon 1990,

Todd and Tukul 1981, Coates 1981). This suggests that there may be a deeper issue in this debate; an issue that also lies behind the question of city size and sustainability.

Radberg (1995), when reviewing the form of cities required to achieve sustainability, described the rationale for a more compact city which can conserve energy. He then set out the form of a city for achieving green objectives that are ‘related to the ecological perspective’ for ‘recycling and cultivation’; this city is ‘greener, more ruralized, more spread out.’ He therefore raised the questions: Is there a conflict between the low-energy city and the green city? Is there a fundamental conflict between the need to have more urban land for the green city in order to do local ecological processing, and a low-energy city with its need to minimize travel distances and hence have a frugal use of land?

The resolution of this issue as suggested by Radberg (1995) was to enable some parts of cities to be developed more intensely for reductions in energy, and other parts to be more reduced in their density so that ‘greener’ activities could occur there. The evidence, however, is that those planners who support the reduction of density are not able to accept that any density increases are worthwhile (e.g., Troy 1996). On the other hand, studies of urban ecology innovations by Scheurer (1999), confirmed by Beatley (2000), found that there are no increases in ecological activity in low-density areas. Indeed, the best examples of urban ecology (recycling, solar design, storm water retention, permaculture ...) occurred in denser developments, mostly in inner city areas where communities were able to create innovative experiments, or in intentional rural or urban-fringe communities. In the car-dependent suburbs urban ecology innovations are rare.

Newman and Kenworthy, (1999) tried to resolve the issue of density and the green city. They suggest that green innovations can indeed occur anywhere in a city, although experiments may best be applied in rural areas, especially in places where rural population decline is occurring. However, the broader global sustainability agenda cannot be subsumed by this new rationale for density-lowering; cities need to reurbanize while conducting simultaneous improvements in urban ecology. They suggest that the difference in attitude between the two groups is as much due to confusion over where different approaches to sustainability should be employed. In simple terms, the city should be allowed to become more urban, and the countryside more rural, if the multiple goals of planning and sustainability are to be met.

A resolution of this issue may not occur while people still use the word ‘sustainable’ to describe extensions of low-density, car-based development (even if designed with New Urbanist principles). The strong emphasis on reductions in energy that is now

associated with sustainability will probably mean that car-based development increasingly will have to be described using other words that are less demanding of their global contribution.

Planning, Politics of

Planning—here defined as current efforts to affect future outcomes—is a ubiquitous human activity in both public and private life. Individuals plan when they choose their career paths, build families, and save for their retirements. More formally, both corporate managers and government officials regularly develop detailed plans to guide the future activity of their organizations. No society or time-period has a monopoly on planning. Indeed, examples of planning can be identified in virtually every culture and epoch. Some of the best-known episodes in the ancient literature (e.g., the biblical account of Joseph's grain storage) and the most celebrated public works projects in history (e.g., the building of the pyramids, the Great Wall of China and the eighteenth century reconstruction of Paris) were, fundamentally, exercises in planning.

A major aim of planning is to cope with uncertainty. By delineating precise goals, planners seek to stabilize and shape subsequent conditions. Although (nearly) everyone plans, some do so as a career. In the USA today, planning is a recognized profession with barriers to entry, distinct graduate training programs, and particular methods, modes of discourse and internal status rewards. Many planners work for government agencies or as government contractors.

1. Planning Defined

The term 'planning' has no fixed technical meaning in the political science or public administration literatures (Meyerson and Banfield 1955). It refers to activities ranging from socialism to program budgeting to purposive efforts to manage land use, municipal zoning, and regional development. The denials of certain planning theorists notwithstanding, planning is inescapably political because it reflects and reinforces social values (Benveniste 1989). Yet planning and politics may also be in tension with one another (Banfield 1961). At its most heroic, planning seeks to pre-commit major aspects of a society in a particular long-term direction designated by central elites. Yet knowledge is always partial and social conditions inevitably change. Heavy reliance on central planning thus risks reducing opportunities for social learning and partisan mutual adjustment, processes that are essential to a well-functioning polity. To the extent that planning accommodates such vital error-correction and conflict-resolution processes, however, it becomes hard to distinguish from ordinary forms of policymaking (Wildavsky 1979).

At least three (overlapping) dimensions of government planning may be distinguished. First is whether the objective of the plan is to shape the future operations of the overall economy (economic planning) or, alternatively, primarily to affect the

government's own internal administrative operations (administrative planning). A second important dimension concerns the scope of the plan—whether the intellectual demands, and aspirations, of the planning effort are large (synoptic or comprehensive planning) or relatively modest (strategic planning). Finally, one can distinguish between plans that rely on coercion to effect change and those that seek to achieve their goals through voluntary compliance (indicative planning).

1.1 Economic Planning

Throughout the twentieth century, economic planning has been an important response to the perceived moral failings and practical defects of capitalism in both Europe and North America. Prior to the 1980s, the governments of the former USSR and its Eastern European satellites attempted economic planning on a grand scale, seeking directly to control all means of production (as well as consumption patterns) through centralized decision-making (Berliner 1957). For many, the tragic experience of central economic planning stands as a political symbol of the inherent limitations of socialism. More concretely, this experience is a legacy that the peoples of Russia and Eastern Europe are struggling to overcome.

Under Stalin and his successors, central Soviet economic planning was organized hierarchically. The top state planning agency, Gosplan, established the target rate of national economic growth and the allocation of production across industrial sectors and geographic regions. This overall national plan was then broken down by various ministries into directives assigned to local economic units. Finally, managers and engineers at the factory or farm level were required to implement particular instructions. Until the 1960s, the USSR reported strong economic growth. By the 1970s, however, it was apparent that productivity had slowed drastically and that resources were being grossly misallocated. While military facilities could generally obtain whatever they needed, the domestic sector was being starved. Living standards deteriorated. In 1987, President Mikhail Gorbachev announced a policy of *Perestroika*—restructuring—designed to resuscitate the moribund economy (Heilbroner 1993). But the system collapsed.

Critics argue that the Soviet planned economy failed for two main reasons. The first is inadequate information. Very early on the free market economists Ludwig von Mises and Friedrich Hayek insisted that a socialist system was doomed to fail because central economic planners, lacking the price signals of a market system, would be unable to obtain the information required to promote economic efficiency (Von Mises 1935, Hayek 1948). In fact, economic planners in the Communist world—as Polish economist Oskar Lange anticipated in an important 1938 analysis of socialism—were often able to gain much of

the information they needed by monitoring changes in plant inventory levels (Lange and Taylor 1938). The more important reason for the failure of socialist central planning, it seems, was that actors typically had little or no economic incentive to respond to their directives (Heilbroner 1993).

Although Soviet-style comprehensive economic planning was never accepted, the idea of economic planning has long enjoyed intellectual support in the West, even in the USA. The terrible human costs of the Great Depression weakened elite and popular faith in *laissez faire* capitalism and ultimately led to new forms of government intervention in the economy. Most Western governments assumed responsibility for planning for full employment. In France, 'indicative' planners sought to achieve a voluntary exchange of information among business and labor leaders, thereby allowing the French government to use its fiscal and regulatory tools to shape private investment decisions (Lindblom 1977). In the USA, a President's Council of Economic Advisers was established in 1946 to promote stability and growth. During the 1950s and 1960s, Keynesian fiscal planners actively sought to manipulate the level of consumer demand and macroeconomic output. The large tax cut of 1964 was explicitly justified in Keynesian terms. The era of activist Keynesian economic planning came to an end in the mid 1970s, however, with the simultaneous appearance of high inflation and slow growth (stagflation), which contradicted the assumptions of Keynesian models. While use of automatic stabilizers remained a fixture of fiscal policymaking, US politicians in particular lost confidence in the ability of economic planners to 'fine-tune' macroeconomic policy to the business cycle.

1.2 Administrative Planning

In the West, it is in the realm of public administration that one can identify genuine attempts at synoptic planning. Comprehensive government planning has long been central to normative theories of public administration. The influential French administrator Henri Fayol (1841–1925) argued that a 'good plan' requires clearly defined, written, comprehensive objectives together with the resources necessary to carry out these tasks. In the USA, broadly similar concepts found expression in the scientific and executive management movements of the Progressive and New Deal eras. The normative commitments and pragmatic understandings that emerged from these movements (e.g., 'one-best way' thinking; the emphasis on hierarchy and span of control; the separation of politics from administration) have had a significant impact on USA administrative practice and doctrine. In a classic statement in 1937, Luther Gulick, a member of the New York Bureau of Municipal Research who served on Franklin Roosevelt's famous Brownlow Committee, defined the executive function by the acronym

POSDCORB (planning, organizing, staffing, directing, coordination, reporting, and budgeting). Effective planning was thus held to be the crucial first step to the achievement of rationality and technical efficiency in government administration. In the USA, administrative planning enjoyed a revival in the 1960s (Schick 1975). Hundreds of federal and local statutes mandated the formulation of plans for allocating inter-governmental grants, designing cities, and other purposes. The centerpiece of the new administrative planning was PPBS—Planning, Programming, Budgeting Systems—which essentially demanded that federal agencies engage in synoptic planning to promote the public interest. Administrators were to (a) articulate precise program goals, (b) comprehensively list alternative ways of achieving these goals, and (c) analyze the costs and benefits of each significant option. PPBS was introduced in the Pentagon in 1961 by Defense Secretary Robert McNamara. By 1965, President Lyndon Johnson ordered PPBS to be extended to nearly all federal, civilian departments. The promise of PPBS was considerable: Planning and policy analysis would be used to increase administrative effectiveness. Defective programs would be found wanting and, it was hoped, replaced with superior alternatives. The actual results of PPBS were disappointing to say the least, however. The reporting and monitoring requirements of the planning effort created a paperwork burden that quickly overwhelmed government officials. PPBS performed especially badly where, as was the case in many domestic agencies, bureaucratic outputs were soft and hard-to-measure. Most importantly, PPBS failed to accommodate the political and organizational incentives of budget actors. The Nixon Administration formally abolished PPBS in 1971 (Knott and Miller 1987, Kettl 1992). The failure of PPBS lends support to Aaron Wildavsky's argument that a fragmented and seemingly uncoordinated budget process generally does a better job of allocating public resources than does a system in which central planners make a synoptic, integrated evaluation of budget alternatives (Wildavsky 1964). Despite the manifest failures of PPBS, similar, comprehensive-planning exercises were adopted subsequently by US governments (e.g., zero-base budgeting and management-by-objectives).

Given the severe limits of synoptic planning, why have so many governments persisted with these sweeping reform efforts? Probable reasons include: there may be a political benefit to appearing 'rational'; planning exercises may enable elected officials to give respectability to things they wish to do for other reasons; and focusing on planning procedures is often easier than making substantive decisions (Knott and Miller 1987). The enduring interest in synoptic government planning may actually rest less on science and rationality than on a secular faith in the perfectibility of man (Wildavsky 1973). Indeed, in an important account of paradigmatic failed attempts at 'state

simplification' (e.g., the Great Leap Forward in China, collectivization in Russia, compulsory villagization in Tanzania, Mozambique, and Ethiopia), political anthropologist James Scott argues that the hegemonic planning mentality is supremely unscientific in the sense of being uncritical, unskeptical, and contemptuous of the importance of practical, local knowledge and informal processes in the face of unpredictability (Scott 1998).

2. Limits and Possibilities of Planning

Although synoptism has failed everywhere it has been tried, more limited forms of government planning clearly have succeeded. The Controlled Materials Plan of the USA in World War Two, the American Social Security program, the massive interstate highway system—each of these initiatives was bureaucratically 'planned.' Long-term goals were articulated, the stated objectives were (more or less) achieved, and the political outcomes were, if hardly uncontroversial, at least defensible. Planning works best when it is highly bounded, is focused on a specific problem, and is economical of analytical talent (Lindblom 1965, 1977, see also Devons 1950). Thus, like the formal hierarchies through which it tends to be implemented, planning has its organizational place (Alexander 1992). The challenge is to keep it there—and to render the practice and results of planning compatible with processes of social interaction.

Planning Theory: Interaction with Institutional Contexts

During the twentieth century, the concept and practice of what is variously called town design, spatial planning, territorial management, and town and country planning developed into a complex area of public policy. The theory informing this policy field has been the product of continual interaction between ideas about how to do planning, the experience of planning in practice, the intellectual context available to those thinking about planning, and the agenda of problems and opportunities which planning has been harnessed to address. Inherently, the planning enterprise is caught up in institutional contexts, which shape its meaning, its material expression, and its consequences. This contribution illustrates the interaction between ideas about the nature, purpose, and method of planning, the context of their production and the practices at which they have been directed.

1. Cities, Governance, and Planning

Few of the ideas about planning which evolved in the twentieth century came initially out of academia. There was no significant academic infrastructure for the field until the last quarter of the twentieth century. The origins of twentieth century planning ideas lay in the experience of rapidly urbanizing societies, and the perceptions of injustice, disorganization and threats to human health and happiness which urbanization seemed to bring. These promoted political movements, pressure group politics, expert evangelism, and attempts to transform city government to cope with the complexity of issues which arise in large cities. The focus of attention ranged from the neighborhood, the city, the region, the process of governance and the

overall organization of society. Two core ideas have informed these otherwise very diffuse endeavors: firstly, that through appropriate governance action, it is possible to 'make a difference,' especially in making cities and societies more sustainable and just; secondly, that the spatiality of social processes and the qualities of place are important dimensions of well-being.

These two ideas have been developed in very different ways as illustrated below, with the aim of highlighting both the situatedness of planning ideas and how their impacts are highly dependent on the specifics of institutional milieu.

1.1 The Good City

In the early twentieth century, planning was generally understood as focused on cities, on how to manage the congested and sprawling consequences of the urbanization arising from industrialisation and new transport technologies (Mumford 1961). Throughout the century, there was concern about the qualities of cities as living places, as aesthetic products, as business locales, and as biospheric relations. 'Theories' of urban form and the arrangement of regional space dominated the discourses of city planning until at least the 1960s (Boyer 1983, Hall 1988). Protagonists, a mixture of campaigners and specialists in urban development (architects, engineers, and surveyors), battled over the relative merits of different forms. By the 1950s, most European states had some form of urban planning and land use regulation embedded in their central and local government policy frameworks and competencies.

This success in institutionalizing the idea of city planning was soon overtaken by vigorous critique of the predominant focus on urban form. Sociologists such as Herbert Gans in the USA argued that cities should be understood through the way people lived in them rather than through their physical form. Jane Jacobs, a fine observer of the way people used urban neighborhoods, argued against planners' ideas of demolishing old neighborhoods to replace them with modern buildings and the separation of living and working spaces. Regional economists and geographers challenged assumptions about the dynamics of urban growth embodied in the urban plans produced by architects, engineers, and surveyors. The emphasis of the earlier generation of town planners on achieving urban quality of life for the mass of the people was replaced by a concern with distributive justice and the 'socially just city'. This idea emphasized that the poor should not draw the short straw in the distribution of access to urban living space. Peter Hall showed that the containment of British cities by greenbelts, far from achieving gains in quality of life for ordinary citizens, had made housing generally more expensive and led to deteriorating conditions in the UK's inner cities. By the 1970s, Marxist analysts had joined the

debate. Manuel Castells showed, in a study of a French city, that the aim of urban planning to improve the quality of life was a mask behind which developers and business interests could pursue strategies for realizing land value gains. This critical story had resonance in other parts of Europe where urbanization was proceeding apace, producing substantial development gains to landowners and developers. It was echoed in examples of urban renewal in the USA.

As a consequence of this critique, at least in Europe, coupled with a slowdown in the pace of urban growth, the idea of large-scale comprehensive planning fell into disrepute. Urban management practices focused on the fine grain, the neighborhood, the site, and the urban renewal area. Attention in the 1970s and 1980s turned to projects and mechanisms. The focus on the physical form of the city was displaced by ideas about appropriate planning processes (see below). Architects, engineers, and surveyors were replaced as a source of expertise for planning by regional economists, policy analysts, and those specially trained as 'planners'. The discussion of 'planning theory' turned away from ideas about what the city as such could be like. Influenced by postmodern ideas in urban design and postmodernism in philosophy, a critique developed which suggested that the whole idea of attempting to 'plan' such a complex phenomenon as a 'city' was oppressive to the multiple realities and possibilities of urban life.

By the end of the twentieth century, a new wave of interest in the quality of cities, rural areas, and urban regions was swelling up in policy arenas and among commentators on planning. The pressure for this came in part from an increasing awareness of new economic and social realities. The recognition of the openness of urban economies to the dynamics of global economic forces raised widespread concern about how to 'position' cities and urban regions in a landscape of competing regions. The appreciation from direct experience of lifestyle diversity, and its consequences for the ways different groups were using the space of an urban region, made people aware that traditional models of self-contained, hierarchically-ordered cities no longer captured the reality of urban life, especially as affected by new technologies (Sandercock 1998, Beauregard and Body-Gendrot 1999). Most influential of all were the ideas associated with the rise of a new environmental consciousness in the last quarter of the twentieth century. This brought with it conceptions of the limits which the natural environment placed on human actions, and of the need to consider trans-generational impacts not just short term ones.

This led to a wave of interest in the 'Sustainable City' (Satterthwaite 1999). For some, this meant minimizing adverse impacts on natural environments, linked to ideas about 'ecological footprints' of urban development, and conceptions of the 'carrying capacity' of environmental systems. For others, it emphasized keeping cities compact and preventing land

being used up in development. Others enlarged the concept to integrate the concern with social justice to that of 'environmental sustainability.' The dominant concept in public policy in much of western Europe by the turn of the twentieth century was 'sustainable development,' which combined the principles of minimizing ecological impacts with ways of continuing to promote economic development. However, it is clear that these two dynamics do not comfortably co-exist with each other. There are also tensions with notions of social justice, the multi-cultural city, and fostering innovative plurality. The reawakened emphasis on urban futures in planning theory thus opens up a complex set of issues that had hardly begun to be developed by the end of the millenium.

These ideas and debates about the quality of the 'good city' and the 'good environment' were shaped by the changing dynamics of urbanization processes, as well as changing expectations and values. In turn, concepts from planning theory have influenced the practices of urban management. Planners' ideas have molded the restructuring of existing urban areas, the design of new towns and settlements, and residential neighborhood design. They have affected the form and location of transport projects. They have shaped the evolution of urban street scenes through the impact of land use regulations. These regulations have in turn influenced the way land and property values are distributed and property development processes have evolved. Planners' ideas achieved this impact by framing the organizing principles and discourses used by governments in developing policy frameworks and organizing competencies for planning 'systems'. However, the organizing principles and discourses of one era become embedded in practices and can come to outlive their usefulness. By the turn of the millenium, in many parts of the world, 'planning' as practiced was identified as 'part of the problem' of governance processes that do not match the aspirations and challenges of contemporary cities and regions.

1.2 Good Government

For the protagonists of early twentieth century city planning, the everyday business of politics and government was 'part of the problem.' They sought to show a way forward by striding out ahead with their plans and designs, apart from this messy world. By mid-century, an alternative idea had taken root. Planning was a way of 'doing government' itself. In Europe, socialist movements promoted the role of planning as an alternative to allocating resources through market processes. In the USA, planning was promoted as a way of improving the quality of local government. Clientelist practices were well developed in many cities, with adverse consequences for both the efficiency and effectiveness of public policy. Bureaucratic management was no better, as 'playing by the rules' led to

government actions which did not adapt to the dynamics of changing situations or local specificities. The way forward, strongly advocated in the University of Chicago School of Planning in the 1950s, was to adopt contemporary principles of business management. This meant developing strategic frameworks to articulate the goals of an organization. These could then be translated into policy principles or objectives which individual officials could use as guides as they developed responses appropriate to specific situations. This powerful idea, with its focus on 'means-ends relationships,' was strongly linked to the promotion of democratic government. All the steps justifying a particular policy could be explicitly identified and implemented by logical analysis and scientific evidence. Officials could be held to account in relation to their performance in achieving an organization's goals, while the process of strategy-formation made these goals and their justification transparent to citizens (Faludi 1973, Friedmann 1987).

Initially, it was assumed that the work of 'policy planning' would take place in a world of technical experts, reporting to politicians. As Western democracies have become increasingly educated and pluralistic, distributing power and knowledge ever more widely among business groups, pressure groups, and citizen mobilization movements, this position has been challenged. However, concepts of strategy, of evaluation of policy ideas and performance in relation to objectives, and of the systematic link between policy and implementation had become deeply embedded in expectations of government behavior by the end of the twentieth century. City planning practices have been transformed by these shifts in the way government is performed. Planning theory has both influenced the design of spatial planning processes in many parts of the world and learned from their practice.

At the core of the original idea of a 'rational planning process,' as it was often called in the 1960s and 1970s, was the view that governments—and their teams of experts—needed to be able to explain why a particular strategy was appropriate in a particular context, how it would be implemented, and whether it had been implemented. It became linked to the development of ways of making strategic and policy plans, techniques of evaluating alternative options, appraising the impacts of projects, the development of indicators to evaluate performance, and attempts at modeling situations—for example land use and transport interactions—to assess the likely impacts of different courses of action. All these are still in common use in twenty-first century urban and regional government, providing a methodological kitbag for planning office staff and consultants.

However, these early ideas attracted criticism almost as soon as they were propounded. The overall approach was challenged as deeply instrumentalist—defining the purpose of government in terms of achieving specific objectives effectively. The meth-

odologies drew on welfare economics, with its utilitarian assumptions. The approach assumed that policy ideas were translated into action in a linear way, from 'top' to 'bottom' of an organization or government system. It was seen to be over-generalized, failing to consider the differences, which might arise in different policy fields and in different institutional contexts. It also handed power to the experts, as the early city planning ideas had done. Politicians, lobbyists, and citizens were pushed to the sidelines. In the 1950s, a famous study by Meyerson and Banfield in Chicago showed that local politicians were not prepared to accept the restraints on their actions, which the rational policy-planning model implied. In the 1960s and 1970s, scholars such as Charles Lindblom, Amitai Etzioni, John Dyckman, and Richard Bolan began to show how contexts might limit how far a policy-driven planning practice might go. Others criticized the approach as promoting 'corporatist' practices, entrenching the influence of local business and political elites through their power to shape and overturn strategies. An alternative was to accept the increasingly pluralistic form of local politics, and develop a local politics around competing plans, produced by different interest groups. This approach, promoted by Paul Davidoff, became known as advocacy planning (Faludi 1973). The experience of policy practice began to look less and less like a strategy-driven process. Instead, analysts noted that the content of policy seemed to be negotiated in the flow of action, rather than being set in advance.

By the late 1970s, planning theorists turned their attention to issues of policy 'failure' and implementation 'gaps,' following landmark studies by Aaron Wildavsky and others. This work looked more closely at the institutional context in which policy frameworks were articulated and the ways planners, understood as experts and government officials, went about their tasks. It identified the problems, which arose where policy ideas were not sufficiently 'owned' or understood by politicians, or by other parts of public administration which controlled significant resources or regulatory powers. There were close parallels with work undertaken in business studies. This analysis highlighted the difficulty of promoting strategy-driven governance processes where other ways of 'doing governance' controlled the culture of local government. It also showed that 'field level' actors, officials, and experts working up the details of policies, or acting at the interface between officials and the clients of public administration, developed their own ways of understanding policies and how they might be applied.

This led to a critique of the rational planning process as a 'top down' viewpoint, challenged by a 'bottom up' viewpoint of the actors 'on the ground.' (Barrett and Fudge 1981) The linear model of the policy process was increasingly challenged by conceptions of policy development as an interactive process, continuously evolving over time and drawing in different actors at

different stages. In this formulation, planning was no longer either outside government, nor imposed on governments in an attempt to transform their processes. It was caught up 'inside' politics and governance processes. In the 1980s, a significant strand of work associated with John Forester, Charles Hoch, and Howell Baum, began to address questions of the way planners committed to progressive values operated in these ethically challenging situations (Forester 1989, Campbell and Fainstein 1996).

During the 1980s, a major conceptual reorientation brought new ideas about the nature of policy processes to a central position in debates in planning theory. These built on the earlier work on 'implementation processes' in two ways. Some analysts focused on the way experts and officials made sense of the complex situations in which they found themselves. Others began to explore the way policy agendas and the relations of governance mutually constituted each other in interactive processes. Both emphasized the significance of the frames of reference and the 'social worlds' which those involved in policy arenas brought to bear on policy design and implementation. Policy development was presented less as a technical exercise in calculation and design, and more as a social process of articulating ways of thinking and ways of acting which could command support among a wide range of players in urban and regional contexts where power was likely to be diffused in complex ways rather than concentrated in the hands of a single elite. Collaborative, participative forms thus challenged top-down and 'producer-driven' approaches to public policy. Such ideas were infused with the much wider critiques of positivist science and linear models of knowledge and application developing in the 1980s in the social sciences generally. Some argued that planning was an impossible task, caught up in the discarded clothes of 'modernity.' Others, and notably John Bryson, Judith Innes, and Maarten Hajer drew on emerging interpretive approaches. These emphasized that policy meanings were actively constructed by participants through communicative processes which, if effective, could recast policy 'discourses' and redirect resource allocation processes and regulatory practices (Healy 1997, Innes 1995).

In parallel, there was an explosion of attempts in various parts of the world to develop new, more participative and collaborative forms in planning practice. These were partly promoted by the idealism of those pursuing a democratic version of the sustainability agenda, notably in the practices of producing Environmental Audits and Appraisals for localities, as encouraged by the World Environment Congress in Rio in 1992. But they were also a manifestation of a struggle to recast the forms of governance inherited from mid-century in Europe and the US. While neo-liberal strategies sought a way forward by reducing the burden of government, through strategies of 'privatization' and 'deregulation,' alternative strategies pro-

moted models of more participative democracy, which could reduce the perceived gap between the worlds of politics and government and the worlds of citizens. The objective was to refocus governance activity around the concerns of civil society and the economy, rather than those of the 'producers' of government.

By the late 1990s, ideas about consensus-building practices and collaborative strategy formation, collected and consolidated by planning theorists, were being rapidly internationally circulated to help fulfill in practical ways the ambitions of politicians and officials trying to move in new directions. In this context, the value of policy effectiveness embodied in the 'rational planning process' was supplemented by a concern with 'building democratic culture' (respectful and 'citizen-centered' styles of governance). Proponents of the new communicative planning argued that strategies that were developed interactively among affected parties (stakeholders) led to greater 'ownership' which in turn provided the social and political resources through which strategic directions could be maintained. They also argued that such processes brought civil society into a much stronger position to shape public policy agendas.

1.3 Qualities of Place and Qualities of Governance

By 2000, there were vigorous debates in the planning field about this new agenda. As in the earlier discussion of the 'rational planning model,' a key issue was the qualities of the institutional context in which such practices could flourish and how far their promotion could induce changes in the context. However, there was much less discussion of how these 'good governance' ideas might link to the qualities of a 'good city.' The two strands of thinking in planning ideas largely proceeded separately in the late twentieth century. They also potentially challenge each other, as the one stresses qualities of process and the other stresses qualities of places and their diverse relations. A governance process informed by the citizens 'of' a locality, which proceeds in a richly participative way, is likely to encounter multiple ideals about a 'good city' and a 'good living place.' What may emerge through processes of debate, struggle, and conflict resolution may be far removed from the ideals of a good city being developed in debates among professionals.

2. Planning Theories in Context

The enterprise of planning is profoundly committed to changing the ways things are and to transforming realities, whether those of cities or their governance. It is inherently normative in its value orientation, infused with the belief that deliberately designed actions today

can have beneficial impacts tomorrow. Those who reject the idea that this is desirable or possible—*anarchists, extreme free marketers and cultural post-modernists*—will reject the enterprise of planning. Yet the idea that, in democratic states, governments should have policies and should be judged on how effectively they follow them through, is one of the great inventions of the twentieth century. It is being carried forward vigorously into the twenty-first century. What are changing, however, are the conceptions of where policies should come from, how they should be focused and who gets involved in their articulation and implementation. At the beginning of the twenty-first century it is not enough for policies to be designed by experts. The quality of government is increasingly judged by the way its policy formation attends to the multiple voices of complex societies, by its skill in recognizing the complexity of economic, social, and environmental dynamics, and its appreciation of the specific realities of the way policy programs are realized.

In this context, a policy focus on 'place quality' has a new salience. Such a focus, if grounded in the specific contingencies of particular places and the multiple perceptions and meanings of those with a stake in them, can connect the issues which concern citizens and businesses in ways which make sense to them. These tendencies recreate a policy environment in which the enterprise of planning has much to contribute, provided it can release itself from its 'entrapment' in the past and reconnect the debates about the qualities of place to those on good governance. Three recurring themes in the discussion of the 'good city' and 'good governance' represent important challenges for future spatial planning and territorial management practices.

2.1 Ideas and Actions

The first challenge focuses on the relation of theory to practice. The history of planning thought shows the many ways in which planning ideas filter into the construction of concepts, goals, and norms which guide specific actions—through advocacy and campaigning which impact on popular perception and politicians' agendas; through the design of planning systems and formal norms; through the ways these are interpreted in administrative and legal arenas; through the formulation of explicit strategic frameworks and the ways these get translated into routinely used concepts and norms; and through the training of 'planners' and the professional organizations which bring 'planners' together. Through continual interaction with these worlds, planning ideas are themselves changed. The contribution of planning thought in the twentieth century has been its preparedness, however ineffectively it is often developed, to link together the

philosophy of normative action, the social science of urban and regional dynamics and the fine grain of the practices of urban and regional governance. The challenge has been to draw out the significant strategic processes of governance which affect the qualities of places and territories, as lived, experienced, and given identity in multiple social processes (Friedmann 1987).

2.2 Substance and Process

The geographer Ed Soja has remarked that twentieth-century thought has had a peculiar difficulty in perceiving the impact of 'being in a place' and of the spatiality of social relations. The autonomous individual in a 'free society,' or the social group as a 'class' in relation to other social classes, has been much more dominant. Contemporary culture, however, notices all kinds of cleavages and fractures, and stresses the complex relations individuals may have with others. Grasping the significance of place and territory in these complex representations and relations, and developing governance processes in which to give them voice, is a major challenge for urban and regional politics and policy. In planning theory, there has long been a debate about how to relate the 'substance' of policy to the 'process' of policy development, with theories being criticized for giving too much weight to one or the other.

If the predictions made in the previous section are correct, then the second challenge for planning theory is to contribute to the co-evolution of the 'substance' and 'process' of territorial management-policy frameworks. This has major implications for institutional design—who contributes what, when, and where. It also has implications for the articulation of values. There were major debates in the mid-twentieth century about whether planning was 'value-free' or 'value-full'. If 'value-full,' were the values about process (fair, just, 'rational'), or about substance (achieving specific goals, for example, aesthetically-pleasing environments, quality of life for ordinary people, redressing the unequal distribution of resources and power etc.)? By the end of the century, process values had been extended to include qualities of inclusion, empowerment, and respect to all citizens, while substance values were infused with ideas about environmental sustainability and social justice. However, if the substance and process of governance for complex territorial problems are seen to co-evolve, then it must be expected that values too co-evolve. This implies the development of critical capacities for 'reflection-in-practice' on what is evolving, what it might lead to and what values might be promoted as a result (Schon 1983). In work in planning theory, this has led to a critique of planning strategies and the design of planning systems. It has also focused on the personal dilemmas of 'doing' planning work.

2.3 System Maintenance or Transformation

The third challenge in planning theory lies in the approach to social change. Behind any idea of the 'good city' or 'good government' is some model of the nature and dynamics of social organization. For some advocates of planning ideas, it is the model itself that needs change. For others, the model needs correction to make it work better. As John Friedmann argued in the 1960s, some planning ideas sought to maintain basic systems. Others aimed to transform them. At the time, he was contrasting the management needed to trouble-shoot in western democracies with the transformations needed in illiberal Latin-American dictatorships, newly experimenting with democracy. By the 1970s, he had become much more radical, demanding 'social transformation' in over-urbanized capitalist societies, dominated by global corporations.

Throughout the twentieth century, people have been attracted to the planning field through transformative idealism. In the second part of the century in Europe, the target of transformation was a form of capitalism which dominated life chances, structured the way urban and regional space was used and damaged environments across the globe. For many, it was a shock to discover that the 'planning systems' and 'planning practices' which actually evolved, seemed deeply committed to maintaining the very practices which they had sought to challenge. Ideas about alternative ways of organizing society, however, come up against the reality of the dynamics of social change. In some periods of tumultuous social change, any kind of planning is an impossibility. In some periods of entrenched stability, similarly there are few cracks of opportunity to mobilize to do things differently. Most of the time, most situations are somewhere in between. In the contemporary world of complex relationships and diffused power, change happens both through big events (for example, the OPEC oil crisis, the collapse of communism, the 1987 property crash, the rise to power of neo-liberal governments, etc.) and through lots of small shifts and mobilization episodes. Planning processes can help these shifts along. Instead of making plans which are assumed to be predictions of what will happen, making plans becomes more of an activity of social mobilization, encouraging new ways of understanding situations and developing new ways of working. Strategy development in such conceptions takes on more of the character of collective invention and risk-taking in trying to shape futures rather than the mid-century assumption that government could command resources and control futures.

3. The Contribution of Planning Theory

These debates in the planning field provide rich resources for imagining, developing, and critiquing governance practices as they impact on urban and regional dynamics in the twenty-first century. Formal-

ized in the planning-theory literature, they range through philosophical debate, through analysis of systems and practices, and through discussion of the situation of 'doing planning work.' If the planning field is to realize its potential to contribute, imaginatively and critically, to the 'turn' towards more place-focused policy agendas, planning theory needs to maintain a close and multi-faceted engagement with these evolving practices.

There are many 'windows' through which this engagement has developed. One is that of the 'planner,' working within specific contexts trying to make things happen differently. This has been the key contribution of John Forester, whose work speaks sympathetically to planners in complex situations around the world (Forester 1989). Another is local institutional practice. In recent years, this work has been closely linked with the disciplines of urban politics and urban and regional geography, exploring questions about the relation between politicians, political regimes, experts and citizens, and the way planning strategies and tools have been used, in particular institutional milieu. A third 'window' has focused on understanding the design of governance systems. This has examined competencies, law, resource allocation systems, and appropriate expertise, the 'top-down' levers of policy change, and how these interact with 'bottom-up' interpretive practices. Much of this work has been informed by the search for ways of changing governance practices. A fourth 'window' has concentrated on ideas about the good city and the good society, especially in relation to ideas of environmental sustainability and multicultural societies and on how these have worked out in practice. The critical challenge for the development of planning as an enterprise is to recognize that these different 'windows' do not represent separate compartments of the planning field. They merely cast a more intense lens over a particular set of relations. All the others are still there, and need to be recognized as present, even if not the focus of a particular study.

The role of planning theory, as a distinctive task in this complex and dynamic institutional terrain, is to provide a critical imagination and structuring ideas for the dynamic invention processes which are continually unfolding in political communities in cities and regions. It should offer evaluative vocabularies for the recording and critiquing of these processes, both in relation to their content and their procedures. It should interpret emergent patterns and assess their consequences. It should draw in ideas from other fields and translate them in ways understandable to the various thought-worlds caught up in city governance. It should consolidate the distinctive understanding evolved by engagement with this activity and make it available to those working in other fields. This implies that the task is always an 'in-between' one. If the 'practitioners' of planning theory withdraw too far from the worlds of those engaged in 'doing planning,'

then they lose their capacity to record, shape, connect, and translate. If they stay too close to the 'doers,' they are unable to see beyond what the doers themselves see, and therefore cannot 'add value' to the work of doing. The challenge for planning theory in the twenty-first century is thus to enrich the evolution of public policy focused on place quality and to do this in a way which fosters the flow of ideas between the many arenas engaged in shaping urban and regional governance.

Planning Theory (North American)

1. The Invention of Planning Theory

In the quarter of a century prior to World War I a small international movement centered in the North

Atlantic Basin sought to establish 'city planning' (under one or another of its names) as a professional craft and an imaginative sensibility. The movement cast itself in a heroic role. The new practice of planning, speakers at the founding conferences insisted, would correct and tame (what they represented as) the 'wild' and essentially 'unplanned' urban growth of the nineteenth century. The new practice would infuse the fragmented work of professional architects, social workers, hygienists, and civil engineers with an integrative civic vision. The image of the well-ordered city—symbolized by a plan that would guide its growth 'tomorrow'—was presented as a global icon of modernity. Chicago, New York, London, Birmingham, Paris, Berlin, and Vienna would learn from one another and tutor Tokyo, Shanghai, Cairo, Delhi, Colombo, and Rio de Janeiro (Sutcliffe 1981).

Despite their expansive aspirations, the leaders of the planning movement—both before and after World War I—built their professional careers within a conception of cities as well-bounded spaces filled with physical structures that organized 'public' activities. (The founders argued among themselves: Were houses public or private, and were they appropriately part of the planning brief?) Through the first half of the twentieth century the 'theory of town planning' was articulated largely in speculative proposals for new spatial forms, in the tacit assumptions of working plans, and in textbooks legitimating the 'rational' integration of 'architecture and urbanism.' The movement did not develop a distinctive theorizing tradition assessing the connection between the design of planning practices, processes or institutions, and the character of plans; between the character of plans and of the worlds they shaped (Choay 1997).

In the second half of the twentieth century, all of that changed—though not everywhere in quite the same way, and certainly not in an instant. The demand for professional planners grew dramatically after World War II, and universities responded by creating academic programs. Where planning education remained an adjunct of engineering or architecture, procedural theories played a relatively small role in shaping the new curricula or the public statements of the professoriate. Where, however, planning was articulated as a distinctive craft, the success or failure of 'its theory' were vital elements of the new professional identity. ('Professions,' it was widely claimed, 'needed a theory.')

That 'need' did not, of course, sweep away the intellectual difficulties that made the construction of procedural planning theories so difficult. The familiar forms of social theorizing were (and continue to be) designed to explain repeated historical behaviors, or to forecast the path of systems that we cannot, or do not choose to, change. In contrast, planning processes in their varied forms attempt to control (rather than to explain) a world that does not yet—and may never—exist. No matter how sophisticated, planners find

themselves torn repeatedly by the discovery that when, imaginatively, they unfreeze relations in order to change them it becomes harder to anticipate the outcomes of their actions, mistakes are legion, and the burdens of control grow heavy. The internal intellectual history of the attempt to construct and validate theories of planning in the last half of the twentieth century is centered in that dilemma.

The builders of the epistemic community devoted to planning theory created a full array of disciplinary artifacts: Journals, conferences, anthologies, review articles, 'fields' for doctoral students to master, careers, and stylized self-criticisms. Inevitably, favored failings were part of the community's identity. Insiders worried that their enterprise was too theoretical or not theoretical enough; that it ignored the spatial core of urban planning in order to run after foreign gods, or that it was too insular in its close attention to planning professionals.

Some of the builders—both early and late—imagined that they might in time satisfy the aspirations of practitioners and educators for a coherent and cogent theory that would guide and legitimate professional city and regional planning. At mid-century, the small Program for Education and Research in Planning at the University of Chicago, radiating confidence in the promise of rational planning, achieved an abiding place in the mythology of the planning Academy despite—or perhaps because of—its premature demise. By the end of the century, however, that promise seemed to most members of the community of theorists either misguided in principle or unachievable in practice. At its conferences and in its journals, the community acted as a loosely coupled network of distinctive and often contending groups. Planning theory—in the singular—appeared as an ironic misrepresentation of the varied products of those distinctly plural circles.

Individual theorists have not, of course, been immune from the arrogance of expertise. The procedural authority of the community of theorists has, however, been extremely limited in most political regimes. Unlike architects and engineers, theorists have never been certified by public or quasi-public authorities. Nowhere is the approval of a board of theorists required to validate procedural designs or to approve the sale of malpractice insurance. Theorists are not legally responsible for flawed organizational proposals, incoherent arguments, or the misreading of texts. They do, of course, hold each other accountable for simple foolishness, complex confusions, and the corruption of novices but their (loose) mutual discipline cannot be more demanding than the structure of the field will allow.

Perhaps because of that freedom from responsibility, the theorists have been intellectually ambitious. Undeterred by ordinary scholarly boundaries and without asking anyone's permission, they have extended the privileges of membership in their com-

munity to 'colleagues'—dead and alive—who had little direct connection with city and regional planning, and who rarely noticed the appropriation of their work. Sins of omission play a more important role in the stylized self-criticism of the community than sins of commission. A claim that a voice has been neglected commands the community's attention in the way that a broken tooth commands an inquiring tongue.

Whatever their initial aspirations, the theorists have not created a confident science of planning. To those who read, they have, however, suggested both alternative planning modes and subtle similarities in overtly different circumstances (Krieger 1981, Verma 1998). They have sustained an integrative bridge across diverse domains—land use, environmental and social policy, the design of policies and the associations of civil society, and local and regional economic development—that stretch far beyond the conventional scope of urbanism. Planning theory at the end of the twentieth century appeared as a counterbalance to the authority of local practices, legal mandates, urban regimes, technical expertise, and settled professional doctrines. Those were, however, powerful enemies. It is little wonder that theorists—offering at their best only criticism, questions, and suggestive intimations—lived at the margins of the professional planning enterprise with its characteristic and quite sensible respect for tacit knowledge and uniform practices. Within the main body of professional practitioners, theorists prospered only when they created formal protocols for representation, design, evaluation, and negotiation that could be replicated in many settings and invested with political authority. Geographic Information Systems (now inflated to Geographic Information Science) were the rage of planning agencies at the end of the century. GIS were, however, only the latest in a long series of tools—first among them, cost/benefit analysis—whose substantial philosophical baggage is characteristically left at the agency door (Pickles 1995).

2. The Platform of Planning Theory

The conception of 'architecture and urbanism' that was displaced by planning theory had integrated four assumptions:

- (a) the object of planning was the physical form of a settlement;
- (b) designers could specify the ideal, rational form for a settlement in a particular site;
- (c) rational forms had wholly predictable and appropriate outcomes; and
- (d) rational form should dominate other design preferences or proclivities.

The critical challenge to these assumptions was articulated on the one side in a direct assault on geographic determinism and the cogency of architectural conceptions of urban form; and on the other

side, by an almost casual dismissal of the 'dream of a rational city.' The texts that codified theories of spatial design and the debates of the first half of the century virtually disappeared from the 'talk' of the emergent community of theorists. Nigel Taylor, in his history, *Urban Planning Theory Since 1945* (1998) lists five mid-century texts in the 'physicalist' tradition: none of them was included in the bibliography of Andreas Faludi, *Planning Theory* (1973b), Kevin Lynch, *Good City Form* (1983), or John Friedmann, *Planning in the Public Domain* (1987). Faludi (1973a, p. x) characterized his own frequent use of physical planning examples as 'coincidental, a mere reflection of the fact that is the field where I come from and in which I teach.' Friedmann did not include 'urbanism' in his graphic presentation of distinctive planning traditions since the great revolutions of the eighteenth century. New recruits into the community of theorists should (in his account) place themselves in one of those traditions as heirs of an Enlightenment belief that scientific knowledge can and ought to be applied effectively to social improvement.

The combination of a frontal and a 'casual' challenge to the integrative conception of architecture and urbanism created an intellectual space in which it was possible to rethink the practices of architecture and urban design, and to create a platform for the construction of planning theory as a field of inquiry and reflection. The major premise of that platform was that though planning processes, settings, and outcomes were entangled, it was useful to distinguish between them. Within the framework of that heuristic distinction, theories of planning should articulate and explain the attributes of each element and illuminate the relations among them: If planners—lay or professional—act in a particular way in settings of such and such attributes, what are the likely outcomes? If they seek outcomes of a particular sort in a given setting, how should they plan? What sort of outcomes should they seek, and should their choices vary from one setting to the next? The intellectual history of planning theory is usefully understood as a tale of a community learning to live on that platform—a stage of its own making. (The best way to follow this tale is probably through the series of anthologies cited in the bibliography.)

The practitioners who shaped the early-twentieth-century planning movement embraced an ambitious conception of planning as a process—and as a profession—that was uniquely rational, scientific, or self-conscious; that looked into the future and across conventional institutional domains; and that served the public interest or other comparably admirable objectives. The emergence of the new planning academy after World War II did not dim that heroic self-image. The rationality of urban form was, however, replaced by the intellectual claims of a toolkit of protocols for representing complex systems and their cybernetic controls, for evaluating projects and

programs, for modeling urban land use and transportation patterns, and for revealing the dynamics of location, spatial differentiation, and interpersonal negotiations. Those protocols—*inter alia* systems theory, experimental design, mathematical simulation, factorial ecologies, and game theory—had a profound impact on the first postwar generation of theorists, displacing the integrative conception of urbanism but retaining an essentially rationalist justification for professional planning. The mission of theory was not to describe or explain planning processes but to shape them so that they were ethically compelling and instrumentally effective (or even efficient). Normative theorizing would embed those demanding criteria in the identities of individual planners, the practices of planning agencies, and the norms of a disciplined profession. (For exemplary statements of that rationalist ethos, see Chadwick 1971 and Branch 1990.)

Those ambitious rationalist protocols and aspirations did not control the platform for very long before they evoked a critical counterattack on the ‘new utopians’ and the pathologies of technocracy (Boguslaw 1965). Some of these attacks came from theorists who had never been true believers in an age of uniquely rational planning. Perhaps more interesting, were subtle changes in the thought of rationalists (such as Melvin Webber or Britton Harris) responding to the difficulties of managing the indeterminate complexity of ‘wicked’ problems, and of bringing knowledge to bear upon even simple planning issues when ordinary words carried so many conflicting meanings (Rittel and Webber 1973, Vettoretto 1997, Harris 1989, 1997). Both internal and external voices challenged the assertion that a corps of professional planners could articulate and defend a unique social welfare function, or that the difficulties of collective action could be resolved consensually by privileged institutions or tools. Accounts of urban and regional planning activities that dealt only with the behavior of professional planners obscured the ways in which a great many agents attempted to plan, playing both with and against one another. It may be useful to represent planning as a system, but neither the governor in that system nor the feedback loop need appear as a professional planner or agency. In many settings, governance is the work of a political regime, a market, or an interorganizational field. In Charles Lindblom’s account, the ‘intelligence of democracy’ depended on the design of interaction as well as the practice of analysis. Theories addressed only to the creation and maintenance of an expert profession of analysts could not explain adequately the dynamics of those interactive processes, institutions, and practices. Nor could they provide compelling support for their redesign (Lindblom 1965, 1990).

The critique of the rationalist toolkit was extended by a reinterpretation of reason and rationality. These ideas, circa 1950, justified claims as fitting within a

coherent world view; and as cogently linking a chain of assertions to core propositions without violating legitimate rules of discourse. By 1975—or even earlier—the implications of these criteria had been altered substantially by the recognition of multiple worlds, discursive formations, and pragmatic tests of truth claims.

Paradoxically, the shift was signaled most clearly by the simultaneous publication in 1973 of Andreas Faludi’s anthology celebrating the achievements of postwar planning theorists, and his own treatise synthesizing these achievements in an account of three polar modes in which intelligent professional agencies sought to enhance human growth: blueprint vs. process, rational comprehensive vs. disjointed incrementalist, and normative vs. functional planning. By articulating these polarities as foundations of a positive theory of planning, Faludi revealed how little the community of theorists knew of the variability of these modes over time; and of the ways in which the field of planning organizations and institutions responded to the attributes of the settings upon which it acted. The description of three polarities virtually begged for additional options that would—and that did—enrich the planning repertoire, but that also made it impossible to cultivate a complete general theory of planning. Though Faludi’s description of ‘human growth’ as the goal of planning had a distinguished intellectual pedigree, it was obscure and (in the event) quickly dominated by the intense interest of theorists in John Rawls’ (1971) conception of ‘justice as fairness.’ The theorists, though deeply engaged by the philosophic disputes surrounding *A Theory of Justice* (and subsequently by Rawls’ responses to his critics), did not, however, agree unanimously that justice was a superordinate goal that should guide all planning choices, that the conditions of the original position would yield a rational consensus on Rawlsian principles, or that the distinctions between rights and goods (and thick and thin) were compelling.

In practice, reason and rationality had always spoken with diverse voices. In the last quarter of the twentieth century, they were intractably pluralistic in theory. Pluralism implied that reason and rationality were neither permanent nor universal criteria. Encoded in planning doctrines, they were precious but temporary and local public orders. In different ways, both Richard Rorty and Jürgen Habermas—as they were coopted by the community of planning theorists—defined the planning ‘problem’ as the design of legitimate ‘conversations.’ Closer to the core of the community, the fascination with ‘participation’ as a remedy for the putative flaws of both autocratic and representative institutions privileged the voices of engaged advocates rather than heroic rationalists.

Without the taming influence of a commanding conception of rationality, the pluralist expectation encouraged an increasingly complex conception of the architecture of the intellectual field. In both positive

and normative theorizing the distinctions between process, setting, and outcome could be drawn in many different ways. A development coalition committed to promoting growth might be treated as a setting permitting a comparative study of professional planning processes in an array of urban regimes. A theory trying to explain differences in development patterns might, however, represent the coalition as the most important dimension of the urban planning process. The theorist in such a field is a designer adjusting and readjusting the three elements in order to find a process that can deal with a setting, a setting that can sustain a process, and a conception of outcomes that will not shatter a rightly cherished world. The theorist as critical reader unpacks that complex judgment to test its credibility and its delight: Is that a world worth making?

By the mid-1980s many members of the community of theorists had accepted an image of their field as a lively but not very tidy patchwork—wall *bricolage* was the fashionable descriptive image. As theorists learned to create sensitive ethnographies of practice, to test the cogency of procedural typologies, and to appreciate the disjunction of what Thomas Schelling (1979) described as ‘micromotives and macrobehavior,’ the harder it became to make sense of the wall. Even the most elaborate plans—symbols of the authority and heroic aspirations of practitioners—were understood by theorists as vulnerable to the (highly variable) interpretations of uncontrollable readers and the secret influences embedded in the everyday language of planners. In Judith Innes’ (1990) report of her own conversion, the new ‘interpretive or phenomenological view of knowledge’ was ‘more contextual, more evolutionary, and more complex’ than the positivist scientific model in which she had cast her 1975 account of social indicators.

That was not, however, the end of the tale. Whatever their view of the political roles and possibilities of professional planning, theorists worried lest the literary forms of their arguments alienate both students and experienced practitioners; that it would encourage skepticism, and an insidious delight in uncertainty. They fantasized about a postmodern ‘abyss,’ in which both practical confidence and public meaning were lost.

The community struggled with those fears in the last two decades of the twentieth century. The attempt to control a pluralism that was deeply treasured took at least four different forms—some new and some part of its initial endowment. The first responsive form, as in the complementary work of Ernest R. Alexander (1996) and Andreas Faludi (1996), accepts the difficulty of articulating and defending a complete general theory of planning. It insists, however, that the patchwork of typologies, ethical claims, and empirical findings can be integrated by a robust planning doctrine into a series of contingent protocols: Within the frame of such a doctrine, if a situation changes

from A to B, there is a shift from the now inappropriate mode to another that better fits the current setting. These protocols are more complex than a single theory but not so difficult (or so numerous) that they deny the possibility of achieving consensual agreements on the nature of processes, settings, and outcomes, and their relationships.

The second response addresses pluralism and the patchwork of theory in a quite different way. Surely, the worlds we plan are remarkably varied and often the devil is in the details of those differences. Nevertheless, the advocates of this response—such as David Harvey (1985)—insist, there are really only a small number of compelling ways to describe and explain planning processes, institutions, and practices; only a small number of compelling ethical systems and principled social conflicts. We misrepresent the condition of planning theory, they insist, when we fail to recognize the ways in which the great global systems—e.g., capitalism, statism, democracy, colonialism, racism, liberalism—are defended by the construction of the illusion of huge variations and the exaggerated promise of plasticity.

The third response divides the patchwork of theory into two parts. One—planning proper—is subject to all of the familiar perils of indeterminacy, complexity, and interpretive variety. The second part is the domain of planning support systems that tame those perils (even if they cannot eliminate them) by establishing consensual representations of ‘fact’ and ‘structure,’ allowing us to elaborate the implications of our own images and plans, and stabilizing public orders (Klosterman 1997). Serious support requires, of course, that the choice of representational modes and data sets address the protean requirements of planning processes. The support we seek when we are encouraging divergent thinking early in a planning process would be disruptive or inadequate as we fill in the final details of a fully elaborated scheme. Data sets or maps that cloak essentially contested meanings in a formal garb cannot transform (or support) planning debates: They only reproduce them. Strategic planning *may* not be well-served by the data that regulates operational management; or organizations in a turbulent environment by the information practices of a placid field (Emery and Trist 1965).

Finally—in what is often represented by its critics as the dominant school within the community (Healey 1997, Yiftachel 1999, Throgmorton 1999)—the communication strategies that have accentuated the pluralism of both planning and planning theory have been engaged to limit the perils of pluralism. Initially, the project of communicative enlargement served principally to encourage the voices of silent groups and to ‘pay attention’ to their lives, to democratize access to knowledge, and to multiple the opportunities to be heard. This project is by no means completed to the satisfaction of its partisans, but it has now taken a somewhat different turn. How is it, many theorists

(e.g., Baum 1997, Forester 1999, Mandelbaum 2000) wonder, that we sometimes manage to understand and change one another, and to resolve moral conflicts? What sorts of rhetorical practices and what sorts of settings sustain a practice of reflection, successful mediation, cooperation within and between organizations, and mutual trust? How—even more profoundly—may strangers learn to deliberate across the ordinary divides of adversarial democracies? What does ‘justice’ require of our speech and of the distribution of knowledge?

The current theorizing about communication in planning is capacious. It is not only about talk and texts, but about the ways in which symbolic meanings are imputed to actions and symbols are acts; about the ways in which arenas, forums, and courts (Bryson and Crosby 1992) shape communication patterns. The focus on communication accommodates ethnographies of planners at work, close studies of the dynamics of communities as moral associations, critical assessments of the networks that support the ‘new information technologies,’ civil societies and political regimes at every level, and the detailed protocols (Friend and Hickling 1997) that support the work of complex task forces. Inevitably, the links between these diverse intellectual forms sometimes seem very fragile, and the communication explanation and remedy tendentious. The power of the communication approach lies in the ways in which it makes sense of the diversity that theorists discover as they engage one another on the shared platform. Though theorists have not articulated a consensual set of findings or shared uncertainties, they have found a way to talk about their disagreements, to identify themselves within intellectual traditions, and to map prospective bridges across contested grounds.

S. J. Mandelbaum

Plasticity in Human Behavior across the Lifespan

The concept of plasticity originated in the medical sciences and refers to the capacity of organism to be modifiable. This variability and flexibility enables human beings to adapt to a great range of new and changing environmental conditions. Starting from this origin, the concept of plasticity has been applied to a broad scope of phenomena, the plasticity of nervous systems, changes in observable behavior patterns, and life trajectories.

Neuronal plasticity research, for example, addresses the biochemical and neuronal processes underlying the development and the variability of behavior over the lifespan; that is, it refers to the mechanisms of brain development that involve changes in structure and function (brain plasticity). A key concept in this field was the 'critical period' (Wiesel and Hubel 1963) which refers to a phase in the lifespan when neuronal structures are highly malleable based on the level and type of activity exposed to. For organisms at increasing maturity levels it was expected that neurostructural plasticity decreases with age and is absent in the mature cortex. However, subsequent research revealed substantial plasticity in the mature adult cortex, for example after lesions, strokes, and nerve damage or—even more important—after learning occurs (e.g., Buonomano and Merzenich 1998, Recanzone 2000). Studies showing activity-dependent plasticity on brain structures and transmitter systems in

the aging brain provided convincing evidence that brain plasticity is not restricted to juvenile stages of development, but at least in the human species covers the entire lifespan (e.g., Cotman and Neeper 1996).

In contrast to neuronal plasticity research, the focus in lifespan psychological plasticity research lies on identifying the range and the conditions of behavioral modifiability as well as their age-related constraints across the entire life course (behavioral plasticity). In that context, the concept of plasticity generally refers to the ability of human beings to display rather different patterns of behavior as well as different life trajectories (Baltes and Willis 1982, Lerner 1984). So, plasticity can refer to variability of life course patterns (ontogenetic plasticity) or to the variability of a performance in a specific moment in time (concurrent plasticity). Moreover, the study of intraindividual behavioral variability is not restricted to cognitive functioning but extends to noncognitive domains such as motivation and personality. To understand changes in behavioral and ontogenetic plasticity across the lifespan, broader theoretical frameworks of human functioning have to be considered that take the dynamic and complex interplay between evolutionary/biology-based and culture-based influences on the nature of lifespan development into account (Baltes et al. 1998, Finch 1996).

1. Human Behavioral Plasticity as a Product of Evolution and the Foundation of Culture

Much of the behavioral and ontogenetic plasticity is based on the phylogeny of mammals, a biological strata characterized by open behavioral programs (Mayr 1974). With few exceptions, human behavior is not regulated by preprogrammed stimulus-response patterns, but entails the potential to adapt to a variety of ecologies and stimulus constellations. This plasticity opens behavioral patterns both in terms of concurrently available behavioral options and—even more important for ontogenetic change—in terms of acquiring new behavioral patterns. This holds too and is even accentuated when one views the evolution of the human mind from a perspective of evolved domain-specific behavioral and cognitive modules (Cosmides and Tooby 1994, Fodor 1983), which are open to ecological and cultural variations. In the course of human phylogeny such evolved mental modules have escaped domain-specific encapsulation (see Fodor's original conception of encapsulated modules, Fodor 1983) and thus provided the building blocks of human intellectual capacities and behavioral adaptiveness. This variability in behavior and development is as much a product of evolution as the more narrowly constrained behavioral systems of other species (e.g., Wilson 1980).

Behavioral plasticity opens the potential for systematic influences of experiences, most notably in-

fluences of socialization and instruction. Both on the part of the socializing agent and recipient, flexible regulation of behavior in the interaction allows the partners to move beyond preformatted parenting and attachment programs of behavior, and reach out for the social—and ultimately cultural—transmission of experience between generations, and more generally between experts and novices. The ability to instruct and to profit from instruction probably is the critical difference in behavioral regulation which sets *homo sapiens* apart from other primates (Tomasello et al. 1993). Only humans seem to intentionally instruct their children (or nonexpert adults) to modify behavior in accordance with a standard or goal. They correct, model subcomponents, and thus selectively modify error-prone behavior of a partner to fit a certain standard. This specific instructional potential of human interactions is the vehicle of fidelity in information transmission (Tomasello et al. 1993), the prerequisite of cultural heritage. In modern societies this instructional potential has led to the institutionalization of instruction in educational institutions, such as schools and universities. Instructional interactions between humans and the training in educational systems have in turn greatly amplified the range of plasticity in human behavior. The combination of evolutionary potential and cultural transmission can thus generate an immense, albeit not infinite, universe of behavioral plasticity in many potential developmental pathways. Indeed, this great potential for variability, plasticity, and adaptivity in human ontogeny is a cornerstone of lifespan developmental theories (Baltes 1997, Lerner 1984).

2. Plasticity of Performance Across the Lifespan

The range of plasticity in performance in diverse domains of functioning (e.g., athletic, intellectual, creative) is determined by the joint influences of either the genotype-related component of performance, that is, genetically-based interindividual differences in performance, or the phenotype-related component of performance, that is, intraindividual differences based on current performance factors (e.g., motivation, alertness), accumulated investment, and instruction. While genotype-related influences delimit the range of plasticity for any given individual, the phenotype-based influences determine whether this potential of plasticity is actually realized (Kliegl and Baltes 1987). Specifically, these four influences are the following. First, there are age-graded differences in the baseline opportunities for maximum performance. It is well known and empirically established that across the human lifespan, performance in various domains of functioning undergoes radical changes, typically reflecting an inverted U-shaped trajectory, with a maximum performance potential at a given age (Lehman

1953, Simonton 1988). Age of maximum performance is relatively early for most athletic disciplines, particularly the track-and-fields sports (Schulz and Curnow 1988), and moves further into adulthood for areas of peak performance which require extensive expertise, such as soloist musical performance (Ericsson et al. 1993), science, and poetry (Simonton 1988). Second, a great many contextual factors can influence an individual's baseline reserve capacity (Kliegl and Baltes 1987). Thus, the component of reserve capacity which influences current performance can be optimized by improving motivation, alertness, clarity of task instruction, and other contextual factors. Albeit opening up many avenues for intervention to promote improved performance, these performance factors are problematic from the perspective of basic research (Salthouse 1985). The performance factors can vary with age and thus confound age differences, so that accurate assessments of latent performance potential at different ages is compromised. Baltes, Kliegl and their colleagues have proposed the methodology of Testing-the-Limits as a research strategy to assess cognitive reserve capacity in terms of latent performance potentials. This research paradigm optimizes performance factors for all individuals and assesses their ability to profit from a training designed to construct a specific cognitive skill, for which the different age groups do not hold differential experiences (Kliegl and Baltes 1987). This latter component of instruction-related plasticity of performance is the third influencing factor, addressed next. Third, performance can be optimized by providing appropriate instruction. The influence of instruction on performance is a long-standing research topic in diverse fields of study and approaches to psychological functioning. Vygotsky conceptualized the zone of proximate development as the range of potential performance an individual can attain with the help and instruction of an expert interactive partner (Vygotsky 1978). This conception about developmental reserve capacity in socially constructive interactions has spawned much research on social facilitation in parent-child dyads (scaffolding, Wood et al. 1976; apprenticeship, Heckhausen 1987, Kaye 1982, Rogoff and Wertsch 1984), child-child interactions (Rogoff 1990), cognitive aging (development-enhancing interventions, Kliegl and Baltes 1987), and educational psychology (see zone of potential development, Brown and French 1979). Finally fourth, plasticity in performance is a function of the individual's long-term investment in a given area of skill or expertise. Research on life-course trajectories of peak performance across a wide variety of domains has demonstrated repeatedly that world-class levels of performance require extensive and high-quality expert-guided training and practice over long periods of the lifespan, particularly in the early phases of acquisition (Ericsson and Charness 1994, Simonton 1988). This powerful effect of focuses and prolonged

practice and training is itself the best witness of the impressive plasticity of human performance across the lifespan.

3. Cognitive Functioning in Old Age: A Case in Point

An extensively studied area of human behavioral plasticity is cognitive functioning in old age. Numerous studies have demonstrated declining performance in fluid intelligence performance with increasing age among older adults (Salthouse 1985). This pattern of age related decline has been challenged to be reflective of true latent performance potential, since many factors such as motivation or lack of recent practice could produce performance differences such as those found between older and younger adults in intellectual functioning. This critique prompted researchers to optimize performance conditions for older adults for instance by using ecologically valid tasks. Moreover, specifically designed training programs were administered to promote improved performance in older adults (Verhaeghen et al. 1992, Willis 1989). Examples of early training studies are among others the Penn State Adult Development and Enrichment Project (ADEPT) and the Berlin PRO-ALT project (for review see, Baltes and Lindenberger 1988). These studies demonstrated substantial benefits of older adults' fluid intelligence performance from cognitive training. For tasks that were similar to those addressed by the cognitive training, older adults improved their performance. However, the training effect showed no transfer to other fluid intelligence tasks. Additional studies comparing the benefit of guided instruction with self-regulated practice showed that self-instruction was as effective in improving cognitive performance in older adults as was guided instruction. This suggests that a large share of the old age plasticity in cognitive functioning is due to the activation of already available cognitive skills, which have been fallen into disuse over the adult lifespan.

The findings of preserved substantial learning potentials up to old age and the possibly arising optimistic view of unchanged cognitive plasticity over the entire lifespan had been put in perspective by Testing-the-Limits studies aiming to delimit maximum performance potentials (Kliegl and Baltes 1987). In this research, cognitive skills are taught to subjects using specific training programs to construct an expertise in a certain cognitive domain, for example in the domain of memory for nouns. In this way, an expertise is cognitively engineered, so that the researchers know the component abilities, and can thus specifically compare subjects at different ages in terms of specific subskills. Subjects are trained extensively until they have reached asymptotic performance levels. Once maximum performance levels are achieved, time constraints are introduced. The findings indicate that

although older adults can reach high levels of performance (e.g., in recalling nouns), their maximum (asymptotic) performance level after extensive training is much lower compared to younger adults. Moreover, their functioning breaks down when they encounter severe time constraints. Thus, at limits of functioning, age differences are magnified and reveal the potentially underlying neurobiological constraints associated with the biology of the aging brain (Baltes and Kliegl 1992). Finally, Testing-the-Limits methodologies have been successfully employed to identify elderly at risk of dementia (Baltes et al 1992) and distinguish pathological from normal cognitive aging (Reischies and Lindenberger 1996).

4. Plasticity in Personality Across the Lifespan

Processes of self-regulation, personality, and subjective well-being show much less systematic age variation than cognitive functioning. Indeed, the stability of life satisfaction, self-esteem, perceived control, and overall happiness in itself is proof of the adaptive plasticity of these processes. The age-normative shift from a predominance of perceived gains to ever increasing risks for decline (Heckhausen et al. 1989) would lead one to expect concomitant declines in indicators and components of subjective well-being. Instead, emotional balance remains resilient across the life span (Staudinger et al. 1993).

This resilience of the emotional balance to lifespan changes is one of the key achievements of the human motivational system, which has evolved to manage the challenges associated with the relative dearth of biologically-based predetermination of behavior. The relatively weak biological regulation of behavior furnishes a regulatory need to achieve and maintain selectivity in behavioral investment, and to compensate for the ever-present failure and loss of a behavioral system that is underdetermined and thus highly error-prone. Both selectivity and loss compensation, key concepts in lifespan developmental research (Baltes et al. 1998, Schulz and Heckhausen 1999, Carstensen et al. 1999), require adaptive motivational processes, which focus volitional investment into a chosen goal and buffer the potentially negative effects of aging-related losses. Typical examples of such metamotivational processes (i.e., secondary control, Heckhausen and Schulz 1995) which facilitate goal striving, are upward social comparisons with superior or advanced others, who can serve as models for self-improvement (Heckhausen and Krueger 1993), and enhanced valuation of the chosen compared to competing goals. Examples of metamotivational processes, which compensate for the negative effects of losses or failures, are self-enhancing comparisons with inferior others, self-protective attributions which take credit for gains but refuse to take blame for losses, and the adjustment of goals to fit one's real potential (for the latter example

see also Brandtstädter and Renner's conception of accommodation, Brandtstädter and Renner 1992). In general, the age-graded structure of opportunities and constraints sets the stage for the individual to use the age window of maximal opportunities to strive for a given goal. The regulation of motivational investment requires substantial plasticity in that the individual needs to enter cycles of engagement and disengagement with various developmental goals (Heckhausen 1999). Motivational engagement and disengagement with specific life goals should be contingent and flexibly adapted to changes in opportunities and constraints across the lifespan.

J. Heckhausen & T. Singer

Play and Development in Children

1. Introduction

The study of play has held particular allure to social and behavioral scientists, at least since Groos (1898). Since that time it has been assumed that play serves an important role in children's development into adults. An important step in documenting the importance of play should be defining play in terms of the ways in which it is different from forms of behavior not considered playful.

2. What is Play?

No one definition of play is necessary or sufficient, yet child psychologists (Pellegrini and Smith 1998) and ethologists (Martin and Caro 1985) agree upon some

common definitional criteria: play does not seem to serve any apparent immediate purpose. This assumes that children are less concerned with the outcome of their behavior than with the behavioral processes *per se*.

Play has also been defined according to phenomena that precede (e.g., an atmosphere that is familiar, safe, and friendly, a minimally intrusive adult, and children who are free from stress) and succeed play behaviors (e.g., behavior is categorized as play fighting, not aggression, if children stay together after the conclusion of the bout; if they separate, it is defined as aggression). Caution is needed as in this case as antecedents and consequences of behaviors can be considered as elicitors and outcomes, respectively, of those behaviors, rather than as components of the behavior *per se*.

3. Forms of Play

Different forms of play occur from infancy through adolescence and they have distinct antecedents and possible functions.

3.1 Exploration

Exploration is an information-gathering venture (e.g., mouthing and simple manipulation of objects) (Belsky and Most 1983). Through exploration children come to know their environments.

Exploration dominates behavior for the first 9 months of life. By 12 months, play and exploration co-occur. By 18 months play accounts for more of the child's interactions with the environment than does exploration (Belsky and Most 1983). Exploration also precedes play to the extent that children of all ages must explore an object, or know its properties, before they can play with it. The knowledge resulting from exploration is basis for play.

3.2 Fantasy Play

Fantasy, or pretense, is the paradigm case of play during childhood. Fantasy involves an 'as if...' orientation to the world and involves actions, use of objects, and verbalizations and nonliteral meanings; often, it involves playing a distinct pretend role such as mummy. Fantasy begins during the second year of life, peaks during the late preschool years, and then declines (Fein 1981) and there are reliable gender differences: girls engage in fantasy play both more frequently and at more sophisticated levels than do boys.

Fantasy play is influenced by familial variables as well as play props and play partners. Children who are securely, compared with insecurely, attached to their

mothers engage in more sophisticated pretend play (Roggman and Langlois 1987). Regarding props, play themes generally follow the themes inherent in the props available (Pellegrini and Perlmutter 1989). Further, children's pretense is more sustained and complex when they are playing with friends, compared with acquaintances, possibly because the mutuality and emotional commitment of friends may motivate children to sustain cooperation (Howes 1992).

3.3 Locomotor Play

Locomotor play is play that is physically vigorous, e.g., chasing and rough-and-tumble play (RandT). The less 'thematic' and nonsocial forms of vigorous play, such as running and jumping, account for close to 20 percent of the activities of 3- and 4-year-olds and then declines during primary school years (Pellegrini and Smith 1998).

Vigorous play is shaped by both hormonal and social events, resulting in reliable gender differences (Pellegrini and Smith 1998). During the course of normal fetal development, androgens predispose males to be more physically active than females. Socialization practices, such as father engaging in vigorous play with sons more frequently than with daughters, reinforce the difference.

4. Functions of Play

Paradoxically, play is defined in terms of its 'purposelessness' yet seen as serving an important function in children's development. The paradox can be reconciled by supposing that the apparent lack of immediate function actually conceals a function delayed in development.

4.1 What is Meant by Function?

Function has at least two meanings in the social and behavioral sciences. First, function can be defined in terms of an evolutionary history. A behavior is functional if it has added to the reproductive success of individuals. Functions can also be defined in terms of beneficial consequences during the lifespan of any particular individual. Benefits may be accrued immediately or during the period of childhood, or deferred until adulthood.

4.2 Immediate or Deferred Functions

Most theories of play have proposed that the benefits of play are not immediate to the period of childhood but deferred until later in development. In Bateson's (1976) terms this view presents play as a 'scaffolding'

metaphor: play functions in the assembly of a skill and then is disassembled when the skill is complete. This remains an influential view, even though empirical studies have not provided support for this claim (e.g., Martin and Caro 1985, Pellegrini and Smith 1998).

Alternatively, play may not be an imperfect version of adult behavior but may be adapted and beneficial to the specific niche of childhood. Bateson's (1976) metaphor for the immediate functions of play is metamorphic (e.g., the sense of mastery associated with children's play probably relates to children experimenting with new activities).

5. Making Functional Inferences

Function can be inferred using cost-benefit analyses, consideration of design and contextual features, and experimental enhancement or deprivation of play components.

5.1 Cost-Benefit Analyses

With cost-benefit analyses we assume a correspondence between high costs and high benefits; low costs imply low or high benefits. Play can be costly in terms of time, caloric expenditure, and survivorship (e.g., danger). Basic cost data on children's play is, however, scanty. Yet there are some hints from the animal play research which suggest that play accounts for a limited portion of an animal's time and energy budgets—around 10 percent (Martin and Caro 1985, Pellegrini and Smith 1998). Consequently, we conclude that benefits are probably low and deferred as immediate benefits are more likely to be reaped given risks associated with survivorship.

5.2 Design Features

A design-features argument involves explication of similarities between aspects of play behavior and similar features in mature behavior. Design feature arguments have been made most frequently for RandT as its fighting-like features (e.g., wrestling) should relate to fighting skills and dominance. Problems associated with this design-features approach to the study of function relate to the fact that a mature behavior may develop from many different antecedents (Martin and Caro 1985).

5.3 Experimental Deprivation Studies

A few experimental play-deprivation studies have been conducted where juveniles are deprived of an aspect of play. The assumption is that deprivation of an aspect of play, if it is developmentally important, should

result in a 'rebound effect' when children are given the opportunity to play again; children compensate for the deprivation by engaging in high levels and longer durations of play. Most deprivation studies can be criticized on the grounds that more than one thing is involved when we deprive children of play (e.g., depriving children of social play simultaneously deprives them of social interaction).

The effects of depriving children of play opportunities have largely been limited to studies of physical play. In different field experiments, Smith and Hagan (1980) and Pellegrini et al. (1998) experimentally deprived children of opportunities for physical play. Across all experiments the results showed that increased deprivation led to increased levels of play when opportunities for play were resumed. We argued that children rebounded after deprivation so as to overcompensate for lost opportunities for physical exercise, which serves important training functions.

5.4 Experimental Enrichment Studies

With enrichment procedures, children are given opportunities to engage in play that vary according to theoretically relevant dimensions, such as conceptual conflict (Pellegrini 1984), and their effects are measured. Most of the criterion measures in these studies are taken in close temporal proximity to the training, thus assuming that play has immediate rather than deferred benefits.

There have been numerous studies examining the effects of and pretend play enrichment on various dimensions of children's social cognitive status, such as role taking. Most of these studies showed positive benefit effects of play; but they must be interpreted very cautiously, primarily because many play enrichment experiments have serious internal validity problems (Smith 1988). For example, many experiments confound play treatment with adults tutoring children in play and most effects are due to experimenter bias.

6. Conclusion

We have outlined some of the basic definitional and developmental tenets of play. The role of play in children's development is still a controversial and unresolved topic. Cost-benefit analyses suggest that there should be benefits; but they may be relatively small and possibly limited to the period of childhood, rather than deferred until after childhood. Suggested benefits include physical fitness (for physical play), fighting and dominance skills (for RandT), and affiliative and theory of mind skills (social and pretend play).

With this said, however, we note that much more research is needed before we can make sound conclusions regarding the developmental functions of play. Most basically, more descriptive studies of

children's play, documenting costs in terms of time, caloric expenditure, and survivorship in contexts other than school are needed. This information could be used in the service of cost-benefit analytic studies of play. Correspondingly, these features could also be used to test functional hypotheses more directly using field experimental methods.

A. D. Pellegrini and P. K. Smith

Play, Anthropology of

Malleable, flexible, fluid, uncertain, changeable—all are adjectives that are used to describe play, whether as a medium of cognition, practice, or communication. Play refers to a complex of universal phenomena

among human beings that also are found among numerous animal species (Fagen 1981). All peoples, though they may not distinguish in semantic terms between play and other behavior, likely engage in playing as they shift into a conditional or subjunctive sense of being, one that opens toward a multiplicity of possibility. The mathematician and the theoretical physicist play during the process of shaping their ideas no less than children imagine, practice, and repeat their inventions in their play. Useful overviews of play phenomena are given in Spariosu (1989), Schwartzman (1978), and Sutton-Smith (1997).

Despite its pervasive presence, play is perhaps the least concrete of phenomena and therefore one of the most difficult to define. Any useful definition of play highlights its multiplicity of potential experiences. The anthropologist, Bateson (1972) perceives play as paradoxical, in that it is and is not what it seems to be. The classicist Spariosu (1989) terms play, amphibolous, or going in two directions at once. In a succinct manner, the anthropologist, Droogers (1996) defines play as, 'the capacity to deal simultaneously and subjunctively with two or more ways of classifying reality.'

1. Play and Reality

There is an intimate relationship between play and reality because play is first and foremost experiential, whether personal or social, and reality does not exist without its experiencing. In the creation and practice of realities of play, the imagination is crucial. Without the cognitive, the capacity to imagine realities, there is no play, just as, without the practice of experience there is no reality.

Play raises to the fore issues of alternative realities, the role of these and other multiplicities in social and personal life, and their consequences for human cognition and practice. The cognitive perceptions of play enable persons to enter into alternative realities, and perhaps into the simultaneity of multiplicity. Cognition is related intrinsically to how realities of play are imagined and framed differently from other realities. The practice of play entails the sensuous embodiment of these alternative realities; and, so, the subjective experiencing of play from within these imagined contexts that offer a sense of release, freedom, exploration, and perhaps exhilaration. The communicative component suggests that these specialized contexts of play are able to comment on the social orders from which they arise, and to send these messages back as the participants in play return to the reality of nonplay. Therefore contexts of play are metacommunicative in their relationships to social order: play communicates to its participants not only *how* to play but how such playing relates to social order. That play is framed as imaginative and malleable, and that through these qualities it generates and conveys metamessages informing players as to

how to relate to aspects of social order, makes play perhaps the most fruitful of contexts of socialization, both for children (Briggs 1998) and for adults.

2. Framing Play

Given that play constitutes domains that cognize, practice, and communicate the shaping of imagination, are these domains to be conceptualized as incisively distinct from domains of serious reality, of not-play? This is the implication of Bateson's highly influential theory of the framing of play which separates play lineally from the serious, or not-play. According to Bateson, the cognitive metamessage, 'This is play,' brings into existence the play frame which cleaves between the seriousness of everyday reality and the imaginings which are practiced within the frame. One may adduce from this not only that play comes into existence as a corollary of its framing but also that play, and the practice of its imaginative multiplicities of possibility, is located within the restrictions of its framing. Viewed from outside the frame, play is make-believe activity that in fact does not exist. Experienced from within the frame, play may well be utterly engrossing in the embracing reality of its presence. These views accord well with Johann Huizinga's (1970) classic study of how civilization emerged through the plastic premises of play; although in the process, play itself became a temporary sphere of make-believe activity, secluded, limited, and bounded in time and space. Once play is framed through lineal cognition, it becomes a world unto itself, one of temporary limited perfection with its own internal teleologies (Gadamer 1988). Within itself the practice of play may well proceed in deadly earnest.

2.1 Play and the Playful

Sutton-Smith (1997) offers a useful modification to the binarism of a reality either of play or of not-play, of make-believe or of serious reality. Sutton-Smith distinguishes between play and the playful. To build on his argument that the playful plays with the very framing of play itself, one can add that the playful is a mood, an attitude, that may permeate both serious reality and play, or that suddenly may surge into presence within the mundane. In either instance, the playful is full of the impulse to perceive and feel in ways other than those offered by the immediacy of a given reality. The abrupt presence of playfulness disrupts the most routine of expectations. Playfulness injects speedy uncertainty into the most expected of social practices.

The playful attitude within mundane reality may be integral to the existence and organization of the latter; while play itself may be more 'distant,' as it were, from mundane reality. Playfulness and play complement

one another. The eruption of playful feeling and perception are a significant key to establishing the play frame in relationship to mundane reality. But the play frame itself directs the kinds of ludic or make-believe activities that take shape within it, relatively separated from mundane reality.

2.2 Play and Foundation-for-form

In order for a play frame to come into existence there seems to be a need for a form of reference, a foundation-for-form or organic model that can be altered in systematic ways and turned into someone or something else. Nonetheless, whatever is changed retains crucial similarities to the form of its foundation and so remains intimately related to it. For example, The medieval European Feast of Fools which mocked the traditional Christian Mass needed the latter so that this could be inverted and altered. The play-mass, performed in church by priests, would have had no significance for participants were it not derived from and contrasted with its everyday analogue, the sacred Mass.

To take a more mundane example, when one little American girl, aged seven, turns to her sister, aged five, and says: 'Let's play sisters,' she is establishing a play frame within which these girls can play the foundational form of their sisterhood, imaginatively and perhaps with novelty. Play changes the known signs of form into something else by altering the reified boundaries that define and characterize the phenomenon. These girls will still be sisters, but they will be able to explore, practice, and experience their sisterhood with a difference, with license, in ways perhaps closed or unimagined within their usual relationship. They can play with the strangeness of being sisters. In turn, they may carry the messages of their experience back into their ongoing relationship as sisters, changing this in minute but additive ways. Hypothetically, they playfully may enter into play-sisterhood whenever they desire.

3. Attributes of Play

Play is a way of organizing activity, rather than any particular set or content of activities (Miller 1973). Any activity may be altered playfully, and played at. But in order to do this the everyday, instrumental perception of how means lead to and produce ends must be loosened, stretched, or perhaps uncoupled entirely. Goals exist in play, but the means to attain them are given degrees of autonomy. This is why play behavior can be endlessly repetitive or follow a crooked line around artificial obstacles. The patterning for play may be suggested by how the foundations-for-form that are used in playing function in the everyday. Say that the two little sisters and their friends place chairs in a row, the back of each facing

the seat of the next, and that these children imagine these chairs to be a train. The children practice playing train, until they decide that the train is a plane, and the row sprouts wings, carrying its passengers, but then is turned into a bird flying off with children on its back, becoming a row of chairs in school and kindergarten that is also a plane. In each instance, one foundation for form (train, plane, bird) is imagined to take the place of another. Each such organic model is voluntarily turned into a foundation for imaginative practice that plays in turn with the multiplicity of these organic models, one after the other or as hybrids of one another (a row of chairs that with near simultaneity is train, plane, bird).

The perception and practice of play brings into being something that had not existed before in quite the same way. This is done by changing the shape and positioning of boundaries that categorize phenomena, thereby altering their meaning. Each shift by sisters into playing sisters seems like a repetition, yet is instead a different beginning since it imagines anew and plays with the very possibilities of sisterhood. Even a slight change in the boundaries that give shape and significance to phenomena involves some degree of destruction and recreation. In its cognition and feeling, play is associated closely with creativity, creation, and destruction.

Play is frequently implicated in the making of change. Change is the making of difference, even if this difference seems to mimic or eventually to reproduce an earlier state. Play introduces malleability into social and cultural life, taking apart the given and perhaps offering alternative visions and practices. Play often is involved in learning something new, through open-ended repetition, variation, exaggeration, and experimentation. Play is not unusual in the liminal phases of initiation rituals (Turner 1969), healing rituals (Kapferer 1983), and mortuary rituals of tribal peoples, when initiates, the ill, or the dead undergo profound transformations of being. Playfulness, in a more postmodern idiom is central to the practice of certain neo-shamanic rituals whose goal is the transformation of consciousness (Lindquist 1997). These and many other changing conditions involve shifts of cognition, practice, and communication. More significantly, change (creative or reproductive) usually involves fragmentation, destruction, or transformation of some sort, whether temporary or permanent, and these processes are often violent. The violence of change and change through play are often closely related. Some form of destruction and violence (to cognition, feeling, body and being) is involved in the shattering suddenness of the playful and in play.

4. The Truth-values of Play

The relationship between play and violence relates to how play has been conceived, and to the truth-values accorded to play. In his survey of philosophical ideas

of play, Spariosu (1989) finds two trends, one that stresses the practice of play as prerational (with its roots in ancient Greek thought and poetry), and the other that emphasizes play as rational activity. In prerational thinking, play is full of violent agon and power, strongly and pleasurably emotional, arbitrary in its appearance, experienced perhaps as ecstatic, and opening toward unlimited freedom. In rational thinking, the naked, enjoyable forces of chaos and disorder, of irrational power and violence, are suppressed in favor of play as rationally framed activity that is set apart from serious reality. Here play is unreal in its irrationality, and therefore controlled, nonviolent, and limited in its freedom. To expand on Spariosu, one may add that the eruption of pre-rational play (akin to playfulness) into everyday life is full of its own unsuppressed truth-value. The truth-value of prerational play is integral to living within realities that overlap and that are continuous with one another—realities that relate to one another as multiplicities of possibility. By contrast, the make-believe status of rational play, framed and contained in special times and places (as Huizinga, Bateson, and others argue) denies any direct or immediate truth-value to play, enabling its practice to be treated as fictive, as ‘just play,’ ‘mere play,’ ‘done only in play,’ and so forth.

4.1 Play and Cosmology

The organization of cosmology demonstrates from another perspective the importance of the truth-values attributed to play. For example, in Indian cosmogenesis, play (or more accurately, playfulness) is implicated in the very creation of cosmos. Thus, varieties of Hindu cosmology and religion embed premises of play—malleability, multiplicity, ongoing change—at a very high level of cosmic organization. In consequence, these self-same premises of play resonate throughout the levels of cosmos. The entirety of cosmos is influenced by premises of play. In this kind of cosmology, play is a top-down idea, responsible in no small degree for the multiplicities of reality that constitute Hindu cosmos and religions (Handelman 1992, Handelman and Shulman 1997).

Here play has high degrees of truth-value and is rarely referred to as make-believe. By contrast, mainstream monotheistic cosmologies, if they pay any attention at all to ideas of play, embed these at a low level of cosmic organization, distant from cosmogenesis and the ordering of religion and society. In monotheistic cosmologies, play is more of a bottom-up idea, lineally framed, rationally contained, and separated from serious reality. Bottom-up play enters cosmology and religion from their conceptual and emotional undergrowth, and therefore is perceived as threatening. Here the messages of play are often positioned in opposition to or as a negation of the order of things; and play is perceived as fantasy,

illusion, and ephemeral; yet also as subversive and as resisting the order of things. But here the practice of play has low truth-value. Thus, the truth-value of top-down play is openly full of power and violence, while these qualities are veiled, hidden, and denatured in the low truth-values accorded to bottom-up play.

5. Game and Play

The idea and practice of game is closely related to that of play and may be understood as a variation of the latter, in the following senses. Game, like play, is a way of organizing activity. Game, too, loosens the relationship between means and ends. But the existence of game depends on relatively enduring rules, rather than on foundations-for-form that are easily changeable. Therefore games constitute distinct, autonomous realities, virtualities, given their internal, rule-based organization which to a high degree determines how they are practiced. Playfulness has less of a role in the practice of games. Games are less malleable and harder to alter than play.

Yet it is precisely because of their ruledness that games can be organized to make directed change through their practice. Lévi-Strauss (1966) comments that game is a systematic way of creating inequality. Game begins with equality between its sides and produces differences which are perceived as significant. The logics of game, in fact, are often close to those of ritual which is intended to generate change through its operations. Traditional Mesoamerican ball-games had game-like aspects, yet they were ritual-like in their relationship between means and ends, perhaps ends of cosmic renewal that their practice was intended to accomplish. More generally, the presence of play and game within rites seem to contribute to the attainment of ritual goals. (This is powerfully exemplified in the roles of clowns in Native-American Pueblo rituals.)

Perhaps in more systemic ways than play, game may awaken interpretive, reflexive feelings about aspects of social and moral order. The highly agonistic Native-American Kwakiutl potlatch, a ritual full of conflict that both demonstrated and reordered social status, produced the ‘play potlatch’ (Codere 1956) in which participants laughed at their own strivings for power and hierarchy. The rigid gender divisions in traditional Iranian society produced games practiced by women in which these distinctions were called into question, mocked, and played with (Safa-Isfahani 1980).

The twentieth century has seen tremendous growth in the use of game as a metaphor for living and social order (Minnema 1998)—Wittgenstein’s language games, Von Neumann’s game theory, war games, educational games, the game of intelligence testing, games people play, the play of quantum mechanics, chaos theory, virtual realities, and so forth. In post-modernist terms, these visions are of life organized as interpenetrating games, none of which give any total

or complete vision of reality, and no certainty about the stability of forms of living. The game metaphor reflects more fluid and mobile social orders that are perceived, correctly or incorrectly, as the creations of individual agency. Television as spectacle has contributed greatly to this growth by telecasting existing competitive game forms and aiding in the invention of new ones. Sports are at the front of these developments. These multitudes of contest (in which violence is close to the social surface if not on it) continuously rank and re-rank participants over and again in hierarchies that are more kaleidoscopic, fragile, and ephemeral than they are enduring. Play as the multiplicities of possibility, and the playful as the eruption of these possibilities in the everyday, are competing with more unitary monotheistic ethos, at least in the visions of the middle-class Western world.

Current thinking on play is reconceptualizing the problem of framing—the problem of relationships among realities, social and cognitive—to open alternatives to the ongoing rupture between play as rational and as irrational. Research on Internet chat groups plays into questions of framing (Danet et al. 1998). Issues of power in and through the practice of play are also related to questions of framing. Thus, ideas of ‘dark play’ (Schechner 1988), when players do not know that they are playing, and ‘evil play,’ when the manipulator of the frame positions herself outside it and plays others, yet pretends to be within the frame and controlled by it, relate to issues of play and power. They echo Bateson’s still enduring thought that a more complex question to ask of a play phenomenon is whether it is indeed this, or whether it is pretending to be so. Imagining the pretense of play is even more powerful than play imagined as such.

Plea Bargaining

Research into plea bargaining ‘in action’, not plea bargaining ‘on the books,’ has been conducted, for the most part, by studying US federal and state courts. Nonetheless, the central theme of this article is that the findings of this research are applicable in a comparative context and can, with some qualifications, help us to understand plea bargaining around the world. Plea bargaining may take different forms, and it might be referred to, or conceived of, as something different, but it does exist in criminal justice systems outside the USA. By examining US studies and the small amount of comparative research available, we can speculate that plea bargaining is a function of the raw material that courts process, and that if we permit an expanded definition of plea bargaining—even allowing for the particularities of various jurisdictions—we will see that this manner of case disposition is a near-universal province of courts. Space constraints preclude a systematic examination of what we know about these dynamics in a comparative sense; this article will discuss general themes and questions.

1. The Typology of Plea Bargaining

While scholars have concluded that plea bargaining was common in nineteenth century British courts (Zander 1998, pp. 323–34), most comprehensive studies have focused on the USA, and most have been conducted in the past 25 years. (For a summary of the early work on plea bargaining, as well as an agenda for future plea bargaining research at the time, see *Law and Society Review* 13 (2), 1979; for useful citations on subsequent related work see McCoy 1993, Vogel 1999.) In the early days, there was a debunking tone to this work, as scholars questioned and tested the assumption that trial courts ‘try’ cases. What was viewed as anomalous in an earlier period of US history—something which might have characterized the more political (and frequently ‘sleazy’) municipal courts—plea bargaining is now understood to be the central method of processing cases in trial courts. Plea bargaining was not an aberration of US courts; it was the norm. In what might be viewed as the epitaph for the role of trials in trial courts, a judge noted: ‘I don’t think that a trial necessarily represents a failure in the plea bargaining system. I really believe that the trial is a necessary adjunct of the system’ (Heumann 1977, p. 150).

While most scholarly attention has been focused on plea bargaining in the USA, recent comparative endeavors have produced data that afford us the opportunity to understand plea bargaining as it exists (in many forms) around the world. While no two nations’ legal systems or plea bargaining experiences are exactly alike, we are at the point where we can begin to construct typologies (explicit, policy, and implicit plea bargaining) that can and should invite future research. Notably, while different forms of plea bargaining will continue to exist, there is a kind of convergence at work, as the institutions, attitudes, and processes of nations around the world begin to resemble each other when it comes to the actual practice of plea bargaining.

1.1 Explicit Plea Bargaining

Plea bargaining in the USA in its most basic and commonly understood form, is the process of active, explicit negotiation between the defense attorney and prosecutor concerning the resolution of the defendant’s case. Most frequently the ‘deal’ revolves around the benefits that will flow to the defendant if he or she chooses to plead guilty. These might include a reduction in a charge, a dismissal of a charge or charges, or a prosecutorial sentence recommendation (or an agreement for the prosecutor not to press a particular sentence). Also, increasingly, the prosecutor might agree not to add a mandatory sentence charge to the defendant’s indictment. Any, or many, of these will be given to the defendant in return for a guilty plea. Generally the exchange is explicitly negotiated, and a

judge may or may not also be part of the negotiating process. When not involved, the judge usually goes along with the negotiations; however, if it is felt that the agreement is not acceptable to the judge, the defendant is usually allowed to withdraw the plea.

This form of plea bargaining, as indicated above, is one in which a negotiation is undertaken explicitly and the parameters of the agreement are agreed upon specifically. While the USA (especially since the late 1960s following the US Supreme Court’s approval of plea bargaining) represents the best example of a system that embraces explicit plea bargaining (indeed, the explicit variety is the one that is conjured up when comparisons with the USA are made), other nations which have experienced increases in case pressure have sought relief through increases in explicit plea bargaining. While it has been proven that this relationship is not a causal one in American courts (Heumann 1977), we can see a correlative relationship in systems such as South Africa’s, for example, which is considering the expansion of the realm of explicit bargaining (and inviting judges into the process) as a response to its increasingly overwhelmed courts (Schwikkard, and van der Merve 1999, p. 352). It is important to note that plea bargaining (involving prosecutors and defendants) was already common in South Africa, and thus was not caused by a case overload; what we are seeing now, in other words, is a development of earlier practice. Other examples of nations that employ more explicit practices include Israel, which allows on-the-record plea bargaining (Harnon and Stein 1999, pp. 239–41), and Canada, which openly encourages pleas with regard to charge and sentence (Roach 1999, p. 75).

1.2 ‘Policy’ Plea Bargaining

A second kind of plea bargaining, neither explicit nor implicit *per se*, is derived from, and relies upon, the policies a prosecutor’s office may have adopted over time. Specifically, the prosecutor may announce that his/her office will not negotiate in specific types of cases (e.g., when a firearm is involved, or certain drug matters). But the prosecutor, without explicit negotiation will, as a matter of policy, substitute some lower charge for defendants who plead guilty to a ‘policy case.’ Thus defendants (or defense attorneys) can be reasonably certain about the benefits that will attach to a plea of guilty. This form of plea bargaining seems to be unique to the USA—a product, seemingly, of the mandatory sentencing guidelines that have stripped some courtroom actors increasingly of the discretion necessary to make explicit deals.

1.3 Implicit Plea Bargaining

A third kind of plea bargaining—what we might label ‘implicit plea bargaining’—takes place whenever a

defendant pleads guilty, with the expectation that the plea will lead to a reward in terms of charge and/or sentence reduction. Unlike the first kind of plea bargaining there is no explicit negotiation; unlike the second type there is no specific policy reward for a plea. In this kind of plea bargaining, the defendant hopes that a plea—a gesture of cooperation or contrition—will yield a beneficial disposition of the case.

Plea bargaining in the USA generally took the ‘implicit’ form until the 1960s, and we can see that in Japan, for example, defendants will often expect a reward for their plea, especially as the national government continues its crackdown on organized crime. (For an interesting discussion of why ‘elite’ USA Federal judges preferred implicit plea bargaining, see Padgett 1990.) Implicit plea bargaining is, based on data we have on other countries, the most common form in the world, but it is also the most difficult to study.

Many nations deny that plea bargaining takes place, and some (the UK, for example) even make plea bargaining illegal. In the early 1970s, several official arms of the government actually tried to stop the publication of a social science study based on defendant interviews, a study which claimed that extensive coercive plea bargaining characterized the British system (Baldwin and McConville 1977). And though a subsequent study qualified the contention about the coerciveness of the process, it still maintained that a variant of what can fairly be called plea bargaining thrived in the UK (Seifer 1980, pp. 179–97).

Japan also takes a more negative attitude toward plea bargaining, declaring it to be ‘illegal’ (Johnson 2001, p. 2). Thus if one were to believe the ‘law on the books,’ one would have to conclude that Japan stands as a clear exception to the argument that plea bargaining is both central to criminal justice systems and quite common as a practice. Yet in one of the few empirical studies of Japanese law in action, Johnson demonstrates that, despite the formal law to the contrary, several modes of plea bargaining are common in the Japanese criminal justice system. An aversion to the ‘crassness’ of the American form of plea bargaining, coupled with the purported illegality of this activity, may lead to denials of plea bargaining’s existence. But these denials are simply wrong—plea bargaining, in various forms, is alive and well in Japanese courts.

We can see this version of plea bargaining at work in some cases in Japan, and in Argentina and Italy (Sanders 1966, pp. 335–9, Carrio and Garro 1999, p. 43, Van Cleave 1999, pp. 272–4). In Japan, abbreviated—very abbreviated—‘trials’ are really uncontested presentations of evidence, which frequently are called ‘slow pleas of guilty.’ Running through these alternatives and others is something like the notion of implicit plea bargaining, the idea that not contesting a claim (inquisitorial systems typically do

not admit a guilty plea) leads to an expectation of leniency in disposition. In France, to offer yet another example, defendants feel that cooperation clearly leads to sentence reductions (Frase 1999, p. 169).

One thing that tends to disguise plea bargaining in other nations (and to allow for official denials) is the existence of functional equivalents. These equivalents represent this form of negotiation in its most ‘implicit’ manner. In Germany, for example, the prosecutor can either waive cases if it seems there is no public interest in prosecuting them, or issue a ‘punitive order’ (more of an administrative than a criminal resolution of the case) when it appears that trial alternatives are not desirable. ‘The prosecutor’s offer of a conditional waiver as well as the punitive orders have been considered a German variant of plea bargaining.’ (Blankenburg 1996, pp. 284–5, see also Weigand 1999, pp. 208–9).

2. Trends in Plea Bargaining in the USA

Because plea bargaining can take place in a variety of ways—all of them by definition subtle and discrete—this manner of bargaining presents scholars with the greatest challenge; to perceive, isolate, and understand negotiations of this kind seems to require the kind of comprehensive comparative studies that have not yet been performed. The implications for defining plea bargaining in these three ways ought to be made clear. Explicit bargaining, for a long while, was viewed as illegitimate, with judges in court often concerned with demonstrating for the record that nothing had been promised in return for a plea (see, e.g., Blumberg 1967, pp. 88–94); so for much of the twentieth century, plea bargaining in the USA assumed either the ‘policy’ or ‘implicit’ form. The recognition of the centrality of explicit plea bargaining by the US Supreme Court, however, rendered this unnecessary, and enabled plea bargaining to take place more openly in the court (*Brady vs. US*, 397 US 742 (1970); *North Carolina vs. Aflord*, 400 US 25 (1970); and especially *Santobello vs. New York*, 404 US 257 (1971); see also *Bordenkircher vs. Hayes*, 434 US 357 (1978)). With the advent of mandatory sentencing guidelines, however, many jurisdictions around the country have been forced to return to the more subtle, implicit manner of bargaining—moving the USA closer to the ‘backroom’ style of bargaining that takes place around the world and exemplifying the ‘convergence’ discussed above.

Policy plea bargaining and implicit plea bargaining, on the other hand, have more subtle implications. Both allow jurisdictions—prosecutors in particular—to claim that they do not plea bargain, or that plea bargaining in a category of cases has been proscribed. The symbolic value of such claims should not be underestimated. The ‘bargaining’ image of plea negotiations makes the explicit process vulnerable to accusa-

Figure 1

Guilty pleas (80–90 percent) compared with other outcomes of cases brought before the US courts 1945–97. Source: US Department of Justice, Bureau of Statistics

tions of ‘bargaining with justice.’ This, one might speculate, is why so few nations have engaged in the explicit form of plea bargaining. Even the USA, as we can posit from studies of the impact of sentencing guidelines, is beginning to move back toward the policy and implicit varieties of bargaining. (To appear to be in conformity with a ‘no plea bargaining’ policy, a court system may also make increased use of bench trials. These are often very abbreviated trials in which the defendant does not contest the case meaningfully, but nonetheless has an expectation of some benefit because he/she has waived a jury trial. See, for example, Heumann and Loftin 1979, pp. 417–21.) Yet if defendants still plead with the expectation of benefit, plea bargaining, less explicit, but plea bargaining nonetheless, can continue to flourish.

Some illustrative data on guilty plea rates are instructive. Figure 1 graphs guilty pleas, bench trials, and jury trials (convictions and acquittals) for US District Courts from 1945 through 1998 (the last year for which these data were available). The pattern is quite clear—roughly 80 percent of the defendants whose cases are not dismissed plead guilty. The very limited role of full trials in US courts is evident. Comparably, if we look at some recently reported data from three typical counties in a Midwestern state, guilty pleas (again for cases not dismissed) range from

a high of 97 percent to a ‘low’ of 87 percent (see Hannaford and Munsterman 1999, p. 66). One cannot help but be struck by the prevalence of guilty pleas in Federal and state courts in the USA. One would be hard pressed to find an American jurisdiction in which the guilty plea—or its functional equivalent (e.g., *pro forma* bench trials, or other forms of ‘slow pleas of guilty’)—does not comprise at least 70 percent of dispositions, with the usual percentage considerably higher. (Regarding these pleas in their many forms, see Mather 1979, pp. 55–6, 69–70, 78–9.)

As the 1945 data suggest, and other data demonstrate, plea bargaining is not a new phenomenon in US courts. Defendants pleading guilty for a putative reward and waiving the ‘Miranda rights’ (rights of the citizen when faced with police interrogation, such as the right to remain silent, right to legal counsel etc.) are the norm, not the exception in these courts, and this pattern has been consistent for some time (see, e.g., Heumann 1977, pp. 29–30, Padgett 1990, pp. 413–50, Zander 1998, pp. 323–4, Vogel 1999, pp. 161–246). Indeed, at least one scholar has argued that plea bargaining increased with the adversarial nature of the courts (Feeley 1997, p. 323).

Contrary to a popular belief, and indicated by its history and its prevalence in our courts at the time of writing, plea bargaining must reflect something other

than a response to caseload pressure. The common belief that plea bargaining is caused by case pressure has been disproved by studies of American courts, and, based on the research we have thus far, we can speculate reasonably that it would be disproved in a comparative context as well. While we are aware that plea bargaining takes place (in some form) in the nations that have been studied, we are still unsure as to *why* this manner of negotiation takes different forms in different nations. That is, why is it that the UK tends to practice and to view plea bargaining in one way, while Japan proceeds in another? The results and motives are often the same—prosecutors induce (or accept) a guilty plea and deliver (or end up providing) some kind of ‘reward.’ So what is it, specifically, that distinguishes nations and their experiences in a comparative context? Would we find the answer in a study of institutions? Culture? History? We both invite and eagerly await scholarship that concentrates on these important questions.

3. *Why Plea Bargaining?*

To develop a rationale for plea bargaining, we must begin with the defendant’s expectations/preferences. Though data may be unclear and variable depending on circumstances, most defendants believe that in most cases ‘it pays to plead guilty’ (Brereton and Casper 1982, pp. 45–70). Defendants often believe that their plea will be rewarded in terms of charge and/or sentence reductions. Why they think the system so rewards them varies with defendants, and seems to reflect the variety of justifications for such a reward advanced by prosecutors, judges, and defense attorneys. Some feel that the system appreciates the appearance of contrition that a plea represents—a theme frequently heard in court is that ‘pleading guilty is the first step to rehabilitation.’ Others feel that they are saving the state the time and expense of a trial, while others who provide information about associated crimes and criminals believe they should earn a reward for their contribution. Indeed, some Japanese scholars urge an increase in plea bargaining in order to obtain more information from defendants about organized crime (Johnson 2001, p. 35).

Finally, defendants feel that by pleading guilty they ensure the state some certainty—a certainty they themselves, in fact, enjoy more. In this sense defendants might be characterized as, almost naturally, in ‘plea bargaining mode,’ they seem to enter the system expecting a bargain. A study of the intentions and expectations of defendants, across nations and cultures, could shed some light on the internal dynamics of criminal justice systems around the world. Is ‘bargaining mode,’ for example, a product of a ‘bargaining’ culture—or one reputed to be interested in ‘dealing’—or do defendants naturally have this inclination without state encouragement? A study that con-

trolled for other nations’ reputations and cultures might yield answers to this question.

While defendant choices and expectations drive the system, complementary calculations by the system’s professional actors actually shape the defendants’ views. Prosecutors, as we know from studies of American courts, are influenced by saving money and time in many of their cases and (all things being equal) value defendant pleas. Also, to the prosecutor, even in the many open-and-shut cases (often known colloquially as cases which are ‘born dead’) that come through the office, there is always some uncertainty about post-trial outcomes; pleas remove any uncertainty, no matter how low the probability of acquittal (Mather 1979, pp. 41–2, 65–72. For the comparable concept of cases that are ‘born dead’ see Heumann 1977, p. 60). Without the data to predict with certainty, it seems reasonable to suggest a kind of ‘prosecutorial culture’ that might transcend national borders and even legal systems. That is, while we should be careful not to generalize too much, it seems reasonable to expect significant similarities in the attitudes (and certainly headaches) of prosecutors around the world.

Defense attorneys make similar assessments about minimizing pointless work and about ensuring certainty. Finally, judges also value the ostensible finality of pleas, and the reduction of the probability of appeal after a plea. Avoiding reversal on appeal, we know from the American experience, is one factor that is said to weigh large in the support that judges give to pleas. But does the same concern apply in other settings and legal traditions? Again, these actors (and others) are an active part of legal systems around the world. What then is the explanation for the different plea bargaining patterns we see in our initial comparative assessment?

While the above discussion outlines adequately what we know of plea bargaining up to the turn of the millennium, the standard explanations for plea bargaining ought not to obscure two very important considerations. The first we might call ‘all is not rosy in the plea bargaining world.’ The explanations we have given read as if defendants walk arm-in-arm with prosecutors, defense attorneys, and judges into the wonderful world of pleas. To some extent, many guilty defendants do take pleas, do so without coercion, and do so aware of the advantages of their choice. But all is not rosy, particularly for defendants who want to opt for trial. There is no question that in the US plea bargaining system there is generally a very strong inclination toward a plea; defendants who insist on trials are often in conflict with this clear reversal of the ‘presumption of innocence’ standard. Though we do not have good evidence for this, defendants may suffer harsher (i.e., harsher than the plea offer) dispositions upon conviction. Though these dispositions can be rationalized (there is no penalty for trial; pleas were rewarded because of the possibility that a trial might

lead to an acquittal; defendant not penitent; etc.), the specter of trials being viewed as unacceptable options in a plea bargaining world is distasteful.

Second, it is important to clarify the case-pressure/plea-bargaining argument. We have said that case pressure does not cause plea bargaining; both contemporary courts and those of the past with no realistically conceivable case pressure plea bargained most of their cases; crowded or uncrowded courts plea bargain for the reasons we have indicated. However, to say that plea bargaining is not caused by case pressure is not to say that case pressure may not affect plea bargaining; for many US courts, volume may be substantial and staffing less than optimal. In many courts, case pressure may affect dispositions, but we do not have a clear sense of how this might operate. Several possibilities come quickly to mind—rewards for pleas, which may exist in a ‘no pressure’ system, might become even greater; the reward for a plea may stay the same, but the ‘penalty’ for trial may be increased; the prosecutor may choose to screen out more cases through dismissals.

Case pressure, while not the cause of plea bargaining, can still affect the nature and form of the negotiation entailed, and we need more comprehensive comparative data on the effects of this pressure in other national settings. Recognizing that plea bargaining is fundamentally not a function of case pressure helps us to understand the centrality of pleas in US courts; acknowledging that case pressure can affect court disposition patterns helps us to understand why so many assume (incorrectly) that plea bargaining was adopted to manage heavy caseloads. We can speculate as to the relationship between plea bargaining and case pressure in other nations, but without data that considers the multiple variables involved, we are limited to our conjecture.

4. External Influences on Plea Bargaining: The USA as a Case Study

The single most dramatic change in American criminal court processes in recent years has been the increased use of mandatory sentences in particular, and adoption of sentencing guidelines in general (see *Punishment: Social and Legal Aspects*). In an effort to reduce judicial discretion in sentencing, the US Congress and individual states have circumscribed this discretion by requiring mandatory minimum sentences in certain cases, and generally requiring sentences within a narrow sentencing grid for defendants with particular background characteristics (e.g., number of prior convictions) who are convicted of particular crimes (see Tonry 1996, pp. 6–12, DuBow 1998, pp. 231–45). However, in limiting the open exercise of judicial discretion in the interests of reducing disparity in outcomes, the effect has actually been to increase (but mask) the discretion of prosecutors, while confining

these activities to the ‘backroom.’ By constraining judicial discretion, prosecutorial discretion has been enhanced; restricting sentencing ranges for judges has promoted less visible, but equally consequential, sentencing practices by prosecutors.

The significance of increased prosecutorial discretion in the USA, as suggested above, seems to be that—among other things—American plea bargaining is beginning to appear more like the negotiations that take place in other nations. This ‘convergence’ as we might call it, has tempered both the desire and capacity for actors in the American system to engage in explicit plea bargaining; ‘deals,’ therefore, increasingly must be of the ‘implicit’ or ‘policy’ variety. While this makes plea bargaining more difficult to study—relegated, as it is, to the literal and metaphorical ‘backrooms’—it presents scholars with an interesting series of questions to consider.

5. Conclusion

As we move beyond the exploration of plea bargaining itself, a number of very important matters—e.g., the relationship of plea bargaining to sentencing reform and to court caseloads, the effects of culture, traditions, and institutions on plea bargaining activities, and the appearance of a convergence of plea bargaining practices, move to the fore. These are matters that should be high on our research agendas as we begin to fashion a new, better informed, and less naive set of plea bargaining questions for the twenty-first century.

Plural Societies

The idea of the ‘plural society’ was first coined by a British colonial administrator, Furnivall, on the basis of practical experience in Southeast Asia, in his classic volume, *Colonial Policy and Practice: A Comparative Study of Burma and Netherlands India* (1939), more as a descriptive device than as theory. It reflected the condition, common in colonial and later, newly independent postcolonial states, of deeply divided societies, usually along ascriptive lines of ethnicity or race (sometimes called ‘communal’), but also of culture, religion, or language. Characteristically, such societies are deeply segmented, with weak institutional integration and little consensus over ‘national’ agenda, unity, or identity. These tendencies are enhanced by the fact that the core values of each of the constituent (ethnic or other) communities are often incompatible, and that they each pursue separate goals and interests, in a fashion which Furnivall described as ‘mixing’ without ‘combining,’ and ‘meeting only in the market place,’ for basic economic needs. In the colonial context such societies were held together largely by coercion rather than consensus. Boeke, a Dutch colonial administrator in Furnivall’s tradition, developed similar ideas about segmented societies in his *Economics and Economic Policy of Dual Societies, Indonesia as Exemplified by* (1953), which he conceptualized in binary (‘dual’) terms, highlighting the colonial/indigenous cleavage, particularly in the domain of modern vs. traditional economic institutions.

One common source of confusion arises around two diametrically opposed meanings of the form ‘pluralism’ which may refer either to the *plural* society, or to its obverse, viz. a cohesive *pluralist* society integrated through a multiplicity of cross-cutting linkages, as conceptualized by such political scientists as (Dahrendorf 1959). This represents a continuation of the tradition of Alexis de Tocqueville, whose model of nineteenth-century America as knit together by webs of associations, helped to neutralize ethnic and other divisions.

Beginning in the 1960s, when most colonial states achieved independence, the term ‘plural society’ migrated into academic discourse, as anthropologists, sociologists, and political scientists attempted to inject

some theoretical rigor into the study of such weak states, held together as much by coercion as by the market. Among the pioneers were Smith and Kuper writing initially on (especially South) Africa and the West Indies. Together, they edited *Pluralism in Africa* (Kuper 1969), while Smith also authored *Stratification in Grenada* (Smith 1965b) and *The Plural Society in the British West Indies* (Smith 1965a). Smith and Kuper distinguished three types, or levels of pluralism. Cultural pluralism, as a form of extreme heterogeneity, sets the necessary, though not sufficient, preconditions for social pluralism, which is marked by the existence of relatively closed communities with separate core values and institutions and engaging in few cross-ethnic contacts. Finally, where constituent groups within a state are 'differentially incorporated,' or have unequal civil and legal status as citizens, there exists a situation of structural pluralism, a feature often found in racially divided societies. These writers, and to some extent Van den Berghe (1970), largely due to the particularities of the societies they studied, were most concerned with the type of pluralism known as ethnic stratification. Most common in 'white-settler' (hence, not strictly postcolonial) societies, social structure is envisaged in the form of a vertical hierarchy of ethnic/racial communities, which are simultaneously ranked as classes (occasionally called 'eth-classes'), the most egregious example of the era being apartheid South Africa.

In other world regions, such as Southeast Asia, another kind of plural society was identified, where the ethnic/cultural/communal sections, rather than being ranked hierarchically, live side-by-side as 'parallel,' 'pillared,' or 'segmental' communities (Benedict 1962, Morris 1967), each largely institutionally self-sufficient. Characteristically, individuals in such societies are primarily identified as members of their collectivity (or 'ethnicity'), which constrains them in most activities and life-chances, from religion, kinship practices, education, and occupation, to political party membership. In maximally plural situations (Despres 1968), there is little opportunity for autonomous individuals to act independently or to forge cross-community ties without reference to the 'basic givens' of their birth status. 'National' unity consists of little more than opportunistic alliances of multi-ethnic elites, while most other societal institutions and relations remain divided along ethnic lines. Societies of this type included Indonesia (Geertz 1963), Malaysia (Ratnam 1965, Nagata 1979), and Mauritius (Benedict 1962), where the presence of colonially-imported immigrant communities of Chinese and Indians exacerbated the cleavages and even conflict. In these places, and in such comparable plural states as Nigeria, Sri Lanka, Guyana, and Fiji, even national political elections are fought along communal lines, where the principal unity and co-operation emerges at the top, through cross-ethnic connections among elites for their mutual advantage. Political scientists describe

such electoral arrangements as 'consociational' (Lijphart 1977), and these are probably implicated in the familiar 'crony-capitalist' style of leadership of many rapidly developing states, such as Indonesia and Malaysia.

Where the impetus for linking social, economic, and political institutions and issues to ethnic identity is state policy, there is little prospect for any form of assimilation ideology or practice, with all its implications for lack of national identity or shared 'imagined community.' In face of internally contested goals and identities, departments or ministries of 'national unity' are sometimes created to impose or direct what daily living cannot, but without some 'depluralization' (Kuper and Smith 1969), both the objective structures and subjective perceptions of separateness persist. Until this happens, in the view of some political scientists of the 1960s and 1970s, societies are not yet politically modern (Inkeles 1969). What is needed to overcome these problems, according to Geertz (1963) is an 'integrative revolution,' whereby transcendent civic loyalties come to supercede particularistic ones, or turned to the benefit of a more cohesive state. In effect this involves the creation of more cross-cutting institutional and individual networks in the public domain, based on superethnic principles and issues, of a neutral political space corresponding to a pluralist or even to a 'civil society'. While it has been claimed (Eriksen 1994) for Mauritius, that such deppluralization is achievable over time, particularly under the impact of an open market economy, and arguably that even South Africa is moving in this direction, it is at best an unpredictable and oscillating process. Evidence (Eriksen 1994) does suggest that some communal cleavages can be retooled to work for, rather than against, national unity as in Mauritius and Trinidad, whereas post-Suharto Indonesia, post-Abacha Nigeria, and contemporary Sri Lanka, on the other hand, remain vulnerable to the centrifugal tendencies of their internal plural divisions. As Tambiah (1989) has suggested, the initial post-colonial euphoria of nation-building may be sufficient in the short term to paper over the plural cracks, but they do seem to re-assert themselves subsequently as a new round of internal ethnic resource and power politics, or 'retribalization' (Cohen 1974) comes into play. The language of 'ethnonationalism' covers many of the same problems, in the sense that ethnonational movements represent politically mobilized ethnic communities, which may eventually be consummated in an independent or secessionist state, in the manner of Croatia, Serbia, Macedonia, and Bosnia of the 1990s. Others are not (yet) consummated, but remain poised for secession from larger (plural) states, as in Quebec or the Tamil northeast of Sri Lanka, exemplifying the perennial problem of such polities.

In one variation of the plural society's political and socially fissiparous tendencies, the binary type is considered by some observers (Milne 1981) to be the

most fragile. In his selections of 'bipolar' plural states, notably Malaysia, Guyana, and Fiji (to which could be added Sri Lanka and Belgium), the argument is made for the presence of a zero-sum or winner/loser mentality in matters of resource and power distribution, such that A's gain is invariably construed as B's loss, and vice versa. In situations of multiple division, where three or more communities are present, there are more possibilities for cross-cutting coalitions, whereby groups make different alliances according to interest, such that one can neutralize another, and this is particularly clear in the case of political party relations. In practice, however, even in situations where three or more nominal parties or plural segments exist, the actual arrangements may operate in *de facto* binary fashion. Thus in Malaysia, where three principal ethnic-based and several other political parties play the electoral field, in most major issues the public rhetoric is framed in terms of Malays (or Muslims) vs. non-Malays (or non-Muslims), the second category consisting of a collective assortment of other ethnic and religious constituencies. In Indonesia, the plethora of indigenous ethnic groups are packaged politically and symbolically as one (*pribumi*) in face of the (relatively tiny) immigrant Chinese community. Similarly, in Canada, the array of diverse immigrant ethnic communities count as a single unit (the 'Rest of Canada/ROC') or Anglophone, in opposition to Francophone Quebec in the business of federal politics. The reduction of multi- to bipolarity significantly affects the oppositional character and abrasiveness of internal relations, at least at the maximal political level.

Plural constructions of society tend to focus exclusively on the divisiveness of ethnic, racial and cultural, or religious identities and their derivative institutions. Conspicuously missing in most of the plural literature is any reference to class stratification and its potential for the creation of cross-cutting cleavages, or, viewed from another perspective, of unity in a different direction. Where class enters the picture at all, as in the writings of Kuper and Smith, the emphasis is on the fact that each ethnic/racial selection is internally stratified by its own unique set of strata, none of which correspond with those of any other, hence their cooperative, class-action potential is neutralized. No South African black miner would find common cause with a white worker in the same sector, nor a Malay with a Chinese rubber tapper. However, the deflection of class to ethnic/racial images is often as much the product of a state worldview or agenda, whose interest it is to frame all local issues in ethnic terms and to rule by playing off one community against another. This is also intended to a void labor unrest or economic instability, and is reinforced by banning unions (or channeling them along ethnic lines), and other class-like activities. One consequence is that members of such societies spontaneously perceive all inequalities as based on ethnic/communal

or sometimes religious statuses. It is this kind of mindset which causes the Chinese in many countries to be unilaterally classified as the 'exploiters,' while conveniently ignoring the existence both of poor Chinese and rich local elites. Furnivall's 'meeting in the market place' does not necessarily seem to create the de Tocquevillian or Dahrendorfian conditions necessary for a pluralist society.

The lack of attention to the potential or existence of class expression in plural societies may be as much ideological as a reflection of the actual situation. In contrast to Marxian convictions that the fundamental determinant of social inequality is material, and that ethnicity is merely an epiphenomenon of class, plural society theorists maintain that ethnic and racial identities are *sui generis*, the cause of most social inequality and conflict.

Since the late 1970s, the term 'plural' seems to have yielded to or been superseded by the label 'multicultural' in many places. A careful examination of so-called multicultural societies today reveals a number of parallels with the older 'plural' term, in its emphasis on ethnic, racial, or cultural identities as the primary source of diversity and division, often at the expense of class. Some commentators maintain that states which promote multicultural policies, which make a virtue of ethnic difference, and even design many social activities and programs along these lines, are a cynical official device ('myths') to obscure more basic class or race inequalities and lack of opportunities for mobility or political empowerment (Peter 1981) for Canada. Proponents of this view suggest that the choice of the term 'culture' as the operating principle conveys a bland, benign, and misleading image of tolerance and equality of opportunity, turning 'difference' away from ethnic conflict and to the benefit of national unity. Given that most societies today are in the process of becoming demographically, socially, religiously, and culturally more multicultural through immigration, even the older, more stable states of Europe, once confident of their national character and identity, are now rethinking these as they come to terms with unaccustomed internal ethnic and cultural diversity. Particularly pressing are the handling of religious and legal pluralness by the host society. The actual policy responses to *de facto* multiculturalism, however, vary by country and over time, as Germany's (1999) reconsideration of the status of its largely Turkish 'guestworkers' (*Gastarbeiter*) illustrates. In the case of the US, the long-established ideology of assimilation is challenged by ideas of multiculturalism as policy (Walzer 1992, Waldron 1992). Increasingly, the emphasis is on the acceptance of difference rather than on the promotion of homogeneity. Also at issue is the question of recognition of (ethnic/cultural/racial) collectives or group rights vs. the more established privileging of the individual and of individual rights as the underpinning of western liberal democracy (Kymlicka 1995). This has implications for

such 'corrective' policies introduced by some contemporary plural states in the direction of quotas or of affirmative action, which could be construed as benign attempts to condone or perpetuate pluralness (Porter 1975), and hark back to what could be interpreted as compromising the standards of liberal democracy and a civic nation. This dilemma, of simultaneously recognizing group identities and integrity while maintaining liberal democratic ideals, is most articulately treated in Taylor (1992) dissections of Canadian multiculturalism.

A general survey of current world trends indicates a declining emphasis on assimilation as a route to nation-building, from Israel to Australia, largely as a response to accelerated and extensive transnational movements and to the existence of deterritorialized communities. This raises new problems of internal social cohesion within states, as they face the question as to whether multiple identities (and even citizenships) among their populations, (who may simultaneously also be participating in the activities of transnational communities offshore), are necessarily mutually exclusive or to the detriment of the state. The original, rather divisive forms of pluralness may, in certain circumstances, form the foundations of a new style of pluralistic politics of diversity or difference, in dialogic as much as conflictive relations, operating between, as well as within states.

Pluralism

The term 'pluralism' was introduced into political science by the Englishman Harold Laski in a number of essays published mostly while teaching at Harvard University between 1916 and 1920. For the term, Laski was indebted to the pragmatist philosophy of William James, whose book, *A Pluralistic Universe* (1909), Laski hailed as of 'vital significance for political theory.' In philosophy, pluralism, as distinguished from 'monism,' denoted a system of thought which recognizes more than one ultimate principle. Although Laski borrowed the word 'pluralism' from American pragmatism, the ideas he advanced under the rubric of pluralism were taken largely from a heterogeneous group of European, and in particular English, legal historians and political theorists whose work Laski encountered while a student at Oxford immediately prior to World War I. Among the most important of these were the German medievalist Otto Von Guericke;

Frederick Maitland, the preeminent legal historian in England; J. Neville Figgis; and Laski's Oxford tutor, Ernest Barker, who in 1914 coined the terms 'polyarchism' and 'the new federalism' to describe this new set of ideas.

The defining project of the English pluralists (as they would come to be known by the time Laski returned to England in 1920) was to vindicate the rights and autonomy of associations by challenging the modern doctrine of unlimited, unitary state sovereignty. Pluralists drew an invidious contrast between the 'federalistic structure of medieval society,' in which a dense network of autonomous associations flourished, and the modern notion of state sovereignty, which, Maitland lamented, reduced 'to impotence and then to nullity all that intervenes between Man and State.' But pluralism was much more than an historical description of the world we have lost; the concept of sovereignty was not just unfortunate, it was untrue to the facts of social life. 'We say,' Figgis explained, 'that the world is *not*, as a fact, composed of a few vast unities known as States, set over against crowds of isolated individuals; but is a society of societies, each and all with rights, liberty and life of their own.' Corporations were not legal fictions created by the state, but rather were natural organizations with their own autonomous existence. The idea of unlimited state sovereignty, Laski argued, was 'a fiction of logic ... out of accord with the facts of life'; the 'history of societies' showed repeatedly that organized groups, even unpopular ones like militant female suffragists, striking miners, or conscientious objectors, imposed limits on the allegedly sovereign state, forcing public officials to adopt policies to which they were opposed.

Although pluralists like Laski and Figgis frequently appealed to 'the real facts of human society,' their challenge to what they termed 'the monistic theory of the state' was more normative than empirical, though typically the 'is' and the 'ought' were woven seamlessly together. In arguing that 'the state is only one among many forms of human association,' for instance, Laski meant not only to highlight the empirical fact of the social and political importance of associations and groups, but also, and more important, to advance a radically anti-statist normative vision. For the young Laski, the state was owed no more loyalty than other groups; each group, including the state, deserved only the loyalty it earned 'by virtue of its achievement.' The 'ought,' in Laski's mind, derived from the 'is': It was the 'facts themselves' that 'dissolve ... the inherent claim of the State to obedience.' Not all pluralists, however, shared Laski's anarchic and syndicalist sympathies. Others, like Figgis and Barker, for instance, allowed that the state had an important role to play in regulating conflict between associations and thus in creating the political conditions necessary for associations to pursue their own ends. But while Figgis and Laski might disagree on what should replace the

monistic state, they both looked to pluralism less to explain the world than to change it. Their main objective was to help the groups they cared most deeply about, which, in the case of Figgis, an Anglican priest, were religious associations, and in the case of Laski, as well as the guild socialist theoretician, G. D. H. Cole, were labor and the trade unions. And herein lies an explanation for English pluralism's precipitous decline in the 1920s. For pluralists failed to persuade others, or even eventually themselves, that pluralism was the most effective means to help the groups they wanted to assist. Laski himself gradually abandoned or watered down his pluralist ideas because, along with the rest of the left, he came to believe, particularly after the Great Crash of 1929, that labor had more to gain from an active, even paternal, state than from a minimal, pluralist state.

Ironically, at the time that English pluralism as a normative vision and intellectual force was in decline, the empirical study of organized groups was picking up steam in American political science, particularly with the publication of Peter Odegard's *Pressure Politics: The Story of the Anti-Saloon League* (1928) and Pendleton Herring's *Group Representation Before Congress* (1929). These sorts of empirical studies of the role of organized groups in the American political process never interested Laski. Indeed, they only confirmed his belief that the trouble with American political science was that 'everywhere the emphasis is on description and not principle,' a diagnosis diametrically opposed to that held by most American political scientists interested in the role of groups during this era. They believed, with Arthur Bentley, that there was too much moralizing about the evils of special interest groups and too little objective empirical description and analysis of group behavior in the political process. Over the next quarter century American political scientists worked diligently to remedy these empirical shortcomings, such that by 1950, a year before the publication of David Truman's landmark book, *The Governmental Process*, (Truman 1971/1951), Merle Fainsod could conclude that 'there are few fields which American political scientists have cultivated as intensively and profitably as the analysis of the dynamic interplay of interest groups as they give shape to public policy at almost all governmental levels.' (cited in Crick 1959)

In 1950 the discipline was relatively rich in empirical studies of interest group influence but the term 'pluralism' was rarely, if ever, used, though political scientists were beginning to speak of the 'group basis of politics' or the 'group theory of politics.' Truman as well as Bertram Gross had helped to revive interest in Bentley who, in his 1908 book, *The Process of Government* (Bentley 1967/1908), had argued that groups, not laws, institutions, or constitutions, were the essential 'raw materials' of government. Truman followed Bentley in trying to understand the government process by treating groups, specifically interest

groups, as 'a primary unit of analysis.' Over the next decade this increasingly influential mode of analysis would become known by advocates and even more frequently by detractors as 'analytical pluralism' or simply 'pluralism.'

Critics were quick to charge pluralists with believing that groups were all that mattered, often pointing to Bentley's audacious remark that 'when the groups are adequately stated, everything is stated.' But most of those tagged as pluralists, including most especially Truman, never held to anything so implausible. Pluralists looked to groups (in Truman's words) as 'a major explanatory variable,' but explicitly rejected the notion that government officials merely passively registered or mirrored the sum total of organized group preferences. The relative importance of groups and government officials in the shaping of policy, Truman emphasized, was an empirical question, not one to be settled by 'preassigning weights and roles.' Analytic pluralists, to be sure, generally avoided using the term 'the state,' but this was not because their explanations were 'society-centered' or because they believed government officials lacked autonomy or importance vis-à-vis societal groups, but rather because they doubted, for epistemological as well as empirical reasons, that the myriad institutions and officials of government, particularly in the United States, were coherent enough to warrant a locution that treated the government as a unitary actor with a single will (Ellis 1992). The same doubts fed pluralists' skepticism of concepts like 'the public interest' or 'the will of the people,' since society no less than the state was a complex mix of rival interests and objectives. In this respect, the modern American pluralists were kindred spirits of the early-twentieth-century English pluralists.

Another strain of criticism of American pluralism objected not to its focus on societal groups but to its portrayal of the distribution of power within the United States as dispersed. Pluralists, it was claimed, slighted the severe inequalities in resources and power in American society, and believed mistakenly that the system was self-correcting: that the mobilization of one group would necessarily lead to the mobilization of an equal and opposite countervailing pressure. Pluralists were also said to believe that all important or legitimate interests and opinions were represented within the political system, or even that all groups had substantially equal access to the policy-making process. As the ideological dust kicked up in the 1960s has slowly settled, scholars (e.g., Smith 1990, Hirst 1987) have begun to recognize that few, if any, of those scholars commonly described as pluralists harbored such naive views of the political process. The important question, in any event, is not whether it is possible to find someone myopic enough to believe that all groups have equal, or nearly equal, power, but whether pluralists are logically committed to these propositions. How widely dispersed power is within

any given policy domain or in any given place or time is an empirical question that cannot be settled by methodological or theoretical fiat. Nor can it be answered satisfactorily without a comparative perspective: the same distribution of power may be reasonably characterized as either concentrated or dispersed depending on one's comparative referent or on one's normative benchmark. There is no inherent reason that an empirical commitment to the study of interest groups *à la* Truman need predispose the analyst to find any given distribution of political power. Nor need a normative commitment to pluralism, understood as wide dispersion of political influence and power, necessarily predispose one to find pluralism as a sociopolitical fact in any given setting.

The term 'pluralist' is a particularly confusing label because it is often applied to those who conclude that power in a given locale is dispersed rather than concentrated. Pluralism can be a useful term to describe either an empirical reality—one in which there is, for example, widespread dispersal of power, and bargaining rather than hierarchical decision-making—or a normative commitment to such dispersed power, but it does not help to call those scholars who find dispersed power 'pluralists.' When Robert Dahl (1961) finds a pattern of dispersed influence in contemporary New Haven politics, that no more makes him a pluralist than his discovery of concentrated oligarchic power in early New Haven makes him an elitist.

Dahl remains the archetypal pluralist in the minds of many, even though he is not a group theorist on the model of Bentley and Truman. Whether or not Dahl counts as a pluralist, he is certainly among the keenest student of the dilemmas of pluralism. As a graduate student at Yale in the 1930s, Dahl took a year-long seminar on recent political thought from Francis Coker, who had written the entry on pluralism for the *Encyclopedia of the Social Sciences* (1934). There Dahl encountered Laski and the English pluralists as well as Coker's ambivalent critique, in which he praised pluralists for drawing attention to the importance of autonomous groups intermediate between the individual and the state, while also criticizing pluralists for slighting the need for centralized political control. State control was necessary, Coker argued, not only to referee intergroup conflict but also to protect the 'unorganized interests of the general body of citizens' against the organized. Moreover, without active state intervention pluralist group autonomy would result in stronger interests, particularly employers abrogating the rights of weaker interests, particularly wage-workers. Dahl amplified his teachers' arguments in *Politics, Economics and Welfare* (1953). It was one thing, Dahl and his co-author Charles Lindblom said, to recognize (as did Laski) that government officials often could not 'enforce decisions by unilateral, hierarchical means' but must often bargain with

powerful and autonomous groups to negotiate 'temporary armistices.' However, it was 'quite another to turn this social fact into a prescription of the desirable, and to argue in effect that politicians should not even attempt to exercise "the last say," but should turn that power over to national organizations bargaining among themselves.' The fundamental dilemma of a pluralist democracy, in Dahl's (1982) view, is that autonomous associations, groups, or organizations are highly desirable and yet also capable of doing great harm if not controlled by a central authority.

Why is pluralism desirable? Advocates of pluralism see autonomous organizations fulfilling a variety of beneficial purposes. Some emphasize pluralism's role in facilitating individual development and self-expression, while others emphasize the importance of groups in integrating the individual into society. Associations are also seen as seedbeds of civic virtue, an enabling environment in which citizens learn the habits of self-government. A different emphasis is evident among those who stress pluralism's defensive political function, as an organizational counterweight to the coercive powers of the central government. Pluralism's vital contributions to democratic governance has long been Dahl's primary focus, a concern that has renewed resonance as scholars, politicians, and citizens attempt to understand and direct the process of democratization in the former communist countries in Eastern Europe and the Soviet Union. In the absence of vibrant organizational pluralism, the experiences of these nations suggest, it is difficult for formal democratic institutions such as elections, parliaments, and presidents to curb hierarchy and domination.

Pluralism may be essential to the functioning of large-scale democracies but that does not mean, as Dahl himself emphasizes, that pluralism is without disadvantages. To begin with, group leaders may dominate or oppress group members, particularly where the costs of exit from a group are high. Less ominously, the group's elites may fail to represent the opinions of its membership—the elites may be more conservative or more radical, more compromising or more confrontational, than the membership. The English pluralists at times obscured these problems by treating organizations, whether churches or trade unions, as if they were undifferentiated organic wholes with 'real' personalities (even while they denied such a real personality to the state), but American analytic pluralism was rarely, if ever, guilty of reifying groups. Far from treating large groups as if they were homogenous, as is sometimes alleged (Kariel 1968), Bentley and other American group theorists were keenly aware, in Odegard's words, that all groups 'are themselves almost infinitely divisible into subgroups whose interests are not always congruent or compatible with one another.'

A second problem with organizational pluralism is that all groups are not created equal: organized

interests, all other things being equal, have an advantage over unorganized interests, and some interests are easier to organize than others. Autonomy for the lambs may well mean a quick dinner for the wolves. It is the weaker groups, as Schattschneider (1960) argued, who generally have the greatest interest in 'enlarging the scope of conflict' by appealing to public authority and thereby modifying the imbalance in private power relations. Recognition that group autonomy may serve the interests of the most powerful groups is a potent argument against the radically antistatist vision of the English pluralists, but not nearly so troubling to the pluralist vision of post-war American political scientists, most of whom were New Deal Democrats. The problems of group autonomy are real, but they need to be counterbalanced with an appreciation for the equally real limits of central control. Absent the articulation of group preferences and mobilization of group interests, a central political authority would define who was a group and what were legitimate interests. Without group pressures, the state would find it difficult if not impossible to gauge the intensity with which preferences are held. Group autonomy without central control may be bad, but it is no worse than central control without group autonomy.

Other critics worry that, even if all groups were equal, pluralism may, in Dahl's words, 'deform civic consciousness' by fostering particularistic or short-run demands at the expense of a broader common good or long-run social needs. Whether civic consciousness is higher or the common good is more closely attended to in those countries or policy domains where interest groups are less prevalent or less assertive is an empirical question, the answer to which is far from self-evident. A related concern is that private associations may be given essentially public functions, thereby removing or reducing democratic control over governmental decisions. One manifestation of this problem is European-style corporatism, in which bargains are worked out between peak associations representing labor, business, and farmers. In the United States, the problem of alienating democratic control may take the form of powerful groups capitalizing on the fragmentation of the system by 'capturing' governmental officials in a specialized policy domain (McConnell 1966, Lowi 1969). Dispersed power is not inconsistent with groups monopolizing power in specialized segments of the political system. Again, the extent to which this describes accurately the policy-making in any given system or policy domain is an empirical question.

Among the most common criticisms of pluralism is that it was little more than a self-satisfied apologia for American or, alternatively, Western, democracy. Whether or not those who were associated with pluralist ideas were satisfied with the state of democracy in America or Western Europe, there is no reason to think pluralism as a normative vision is inherently

conservative. Hirst (1989), for instance, uses pluralist ideas to launch a blistering critique of the British political system, particularly Parliament's claims to unlimited sovereignty. Measuring Western democracies against an exacting yardstick of pluralist principles, Hirst (1997) finds severely wanting not only the West's narrowly plebiscitarian vision of democracy, in which 'the people periodically choose who are to be their elected masters,' but also the over-centralization of the provision and delivery of public services. Taking pluralism seriously, Hirst maintains, means reshaping governance radically, not only in the nation state but at the level of international institutions like the European Community. Dahl himself draws upon pluralist ideas to argue for a dramatic devolution of power to cooperatively owned economic enterprises. And in the context of the non-Western world, even the tamest pluralist ideas can constitute a bracing challenge to entrenched state power and economic privilege. Writing in the 1968 *International Encyclopedia of the Social Sciences*, Henry Kariel wrote an obituary for political pluralism, which, he said, 'as an ideology ... only lingers quietly as a submerged, inarticulate ingredient of Western liberalism' (Kariel 1968). Over three decades later, it would appear that reports of pluralism's decline, let alone death, have been greatly exaggerated. Particularly as a normative vision, as an antidote to plebiscitary democracy or to centralized state control, political pluralism has shown renewed appeal and relevance across the globe.

Pluralism and Toleration

Pluralism is a characteristic of the contemporary life-world that has developed in the course of modernity into the dominant basis for social freedom and political justice. Today, the features as well as the relevance of this basis have not, gone uncontested (Schultz 1974, Kelso 1978). We generally understand pluralism not only as a diversity, but rather as a right to an equal coexistence and confrontation of natural or social elements which lack a governing principle of unity. Tolerance is closely associated with the notion of pluralism insofar as it

refers to those individual virtues which derive from the recognition of this right to an equal coexistence of a multitude of natural and social elements. Pluralism and tolerance consider the same phenomenon from different perspectives. Whereas pluralism emphasizes the diversity of equally entitled, free groups, tolerance stresses the 'live and let live' of others' liberty.

1. The Idea of Pluralism

Pluralism can be understood in a metaphysical sense as designating those philosophies which allow for a diversity of entities in their explanations of the world. The pragmatist philosopher William James maintained the existence of an infinite number of limited facts, connections, and systems which are in constant flux; which always lead to new relationships and structures; and for the cognition of which, fixed categories and criteria do not exist, only perspective orientation points (James 1909). Pluralism can also refer to the methodological neutrality of the social sciences of an empiristic orientation, to the multiplicity of cultural forms, from which 'all sociology has its starting point' (Scheler 1980, p. 25). Today, the term is primarily understood in a social and political sense in which empirical and normative elements converge.

1.1 Empirical and Normative Elements

Empirically speaking, pluralism denotes the diversity not only of confession and religion (religious pluralism), but also of social groups together with their lifestyles (social pluralism), of basic values (pluralism of value), and of the powers which determine politics (political pluralism). For this many-dimensional diversity, our life-world has primarily benefited from the religious wars of the Reformation, the European Enlightenment, and the Bourgeois and Industrial Revolutions. Through those factors, a process of differentiation was set into motion which dissolved both the relatively homogenous and stable relationships of the so-called Old-European societies and the connection between church and state. Moreover, this process brought forth open societies, the numerous and constantly expanding groups of which had their own interests, convictions, and manners of conduct. More recently, pluralism has gained a new momentum through the process of globalization (Höffe 1999), in particular also through migration movements, many refugees, and those looking for asylum. Second, pluralism purports—and here one finds its normative content—that diversity and difference is acknowledged and approved of; all functionally different groups are equally entitled to develop themselves in a free and unconstrained manner.

The notion of pluralism is of particular relevance in modern democracy theory (Fraenkel 1979, Oberreuter 1980). It is considered here as a critical notion, namely

as that central mediative category between the individual and the state, with which the liberal atomization of individuals just as the omnipotence and an all-encompassing capacity of the state are rejected. In a democracy, so runs the empirical thesis of pluralism; many-faceted powers are at work, which, on the basis of a fundamental consensus over institutionalized arbitration with and against one another, struggle for influence and importance. As far as the normative content of pluralism is concerned, various social forces, notwithstanding their differences in content and function, have the same right to engage themselves in the political process by the means of, e.g., voting, of contributions to public deliberation, or by addressing themselves to members of parliament. These forces include trade groups, unions, and employers' associations; scientific organizations, churches, and political parties; and even civil action groups. Politics is not derived from the conception of a common good which is clearly recognizable, prior to all political confrontations and which does justice to all parties concerned. Political decisions are a result of the constant dispute between competing interest groups which have to mutually monitor one another and, in constantly new coalitions, 'scuffle' together into a compromise which might be accepted by a majority.

1.2 The Critique of Pluralism

The criticism of the idea of pluralism is leveled partly at its empirical thesis and partly at its normative content; the normative criticism pertains to either pluralism of value or political pluralism.

Pluralism of value becomes visible in the form of the ideologically neutral state. It is reproached with relativism and even nihilism, because it does not even acknowledge certain very general values as binding and is held responsible, therefore, for the crises of meaning and orientation which threaten contemporary industrialized societies. Pushed to the fore, the ideologically neutral state will abolish itself, because it cannot legitimize the framework in the limits of which various powers are capable of freely expressing themselves.

The most significant criticism of *political pluralism* stems from Carl Schmitt and his followers, who fear the centrifugal, 'anarchistic' tendencies of pluralism. Through the openness and insecurity of pluralistic democracy, the state's power of decision making is left crippled; moreover, the compromises resulting from such a situation correspond to neither moral nor economical ideals of sound politics.

Supporters of the critical theory hold pluralism for desirable, but contest the existence of the empirical presuppositions for its realization. They point to the socially underprivileged, who are either effectively shut out of participating in the bargaining process of weighing competing interests, or are, at least, clearly at a disadvantage when up against more powerful

organizations. The normative idea of an equal right for all groups is, therefore, rather a postulate than social reality. Other critics maintain a 'standardization of subjects,' who are no longer capable of an autonomous definition of their interests and, hence, of a genuine pluralistic differentiation. Where a free concert of interest groups once existed, one now finds bureaucratic apparatuses in their place, the internal dynamics of which dominates the political scene.

1.3 Pluralism and Liberal Democracy

Political pluralism presupposes two conditions as given. On the one hand, all interests and the groups which represent them should have equal rights in public deliberation and in the process of political will-formation; on the other hand, the common good should realize itself through the struggle of interests between groups of equal rights. Both conditions are fulfilled, even in developed democracies, at best in approximation. For in pluralistic society, citizens with their interests and convictions have no direct access to politics; their access stands in need of mediation through clubs, organizations, and political parties. In this manner, interests and convictions do indeed gain political power, however at different levels of intensity. The mediation of interests and convictions very often leads to perceptible distortions of their influence.

Due to varying historical or social conditions, many interests and convictions are represented more powerfully than others. The explanation of this fact might be seen in the tighter organization of certain associations, to the better support by more potent money lenders, or to the fact that such groups have attractive media at their disposal, or better relations to the mass media. An equality of rights in modern times is not realized through the abolishment of legal privileges, characterizing hierarchical feudal or class societies. Pluralism does not simply describe our social and political reality. It is to a significant degree really a postulate, according to which societies need to be changed and modified.

A modification within pluralism, however, is possible only to a limited extent: first of all, because powerful groups do not freely relinquish their predominance; second, as can be observed sociologically (Olson 1965), many interests are much easier to organize than others, which may lead to the superiority of certain economic groups (employers as much as employees). Furthermore, mergings and the oligarchical tendencies within organizations endanger civic freedom, the essence of pluralism. Dependence on the government gives way to dependence on both the bureaucracy of associations and its functionaries. Finally, even a fair arrangement between a plurality of interest groups does not simply lead to the realization of the common good; for, as a rule, long-term interests get the worst of short-term interests, just as general interests get the worst of particular interests. It is for

this reason that the protection of the environment is so easy to push aside.

In taking an overview of these arguments, one must neither adhere to a conspiracy theory, nor to an extreme criticism of capitalism, in order to preserve a residue of skepticism with regard to the affirmation of an empirically existing pluralism. Hence, the plurality of intermediary groups is without a doubt a pillar of freedom; a pluralistic society is invariably better than a nonpluralistic one; and pluralism itself an important structural element of the liberal-constitutional democracy. Nevertheless, pluralism alone cannot warrant its own significance; it is only a helpful not in any way sufficient organizational form of freedom and equality. One should not easily identify pluralism and liberal democracy because the notion of pluralism brings to light only diversity and competition, and not the complementary elements of commonality and cooperation.

A liberal democracy consists not only of the coexistence and confrontation of a diversity, but also of the regulation of coexistence and confrontation. Regulation brings about community: the mutuality of problems to be solved and, in particular, that fundamental (constitutional) consensus which defines the normative content and the rules of pluralism. In this manner, pluralism shows itself to be a one-sided, nondialectical notion that stresses plurality instead of unity, competition instead of cooperation.

1.4 A Relative Pluralism

Because empirical and normative elements converge in the notion of pluralism, the normative valuation has already begun in the empirical thesis. It is continued with a *pragmatic* consideration: the decentralizing of political power, the institutional and social separation of the process of will formation, just as the diversity of convictions and manners of conduct increase the chance of an efficient coexistence, in which superfluous frustrations and conflicts decrease.

The comprehensive *moral* evaluation begins with an ethical-anthropological insight. Because of its lack of instinct and a wanting specialization of organs, mankind is not fixed to definite manners of conduct. Due to its capacity for language and reason, mankind is much more reflective in relation to its doings and omissions; this not only enables it to act freely and responsibly, but also constitutes a particular challenge. Therefore, mankind, be it as individual, a small or a large group, has the task and the right to develop its own convictions and practices, and to determine and pursue a particular conception of a good life. Different convictions and practices are to be expected, on account of the historical factors under which this process of personal as well as social self-determination takes place. The form as well as the results of self-determination are limited by different perspectives, and a single individual cannot lay claim to the

unconditional 'truth' for himself (Rawls 1993, p. 36). In the pluralism of interests, of values, and of life-plans, the wealth of human self-realization is expressed just as well as the limitation of every concrete design.

On the other hand, different groups are already related to each other through the social division of labor; but the division of labor represents only one of the many aspects which make mediation necessary. Within one's own group, the acknowledgment of interests and convictions is commonplace. However, with regard to other groups, they stand in both competition and conflict with other groups. Because the solution of conflicts is not secured by instincts, there exists the danger of collective self-destruction of mankind. In order to check this danger and, at the same time, to avoid a crude sort of social Darwinism which makes the weak even weaker and the vital and cunning even stronger, general obligations are necessary, which guarantee a humane and just management of conflicts. For that reason, not an absolute and merely a relative pluralism that develops in the context of fundamental commonalities is really desirable.

Pluralism of this sort can encounter the suspicion of being relativistic and nihilistic. Even if modern societies are skeptical of a timelessly valid code of values, even if they do not confer infallibility upon a particular personal, political, religious, or intellectual instance, they nonetheless need at least a few generally valid obligations removed from the opposition of particular designs of faith and existence. Therefore, human rights is accrued a particular meaning: as the personal right to liberty, the political right to participation, and as social and cultural rights, they are the condition and expression of the mutual acknowledgment of fundamentally equal persons. Therefore, human rights refer to those claims which every individual may legitimately raise: they belong to a sphere beyond a legitimate pluralism and which every legal order, every state, especially pluralistic democracy owes to each individual. Through human rights even those minorities which come off badly in the pluralistic struggle of competition are protected (Rawls 1971, Höffe 1995).

2. The Idea of Toleration

Tolerance is realized through the recognition of those groups which are differentiated by interests, beliefs, and lifestyles. In this manner, the idea of pluralism is, through its normative content, aligned from the outset with tolerance; and tolerance, like pluralism, has its basis of legitimation in the idea of justice and in the modern principle of liberty.

2.1 Its Origin in Religious Toleration

Like the general principle of liberty, the particular principle of tolerance found its principal acknowledged

ment only after long intellectual and sociopolitical debate. In this context, religious tolerance plays a particular role (Püttner 1977).

Because polytheistic religions make a lesser claim to truth than monotheistic ones, they do not face many difficulties as far as the toleration of diverse religious beliefs is concerned. Pre-Christian Rome allows all conquered peoples to practice and even propagate their own cults. Yet the Christians were excluded from the rule of tolerance, but not for religious reasons; from their refusal to observe the transmitted gods, one fears a backlash within the entire commonwealth.

As long as the Christians are persecuted, they appeal to the Roman Emperors, referring to the rights which all mankind are due: that freedom of religion is granted internally and externally. But after Christianity is promoted to the status of a national religion, it soon forgets this demand and its underlying principles contained in the New Testament: even the principle of reciprocity (*Matt.* 7,12; also *Tob.* 4,16); the sermon on the mountain; the parable of the weed under the wheat (*Matt.* 13,24–30, 36–43); Jesus' conduct in general of welcoming, but not of forcing his imitation; moreover his magnanimous attitude toward sinners; finally, Paul's conception of freedom of religion as free from enforcement and his admonition to mutual tolerance (*Col.* 3,12f.; *Cor.* 1, 4,12; *Cor.* 2, 11,1; *Gal.* 5,1.13).

Whereas the *Edict of Milan* (313) leaves religious belief to its practitioners and, moreover, differentiates between state and religion and does not admit mortal or corporeal punishment for religious offences, the swift rise of schisms and heresies fills the bishops with such alarm, even in the patristic times, that they begin to bind, as in the Old Covenant, religion closely with political affairs. Especially the conversion to a foreign cult is punished to the same extent as capital crimes and the disruption of civil order.

Granted, medieval Christendom should not to be considered intolerant through and through (Patschovsky 1998). Because it regards the transmittance of faith as a matter of free conscience, the conversion of pagans by force represents a clear exception. Jews are generally and, often, truly tolerated; and for a long time the Christians live in mutual tolerance with the Muslims. But, the heretic in Christendom, accused of both arrogance and impertinence, was considered, like the Islamic apostate, as it were, an outlaw in the eyes of the law. In the eleventh and twelfth centuries, capital punishment extends to the heretic and is maintained until well after the Reformation. The foundation of medieval intolerance, the all too intimate fusion of *Sacerdotium* and *Imperium*, of spiritual and secular matters are all well preserved in Protestant countries, more likely being advantageous to the state than to the church.

In the 'confessional age' (the age of the Reformation), the idea of (religious) tolerance has to be re-established; and it is effected only after hefty intellectual debate and painful political experience. In

order to encourage the victory of tolerance in the form of the religious neutrality of the state, the mutual autonomy of the state and the church, a few fundamental insights first have to be (re)attained. At first the pragmatic consideration of the 'greater benefit,' the fact that in most cases mildness is better suited than force in order to gain back 'lost souls.' Then one also has to reach the insight that the New Testament is based on tolerance and love, moreover, that not only the conversion but also the retention of faith is both an act of freedom and of mercy, and for that reason, cannot be enforced; furthermore, that the church is a free communion, whose task is to be fulfilled in the spiritual, not in the secular realm, and that for this task every possible constraint is useless, as it would at best lead to a feigned and not to a real acknowledgment of faith.

The way for this new form of tolerance is prepared by Christian humanists like Dante, Marsilius of Padua, Nicolaus von Kues, and Sebastian Castellio, who reject all acts of violence against religious dissidents. However, they are still fixed to ideas of religious unity within Christendom, and, therefore, they search for a peaceful reconciliation by way of religious forum and dogmatic compromise between rivaling confessions. On the contrary, mystic spiritualists as well as some sects engage themselves directly for the religious liberty of each individual; they do this by appealing to the Holy Ghost, who forbids every form of slavery in the realm of the religious, including that of the institutional church.

Whereas no lasting success is allotted to either of these thoughts (peaceful reconciliation or religious individualism), the second half of the sixteenth century sees the problem shift from the religious to the 'secularized' level. Theological arguments are succeeded by considerations of politics and natural right, occasionally even of economics; unsuccessful reconciliatory talks give way to efforts of toleration, in which the denominational heterodox gains ground.

Starting in France, where the preservation of the nation is considered more important than the re-establishment of religious unity, the idea of civil tolerance, which unambiguously differentiates between the aims of the state and the aims of religion, is established against the rule of 'one confession, one law, one king.' With the idea of the confessional, later the religious neutrality of the state, the bloody experiences of confessional civil wars which, at the European level, ended in a stalemate, are finally digested. Consequentially, the relative autonomy of the state and church/religion and, with that, of confessional pluralism, is acknowledged as a necessary condition for political, even physical survival. Nevertheless, the numerous edicts of tolerance, which follow on the Peace of Augsburg (1555) and the Edict of Nantes (1598), are issued only reluctantly; Brandenburg-Prussia represents an exception for a long period. In auspicious circumstances, as in France (1685), the

edicts are repealed or, as in Great Britain, where the Catholics remain second-class citizens until the nineteenth century, they are not valid for everyone from the outset.

Because intolerance endangers the free development of business and trade, Europe and North America also have economic reasons to thank for the following two phenomena: that religious liberty does indeed assert itself in the end, and that the remnants of the medieval connection between the state and the church are vanquished. The European Enlightenment, however, plays a particular role in the ultimate victory of the principle of religious tolerance. Inspired by the idea of universal human reason and liberty, such figures as Grotius and Spinoza, Milton, Locke and Voltaire, Lessing (*Nathan the Sage*), later also Schiller (*Don Carlos*) turn to the remnants of dogmatic and political intolerance within the high church and to their corresponding, amalgamated states; moreover, they lay claim to religious liberty as a fundamental personal right to liberty. But, even those propagating the Enlightenment as a rule exclude atheists and nonbelievers from the idea of tolerance, granted, as with Locke, not out of religious but rather out of political reasons; for, whoever does not believe in God cannot take a legally admissible oath.

2.2 *Passive and Active Tolerance*

The idea of tolerance kindled itself on the freedom of religion in Western Christianity. In our advanced, secularized world this idea no longer represents a special problem with regard to the social interaction of diverse confessions and religions. Tolerance is often enough primarily called for in relation to beliefs which are socially, politically, and culturally differentiated. Thereby, a weaker, more passive form of tolerance, the mere toleration of otherness, is to be differentiated from a stronger, more active, and creative form, the openness to differences, yes, even to their candid recognition.

As pluralistic democracy cannot arise nor continue to subsist without the mutual toleration of otherness, tolerance is, at least in the weaker form, a fundamental principle of modern states (for developments see Lecler 1955, Lutz 1977, Becker 1996). However, tolerance is not only necessary under the condition and in favor of a political pluralism. If not always immediately and distinctly perceptible, there are nonetheless differences among mankind: in need, talent, and interest; in taste and in sociohistorical origin; moreover, in the perception and interpretation of the personal or social situation in which one lives. Nor is one free of faults, prejudices, or mistakes. Therefore, at least passive tolerance is held to be a universally valid posture with regard to the civilized intercourse of mankind; it is through just such relations that the coexistence in marriage and family, in industry, in

society, in the government, even between states is made bearable as well as efficient. So, even an enlightened self-interest speaks in favor of tolerance.

However, the core dimension of tolerance is, with that aspect, not yet achieved. Its stronger form, the candid recognition of the other and otherness, is grounded in the dignity and the liberty of every human being. Therefore, tolerance consists not only of that forbearance of the peculiarities and weaknesses of one's fellow man which can be solicited from them and freely granted to them. As the coexistence of individually responsible persons with equal rights is not possible without reciprocal recognition, tolerance is a fundamental condition for the justice of mankind's coexistence in freedom; and, as a condition of justice, it is a claim that can be refused to no one.

For active tolerance, not merely the practical (moral-political) principle of liberty but also a theoretical interest in truth be adduced. Human perception being limited, the open debate of different opinions offers a better chance for establishing truth than the 'intolerant,' namely, dogmatic and of a conviction considered infallible (Mill 1989).

3. *Tolerance as Both a Virtue and a Principle of the State*

Religious liberty is only one example that brings to the fore the specific intellectual and political difficulties which have to be overcome in order for the principle of tolerance to become historically significant. This principle, which goes beyond religious liberty, takes primarily two different forms: tolerance as a personal attitude and as a political principle of the state and of civilization, both forms mutually supplementing and yielding one another.

Whoever affirms the self-determination (the right to life, the will to development, and the liberty) of the dissident is realizing the attitude of tolerance. Only when one has one's own convictions, can one speak of recognizing an 'other'; and only there, where one doesn't indulge in indifference, or in the type of cynical nihilism which plainly lets everything pass as valid, including even gross injustice, can one speak of this particular attitude. Tolerance does not mean the fig leaf, behind which moral indifference and intellectual weaknesses conceal themselves. It is a critical autonomy which does not even allow certain conflicts to arise in coexistence, especially not in situations of competition; and which does not go through the inevitable debates and quarrels with the inexorable severity of a religious war. Whoever is tolerant no longer pursues a life which is founded upon self-assertion through violent conversion, or through the surmounting of adversaries. He or she endeavors to establish a communality on the basis of civil equality and communication to which the following qualities belong: the ability to listen, the capacity to take others

seriously, and finally the willingness to let oneself be taught by new situations and new information. Tolerance is then accomplished by the willingness and ability to sympathize with the views and lifestyles of others.

Like pluralism, tolerance too is grounded in the following factors: the understanding that no one is entirely free from faults; the knowledge of the wealth as well as the perspectival limitations of every concrete instance of self-realization; and the insight into the limits of human knowledge. Tolerance, however, originates primarily in the recognition of the other as a free and equal person, who, on the basis of the inviolable dignity of mankind, has the right to form his or her own opinions, and to live according to them alone, or with like-minded individuals—provided that the exercise of this right does not encroach upon the same right of all others. The virtue of tolerance is one of the most important political virtues of a democratic citizen (Rawls 1993, p. 194).

As tolerance does not represent an end in itself, but rather a condition and an expression of the liberty and dignity of mankind, it terminates at the point where liberty and dignity are violated. Tolerance does not consist, as Marcuse (1965) fears, of the stabilization of existing social states, in the preservation of the status quo, and even less of the (masochistic) acceptance of injustice. Wherever the liberty and dignity of mankind needs to be protected, tolerance crosses over into accusation, criticism, and protest. The obligation to impose on no one a limitation of his or her liberty which is not imposed on all others in the same manner can be considered a criterion for the limits of tolerance. The highest principle of justice consists of this criterion of an equal liberty which is primarily spelled out in terms of human rights.

Because the justification of tolerance is found in liberty and justice, it cannot be left to the discretion of individuals and political powers. Its recognition is not only a voluntarily assumed attitude, but also a duty of justice, the implementation of which the legal order, the state, is responsible. It is therefore a political task to institutionally guarantee basic elements of tolerance, such as human rights. The first task of tolerance as a principle of the legal order and the state is therefore found in the positivation of human rights and their recognition as basic rights (personal right to liberty, political right to participation, and social and cultural rights), or, as the case may be, as fundamental aims of the state (liberty, democracy, welfare state).

As long as human rights are only recognized by coercion, tolerance remains nothing more than an acceptance accompanied by contempt toward those who think and live differently. In order to guarantee the stronger form of tolerance—coexistence based on mutual respect—tolerance as a duty of justice has to be acknowledged on its own terms; moreover, it must become through continuous practice a component of one's personal character, a genuine attitude.

Tolerance as a political principle is only accomplished when this duty of justice is freely accepted as a moral virtue of the citizen.

At the international level tolerance demands the mutual respect of different cultures and traditions, instead of valuing European culture or American lifestyle as the ideal of the development of all civilization and to devalue all other forms as primitive and barbarian. This type of respect was articulated first in Herder's (1774/1994) and later in Hegel's (1821/1970) theory of the 'spirits of nations' (*Volksgeister*), according to which different social and cultural patterns in which different peoples think and live assert themselves in the course of history. As these forms are coherent, they justify themselves to this extent.

One facilitates the recognition of other cultures' intrinsic value whenever one looks not only to that which divides but also to that which binds, that is, universal human attitudes such as readiness to aid, civil courage, and honesty. These commonalities are not only acknowledged as morally binding in the Christian West, but also in the most diverse of societies and epochs. The tolerance that began with religious liberty is accomplished only at the point, where the colorful abundance of personal and sociohistorical self-realization is freely acknowledged as both a task and a chance for creative humanity.

O. Hoffe

Polanyi, Karl (1886–1964)

1. Biographical Notes

Karl Paul Polanyi was born in Vienna on 25 October 1886 to Michael Pollacsek and Cecile Wohl. They had married in 1881 and had six children: Laura, Adolf, Karl, Michael, Zsófia, and Paul. Polanyi's father worked for the Swiss Railways and Vienna's Stadtbahn, before setting up on his own as a railway builder in Hungary. In the 1890s the family moved to Budapest where Karl Polanyi began his secondary studies in the model school of the teachers' training institute in 1898. At the turn of the century Polanyi's father's business went bankrupt and after indemnifying the creditors, the family was impoverished and he was forced to take a job abroad again. In spite of that, there was lively intellectual activity in the parental home. Polanyi's mother, Cecile Wohl, organized a literary salon attended, among others, by Oszkár Jászi, György Lukács and Karl Mannheim. After finishing secondary school in June 1904, Polanyi enrolled in the Faculty of Law in Budapest University. He lost his maternal grandfather and father in 1905, both of

whom had especially deeply inspired him. After attending courses in Vienna and Budapest he took part in organizing demonstrations for the progressive thinker Gyula Pikler, a professor of the Philosophy of Law in 1907. Polanyi obtained his Doctoral degree on 26 June 1909 from Bódog Somló at the Kolozsvár (Cluj) University. In 1908 he became president of the recently formed Galilei Circle, a student body set up to disseminate the scientific world view in readings and debates, without—as Polanyi later self-critically recalled—being politically involved. He qualified as a lawyer in 1912 and began to co-edit the review *Szabadgondolat* [*Free Thought*] in 1913. His writings argued for free education and were devoid of the influence of the church. In 1914, Polanyi was involved in establishing the Radical Party, of which he became the secretary.

However, the next year he was sent to the front and discharged two years later as disabled. During the Károlyi government of 1918, he was a member of the legal committee of the People's Council in Budapest and of the Students' Council. However, on the eve of the Hungarian Soviet Republic in 1919 he delivered a speech against the dictatorship of the proletariat, then immigrated to Vienna. He soon underwent a serious operation from which he took a long time to recover. He was working on a voluminous unpublished work, *Behemoth*, concerned with the destructive capacity of science. In this he says that the future is constantly being remade, therefore it can't give validity to our actions in the present.

In addition to Ludwig von Mises, Jakob Marschak, Felix Weil, and others, he contributed to the theoretical debate about the possibility of the planned economy in which he elaborated a proposal to solve the problem of 'Sozialistische Rechnungslegung' on the basis of the principles of guild socialism. He met a well-known figure of the revolutionary students' movement, Ilona Duczynska, in 1920. They married and had a child, Karoline Helene (Kari) in 1923. In Vienna, Polanyi first worked for Hungarian papers (Bécsi Magyar Ujság and Bécsi Kurir), and then from 1924 to 1933 he contributed to *Der Österreichische Volkswirt*. Having lost his job because of the rising danger of National Socialism, he immigrated to England where he first lived in privation, earning money by giving lectures. He was one of the masterminds behind the Christian Left movement, and concentrated on criticism of the essence of fascism.

This time he joined the Workers' Educational Association and the Extra-Mural Delegacies of Oxford and London, lecturing mainly in general economic history and social theory. His lectures focussed on the shift from *laissez-faire* to regulated capitalism, when state and industry began to interpenetrate, and interference of government with the captains of industry became regular.

In 1940 he became a British citizen, but from that year, he was resident lecturer at Bennington College in

the USA and toured America with lectures. He also worked on *The Great Transformation* first published in 1944 (Polanyi [1944] 1957). After returning to the UK during the war this book earned him the post of visiting professor at Columbia University, New York, in 1947. He lectured in economic history and co-ordinated research into the origin of economic institutions. These efforts were summed up in the posthumously published *The Livelihood of Man* (Polanyi 1977). He continued to do research with a team after his retirement in 1953, publishing their findings in *Trade and Market in the Early Empires* (Polanyi et al. 1957). The posthumously published *Dahomey and the Slave Trade* (Polanyi 1966) was another result of the cooperation.

The family settled in Canada as US authorities had denied an entrance visa to Polanyi's wife. In 1963 they visited Hungary, where Polanyi gave a lecture about the American Economic Sociology. He died of a stroke during the night of April 23, 1964 in Toronto, Canada.

2. The Substantive View

The major question of Polanyi's substantive view is how to identify the place of economies in societies (Polanyi 1947, 1977). He argues that economic activity is embedded in the social and cultural setting and that the predominance of price-making markets does not apply to most primitive, archaic, or even contemporary economies. He therefore taught that the changing place of economies could be best described by combinations of comparative concepts that shed light on the alternative logic of economic reproduction. Polanyi's substantive theory was discernible in its essentials in *The Great Transformation* (Polanyi [1944] 1957) and in the lectures he wrote in preparing it. The book, a critique of the market system, is a derivative of historical knowledge and skills accumulated in political journalism. This is borne out by a later remark of his saying he had two aims with the work he wished to: transfer the more combatant Austrian workers' culture into the English labor movement; and give an up-to-date criticism of capitalism, providing intellectual support to Roosevelt's New Deal. In Polanyi's view, the imminent problem of the market system was not the existence of markets but the turning land and labor into commodities by this system. The analysis of the so-called Speenhamland law, temporarily hindering the creation of a competitive labor market as well as of the ensuing welfare acts, revealed that welfare legislation failed to efficiently remedy the mass impoverishment paradoxically entailed by growth and could only delay the emergence of a labor market from masses of wage workers.

The book was written during World War II, parallel with Hayek's *Road to Serfdom* (Hayek [1944] 1976) and after Burnham's *The Managerial Revolution*

(Burnham [1941] 1960). While Hayek argued that deserting the road of self-regulation leads to fatal social deformation, Burnham envisaged the inevitable predominance of managerial-elitist hierarchies with the growing autonomy of control functions. Polanyi focussed on the double movement of *laissez-faire* economy and society. He derived the respective distortions from the market system and from the degeneration of society's defensive mechanisms. What constitutes the continuity between these and his earlier ideas was the criticism of the market system, the rejection of faith in advancement, the doubt about interpreting class interests as material interests, and the stress on non-anonymous historical processes resulting in the market system.

These ideas can be detected in the study 'Our obsolete market mentality' (Polanyi 1947) and in the volume *Trade and Market in the Early Empires* (Polanyi et al. 1957). However, the emphasis in the former is on the more accurate clarification of the concept of embeddedness, and in the latter, on the empirical analysis of primitive and archaic economic formations.

Embeddedness, according to the substantivist view, is related to the fact that an economic actor is a social being, with a mixture of motives, serving to attain social recognition and social goods. His economic efforts are therefore usually subordinated to these goals. Hunger and gain are not universal motives—Polanyi and his colleagues argued—thus the scarcity postulate, the cornerstone of formal economics, is inadequate. As is indicated in the title of Polanyi's key study, economy can be interpreted as an 'instituted process' in a substantive sense. The term process refers to 'location and appropriate movements,' that is production and transport on the one hand and transaction and disposition on the other.

Institution lends unity and stability to these processes, which can be approached via the forms of integration. Reciprocity presupposes the symmetry of groups, while redistribution is dependent upon collecting and distributing goods or disposal over them, hence it implies centrality. Exchange, in turn, depends on the existence of price-making markets. Not every exchange has integrative significance. Polanyi argued that the simple operational exchange and decisional exchange at a set rate do not integrate the economy, whereas bargained rate exchange does. The forms of integration are not arranged in phases, in stages of development as do the types of List or Bücher (Polanyi 1968); apart from the predominant forms, others are also present, constituting varying combinations. Trade, money, and markets are not necessarily functional upon exchange in the substantive approach, unless they are fitted in a market system. The ports of trade gift trade, and administered trade usually fall outside the market system.

Similarly, only one of the money uses coincides with exchange. The rest of the uses analyzed by Polanyi—

payment use, standard, ideal unit, operational device—do not necessarily tally with the market, being the typical features of the redistributive integrative form of the economy. The market, Polanyi sums up, is not so old a phenomenon, as are trade and money, and though it may crop up in history, it only integrates into a market system in exceptional cases.

While the former book contained an implicit debate with Hayek and Burnham, this one was challenged by *Economy and Society*, the book of Parsons and Smelser, the aim of which was to integrate economic and social theory and to find an alternative explanation on the place of economy in society (Parsons and Smelser [1956] 1957).

3. Polanyi's Influence

If it is contended with justification that Polanyi's views were deeply influenced by the writings of Bücher, Weber, Malinowski and others (Polanyi 1977), it must also be contended that Polanyi filtered these influences and thus conveyed them to late twentieth century social science. His ideas were discussed in several volumes, selections, and bibliographies (Stanfield 1986, Polanyi-Levitt 1990, Mendel and Salée 1991). Substantivism appears to be integrated in the history of sociology as a standard chapter (Hindess 1977).

The *Trade and Market in the Early Empires* volume, as well as the posthumous works edited mainly by his disciples (Polanyi 1966, Dalton 1968, Polanyi 1977) and the disputes coming to a head in economic anthropology suggest that a school was evolving around Polanyi. In economic history, Douglass C. North (North 1977) assessed Polanyi's influence in basically appreciative terms, though criticizing his market interpretation. Polanyi also influenced modern researches centering on the interrelation between state and economy as well as studies of socialist economy and its disintegration.

According to an evaluation, in spite of his marginal academic position, Polanyi was one of the most influential thinkers of the twentieth century. As far as the sociological analysis of the economy is concerned, this statement might be proved. Polanyi's concept of embeddedness became the starting point of the new economic sociology.

G. Lengyel

Police and Politics

Sir Frederick Maitland pointed out in the late nineteenth century that the etymological relationship of the words police, policy, politic, polity, politics, and politicians is very close (Maitland 1885). All are derived from the Greek *polis*, roughly translated as city-state. The earlier English meanings of police reflected this common origin, since police could mean a constitution or a polity. In the eighteenth century, the word came to have a more specialized meaning as 'the civil force to which it is entrusted the duty of maintaining public order, enforcing regulations for the prevention and punishment of breaches of the law,

and detecting crime' (OED). This purely civil meaning was broadened (1837) to include 'any body of men, officially employed to keep order, enforce regulations, or maintain a political or ecclesiastical system.' The wider definition covers gendarmeries under military discipline and security services charged with the protection of public authorities.

The origins of the term have contemporary significance since unsuccessful attempts have been made, particularly in England, to divorce police from politics, and represent the police as nonpolitical guardians of society (Reiner 1992). The police and political authority are, however, intertwined—the police are executors of the decisions and the laws of duly constituted political authorities. In order to do so, they designated as having, in Max Weber's celebrated formulation about the state, the monopoly of the legitimate use of force. As Bittner (1979) remarks, the police 'are equipped, entitled and prepared to deal with every exigency in which force might have to be used.' The legitimate use of force by the police has been confined to the territories of sovereign states. The reality of a police monopoly of legitimate force within these territories has been contested because other agencies, such as prison officers, use physical constraints (Brodeur 1983). Other arguments contend that the actual use of force weakens the authority of the police by pre-empting negotiated solutions to conflicts and provoking sometimes serious opposition to the police (Monjardet 1996). Nonetheless, the concept of police necessarily includes the availability of legitimate force.

1. Police Systems

The long neglected comparative history of the relations between the police and politics has been reinvigorated by major studies since the 1980s (Bayley 1985, Liang 1992, Emsley 1999). In the eighteenth and early nineteenth centuries, professional police, paid by public funds, appeared. In the more developed parts of continental Europe, the purposes of the police were to secure the institutions of the state, enforce the law and the decisions of the ruler, and to protect propertied classes and property, both public and private, against criminals, calamities, and disturbances. In the English experience, except in London where the Metropolitan Police was established in 1829 by Act of Parliament, the modern police emerged from the office of constable, a medieval institution with equivalents elsewhere in Europe, who was charged with public tranquility at the local or parish level (Emsley 1996). In the United States, policing developed first at the local and state levels but, in the twentieth century, there was a proliferation of law enforcement agencies at the Federal level (Federal Bureau of Investigation, Drugs Enforcement Administration, Secret Service, etc.). However, the Federal agencies, in terms of numbers of police officers, constitute only a small proportion of the whole.

A distinction is made, sometimes too sharply, between an Anglo-American and a European 'continental' tradition of police-government relations (Mawby 1990). In general terms, hierarchically organized police forces controlled directly by a central government minister were characteristic of the most powerful continental European states. Mutual suspicion has often characterized police and politicians' attitudes on either side of the Anglo-American/continental European divide. The centralized systems have been regarded in Britain and the United States as instruments, often improperly used, in the hands of unscrupulous politicians. Misuse of police forces by the Nazis and other oppressive regimes gives this view credibility. In addition, national police forces are regarded as unwieldy and inefficient organizations. In the opposing European tradition, there has often been frank disbelief that police activities in decentralized systems can be professionally efficient, properly coordinated, and democratically controlled. They are also regarded as vulnerable to the influence of private interests, and as having uneven quality. Although much attenuated, this mutual suspicion has not entirely disappeared.

Differences between police systems have diminished because of a mutual learning process and because of internationalizing influences. Tendencies are apparent towards centralization in the British and some federal systems and to decentralization among the centralized continental systems. In the 1990s the British set up the National Criminal Intelligence Service (NCIS) to counter the increasing national and international mobility and activity of criminals. Local security plans, local coordination of policing, and more municipal police forces have modified the system of uniform central control. There have been increasing international police contacts and cooperation, and increased commonality of police methods and techniques, which, in turn, have an impact on police organization. The 'projection outwards' of police systems to the rest of the world, first through the European colonial empires and then US world influence after World War II, has resulted in hybrid systems and, as in Japan, some ingenious adaptations to local circumstances. Police systems are now distributed along a spectrum of types of organization, rather than based on contrasting models (Marenin 1996, Bayley 1996).

A greater degree of consensus than in the past exists among politicians in the advanced industrial democracies about the proper role of the police. Many of the less economically advanced countries have received assistance particularly from the United States, Britain, and France in police training and methods; they have, as a consequence, attempted to integrate, with varying degrees of success, philosophies about police-political relations. The consensus among the elites of the rich world (now including most electorally important parties of the Left) is that police forces exist to protect

the constitutionally public authorities, to uphold the law, and to protect liberties, rights, and property. Direct political interference in police operations is less and less acceptable. Left wing radicals, often influenced by Michel Foucault (Foucault 1995), dissent from this consensus and regard these beliefs as useful myths to uphold an obnoxious status quo.

2. Police Accountability

The elite consensus leaves intact the longstanding problems of how the police ought to be controlled and made accountable. These problems raise the most politically sensitive question concerning the police—'who guards the guardians?'—a question first asked in imperial Rome by Juvenal (*Satires* 6 1), to which there is no universally accepted answer. In recent years, public concern has been voiced about police malpractice, corruption, violence, and intrusion into privacy. The contemporary policy dilemma is how to preserve a degree of professional autonomy for the police, essential for operational efficiency, while making police forces accountable to elected authorities, accountable before the law, and professionally accountable for their competence (Walker 1998, Wilson 2000).

In liberal democratic systems, the principle of accountability to the law and judicial authorities is uncontroversial but the methods of implementing the principle vary between countries and within countries. The police, in general, are subject to the ordinary law but this has been found to provide inadequate redress for complaints about police malpractice. The result is special arrangements for investigating such complaints (Goldsmith 1991). These arrangements are always the focus of political controversy and allegations are often made that the police have operated above or outside the law (Skolnick and Fyfe 1993). The police usually have considerable operational discretion but there are wide variations in the extent to which they are directly controlled by the political authorities.

Systems of political accountability vary along two dimensions—the extent of decentralization and the closeness of control of the police by elected officials. In the continental European systems, direct hierarchical accountability to a minister who is, in turn, answerable to parliament seems to guarantee the clearest lines of democratic accountability. However, these systems tend to generate three kinds of police-political scandals. These are: allegations of improper instructions given to the police to further political or personal interests of a minister; the political covering up of improper actions by police officers, to avoid embarrassment to the government; and improper police actions encouraged by the government, such as a tough law and order policy.

In decentralized and federal systems, political accountability for different police forces is dispersed. In federations, federal, state, and local authorities control different police forces. Improper behavior by police officers or relations between politicians and the police does not, in these systems, tarnish the whole of the police institution. Police malpractice such as institutionalized racism, corruption, and excessive use of force can, however, become endemic locally. In a constabulary system like that in England where the Chief Constables have a high degree of professional independence, democratic accountability may be indirect (and ineffective) through nominated police committees. The greatest difficulties of accountability arise in societies with deep ethnic, social, or religious divisions such as Northern Ireland, Israel, and South Africa, as well as countries with large immigrant minorities with characteristics clearly distinguishable from the host society (Brogden and Shearing 1993, Brewer et al. 1988). In these circumstances, the police inevitably are regarded by the powerless as oppressive instruments of the dominant group.

3. *New Issues*

Certain policing issues, broadly connected with political accountability, emerged on the political agenda in the last third of the twentieth century, in the highly industrialized democracies. The women's movement has had considerable influence over the investigation and prosecution of certain forms of crime—rape, violence against women, and pedophilia. The movement has also accelerated the number of women police officers in all highly industrialized democracies. The great political importance accorded to drug abuse, expressed by Presidents Nixon and Reagan's 'war on drugs' and their European emulators, has resulted in considerable diversion of resources into the pursuit of drug traffickers and drug abusers, the development of new and controversial investigatory techniques (controlled delivery, money tracking, intrusive electronic surveillance), and international law agreements.

The introduction of 'value for money' financial accounting throughout government has raised new questions about police effectiveness. It has proven politically embarrassing for police agencies, as increased expenditures are rarely reflected in improved clear up rates for crime. The determination to control public expenditure has also created pressures to develop nonstate forms of policing, which had precedents in the period before the establishment of professional police forces. Modern forms were a prominent feature of United States policing since the nineteenth century; such was the fame of the private security firm, Pinkertons, that some Europeans thought it was an official American police department. But private security firms have now become a controversial feature of policing internationally. The

political left has been particularly critical of this development because it seems to provide an increased level of protection for the rich, but right wing supporters of national police forces are also very reserved about it (Johnston 1992).

4. *Transnationalization of Policing*

Developments in the international system must now be taken into account in the politics of policing because the police function is no longer completely constrained by the doctrine of territorial sovereignty. The establishment of international jurisdictions is changing, and has the potential to change radically the basis of police accountability. Protection of human rights has become a major priority of 'the international community.' International judicial protection for these rights is emerging and this erodes state sovereignty. France, for example, was condemned in 1999 by the European Court of Human Rights for torture following the brutal treatment in a police station of a Dutch citizen of African origin.

'Globalization' has led to increased concern about international crime in areas such as terrorism, drug trafficking, money laundering, international fraud, traffic in human beings, and disposal of high value stolen goods. International legal instruments have been negotiated, such as the 1989 Vienna Convention on drug trafficking which has direct effects on domestic law enforcement and criminal investigation techniques, such as 'controlled delivery.' Also, a certain transnationalization of police has occurred. This commenced as early as 1923 with the setting up of the International Criminal Police Commission, the predecessor of Interpol (Anderson 1989). US Federal law enforcement agencies have posted police officials abroad since the World War II—by the 1980s, the US Department of Drug Administration had over 60 offices in 40 countries (Nadelmann 1993). In Europe, Europol and the Schengen System (the compensatory measures of police and judicial cooperation for the abolition of border controls within the European Union) have gone much further in involving international regional institutions in police cooperation (Anderson et al. 1996). Transnationalization, together with the impact of the information technology revolution, undermines the traditional hierarchies of control (including political control) of the police. Policing is becoming a more knowledge-based, networking activity. In due course, this will transform all aspects of the relationship between police and politics.

M. Anderson

Police, Sociology of

Sociology of police as a specialized area of study can be defined as the empirical and theoretical analysis of those organizational agencies—usually but not exclusively established by state governments—that are charged with investigation and prevention of crime

and/or offences against formally adopted routines and rules as well as with maintaining public order, safety, and peace. It embraces the systematic sociological enquiry about the role of police in modern societies, the general characteristics of policing bodies and their relation to other institutions, the institutional development and internal structure of police forces, the collective and individual behavior of their members, and the interactions or relations of those agencies with individuals, different social groups, institutions, and the general public.

1. Police as a Matter of Sociological Concern

Both police and sociology are offsprings of modernity and progressively diversified societies. Although the modern contours of both became obvious only in the nineteenth century—the former as a new formal institutionalization of governance, the latter as an accomplishment of enlightenment and a new academic discipline—there is a line of discourse which can be traced back to ancient times, when Roman emperors struggled to get or keep their rule by using armed forces and when philosophers reasoned about the art of best governance. In spite of the fact, that the modern notions of ‘police’ and ‘sociology’ were not yet discovered then, the reasoning about the necessity of establishing and maintaining a public force to control crime and to ensure public order—and the critical discussion of its actual appearance—is as old as the discourse on the *res publica*.

Later on, the issue of police was embedded into the broader philosophical topic of the state and government—as it was for the early classic sociologists: police were discussed mainly as an instrument for the sovereign’s power to govern. Max Weber’s often quoted notion, that the state is that human community, that successfully claims a monopoly of legitimate use of force within a certain territory, still prevails within academic reflections on the police (Bittner 1991).

With the growing urbanization of the countries in industrial transition, there was also an increasing body of literature on police matters from a pragmatic perspective in the first half of the twentieth century. Yet it took some time for the police to become an explicit and original matter in sociological thought and empirical inquiry, primarily in English-speaking countries.

2. Determining the Subject

At first glance and seen from the surface it seems rather trivial to determine who and what constitutes ‘the police.’ One would expect that the police as a public institution is represented by (sworn) officers, i.e., representatives of the state and its government,

who are (often) specially trained professionals and are invested with certain powers (like the authority to search or arrest a person). Usually this 'apparent' kind of police will appear in public as officers on the beat, a crew in a patrol car, behind a desk in a police station, or as plain-clothes detectives, doing investigations in the field. This is the common and popular image (in the Western world) of what police actually are, transmitted by the media and supported by occasional ordinary encounters. From time to time this picture is widened by the appearance of riot police in full gear, underlining the state's authorization and capability of using legitimately physical force against disobedient citizens or rioting crowds.

When one looks again at who and what constitutes police, the semblance becomes more complicated: on the level of involved actors it becomes apparent that a good portion of the workforce employed by police consists of civilian staff, like secretaries or the clerks in the forensic laboratories; some sworn officers, such as staff who are responsible for conducting statistical analysis of criminal incidents or running a computer program for matching data, are rarely out in the field, while certain field officers, like undercover agents or specialists in charge of surveillance of telecommunication, often do not act openly as police. Furthermore there are other state agents who, having similar powers of investigation or intervention, perform certain functions of policing, but are not seen or labeled as 'police.' One might think here of custom officers, secret agents, public health inspectors, or prison guards. Still others appear in a policelike guise but are clearly not officers (at least lacking their full powers): city wardens, commercial guards and patrols, hired investigators, vigilante organizations like the 'Guardian Angels,' bodyguards, stewards in a football stadium, or bouncers.

As professionals trained to use force legitimately in the name of the state's power, police share this somewhat exclusive right with the military and other law enforcement officials (prison, customs). But on the level of routine work processes, this distinguishing feature is a rather rare event compared to the overall picture of police duties. Instead, research has shown that a considerable part of the modern police workload is not at all focused on crime control and investigation of criminal cases, but consists of responding to general emergency calls, mediating conflicts, regulating motor vehicle traffic, and communication with other institutions or agencies like social services, insurance companies, etc.

Although it might be clear from a commonsense point of view, what 'police' actually are—basically that formal institution which is vested with the powers and resources to respond to criminal acts or public order disturbances and calls itself 'police'—the subject in question gets more diverse, the more we see it from a perspective of a peculiar organized social activity rather than as a matter of institutionalism. Thus a true

'sociology of policing' would cover a wider area and embrace more organizations than the initial 'police studies.'

But even from an institutional approach one has to speak of 'the police' either from a very abstract level or from a single case point of view only. Besides the common similarities in terms of historical developments, organizational models, practical strategies and tactics, and legal accountabilities, every country's police system has its own particularities and unique arrangement of forces.

It should not be overlooked that police as a subject of sociological interest is linked in many ways with other social systems, all of them carrying their own, often overlapping, bodies of literature: as an instrument of executive governance 'the police' can be seen as a segment of the *sociology of the state*. Its quality of being an important part of the criminal justice system and its more or less explicit legal bindings does make it a component of the *sociology of law*. Last but not least, on the level of empirical studies there are clear ties to the field of *organizational sociology*.

3. Changes in Focus and Emphasis

Although some academic work on the police can be traced back to the 1950s, the first surge of sociological studies of police work occurred as an aftermath of the increasing social and political changes which affected most countries of the Western world from the early 1960s on. In a time when social and political conflicts were brought onto the streets, and rising concerns about crime and disorder became a public issue, 'the police became increasingly visible, controversial and politicized in response to these tensions and pressures' (Reiner 2000, p. 210).

According to Cain (1979), five types of studies, following a rough chronological sequence in the shift of areas of interest, can be identified for this period: (a) a law-related concern with civil rights, when confronted with police powers and discretion; (b) examinations of the police organization by participant observations (Skolnick 1966 and Manning 1977 are well-known examples); (c) studies of the role the police take in the social construction of deviants and the fabricating of public images of deviance; (d) analysis of the interactions and relationships of the police with the social environments they are working in; and (e) studies questioning the political contexts, presumptions, and consequences of police activities. It can be said that all these topics overlap in a way and have persisted during the following decades. There are two important points to note: one is that the main characteristics of this work, coming out of universities, were motivated by a concern with issues of police deviancy and generally tended to be critical of the police as a powerful institution of the state. The other

is that this research was created overwhelmingly in the USA and the UK.

In a second wave from the early 1980s on, police research was done more often outside the academic sphere. Governmental bodies like the Home Office in the UK began actively to do their own research on police issues. Furthermore think tanks and independent research organizations began to enter the field to offer their own agendas and expertise. This development enlarged and in a way altered the agenda of police research and with it the accessible knowledge on the sociology of police. Thus the momentum of studies changed—beyond the Anglo-Saxon universe—from an outside critique of police behavior and police institutions to questions of good practice and evaluation of reform measures, generated under policy and managerialist perspectives (Reiner 2000).

4. Current Theory and Research

It is still the case that the bulk of police studies which are relevant for the sociology of police in one way or the other is produced in English-speaking countries, with the USA in a clear lead. This might be seen as the reason why, on an international level, the discourse on police and policing issues mainly reflects on these countries. For example debates on 'community policing' or 'zero-tolerance strategies' originate from the development of police policies in the USA. But as matters of cross-border and international police co-operation have become more important since the early 1990s, there is a growing interest in comparative perspectives (Brodeur 1995, Findlay and Zvekic 1993).

The contemporary sociology of police and policing has to take two aspects into account. First of all, there are quite a lot of significant differences in how police institutions are organized and how policing is actually achieved between different countries. This is mainly due to the diverse national historical background. The diversity lies particularly in the arrangements of the police system influenced by legal, political, and occupational cultures (Busch et al. 1985, Monjardet 1996). The other aspect is that when it comes to the level of policing, i.e., how police work is actually achieved and what kind of resources and strategies are used, some striking similarities and convergences can be noted. There seems to be an increasing transfer of issues in the international police discourse.

The sociology of police is fed in a significant way by historical research on police institutions and forces, be it on the local or the national level. These studies show that there are certain issues in reflecting on police and policing, which have persisted for a long time, most prominent among them effectiveness, deviance, and accountability.

Contemporary research on police and policing embraces also immanent occupational and organizational aspects like recruitment and education, gender

and minority issues, the role of unions and professionalism and specialization. The question at stake here is what police are actually doing.

A good portion of police research literature is still concerned with issues of internal as well as external control mechanisms of individual and institutional police behavior. In this respect the institutional autonomy of the police in the face of the government and the judiciary is one side of the question, the control of the behavior of individual officers another (Marx 1988).

Increasingly matters of police management and evaluation are discussed, especially connected with institutional police reforms in the UK. Modernization seems to have been an enduring issue in police reform since the 1970s.

In theoretically oriented academic research the emphasis is clearly shifting from an institutional understanding of police towards policing as a socially structured, dynamic, and multilayered process. The background for this hidden paradigm shift is on the one hand the growing role nonstate policing bodies (security enterprises, insurance companies, vigilant citizens etc.) are gaining in many countries (Shearing and Stenning 1987) and on the other the increasing relevance of technology and information for the police (Ericson and Haggerty 1997).

5. Methodological Issues

The police is a specific institutional field and bears special problems for sociological research. Studies on police and policing in a sociological sense started to be done by university researchers. As long as police behavior could be observed from the outside, especially in respect to its effects on citizens, it was a matter of external description and analysis. In a way these studies could be seen as a type of 'legal journalism,' mostly case-oriented. A new field of empirical data was opened, when researchers were able to do participant observation of police work. With that, the internal perspective of the field actors were reflected in the research on police. Of course, there have always been some difficulties for police organizations granting outsiders access to internal functional mechanisms, because it carries the risk of 'occupational secrets' becoming subjects of public discussion.

Generally, from a methodological point of view three points deserve attention. First, police studies relevant for sociological interests can be roughly divided between pure empirical, pure theoretical, and those studies which combine or at least claim to combine both aspects.

Another issue is, who initiates and/or carries out the research in question. It might make a difference for methodological approaches, as well as for the broadness of the theoretical perspective, if studies are done by researchers coming from police or other govern-

ment institutions or whether they are carried out by university institutes. Furthermore there is a clear difference between research *for* and research *about* the police. Usually the former tends to be preoccupied with practical issues or management problems. Although there quite often exist interesting sociological aspects within these perspectives, a genuine sociology of police and policing is coupled with research *about* the police, i.e., its meaning in relation to the law, the state, or society in general.

Finally, the term 'police' might be a category too broad when it comes to empirical analysis and theoretical conclusions. Not only do national police systems embrace a variety of more or less specialized forces, with specific, sometimes unique ways of division of labor among units, but police organizations also refer to very different geographical ranges of jurisdiction. This situation becomes more complicated when nationally focused studies are compared on an international level: for a full comprehension of the differences and convergences national particulars have to be taken into account.

6. Future Directions of Theory and Research

There seem to be three major paths of future research which will contribute to knowledge about the sociology of police. One line of advancement will come from the shift that police institutions will be interpreted more and more in terms of the market. One issue will be what can be called the 'economy of police and policing.' In this regard commercialization of police functions will become more important, not only in terms of private police or privatization of policing but also in terms of adopting service orientation as a primary goal and private business structures within the framework of public police. Another research topic will be connected with the growing internationalization of police work. The emerging concept of liaison officers, the creation of multinational task forces—Schengen and Europol as well as Interpol arrangements on policing, etc.—are headed toward changes in particular in the relationship between policing and space. Finally, recently emerging approaches in maintaining order in transnational zones of disorder (i.e., the former Yugoslavia), established drug control policies, and antiterrorism policies, demonstrate the apparent convergence of internal and external security and safety concepts, and convergence between military and secret services on the one hand and police on the other.

Policing

Public police are a bureaucracy created by political and legislative processes to enforce the statutory or common law of crimes, and to maintain public order and safety. Police in democratic states are accountable to the law and to democratically elected legislatures and executives. A 'social science' understanding of police draws upon theory and research in sociology, urban anthropology, law, criminology, history, and political science.

Social science research on policing scarcely existed before the 1960s. Moreover, observational and survey research on policing has largely been restricted to democratic regimes. Even in those, social science research may be constrained by police officials who limit access to investigators. Since the 1960s—a decade of rising crime rates, riot, and social protest—socio-legal research on police has flourished. An it has spread to democratic states around the world, including Canada, Eastern and Western Europe, Israel, Japan, Australia, India, Brazil, and South Africa. While earlier social science primarily sought to analyze police organization, role, and culture, later social science attempted to apply these insights to policing strategies and accountability.

1. Police Organization

Police structures vary. Some nations, like France, Italy, and Israel employ centralized police systems. The police in Japan, Australia, Great Britain, and Brazil are moderately decentralized. Police in the United States are decentralized, and include federal, state, county, urban, suburban, and rural forces. Nevertheless, like other bureaucracies, the police are everywhere shaped by social and economic conditions, by the interests and values of those who exercise or have access to state power, and a concern—or lack of it—for civil liberties and rights. Thus, police can differ significantly depending upon language, politics, tradition, and ideology.

1.1 Police Organization in Totalitarian States

In the first half of the twentieth century, aside from the militarized and centralized German police of the Nazi era, Soviet policing supplied a formidable model for policing a security state. From the beginning of the Bolshevik regime, the Cheka, the Soviet secret police, were given extraordinary powers to arrest, imprison, even to execute, in the interest of defending ‘the dictatorship of the proletariat.’ The detection and prevention of crime to provide public safety was secondary to the task of preserving the dominance of the political system. In contemporary China, although the police are striving for some independence, they have been regarded as a coercive instrument to serve the Communist party’s needs. Nations in transition from dictatorship to democracy have struggled to transform the police from their formerly authoritarian responsibilities to what would be acceptable in a democratic nation, where police are accountable to the political authority of elected officials.

2. Democratic Policing

Historians generally credit Sir Robert Peel’s London Metropolitan police to be the original, remarkable, and sustaining model for democratic policing. Yet the passage of *The London Metropolitan Police Act* of 1829 followed three-quarters of a century of deep suspicion and failed attempts to create a police force. Peel’s achievement was to coordinate London’s need for public order with democratic concerns and values. In 1826, before submitting the police bill, he abolished the death penalty for over 100 offenses, and removed numerous criminal penalties entirely. To win the support of the Whigs for his police bill, he temporarily excluded the City of London from the authority of the new police. To quell the fears of an emerging working class, he designed blue uniforms for the police to distinguish them from the army’s red coats; and, what

in retrospect must be seen as a brilliant and radical move, the men in blue did not carry guns while patrolling.

Furthermore, Peel and Colonel Charles Rowan, whom Peel appointed commissioner of the new police, strongly urged moderation in the actions of the police to gain public support. Although the purpose of the police was to protect private property and to maintain public order, it was understood that police power would be restrained by the rule of law, minimum use of force, and public opinion. As time advanced, and as class conflict diminished, English police were perceived to be efficient, incorruptible, accountable, and non-partisan.

All this was to change after 1960. Urban riots, rising crime, and police scandals combined to undermine the warm confidence the public had shown the British police for more than a century. ‘From almost complete invisibility as a political issue, policing has become a babble of scandalous revelation, controversy and competing agendas for reform’ (Reiner 1992, pp. 73–4).

British historians have offered revisionist, theoretically Marxist, interpretations of the origins of the English police, emphasizing their role in diminishing class conflict in the development of Great Britain’s industrial capitalism. Like their American counterparts, British sociologists have observed the power of subculture and political belief to mediate the influence of law on police behavior. Others, especially McBarnet, have implicated the legal structure—judges, senior officers, vague laws, case law, including those purporting to protect civil liberty—as the basic source of police deviance (McBarnet 1983).

2.1 The Police in the United States

No police department in America was so carefully planned and organized as the London Metropolitan Police. ‘The employment of police in municipal administration was governed not by theory but by convenience’ (Lane 1967, p. 221). Public order and rioting posed a more serious problem than crime in early nineteenth-century Boston, when the city established its first full-time police department in 1837. The precipitating event for the creation of the Boston police department was akin to a race riot, as roving bands of Protestants destroyed nearly every Irish Catholic home on Broad Street. Similarly, the creation of New York City’s police force reflected a growing intolerance for riots and disorder rather than a response to an increase in crime (Monkkonen 1981, p. 553). Nevertheless like their eighteenth-century London contemporaries, New Yorkers thought themselves engulfed in a rising tide of crime and disorder. Negro slaves made up one-fifth of New York City’s population and were ‘an unstable and unruly element often

treated with great brutality' (Richardson 1970, pp. 4–5).

Interracial and interethnic hostility have always posed a problem for policing in democratic nations as well as totalitarian ones. In the United States, the combination of immigration, expansion, and slavery stand behind contradictory images of America as a land of promise and of oppression. The themes of brutality against blacks, of discrimination against immigrants, of immigrant hostility toward blacks—all set against a turbulent background of social and class conflict—arise time and again in American history.

Over time, American cities witnessed a progressive exchange of functions between the citizenry and the police. Initially, the citizenry were responsible for guarding themselves against criminals through a watch system. As other agencies assumed responsibility for other areas of municipal administration, the police began to be increasingly concerned with crime. Not until the turn of the twentieth century did the American police fully resemble the blue coated forces of the present.

Twentieth-century changes in the American police reflected population growth and diversity in cities, changing social and political organization of communities and neighborhoods, and in technology available to police. During the first reform wave, from the late nineteenth century to the Prohibition-inspired 'roaring twenties,' progressive elites (such as Theodore Roosevelt and his political associates) attempted to wrest control of the police from corrupt and powerful political machines (such as Tammany Hall in New York City). They also instituted civil service examinations and other measures intended to insulate officers and commanders from political influence.

The second wave, in the 1920s and 1930s, reacted to police scandals associated with national Prohibition. The 1931 Wickersham Commission report (1931) documented shocking corruption and brutality in the criminal justice system and motivated police professionals, such as August Vollmer, to introduce reforms. The efficient, seemingly incorruptible, semi-military Los Angeles Police Department, of the 1950s and 1960s, headed by William H. Parker was hailed as a model of such 'legalistic' professionalism, although the police behavior in the Los Angeles (Watts) riots of 1965 was to suggest otherwise. That riot was not as hurtful as the 1992 riot following the Simi Valley acquittal, in a California court, of the police who beat Rodney King. But at the time it took the largest toll of any riot in American history and was followed by significant riots across the nation, most prominently in Cincinnati, Cleveland, Newark, and Detroit.

The Civil Disorder (Kerner) Commission (1968) found that, in the first nine months of 1967 alone, there were 164 disorders of varying intensity, of which 41, in 39 cities, were considered 'major.' The report singled out the police as the activating cause of the urban riots that had shocked and mystified the

American public. The 1960s was also a period of anti-Vietnam war protest, generating hostility between police and protesters.

A third reform wave followed, continuing into the twenty-first century. Social science theory and research was, and remains, implicated in this project. Two main subjects dominate: sociological theories of police role, culture, and discretion, based mainly on participant observation; and theories of police administration, especially community-oriented, problem-oriented, and quality-of-life policing, sometimes grounded in participant observation, but also based on theory and experimentation.

3. *Reorienting Police*

Historically, the police emerge as a significant, and sometimes controversial, agency of social control in periods of social and economic transition accompanied by crime and social unrest. In democratic societies, policing generates issues of how police should best be organized to deal with crime, and to be accountable to the communities they serve. Police researchers who had studied the 'professional' reactive model of policing in the 1960s and 1970s became increasingly skeptical of the capacity of police to satisfy community demands for public safety and dignity. Two decades of research suggested that motorized patrol scarcely deters crime, that detectives can solve only a small percentage of crime, that rapid response doesn't solve crimes, since by the time police are told of the crime, the offender has gone. Moreover, four US Presidential Commission reports (as well as Great Britain's Scarman Report) showed how supposedly neutral and detached policing styles could generate deep mistrust of police and estrangement from the communities they policed.

Three new approaches to police organization, values and purpose were articulated and eventually studied by social scientists in the attempt to reduce crime, increase public safety, and renew some degree of confidence in urban police: community oriented policing (Skolnick and Bayley 1986, Moore 1992), problem oriented policing (Goldstein 1990), and quality of life policing (Kelling and Coles 1996, Livingston 1997). Most social scientists agree that policing is only one of a number of causes affecting crime rates, and even then demands considerable organizational rethinking and practice (Blumstein and Wallman 2000).

3.1 *Community-oriented and Problem-oriented Policing*

By the 1980s, police relations with the communities they served had become a major issue for industrial democracies in Western Europe, Australia, New Zealand, Canada, Japan, and in the United States. James Q. Wilson had demonstrated that American police departments of the 1960s had adopted 'styles'

of policing—‘legalistic,’ ‘watchman,’ ‘service’—that greatly influenced their performance. ‘Community-oriented’ (COP) and ‘problem-oriented’ policing (POP) are best understood as styles of policing which, although widely discussed and praised, have not generated a consensus as to their meaning or effectiveness. Nevertheless, although there is no standardized set of precepts of COP, three elements are generally regarded as central: (a) that police and citizens are ‘co-producers’ of crime prevention; (b) that policing be decentralized, with focus on neighborhood groups cooperating with police; and (c) that patrol be reoriented, from vehicles to streets. In addition, COP seems especially sensitive to the police need for racial, linguistic, and gender diversity.

PO Policing is frequently associated, and sometimes confused, with COP and for good reason. Each stresses community involvement. Each is critical of traditional ‘incident oriented’ policing. POP suggests that police managers review ‘incidents’ in consultation with community members to focus on underlying causes. Furthermore, POP envisions the police executive as a skilled politician able to mobilize the larger community—the media, and organizations within and outside of government—in the service of addressing underlying problems.

3.2 *Quality of Life Policing*

In an influential essay, James Q Wilson and George Kelling (1982) maintained that disorder and crime are usually inextricably linked, in a kind of developmental sequence. Just as a broken window, if neglected, leads to more broken windows, minor disorders (such as littering, loitering, public drinking, panhandling, and prostitution), if ignored, invite more serious criminality. Applying the theory as chief of New York City’s Transit Police, William Bratton and his associates scrupulously removed graffiti, and cracked down on turnstile jumpers, panhandlers, and others violating subway regulations. The result was an astonishing reduction of subway crime and a comparably successful rise in ridership.

With the election of Rudolph Giuliani as New York City’s mayor, Bratton became Commissioner of the New York City Police Department (NYPD). He merged the Transit Police into the NYPD and introduced many of its precepts. In addition, he set up a sophisticated computer mapping system (COMPSTAT) to assist police commanders in allocating resources, and to hold them responsible for crime reduction. New York City crime rates subsequently declined sharply. Although proving cause and effect is difficult, since other factors might have contributed (improved economy, higher incarceration rates, changes in drug preference, demographic shifts) close observers of the police acknowledge that these police strategies reduced crime. Bratton’s successor,

Howard Safir, employed the strategies more aggressively. The aggressive policing, plus highly publicized instances of excessive force, led to hostile relations between the police and the communities they serve.

4. *Discretion, Culture, and Deviance*

Wherever social scientists have observed police in action, as patrol officers or detectives, in Amsterdam, London, Los Angeles, New York, Sydney, or Toronto, their orientation to the job appears to be influenced by a profusion of unwritten rules and understandings significantly influencing conduct and misconduct. Sociologists and criminal law trained observers of the 1960s were impressed by the vast amounts of discretion that police enjoyed. Police on patrol were seen ignoring minor thefts, drunkenness, disturbances, assaults, and malicious mischief in the interest of maintaining public order. These discretionary practices rendered a significant part of the criminal justice process invisible and unreviewable.

William Westley’s pioneering study of the Gary, Indiana police examined how the strains of the occupation—dealing with criminals, the insane, the intoxicated, often in an adversarial relationship to the public—influenced police conduct—and misconduct—on the job (Westley 1970), Skolnick (1996) built on Westley’s insights to develop a theoretical role construct, the policeman’s ‘working personality.’ Skolnick asserted that significant features of the police role—danger, authority, and accountability to superiors—were a precursor to understanding how police perceived and acted upon the world around them.

Bittner (1970) contended that the core of the police role is their capacity to employ force. Although police often aid sick and troubled people, Bittner asserted, their main involvement is to provide coercion where needed. By now social scientists have produced a substantial literature documenting the role strains, ordinary practices, and cultural understandings of urban police.

4.1 *Code of Silence*

Although subcultural understandings vary, the legendary silence code seems to be the one powerful norm uniting police across departments and nations. Maurice Punch, who studied police deviance and corruption in New York, London, and Amsterdam, writes that police operate by a code of silence which ‘dictates that you do not ‘rat on your mates,’ (Punch 1985). In Los Angeles, more than 20 police officers witnessed Rodney King’s beating. Those who administered it must have assumed that those watching would not come forward and would back up any stories they would tell; and that departmental super-

iors would believe them. Officers in the New York City Police Department's 70th Precinct did not protest when they saw Officer Justin Volpe marching around the station house, waving a broken broomstick stained with blood and feces, the residue of his sadistic anal attack on Abner Louima.

Testifying before the 1933 Mollen Commission in New York, which was investigating a pattern of corruption that had grown into vicious criminality, Officer Bernard Cawley affirmed the silence code, and the reason behind it: 'Just say if a cop decided to tell on me, his career's ruined. He's going to be labeled as a rat.' The code of silence may be that of aspect of police culture most frustrating to the general public and to officials responsible for police oversight, including prosecutors, judges, legislators, and high ranking police officials.

4.2 Excessive Force

Following his study of police violence in American, Caribbean, and South American cities, Chevigny concluded that police organized on a highly military model, in socially stratified societies which have slight regard for rights, and a tradition of private vengeance are more likely to permit police to use arbitrary violence (Chevigny 1995). 'Police brutality' is an evocative media term, but it has no legal referent. To ask someone to move on, to employ physical coercion, or to shoot to kill, are all appropriate police conduct, depending on circumstances. Nevertheless, since every arrest, every handcuffing, involves an imposition of force on an essentially unwilling person, departments develop subcultural understandings about how to deal with people who challenge police authority. The widely televised beating of Rodney King by Los Angeles Police Department officers revealed a use of force so brutal it shocked viewers around the world. Yet a suburban, predominantly white jury found that the force was not 'excessive' since King was allegedly resisting arrest. (In a second, federal trial, held in Los Angeles, the officers were found guilty of violating King's civil rights.)

A blue ribbon commission (headed by Warren Christopher to investigate the complicity of the LAPD in the beating found that the LAPD reflected a counter-productive organizational culture. Officers were rewarded for the number of calls they handled and arrests they made as well as for being 'hard nosed.' Based on its time-honored notion of 'professionalism,' the department, the Christopher Commission concluded, 'emphasized crime control over crime prevention and isolated the police, from the communities and the people they serve,' and evidenced a 'siege mentality' (Christopher 1991).

In New York City, a particularly sadistic assault on a Haitian immigrant, Abner Louima, followed by two shootings of innocent African-American men (Ama-

dou Diallo and Patrick Dorismond) led to angry protests against police use of force, especially deadly force. As in Los Angeles, critics pointed to the police culture and organizational strategies—especially 'zero tolerance' for street infractions—to explain the use of excessive force.

4.3 Culture and Corruption

Although researchers have distinguished among levels of police culture in management and street cops, usually, students of police culture have focused on street cops. Subcultures of police departments generate understandings about low-level deviance, such as when it is permissible to accept a favor, a free meal, a discount on purchased goods, or an outright money bribe. Corruption scandals have tainted the police in London, Amsterdam, and Brussels, as well as in the United States. Low level corruption can all too easily slide into a higher level, diluting the distinction sometimes made between 'clean' and 'dirty' money. That distinction was to break down in New York when the Knapp Commission found that officers had extorted money or narcotics from drug dealers, had failed to take enforcement action against narcotics criminals, and had given false testimony. Around a quarter of a century later, the Mollen Commission found that lying under oath was so routine the New York police had a word for it—'testilying.' A 2000 corruption scandal in the Los Angeles Police Department—which includes allegations of police shooting and killing drug dealers, beating them, stealing and selling drugs, evidence planting, false arrests, and perjury, has given the LAPD the unwelcome distinction of being the first major US police department to be monitored by the federal government.

5. Private Policing

With the development of mass private property in the United States—e.g., gated communities, malls, industrial and amusement parks—more than double is spent annually on commercial private security (\$90 billion) than on public policing (\$40 billion). Other countries, like South Africa, maintain an even higher ratio of private to public police. In light of this growth, private policing has come to have significant implications for theories of social control in democratic societies.

Although private policing sometimes resembles, overlaps, and is confused with public policing, private policing is distinctive in one major respect. Unlike public police, private police are primarily accountable to their employers, not to the citizenry. Thus, private policing is ultimately grounded in different interests, in turn influencing its understanding of its role and practices.

While public police may act as 'peacekeepers' they are nevertheless authorized and expected to enforce the criminal law, which, at least in theory, imposes punishments based on just desert. Private police, by contrast, primarily enforce norms instituted by their employer. Thus, private police usually address violations of institutional standards of comportment (dress codes, noise levels); try to prevent material damage to property (through theft, vandalism, or terrorism); and seek to avoid disruption of routines (disorderliness) of the sites for which they are responsible—such as universities, hospitals, offices, industrial parks, or airports. To achieve these goals, security firms typically adopt a *preventive* approach to misconduct—which community- and the problem-oriented police do as well—thus blurring the distinction. Indeed, Ericson and Haggerty (1997) have argued that, like private police, modern police have largely become risk managers rather than crime controllers.

In the United States, laws protecting ownership of property permit private clients to define the meaning of security and order within their property boundaries more narrowly than public police, modified only by constitutional and legislative limits protecting free speech, minorities, and women. For example, behavior acceptable in a public park, e.g., walking barefooted, may be unacceptable in a restaurant or private place of amusement, such as Disneyland. The typical sanction for violating private property rules in *exclusion* or *ejection*. Low-level criminal behavior, such as smoking a marijuana cigarette, may also result in ejection or the threat of ejection, rather than the punishments embedded in criminal statutes.

Private police in the United States are not constrained by constitutional protections (e.g., the Fourth Amendment), nor are they limited by the same kinds of civil liabilities (e.g., §1983 civil rights claims) to which public police are subjected. Private security typically derives its powers from, and to an extent is controlled by, the laws of property, contract, and labor. Nevertheless, though many states do regulate the licensing of guards and their ability to use firearms, private policing in the USA remains largely self-regulating.

6. Controlling Police Misconduct

Procedural law, especially under the US Constitution's Fourth (search and seizure) and Fifth (self-incrimination) Amendments, sets boundaries for police who are investigating crime by excluding evidence obtained in violation of these safeguards. Nevertheless, such protections have been narrowed by the US Supreme Court, especially in connection with drug enforcement.

Since street law enforcement involves stopping, questioning, sometimes searching and arresting, as

well as ordinary peacekeeping, complaining citizens usually report one or more of the following: excessive force (hitting, pushing, tight handcuffs); abuse of authority (ordering change of location); rudeness; and ethnic slurs. Citizen Review Boards have become increasingly relied upon to address such issues and are found in Canada, Australia, Northern Ireland, and the United States. In the USA more than 80 percent of major cities have introduced such organizations. Walker (2001) concludes that policy review and change is more important than officer punishment to raise departmental performance, particularly since it is difficult to resolve cases where an officer and a complainant offer conflicting accounts.

External monitors, Walker believes, should prove more effective than citizen complaint review in elevating police performance. Civil liability suits, and most recently, federal and state oversight, have also been initiated to control police departments which appear to have deviated from their mission, either through corruption, excessive force, racial discrimination, or all three. There are no perfect models for policing or for controlling police. There is more agreement by social scientists and the public on what should not happen—corruption, brutality, racism—than on the mechanisms for controlling police. Nevertheless, certain themes related to police accountability are evident in the social science literature. First, police organizations are influenced by ideology, the most significant being a commitment to political democracy. Yet even within democracies, policing is influenced on a daily and regional basis by politics and power relationships. Second, policing is strongly influenced by the sub-cultural norms of policing. Third, courts possess only slight capacity to constrain police discretion on streets, neighborhoods, or management offices. Fourth, victimless crime enforcement breeds corruption, brutality, and even racism, as when minorities are racially profiled to enforce drug laws. Finally, police are more effective and accepted to the degree that they involve communities in developing their policies and practices.

J. H. Skolnick

Policy History: Origins

1. Introduction

Public policy is as old as the history of human governance. All rulers, irrespective of the form of public rule, have sought to shape and manage the substantive order governed under their authority. Modern public policy composes a narrower domain. Co-extensive with the complex, and continuing, process of state formation (and de-formation) begun in late medieval and early modern Europe (Tilly 1975), public policy has come to refer more specifically both to what governments do as they transact with civil society, the economy, and states within a global state system and to the creation and deployment of knowledge about these sites of authoritative transactions. The semi-independent origins of policy knowledge and policy activity constitute my subject. I focus primarily on two formative moments in the West: (a) the early modern period marked by the growing concentration of state sovereignty over territory and people, and (b) the midnineteenth through to the early twentieth century when the ‘social question’ and unaccustomed levels and forms of international violence pressed to the fore. ‘Origins’ itself a word with

a composite meaning. It refers both to the beginnings of a process and to the constituent elements of what comes next. The results of decisions taken at the critical junctures I discuss, set in motion developmental pathways that further defined the contours of modern public policy.

2. *Early Modern Europe*

The very existence of public policy in the modern sense can be traced to sixteenth and seventeenth century postfeudal Europe, a period marked by the accumulation and concentration of sovereignty into national territorial states (Watkins 1934). These units claimed unique authority within their borders and recognized boundaries demarcating states from each other (in this way, international relations became distinguishable from domestic politics). Each State possessed sovereignty based on law, and with it legitimate force within a distinctive territory, an ensemble of institutions, and a vision and articulation of the common good. With these attributes, the State emerged as a calculating actor vis à vis other States, the newly separated economic sphere, and a newly distinguishable civil society (Skinner 1989).

This consolidation of sovereignty into increasingly centralized units produced the standardization of laws, coinage, taxation, language, and responsibility for security, all of which were requisites for systematic public policy. A corollary process was that of a growing set of structural separations within national boundaries distinguishing the realms of sovereignty, property, and civil society. Now, states could not simply impose their will despotically. They had to create and deploy policies to transact and coordinate with other powerholders. State–society relations now became reciprocal as policy came to be synonymous with the outputs of governments seeking to regulate an increasingly challenging environment (Mann 1988; Tilly 1990; Spruyt 1994).

The modern economy likewise was the product of this postfeudal differentiation of spheres. The key point in the development of capitalism as the dominant framework for economic development came only with the concentration of sovereignty and the establishment of an authoritative framework for property rights and economic transactions on a large scale. Capitalism prospered and urbanization (as well as rural proto-industrialization) accelerated once states emerged that were not merely extortionist but shared an interest in creating the conditions required to organize independent market transactions. Whereas early medieval face-to-face exchanges had taken place in towns whose existence depended on grants of autonomy from local lords, thus creating insecurities outside this tight embrace, by the sixteenth century, kings, in exchange for revenue, protected towns and traveling merchants

on a much larger scale. With states providing a framework for capitalist development and not acting merely as rent-seekers, the linkage between the economy and the polity was utterly transformed into a new kind of strategic game. States did not ensure just any property rights, but only those consistent with state interests; capital did not give obeisance to any state, but only to those that secured its economic activities. The terms of this relationship thus became the first of two fundamental pivots of modern domestic politics in the West (North 1985).

The second was the hinge between the State and civil society. Separated from property, and concentrated in authority, the States of postfeudal Europe had to forge new, and uncertain, ties to civil society. These exchanges were marked by contestable questions about the range of activities over which the State would have authority—that is, the extent of its *hubris* in penetrating and regulating civil society—and about the ways in which members of civil society could affect the activities of the State. With the breakup of the tightly knit juridical, economic, and social units characteristic of feudalism, states could not simply compel by imposition. Instead, it was a condition of their effectiveness that they transact with society and coordinate aims with ‘private’ powerholders.

State–society relations thus became more reciprocal and less arbitrary; over time, the very ability of the State to utilize its authority to intervene in society produced commitments that subsequently bound the State. (Pitkin 1969; Downing 1992; Ertman 1997) The terms of these exchanges became the objects of political struggle and the subjects of expert consideration by political theorists and by political economists. Hobbes, Locke, Montesquieu, Rousseau, Millar, Steuart, the Physiocrats, and Smith, amongst a cast of many, mostly lesser, others, theorized these relationships and sought to find rules of interested engagement between the relevant parties. (Hirschman 1977) At stake was both the scope of responsibility of states for economic and moral situations and the ways in which the actions of states could be shaped by people, interests, and values outside the State itself.

The last key zone of transaction was international. Based on sovereignty understood as exclusive control over a particular territory and its people, a new international system came into being that substituted modern states with claims to unique control for formerly more fluid and overlapping jurisdictions. This change did not occur all at once, and its dimensions and decisiveness were masked for quite some time by the existence of dynastic empires, but the new global order of sovereign actors transformed the meaning of international policy about war and peace. Now, offense was geared to the extension of exclusive geographical sovereignty; defense to its protection. Contests over borders were settled by force or by diplomacy, both of which required new kinds of social knowledge (Doyle 1997).

These three sets of transaction were arrayed in a hierarchy, with the international dimension of war and peace designed to secure or extend sovereignty first amongst them because the existence and protection of such exclusive claims was the premise of the very existence of domestic policy. International policy also defined ambitions for overseas empires and for the guardianship of commerce in the globe's new Europe-centered market system (Zolberg 1981). As conflict between and amongst states now took on a global cast, so, too, did specialized policy knowledge about subjects as wide-ranging as military organization and the human qualities of 'primitive' subject populations.

Producers of modern policy knowledge were those intellectuals who came to understand and manage these new sets of transaction (Bauman 1992). Such policy intellectuals, after Machiavelli, created a modern science of government with two main ends: to point rulers towards more effective transactions among the State, economy, and civil society, and to police, educate, and civilize the population in order to improve its character and render it more rational and governable. They counseled how to expand the policy role of governments to address the security and portability of property under broadly mercantile economic arrangements and doctrines and how to govern populations subject to the authority of the State. Guided by such policy knowledge, as the territorial scope of states either expanded or became more secure, as the infrastructural capacities of governmental bureaucracies grew (including their abilities to gather and deploy statistical and other forms of information), and as a communications revolution in print and in advances to transportation took hold, governments took on increasing responsibilities for the solution of collective problems. These included new roles for both local and national authorities in such areas as poor relief, sanitation, and schooling (de Swaan 1988). Each time a new zone of policy activity was established under public aegis, either complementing or supplanting the responsibilities of private religious or secular responsibility, new specialist managers and intellectuals fashioned distinctive sets of policy ideas to organize these State-based activities. This extension of responsibility transcended even such fundamental divides as the *ancien régime* and post Revolutionary France (Woloch 1994).

In the long epoch from early modern Europe to the nineteenth century, mercantile thought produced a powerful and dominant recipe for state-building and for rules to govern international economic transactions, to shape those joining the State to the domestic economy and civil society. Its main aspects included 'regulation of the economically strong, support and direction for the economically weak, and the State's own enterprise where private initiative is wanting' (Krieger 1963, p. 557; Anderson 1974). At its early moments mercantilism was put to use for

conservative purposes to buttress a social order in crisis; later, under the initiatives of Colbert, mercantilism went hand in hand with the protection of property rights and the reduction of transaction costs to provide a dynamic basis for capitalist economic development. Both facets were integral to the process of State-building in which:

regional rulers utilized provisions for welfare as well as force to extend their control over all the inhabitants of their realms. Indeed, it was precisely the need for such a politics of welfare over a larger area when the old local welfare arrangements were being broken down that went far to establish the ruler as the head of the State. (Krieger 1963, p. 557)

3. *The Late Nineteenth and Early Twentieth Centuries*

During the first half of the nineteenth century, these formulas were pressured by the emergence of independent labor markets of more than local and regional scope (Polanyi 1944; Agnew 1986). With the introduction of such mechanisms to allocate people to jobs and set wage levels, capitalism entered a new phase. Concurrent with the development of labor markets (as well as autonomous housing markets) that helped generate new working class identities, dispositions, and patterns of collective action (Katznelson and Zolberg 1986), the period was marked by the development of compelling conceptions of popular representation and citizenship defined by the American and French Revolutions. All members of civil society now became actual or potential citizens. No longer could citizenship be restricted to those who, by holding property, demonstrated a stake in the existing commonwealth. Instead, the possibility of political (and military) participation was universalized, in the expectation that in a community of citizens people would act rationally in pursuit of individual, group, and common interests. Perhaps more so at this time than at any moment since, citizenship now possessed a radical, emancipatory edge (van Gunsteren 1985).

Within this field of tension, public policy was transformed radically in range and content. In this novel circumstance the 'social problem' emerged as a key category of public policy. This emblematic term condensed the new tensions of markets and citizenship. It put at the core of public life the question of whether, and to what extent, the political relations of citizens might modify the operation of markets, as well as the extent to which the rationale of the marketplace would dictate limits to citizenship. Prerevolutionary approaches to citizenship (whether Roman, medieval, or Enlightenment) had not ignored the connection between citizenship and minimum levels of security, but they had dealt with it by excluding those without economic means from the community of citizens. No longer was this solution possible. As citizenship

became more inclusive, states extended the scope of their policies aimed at organizing markets and mitigating their distributional inequities. Further, a modernist policy intelligentsia, nourished by Enlightenment conceptions of reason, considered citizenship, markets, and their intertwining with the confidence that they could find scientific solutions to ethical problems. Their methods became more specialized, and the professionals overtook the amateurs.

In situations characterized by the crystallization of the new institutions of markets and citizenship, practitioners of social knowledge perforce could accept or repudiate these foundations of policy. Throughout the nineteenth and early twentieth centuries, deep reactionary currents of refusal and restoration, radical renunciations of the new moral economy (Hirschman 1991), and forward-looking blueprints, the most important of which was a powerful Marxist critique and teleology, assertively rejected the new institutional and normative framework of liberalism. By contrast, the great majority of social analysts accommodated with varying degrees of enthusiasm to the new order and to its immanent power relations, and they sought to solve problems within the liberal doctrinal and institutional premises.

Even within this framework, there existed a wide array of alternative conceptualizations, ways of organizing knowledge, and contestations about policies, from right to left (at both poles straddling the liberal/non-liberal divide); but these debates, no matter how hotly contested, came to be circumscribed within a distinctive family of possibilities and they focused on a shared subject matter: the field of tension created by the simultaneous development of transactions between states and markets, especially as they concerned labor, and between states and actual or prospective citizens within civil society. The harsh realities of unequal and exploitative relations between economic actors helped create contentious class representations that intersected the radical impetus of citizenship to produce incendiary political possibilities, making both the modern State and modern capitalism precarious.

In these circumstances, producers of social knowledge—as individual scholars and theorists, and in organized settings such as universities, learned societies, political parties, organizations devoted to policy goals, and governmental bureaucracies—struggled with how to interpret and manage the new transactions linking State and market and State and citizen with very mixed and often confused motives: to preserve the social order and to reform it, and frequently both. Sometimes cast in a language of socialist transformation, sometimes in a conservative discourse, and sometimes in a vocabulary of individual rights, the center of gravity of the new social knowledge in the West was located in various attempts to find reference points and tools of administration for a form of social policy which could integrate conceptions of individual

and collective goods. The policy intellectuals who undertook this quest were not utopians. Most saw no way to go back to a moment before citizenship and (labor) markets (indeed, in Britain, neither progressives nor conservatives in the late nineteenth century sought to return to the pre-1834 epoch, when social policy and economics were treated autonomously), and no way forward to a postliberal era within the ambit of normal politics (Harris 1990; Mandler 1987).

The features of policy and knowledge tended to be nationally-specific. In France, an optimistic anticlerical and republican program of the pupils of Comte and then of Durkheim articulated with the Third Republic. In Britain, New Liberalism conquered the field, displacing and reshaping virtually all its competitors; as it did in the United States, within the framework of Progressivism. In Germany, like so much else, social science and policy studies suffered the fate of the country's precarious liberalism, developing especially skittish qualities (Lepines 1988; Ringer 1969).

4. Modern Policy Knowledge and Practice

The place of pride in social analysis in the *ancien régime* had belonged to the moral sciences. Classical political economy had been elaborated within its embrace. In Britain, figures as diverse as Stewart, Malthus, Ricardo, the Philosophic Whigs, John Stuart Mill, and Bagehot, sought to maintain holistic portrayals of modern society while treating the specificity of the new transactions between its distinctive domains, and to do so by making the role of the State, in form and in policy, the centerpiece of their analyses. These pivotal thinkers were neither traditional political philosophers who deduced the character of the good society from first principles or moral ends, nor were they empirical social scientists who sought to comprehend the regularities governing the new transactions.

Over the course of the nineteenth century into the twentieth, this kind of relatively integrated social knowledge was replaced by professionalized, discipline-based attempts to grapple with the specific tensions inherent in the elaboration of markets and citizenship in liberal societies. At stake was the character of the extended responsibilities and jurisdiction of the State with respect both to markets and citizens. From the vantage point of the transactions between the states and markets, the central issue was how to shape the State's interventions to make markets function effectively and to make their distributional effects tolerable. From the perspective of transactions between states and citizens, at issue was the balance between freedom and domination. From the standpoint of international relations, the key issue was how to regulate the quest for power and plenty in a

manner that enhanced the prospects of peace and prosperity. Together, these questions elaborated the themes of moral philosophy under radically revised conditions (Thomas and Meyer 1984).

These were the concerns of a new genre of policy institution, the first example of which is Britain's Social Science Association founded in 1857. Created to consider the problems of social economics and to promote legislative reforms in the House of Commons with regard to education, law, penal policy, public health, and the regulation of markets, the Association self-consciously viewed itself as a conduit between politicians and an expanding citizenry with political rights, and it came to play an important interstitial role in the Victorian State by proposing ways to manage the 'social problem' attendant upon the simultaneous existence of labor markets and an expanded citizenry. Like Germany's *Verein für Sozialpolitik*, the Association fused reform and social science in its attempt to provide expert knowledge on behalf of a project its members conceived of as an endeavor of social integration. Working before the development of separate social science disciplines and before the creation of an autonomous and politically ambitious labor movement, the Association succeeded in joining under liberal auspices a wide array of intellectuals as well as Liberal MPs, trade union and cooperative movement leaders, and other reformers in a quest to bring expertise to bear on the project of creating a new liberalism capable of surmounting the now manifest inadequacies of traditional political economy (Goldman 1986).

This subsequent transformation in subject matter, style of work, and institutional organization was no simple linear development. There were two overlapping moments, each characterized by an important partition. In the first, spanning the 1860s through the 1910s, the knowledge community divided into specialists concerned with one or the other transactions of State, economy, and citizenship. Integrated knowledge separated into distinctive zones for the study of economics, politics, and society, ultimately devolving into wholly separate professional disciplines, each with distinctive intellectual tendencies (Oleson and Voss 1979). The second moment, from the 1890s through the 1920s, was characterized by a trend complementary to these new disciplinary divisions: a split between academic practitioners of the social sciences, located mainly in burgeoning institutions of higher education, whose policy concerns and impact were indirect, and scholars whose emphasis was placed far more directly on policy matters and public influence.

As late as 1870, political science was hardly distinguishable from political economy and history. In the next 50 years, political science secured a disciplinary status divorced in large measure from both. It came to focus in a specialized way on constitutionalism, law, political parties, interest groups,

voting and other mechanisms of representation; that is, on the rules of State-citizen transactions. During the same period, political economics shed its adjective and its claim to be an aspect, in its science, of moral philosophy. Recast as a scholarly craft in the mathematical language of post Jevons marginalism, it was not so much that economics no longer wished to concern itself with larger questions of human nature and social organization. Rather, the economists of the period sought to elaborate a science of markets on the basis of an elegant simplification about just these issues, but not for the sake of science alone. This new economics, for whom the key figure certainly was Alfred Marshall, was created in the service of the ethical goals of the period's New Liberalism. Under his remarkable influence, deductive work within economics replaced historical scholarship. This narrowing of focus was accompanied by a widening of theoretical ambition to create an economics as a timeless and institutionless body of knowledge (Soffer 1978).

Indeed, Marshall was an exceptionally important figure at two junction points: between classical political economy and disciplinary social science; and between the latter and the world of public policy. His *Principles of Economics*, published in 1890, explicitly sought to place pioneering analytical techniques at the service of human improvement. While Marshall's economics was neoclassical in the sense that all its aspects concerned the fluctuating equilibrium of supply and demand, this equilibrium depended for him on the subjective decisions of producers and consumers in pursuit of qualitative time-bound goals in pursuit of a better life. Once his new mathematical tools became central to economics, the discipline developed in ways that elaborated technique at the expense of his own value-laden preferences. The new Marshallian economics deepened its scientific capacities at the expense of its practical effects on policy issues of the day and on its ability to analyze, or even take an interest in, the rules of transaction governing the relations of State and market in particular historical settings. Just at the moment when, in the late nineteenth and early twentieth centuries, the social tensions of markets and citizenship intensified under the impact of economic depressions, the radical transformations in industrial size and class structure entailed in the second industrial revolution, international rivalries for markets, a new geopolitics characterized by imperial ventures, and, ultimately, by total war, the academic discipline of economics lost a good deal of its capacity to function as a practical policy science. In part this was a matter of a distancing from practical affairs, in part a flight to abstraction, in part a deliberate decision in favor of the ambitions of science at the expense of the ambitions of moral discourse (Church 1974; Nelson 1987).

By the end of the nineteenth century, classical political economy virtually had disappeared, as had

the gentlemen generalist historians and lawyers who had become archaic figures. These 'all-rounders' were steadily replaced by academic scholars in specialized social sciences and by a growing body of policy specialists who claimed knowledge that both drew upon and crossed over the boundaries that divided the social sciences. Labor experts, social workers, organizers of social surveys, public administration specialists, reformers concerned with social policy, and intellectuals within social movements and political parties—both inside and outside the administrative apparatuses of states—tried to come to grips with the intensification of the problems inherent in interactions between States, citizens, and markets. These policy intellectuals were a novel and distinctive breed. Their main orientation was not to the social science disciplines as such; nor were they amateur seekers after a science of legislation in the manner of their mid-nineteenth century predecessors.

In spite of its abstraction and distancing from practical affairs economics, and economists, were not left without influence. On the contrary, the new scientific economics achieved something of an encompassing contextual role with regard to the development in this epoch of a new kind of policy-relevant social knowledge that coexisted with, and drew upon, university-based social science disciplines. Economics set limits to common sense, by putting on a 'scientific' basis the assumption that market outcomes are likely to be the most optimal, at least in the sense of the most efficient. But if economics emerged secure in this role, policy analysis (unlike the policy studies of today grounded primarily in microeconomics) principally adopted the language of public administration and social engineering. This language, nestled within the assumptions of Marshallian economics, facilitated a self-image for policy intellectuals much like that of the earlier liberals of the Social Science Association which stressed the role of social knowledge in helping to transcend class conflict within a framework that accepted, at least implicitly, the divisions between State, economy, and civil society. The central concern of these policy intellectuals was how to build a State capable of dealing with the challenges of increasingly assertive working classes both as economic actors and as poorly integrated citizens. The focus of these efforts pivoted on what came, only later in the 1940s, to be called the Welfare State, to encompass the cluster of policies and institutions concerned both with the mitigation of market distributions and with the substantive content of citizenship. To one side of this new policy knowledge lay the preliberal conservatism of a Bismarck who had sought to make workers a new estate subservient to and dependent on the State; to the other, lay the strong socialist assertion that only the transcendence of markets and the integration of the domains of State, market, and citizen could resolve the contradictions of modern capitalist societies. The new liberal social knowledge decisively rejected these

alternatives. Public policy today in the West is encompassed within these boundaries.

5. Origins as Consequences: A Post World War II and Post Cold War Postscript

Totalitarianism aside, what is striking is just how encompassing this orientation to public policy proved to be, and how dominant the policies promoted by practitioners of liberal social knowledge had, by the end of World War II, become broadly based on the model established under conditions of extreme economic and geopolitical duress by the American New Deal (Ruggie 1982). With Fascism defeated and Communism the new enemy, this expanded liberalism faced no serious competition in the normal politics of the western democracies. This is not to say that consensus replaced conflict; rather, conflicts about the contours of domestic issues took the form of debates about this or that essentially social liberal alternative, even in situations where some of the most important contestants for power presented more radical alternatives for the long haul. From quite far left to quite far right, political competitors accommodated to liberal principles and institutions. Political contests became no less vigorous, but certainly less fundamental: not capitalism versus socialism or democracy versus totalitarianism (though this antinomy defined the discourse of competition between the Soviet and American blocs), but a politics about rules of transaction between spheres within capitalism and democracy. Coherent repertoires of positions about these questions pivoting on the degree to which the State should be assertive in organizing markets and in utilizing social policy for distributional goals and on how institutions of political participation and the representation of interests should be organized distinguished 'left' from 'right' formulas about State-market and State-citizen transactions. Each position was given voice by its own identifiable policy intellectuals, but together they constituted a single, inherently liberal, knowledge community.

The benefits secured for liberal societies by the robust development of social knowledge by this kind of policy intelligentsia ought not to be gainsaid, especially in light of this century's cruel alternatives. But we should also be aware that by conceptualizing their problems at the level of economic and political market exchanges, most policy intellectuals have left unexamined a host of issues about class and State, inequality and power. By working at the level of transactions between states and markets and states and citizens and by separating these from specialized inquiry by students of international relations, they tacitly have pushed the macrostructures of capitalism and states into the background of their work. In so doing, they have underscored the great normative achievements of liberalism, but also became ac-

complices in the silences deep-seated in the liberal project.

Policy History: Regimes

The concept of regime has multiple cognate meanings. Most broadly, it is used as a synonym for 'political system,' connoting the most general institutions and processes characterizing the exercise of political power. More narrowly, when power is so tightly centralized and controlled that the dictator seems to constitute the entire political system, regime is used to refer to the paramount political elite, as in the Franco regime of Spain or the Nasser regime of Egypt. In international relations, regime refers to the set of principles, norms, rules, and decision-making procedures that actors mutually recognize and adhere to in their interactions. The core meaning of regime shared by these usages refers to the formal and informal rules and institutions that both reflect and shape the distribution and organization of political power and that constrain to various degrees the actions of power-holders. In this article, regimes and the

major subtypes of regimes, democracies, or dictatorships, are discussed in the context of state building and with reference to the concepts of state and government. Next, research into the origins of regime types is surveyed, with special reference to the causal role of public policies. Finally, the causal role of regime types on public policy is considered.

1. Regimes and State Building

The topic of regimes assumed increasingly greater importance in the politics of the West in the seventeenth and eighteenth centuries as state building extended the infrastructural power at the disposal of central rulers. Infrastructural power (Mann 1984) is an attribute of states, and refers to the capacity of state agencies to monitor society, regulate social and economic activity, sanction certain forms of collective action while prohibiting other types, adjudicate disputes, and engage in other activities dedicated to extracting human and fiscal resources to reproduce and enhance state power. Despotic power, on the other hand, refers to varying degrees of formal and informal constraints on rulers; as an attribute of regimes, it measures the capacity of rulers to act without consulting and bargaining with other political, economic, and social groups. While in many historical empires despotic power was virtually unlimited, the practical effect of the absence of constraints was acutely mitigated because, weak in infrastructural power, the state lacked the logistic capacity to implement the ruler's whim. State formation in Western Europe threatened to combine high levels of infrastructural power with high levels of despotic power.

European state formation, however, was accompanied by the structural differentiation of the realms of politics, economics, and civil society. Over time, although operating at a variable pace in different political units, the separation between public and private became more and more evident in both theory and practice. While structural differentiation created new opportunities for rulers to extract physical and material resources, rulers increasingly had to bargain and consult not only with traditional political actors and organizations, but also with representatives of new classes and organizations. Extracting resources, moreover, soon imposed new demands for state coordination and regulation to match the increasing complexity of economy and society. Struggles over the content of public policies such as taxation and military conscription became, by the nineteenth century, intertwined with struggles over the form of the regime itself. Over the long term, state power was both massively enhanced and, via changes in the regime, the disposition of state power by rulers was made subject to new constraints and redirected to new aims.

Regimes are composed of two forms of constraints on despotic power. On the one hand, rulers may share

the political stage with other collective actors possessing political power, such as parliaments, independent judiciaries, and even legally autonomous executive agencies. On the other hand, and perhaps more importantly, rulers may be compelled to negotiate with actors in civil society, such as capitalists, large landowners, religious organizations, labor unions, and diverse interest groups, who possess resources that can be converted into political power. The distribution of power (the relative strength of actors) and the organization of power (the institutionalized forms of interaction) act as constraints on despotic power and thus constitute regimes.

The concept of regime thus falls midway between those of state and government. State refers to the relatively permanent organizations of territorial-based rule used to generate power via coercion and administration; government refers to incumbents holding offices that deploy that power. Regime refers to the organization of power generated by the state and exercised by rulers and other state officials. It thus defines the routinized relations between rulers and other agents within the political apparatus, on the one hand, and between the state and civil society, on the other hand. Critical components of the regime are the formal and informal mechanisms for selecting leaders, procedures for representation and consultation, and rules by which decisions are made.

2. Types of Regimes

The semantic field of regime types is not timeless, but has instead been composed of those types considered legitimate contenders in distinct historical epochs. Thus, in ancient Greece, political theorists judged the best regime from among democracy, oligarchy, and monarchy. In post-feudal Europe, the main alternatives were absolutist versus constitutional regimes, distinguished by whether monarchs exercised both executive and legislative powers or shared legislative powers with an assembly. During the Cold War, regimes were trichotomized into democratic, authoritarian, and totalitarian regimes. With the collapse of the Soviet Union and the transition to democracy made by both authoritarian and former communist countries, current research treats almost exclusively democratic and authoritarian regimes.

Democracy is an example of what philosophers call an 'essentially contested concept,' a concept that straddles the divide between empirical and normative criteria. These normative criteria are evident in the proliferation of subtypes of democracy characterized by rival contentions about the proper goals of democracy, ranging from the defense of individual rights and freedoms of liberal democracy to the extension of rights to the economic and social realms in social democracy (Gutman 1993).

Wishing to avoid the complex debates surrounding this array of goals to be pursued by a regime in order for it to be called a democracy, most scholars engaged in empirical work on political regimes in the post-World War Two period have subscribed to a strictly institutional definition of democracy. In an early and still influential statement, Joseph Schumpeter (1942, p. 269) identified close links between democracy and capitalism, and defined the former as an 'institutional arrangement for arriving at political decisions in which individuals acquire the power to decide by means of a competitive struggle for the people's vote.' A minimal procedural definition, however, runs the risk of committing the 'electoral fallacy:' the failure to recognize situations in which civilian political leaders gain access to office via popular mandate but do not truly represent the electorate; because they win elections via corruption and manipulation of the political process; because they do not exercise *de facto* control over non-elected military officers and state officials; or because civil society does not have the informational and organizational capacity to monitor government actions and express dissatisfaction with policies. In any of these scenarios, elections do not produce genuine accountability of elected officials to the electorate. In many circumstances, then, it may be difficult to distinguish analytically between the institutional procedures of democracy and the goals democratic practices are designed to achieve. Indeed, insofar as both politicians and the electorate understand elections as an opportunity to exchange loyalty for material benefits and readily assent to these practices, then elections may be understood as opportunities to express mutuality and reciprocal solidarity, not as a means of holding governments accountable. In this scenario, votes may truly reflect genuine preferences of the electorate yet, given the cultural construction of the meaning of elections, it is not clear whether to label this regime democratic (Schaffer 1998).

One way to bridge the institutional and the goal-oriented approaches is to return to the definition of regime and consider democracy as a constraint on power. Modern democracies emerged in national political systems that were products of centuries of state formation, producing far greater infrastructural power than any political systems in the past. Barring constraints on despotic power, rulers of modern states would be capable of achieving their preferences by directly imposing them on all other actors expressing rival preferences, by firmly controlling the processes by which decisions are made to pre-empt the expression of rival preferences, or even to shape the consciousness and preferences of less powerful actors. Consequently, unconstrained rulers with infrastructural power at their disposal would be relatively certain of prevailing in conflicts with other power-holders or actors in civil society. Moreover, insofar as the structures of modern states are relatively durable, unconstrained rulers would have relatively permanent power. Finally, in

the absence of constraints, power could be deployed in any and all realms of society, polity, and economy.

Movements for democracy were efforts to contain the arbitrary exercise of power and to redirect its use toward new goals by making governments accountable to and representative of an electorate whose membership was enlarged in the nineteenth century and swelled in the twentieth century. These goals were achieved by placing constitutional limitations on the actions of governments, establishing rights of citizenship, and licensing citizens to participate in the formation of governments and the formulation of policies. As a result, despotic power was sharply constrained: outcomes of conflicts over access to office or policies enacted while in office became increasingly uncertain, and any advantage enjoyed by political leaders became both increasingly temporary and subject to constitutional limitations. The basic principles of democratic regimes, in other words, are that power can be exercised in only a delimited realm of areas; the outcomes of all political conflicts are uncertain; and, therefore, governments are temporary (Przeworski 1991, Lawson 1993).

Making these principles of uncertain, temporary, and restricted exercise of power concrete requires a range of specific institutional arrangements that permit civil society to express preferences and monitor government adherence to them, and that permit an opposition to challenge governments in power with a genuine possibility of becoming the government. Eight institutional criteria are necessary for citizens to have the opportunity to formulate preferences, communicate them to governing authorities, and have those preferences considered in the conduct of government: freedom to join and form organizations; freedom of expression; the right to vote; the right to hold office; the right of political leaders to compete for support; alternative sources of information; free and fair elections; and institutions for making government policies depend on votes and other expressions of preference (Dahl 1971).

By focusing on the institutional arrangements that make the exercise of power relatively restricted, uncertain, and temporary, this definition treats all nondemocratic regimes as a homogenous residual category. In fact, via reference to more specific attributes of the distribution and organization of power, a number of subtypes of authoritarian regimes can be identified, including but not limited to autocratic, totalitarian, absolutist, traditional, monarchic, oligarchic, and sultanistic regimes. By the same token, democratic regimes can—and for many purposes should—be disaggregated into numerous subtypes. Examples of 'modified' democracy in which some features of full democracy are absent include 'controlled' democracy in which parties representing some segments of the political spectrum are banned from competition, and illiberal democracy in which civil liberties are incompletely recognized.

3. *Origins of Regime Types*

The major cleavage in theoretical debates over the origins of democracy and dictatorship divides structuralist accounts that assign primary causal weight to situational factors from agency-based accounts emphasizing the role of political actors who are relatively unconstrained by environmental factors. Structural explanations can in turn be subdivided into nomothetic accounts positing quasi-universal trajectories of socioeconomic change affecting regime types and historically specific explanations. Among the latter, of particular importance are theories that view regime types as functions of particular constellations of public policies.

3.1 *Universal Preconditions*

Building on ideas that originated in ancient Greek political thought and that can be traced through the Enlightenment, the most influential theories of regime change in the post-World War Two period have been those that understand economic development and cultural change to be important, if not absolutely necessary, influences on democratization. Studies relying on increasingly refined conceptualizations, reliable data bases, and sophisticated statistical techniques have largely replicated the findings of earlier, relatively crude empirical studies: a strong relationship exists between the level of socioeconomic development—essentially, increasing wealth accompanied by multiple correlates—and democracy. A number of scholars have suggested that this relationship verges on the status of a sociological law.

Several analytic defects, however, motivate scholars to propose alternative theoretical positions. First, questions remain about the causal mechanisms underpinning the statistical relationship between prosperity and democracy. One of the earliest statements of this hypothesis briefly alluded to a number of causal pathways by which increased wealth would promote the spread of values of moderation and toleration, thereby immunizing polities from extremist politics (Lipset 1959). The articulation of increasingly sophisticated statistical studies linking socioeconomic development to democracy has not been accompanied by commensurate analysis of the intervening causal mechanisms. There is yet no systematic evidence that economic development is causally related to democracy primarily via changes in values. Consequently, many studies of political culture and democracy reject the claim that pro-democratic changes in values are necessarily preceded by socioeconomic development. Instead, the cluster of attitudes seen as conducive to democracy has been attributed to political learning, political socialization, institutional change, international diffusion effects, and habits learned from the

routine practices of politics itself (Diamond 1993). Even these sources of democratic norms of moderation and tolerance, once decoupled from economic development, have been only contingently tied to democratization.

A second problem stems from the ambiguous specification of the causal relationship between wealth and democracy: rising wealth has been hypothesized both as helping to sustain democracy, but also as helping to generate democracy. Statistical tests have frequently conflated the two issues, despite warnings by prominent scholars to maintain the distinction and treat the two issues separately. When statistical tests are designed to discover the exact nature of the empirical relationship, the best evidence is that heterogeneous factors account for the origins of democracies; once established, rising levels of wealth help to stabilize democracy without causing it (Przeworski and Limongi 1997).

Finally, in response to democratic breakdowns in the 1960s and 1970s, scholars criticized the universality of the claim, restricting its validity to the earlier developers in Europe and Anglo-American countries, and contending that modernization in later developers would issue in diverse trajectories of political change. In one variant of this position, scholars argued that economic modernization in the twentieth century might actually require a set of public policies such as capital accumulation and investment in heavy industries that could only be implemented by authoritarian political systems; developing countries faced the terrible dilemma of a trade-off between prosperity and political liberty. Alternatively, socioeconomic modernization disrupted people from old patterns of culture and social interaction, and raised their expectations of increasing material gain. When these expectations could not be met, and in the absence of robust political institutions such as mass parties, political instability and military rule typically followed.

Thus, by the mid-1970s, the prospects for new democracies were considered highly unfavorable. Either economic development would be associated with authoritarian governments or, if one maintained loyalty to the modernization hypothesis, given the global recession of mid-decade and the debt crisis that spread through the developing world in the early 1980s, democracy-inducing development was not on the horizon. Political scientists were thus caught largely by surprise by the wave of democratization that began in Southern Europe in the mid-1970s and spread, over the next two decades, to Latin America, Eastern Europe, Asia, and Africa.

3.2 *Process-based Theories*

Reacting to the predictive failures of both modernization theory and its critical rivals, scholars articulated

a model of regime change that downplayed the role of sociological, cultural, and economic conditions and highlighted the importance of relatively indeterminate transition processes. These transition processes are indeterminate because imperfect information, malleable interests and identities, rapidly changing strategic calculations, and a strong role for contingent events combine in various permutations to preclude structuralist accounts of regime change. In other words, during periods of regime transitions, when previous rules and institutions have been suspended, actors typically find that their identities and interests are subject to change; consequently, it becomes extremely difficult to devise coherent strategies driving goal-oriented behavior; and events that might previously have been considered routine may take on additional significance, forcing actors to recalculate their strategies and their goals. All of these factors do not aggregate into a single model or theory of regime change; rather, they all suggest why the constraints exercised by structural conditions will be loosened, opening up considerable space for politicians to exercise initiative and craft novel outcomes that might have seemed otherwise infeasible. Just as there are no inexorable preconditions for democracy, seemingly unavoidable democratic breakdowns in the past could have been avoided by only incremental changes in actors' perceptions that would have permitted a greater degree of trust and collaboration on behalf of shared goals. Finally, to the extent that relevant actors cannot predict outcomes, normal social science methodology oriented to discovering law-like behavior will be inappropriate to the analysis of democratic transitions (O'Donnell and Schmitter 1986).

The focus on actors and their strategic interactions has undoubtedly been a useful corrective to analyses that focused exclusively on environmental factors. But actor-oriented models may have gone too far in their rejection of any meaningful role for structural conditions, prompting critics to charge this literature with excessive voluntarism. Reviewers of this literature have regularly claimed that its authors too readily dismiss the importance of a range of structural factors other than the level of economic development. Moreover, they point out, it has proven difficult for transitions scholars completely to excise structural factors that regularly appear, either in explanations of individual cases or in the acknowledgement of the 'long-run' causal impact of macro-level factors. Methodologically, these analyses have been overwhelmingly based on countries that have successfully democratized. Persistent authoritarian regimes have not been systematically incorporated into the analysis of regime change. This bias in the selection of cases and the failure to consider the full range of structural factors raises the strong possibility that those cases that democratized might all share one or more structural factors distinguishing them from those cases that have not democratized.

3.3 *Macro-historical Analyses*

It seems highly likely, therefore, that subsequent research will continue to draw on a third approach to regime change: macro-historical studies. These analyses occupy a middle position between the universalism of modernization theory and the particularity of transitions studies by wagering that a relatively delimited set of historically specific constellations of structural factors can be identified that will account for regime change in clusters of cases. In contrast to the emphasis on values and cultural change of modernization theory, the causal mechanisms adduced by these approaches are typically rooted in the conflictual relations of rational actors pursuing their interests.

A seminal work in this approach is Barrington Moore Jr.'s (1966) analysis of the divergent regime outcomes associated with European economic modernization. For Moore, various relations between the crown, landed aristocracies, and urban bourgeoisies at the time of the commercialization of agriculture determined whether modern regimes would be democratic or authoritarian. For democracy, a strong bourgeoisie had to be the dominant partner of landed elites in a coalition that sought to check royal power. When bourgeoisies were not available to play this leading role, divergent relations between landed elites and peasantries determined whether twentieth-century authoritarian regimes would be fascist or communist. Recent theorists follow Moore's suggestion that the relative strength of classes determines regime outcomes, but propose that the key to democracy lies in the weakening of antidemocratic landed classes and the strengthening of pro-democratic urban working classes (Rueschemeyer et al. 1992).

A second approach focuses less on relative class power and more on the consequences of divergent patterns of interclass coalitions. In this approach, groups embroiled in political-economic conflicts seek allies from among urban workers or rural cultivators, or both, as a means of vanquishing rivals. Regime outcomes are by-products of the political bargains sealing these class alliances (Luebbert 1991).

Another macro-historical approach links regime outcomes to patterns of state formation. As European rulers sought to increase tax burdens and to recruit manpower from their populations, they were forced to bargain with other power-holders who controlled access to those resources: landed elites and urban capitalists (Tilly 1990). Those bargains had a powerful influence on the structure of ensuing states and on the nature of the political regime. The availability of liquid capital in countries such as England and Holland, for example, tended to produce less bulky state apparatuses and more restrictions on despotic power, as holders of moveable assets otherwise beyond the reach of rulers were able to secure some control over public policy and more transparent and accountable administrative procedures in exchange for financing war-

making and state building. Indeed, in these instances, many of the limitations on despotic power established in the late medieval period such as parliaments, independent judiciaries, rudimentary rights, and the rule of law persisted into the early modern period and beyond to the twentieth century (Downing 1992). In contrast, in regions where urban capitalists were few in number and limited in wealth, rulers tended to bargain with landed elites. In these cases, medieval limitations on despotic power were abolished, absolutist regimes were established, and the prospects for stable democracy in the twentieth century were diminished.

These state-building patterns have not been reproduced outside of Europe. Instead, a repeated theme of non-European political development has been the deviation from European patterns due precisely to the existence of wealthier European states that financed non-European state formation, precluding rulers in the periphery from the need to bargain with their own populations. Assuming some conditional relationship between taxation and representation, the reliance of states on external sources of finance such as flows of foreign aid or sale of commodities by state-owned companies forms a potent obstacle to democracy. Moreover, the sale of advanced military hardware and the training of officer corps in both external and internal warfare gives third world states a powerful coercive edge over their civil societies and often gives military officers an edge over civilian officials. Finally, in times of crisis, foreign interventions have and undoubtedly will continue to shape regime outcomes in the non-European world.

At their best, macro-historical analyses are equally attentive to historical particularity, large-scale global processes, and the linkages between situational variables and individual action. But the search for clusters of variables explaining groups of cases can easily be replaced by purely idiographic explanations of individual cases, especially as the wealth of plausible hypotheses and of partially confirmatory evidence renders difficult the extension of any one model to multiple cases in different world-historical settings. Moreover the link between macro-structural variables and individual action is more often imputed than carefully theorized and researched. Finally, in light of efforts to capture at least some particularity of individual cases, there has perhaps been insufficient attention to hypotheses motivating more universalistic theories, such as the development of capitalism. It has been noted with increasing concern, for example, that recently created democracies in Latin America and elsewhere may be grafts of formal institutional structures on to deeply antidemocratic behavioral patterns. To what extent can these variants of democracy be explained by late development and global capitalism? Scholars seeking middle-range hypotheses have underemphasized this sort of research, the provenance of large-n statistical studies. Future research may have to give even more weight to both nomological theorems

and the specification and verification of macro-micro links.

4. Regime Types and Public Policy

Political scientists have frequently invoked regime types as an influential cause of public policies, particularly in the study of the political determinants of economic policies. In the 1960s, scholars openly wondered whether economic development in the post-colonial world would require authoritarian governments. By the mid-1970s, the end of the postwar growth period and manifestations of domestic political instability prompted some theorists to suggest the onset of a crisis of democratic governability in the advanced industrial nations as well.

In the short term, the hypothesized implication of democratic regimes is the 'political business cycle.' According to this theory, instrumentally rational political leaders who seek above all else to win elections will use their power to alter the economy by reducing unemployment in the period leading up to elections. After being rewarded by voters with re-election, leaders will impose austerity policies to eliminate the inflation induced by pre-election policies. Under democracy, then, economic policy would always be held hostage to the goals of egoistic politicians, resulting in regular macroeconomic instability that follows a 'stop-and-go' pattern. Over the longer term, the hypothesized consequences of democratic regimes were even more alarming. In the well-known analysis of Mancur Olson (1982), special-interest groups formed, under most circumstances, distributive coalitions that sought to increase the economic welfare of their members, typically via pushing for policies that were highly detrimental to overall growth, such as protection or halting the spread of labor-replacing technology. Under conditions of liberal democracy, there were no impediments to the growth of distributive coalitions other than collective action problems within each organization, problems that were likely to be overcome with sufficient time. Consequently, the fastest growing of the advanced economies in the postwar period were those like Germany and Japan which had experienced a fascist interlude that had eliminated most special-interest groups, granting them a period of rapid growth before the inevitable decline set in. The basic logic of these arguments was applied to the developing world as well. Given a trade-off between consumption and investment, democratic governments were seen as more likely to engage in vote-buying behavior and thus less likely to impose policies that delayed consumption on behalf of capital accumulation and long-term growth.

More recent research and theorizing have cast considerable doubt on these arguments. While data

demonstrates a political business cycle in some countries, that evidence is equivocal. When larger samples of countries are studied, the evidence for a business cycle is very weak. One reason that no such cycle can be shown to be consistently evident is that voters, while certainly influenced by economic matters, are best understood as considering both retrospective and prospective components of the economy, effectively canceling out the efforts of politicians to manage the economy for electoral gains (Lewis-Beck 1988). Arguments about the long-term effects of democratic regimes on economic performance also ignored a host of institutional factors that have considerable impact on economic policy-making and performance. States with democratic regimes, for example, display considerable diversity in their structures of interest aggregation and articulation: they thus offer considerably different prospects for particularistic interests to gain access to policy makers and correspondingly different opportunities for policy makers to act autonomously. More importantly, economic performance is closely linked to the specific features of non-regime institutions. The structure of financial system intermediation and of the trade union movement, for example, have powerful effects on growth, inflation, and unemployment rates as well as on the capacity to adjust successfully to international economic change. Broadly similar arguments about the developing world attribute level of development more to specific institutions such as bureaucratic structures and financial systems than to regime types. Indeed, numerous studies have demonstrated that even authoritarian regimes frequently sacrifice long-term investment to short-term political calculations, and that democratic regimes often have the legitimacy and popular support needed to enact painful reforms.

Policy History: State and Economy

The appropriate relationship between state and economy has been one of the central faultlines of political debate, policy conflicts, and scholarly debates for centuries. Scholars are no closer to reaching consensus on these issues at the beginning of the twenty-first century than they were when Adam Smith first published *The Wealth of Nations* (1776). Yet despite the venerable nature of this faultline, there have been remarkably few efforts to provide a history of the centuries old debate on the most desirable relationship between state and economy. This article represents a preliminary effort to sketch out a brief history of these policy debates, concentrating on the nineteenth and twentieth centuries. The critical ingredients of this history are doctrines, global constraints, and theoretical confusions.

1. Doctrines

The terms of debate on the relationship between state and economy over the last two centuries is radically different from what came before. For centuries, European governments used a variety of mercantilist practices to enhance the economic growth of their territories by setting up barriers against imports, investing in education and technology, providing concessions and other support to promising enterprises, and establishing relief policies to protect the poor from economic hardship (Heckscher 1934, Reinert 1999). There is disagreement over when and how effectively these mercantilist practices were codified into a coherent body of economic doctrine, but there is consensus that for centuries, the use of governmental power to enhance economic development was seen as legitimate and desirable.

The classical economists, particularly Ricardo and Malthus, fundamentally changed the terms of discussion by conceptualizing the economy as an autonomous entity that is governed by its own principles, such as the law of supply and demand. Both Polanyi (1957) and Rothschild (1992) stress the important discontinuities between Adam Smith and the later writers of the classical school. Writing in the shadow of Newton's scientific achievements, they imagined that the workings of the economy were similar to the harmonious movements of the planets in the solar system that could now be fully explained by the laws of physics (Redman 1997). In searching for the economic equivalents of the laws of physics, the classical economists generally viewed the state as an 'outside' force whose actions were likely to interfere with the economy's capacities for self-regulation. In fact, their arguments against various mercantilist policies often emphasized that government actions were likely to have perverse consequences—opposite to those initially intended—precisely because such actions

would disrupt the natural and self-regulating operation of economic laws (Hirschman 1991).

The classical economists recognized that there was a fundamental tension between their abstract model of an economy and the real world in which human beings were organized into separate nations governed by states. Just as their mercantilist predecessors, they were writing in order to shape the policies of their own government; they recognized that their vision of the proper organization of the economy could only be implemented through the use of the state. Hence, they distinguished between appropriate government policies—those that supported the full emergence of the economy as autonomous—and those government policies that were inappropriate—that were likely to retard or interfere with an autonomous economy. But while the classical economists agreed on this distinction, they were unable either to define precisely where this dividing line should be drawn or to develop a theoretically sound justification for its location. In fact, they had profound disagreements among themselves on where the line should be drawn. Despite the centrality of free trade to the classical tradition, one of its key thinkers—Malthus—argued consistently that it was appropriate for England to retain the Corn Laws that limited agricultural imports. John Stuart Mill, who played a critical role in codifying classical economics, also entertained a variety of heterodox policy ideas (Schumpeter 1954).

1.1 Purists and Pragmatists

This inability to derive the proper functions of the state from their abstract model of the economy has characterized the mainstream tradition of economic thought through the entire nineteenth and twentieth centuries (for accounts of this tradition that are less Anglo-American centered than most, see Schumpeter (1954) and Screpanti and Zamagni (1993)). The result has been a continuous tension within the tradition between 'purists' and 'pragmatists.' The purists argue that since we know that expanding the scope of markets improves economic efficiency, it follows that international free trade is always preferable to any form of protectionism. Furthermore, since governments can subvert free trade by providing subsidies to their own producers or by using regulations to discourage imports, it follows that a domestic regime of *laissez faire* in which government exercises the smallest possible role in the economy is to be preferred. Pragmatists, in contrast, starting with John Stuart Mill, have argued that precisely because the real world of actual economies diverges from the abstract model, there is an affirmative role of government that extends beyond establishing the minimal conditions for private contracting. Pragmatists have differed among themselves as to what government actions they would endorse, but some have favored tariff protection of

infant industries, extensive regulatory regimes to overcome market failures, substantial measures to redistribute income, and the provision of a wide variety of public goods, including government participation in planning of the economy's future growth path (Hutchison 1978 is particularly valuable in tracing out the pragmatism of Jevons, Marshall, and Pigou).

But this longstanding argument between purists and pragmatists within the central tradition of economics has usually been overshadowed by conflicts generated by two other important sets of ideas. The first is the challenge to the market model posed by socialist ideas, particularly those of the Marxist tradition. The second is the emergence of a counter tradition in economics that rejected both the methodology and the free trade preferences of the classical tradition.

1.2 Socialism

The socialist tradition predates Marx and includes a range of different theoretical currents, but the Marxist current has been the strongest for almost a century and a half. Moreover, it was Marx who effectively defined the intellectual achievement of the classical economists; he argued that they were the theorists and apologists of the emerging bourgeois social order whose triumph was signaled by the French Revolution. For Marx, this new social order was a coherent system that revolved around the imperatives of profit maximization. Precisely because the capitalist mode of production was a unified system, efforts to reform it were fundamentally futile. Marx repeatedly insisted that the only way for the working class to advance its collective interests was by a revolution that replaced capitalism with a radically different social order in which markets, private property, and the pursuit of profit would be eliminated.

By the end of the nineteenth century, the Marxist tradition developed its own division between purists and pragmatists. Purists continued to oppose any efforts to reform capitalism as inherently futile since they viewed it as impossible to change capitalism's fundamental logic. Pragmatists argued that meaningful reforms could be won that would strengthen the economic and political position of the working class and make possible further advances in the direction of socialism. Since the pragmatist position often resonated with the views of non-Marxist socialists and with the views of reformists in the trade union movement, it played an important part in expanding the state's role in the provision of social insurance, the regulation of industry, and the redistribution of income (Sassoon 1996, Hicks 1999).

While purists in the Marxist tradition and purist defenders of the free market have been bitter antagonists, it is worth stressing that they share certain common assumptions. They both insist that the only

real alternatives for organizing societies are free market capitalism or socialism. They both see any effort to mix socialist and capitalist principles within a single society to be inherently unstable; sooner or later the instability will be resolved by movement to one of the stable poles. Moreover, they have the same view of the globe—that a world divided between socialist and capitalist societies is unstable; the world ultimately will have to be organized by only one of these principles.

1.3 The Counter Tradition

Marxism, however, was not the only oppositional doctrine that was spawned by the theoretical achievements of the classical economists. Starting as early as the 1820s, a counter tradition emerged that challenged both the classical economist's emphasis on the desirability of free trade and their methodological assumptions. But while important work has been done in this tradition in virtually every decade from 1820 to 2000, the identification of this counter tradition is largely retrospective (Reinert 1999). It does not have either the organizational or the doctrinal continuity of either mainstream economics or Marxism. Its founding figure was the German, Friedrich List, who argued that the policy proposals of the classical economists were not universally applicable; if poorer nations were to embrace free trade without qualification, they would never be able to catch up with the world's leading economic power—England. List advocated the use of governmental powers, including tariffs to protect infant industries, as a means to accelerate development of the economy's 'productive forces' (Henderson 1983). The American economist, Henry Carey, also made important early contributions to this counter tradition.

The counter tradition was further elaborated in the 1870s and 1880s by the younger generation of the German historical school, especially in the writings of Gustav von Schmoller. Schmoller rejected both the 'classical tradition' view of the economy as autonomous and their *laissez faire* policy prescriptions (Schumpeter 1954). The German historical school, in turn, inspired both the first generation of academic economists in the United States (Ross 1991) and a group of English historical economists, including William Cunningham, J. W. Ashley, and W. A. S. Hewins who revisited English economic history and found powerful evidence that English economic development had depended heavily on state policies (Koot 1987). In the first part of the twentieth century, further contributions to the counter tradition were made by the American institutionalists and the English Fabians. In the 1930s, despite his orthodox intellectual lineage, John Maynard Keynes joined this counter tradition by breaking with free trade and advocating active government management of the economy. From

the 1930s through the 1970s, this counter tradition was enriched by a broad range of scholars including Japanese economists who are little known in the West (Gao 1997), the Latin American group around Raul Prebisch that developed the idea of import substituting industrialization (McMichael 1996), and others. A particularly important contribution was the study of late-industrializing countries by Gerschenkron (1962).

Political leaders in late-industrializing countries have turned repeatedly to theorists of this counter tradition to help develop policies to accelerate their nation's development. Count Witte, the Russian modernizing minister under Tsar Nicholas II had studied List closely before taking office and followed many of List's policy prescriptions (Henderson 1983, pp. 215–17). After the Meiji Restoration in Japan, the most influential economic work was that of the German historical school. As Gao writes, 'The intellectual roots of Japanese developmentalism can be traced to the German historical school' (Gao 1997, p. 60). More recently, the spectacular economic advances of the South Korean and Taiwanese economies have been attributed to the influence of developmentalist policies inspired by the counter tradition (Wade 1990, see also the important book by Evans 1995).

The boundary lines separating these various currents of economic doctrine have sometimes been vague and indistinct. In the twentieth century, the dividing line between pragmatists within the mainstream tradition and proponents of the counter tradition has been crossed by major figures. (There are also important figures whose work spans the boundary line between Marxism and other traditions; of particular interest are those who have contributed to the theory of market socialism.) Two of the greatest economists of the twentieth century—Keynes and Schumpeter—can legitimately be claimed by both the mainstream and the counter tradition. A further complication is that the mainstream tradition of Anglo-American economics whose successive paradigms were codified by J. S. Mill, Marshall, and Keynes, entered into crisis in the early 1970s. As the influence of Keynesian ideas declined, no single theory has become dominant and the tradition has splintered into a number of conflicting views (Heilbroner and Milbert 1995). This is the theoretical context in which the political influence of the purist wing of the tradition has increased dramatically in the USA and throughout the world.

2. Global Constraints

It would be a mistake to imagine that political leaders have been free to choose among these diverse doctrines in deciding what role the state should play in their particular economy. On the contrary, these diverse doctrines have existed within a global structure of power that has constrained and limited the choices of

political leaders. But this global structure of power has itself been in continuous flux, so that the severity of the constraints has varied considerably over time. Moreover, the constraints also vary within different historical periods; some countries have had more freedom to maneuver because of the specifics of their location.

The constraints are a direct result of successive national hegemonies over what Wallerstein has termed 'the modern capitalist world-system' (Wallerstein 1974, Arrighi and Silver 1999). Dutch hegemony was established initially in the seventeenth century, but it gave way, after an interregnum, to English hegemony in the early years of the nineteenth century. England's hegemony was undermined first by World War I and then by the global economic collapse of the early 1930s. After another interregnum, the US emerged as the new hegemonic power in the final years of World War II. Moreover, the geographical scope of this capitalist world-system has steadily expanded from its European core so that by the middle of the twentieth century, it encompassed the entire globe.

Hegemony represents a combination of economic, military, and cultural power. In the nineteenth century, for example, the new ideas of the classical economists were a constitutive part of the English-dominated global order. Other nations were under pressure to adopt the ideas of free trade and *laissez faire* as a way to gain access to English capital, to avoid England's military wrath, and to partake in the industrial modernity that England exemplified. The same point can be said of US hegemony in the second half of the twentieth century; it is impossible to determine whether the influence of US-sponsored economic doctrines has more to do with financial power, military power, or the powerful imagery of Hollywood and Madison Avenue.

2.1 A Rough Periodization

Even in England, there was a considerable time lag between the writings of the classical economists and the full embrace of free trade. It was only with the repeal of the Corn Laws in 1846 that England began exerting considerable pressure on other nations to embrace the doctrines of free trade and *laissez faire*. Hence, the period from 1850 to 1875 can be thought of as the first great epoch of free trade. During this period, most European nations lowered their tariff barriers and made at least some efforts to embrace *laissez faire* (Chase-Dunn et al. 2000). By 1870, many nations had embraced the gold standard by making their currencies freely convertible into gold (Eichengreen 1996). The gold standard represented the fullest expression of English hegemony, since it was designed to equilibrate automatically the global economy without governmental interference.

The dynamic shifted sharply in the next period from about 1875 to 1900. This was a period of slower

growth and declining prices that in combination with the gold standard placed severe pressures on national economies (Polanyi 1957). The result was a marked retreat from both free trade and *laissez faire*. Tariff barriers increased significantly in this era (Chase-Dunn et al. 2000), and rising protectionism was clearly a component of the rush for empire as the European powers, the US, and Japan moved to establish formal colonies (Polanyi 1957). The trade barriers meant the potential loss of access to both markets and raw materials in those regions that had been colonized by other powers. Moreover, national regulations to control market forces expanded dramatically; this was the era in which government-sponsored social insurance was first developed and began to spread.

The brief period from 1900 until the outbreak of WW I is an anomalous and contradictory era. On the one side, the pendulum swung back in the direction of lowering trade barriers (Chase-Dunn et al. 2000), and international capital movements reached unprecedented levels in this period as the global financial system became more tightly integrated. On the other side, there were few signs of a return to *laissez faire*; the state's role in managing domestic economies and providing social welfare continued to expand in many nations. Governments were under increasing pressure to make concessions to socialist movements that were growing in power and influence. Moreover, in this period, late-industrializing nations, such as Russia and Japan, did not hesitate to use governmental power to accelerate the processes of industrial development. Moreover, the intensification of the military rivalry between England and Germany in this period was very much a continuation of the imperialist conflicts that had emerged in the previous period.

Between 1914 and 1945, nineteenth-century civilization collapsed, and it appeared that the ways of thinking about state and economy developed by the classical economists had become completely obsolete. From Bolshevism to fascism to the experiments of the New Deal, it seemed that there were a multitude of divergent paths for organizing national economies (Polanyi 1957). Moreover, the imperatives of war meant that the major powers, even those that retained democratic institutions, went through extended periods of time when economic life was completely subordinated to political and military control. While much of Asia and Africa remained under colonial control, the larger Latin America nations were able to take advantage of the breakdown of global power to follow the teachings of the counter tradition (McMichael 1996). The overwhelming reality of this period was the human suffering generated by war, dislocation, depression, and unprecedented violence directed at civilians.

During the first period of US global hegemony from 1945 to 1973, the USA struggled, with the help of multilateral institutions, to limit the range of permissible variations in national economic policies. This

meant an intensification of the Cold War to restrain the growth of socialism that had spread to Eastern Europe and China. The process of decolonization meant that this battle was now fought out over a far larger group of nations. But while the USA pushed strongly in this period for trade liberalization, there was no effort to restore *laissez faire*. It was taken for granted that, as with the New Deal regime in the USA, the government would play a large role in the domestic economy in managing the business cycle, regulating private firms, and producing a broad array of public goods. In this period, the pragmatists within the mainstream tradition of economics were dominant with their vision of a mixed economy. The ability of governments to pursue macroeconomic objectives was facilitated further by global rules that severely restricted international capital movements. Even poorer countries were expected to develop ambitious development plans and an elaborate system of foreign aid emerged to finance these efforts. Yet these efforts were biased strongly towards a model of development led by the private sector and countries that were too aggressive in fostering state-led development were pressured to stop (Wood 1986). A few nations, such as South Korea and Taiwan, were able to resist these pressures because of their location close to the fault lines of the Cold War, but their experience was deeply atypical (Wade 1990).

Finally, the period from 1973 to 2000 is the second great epoch of free trade. The steady progress towards reduction of trade barriers that began in 1945 was continued, and it was now joined by the elimination of barriers to international capital movement. The integration of global financial markets reached levels that had only previously been attained in the period between 1900 and 1914. Starting in the late 1970s, with Margaret Thatcher and Ronald Reagan, and intensifying after the collapse of the USSR, the old doctrines of the classical economists were now recycled under the rubric of neoliberalism. *Laissez faire* ideas were reintroduced on the grounds that government efforts to manage the business cycle were futile and excessive levels of taxation and regulation were destroying the vitality of market economies. Trade negotiations were now expanded to dismantle 'non-tariff barriers' that included domestic legislation that had the unintended consequence of discriminating against foreign products. Developing nations were told to scrap their planning processes, to privatize state-owned enterprises, and to end subsidies that made food, transportation, and housing more available for the poor (McMichael 1996).

3. Theoretical Confusions

In reviving *laissez faire*, neoliberals assume that they can distinguish between the legitimate, albeit limited, responsibilities of government and those illegitimate

government actions that are bound to have perverse consequences. But neoliberals have been no more successful than their classical predecessors in providing a theoretically justified demarcation line. That this problem has not been solved after two centuries of work suggests that there are deep theoretical confusions operating here.

3.1 Can the Economy be Autonomous?

The fundamental problem lies with the assumption, introduced by the classical economists, that an economy can be organized around a set of self-regulating markets. Even with the added stipulation that there will be a state and a legal system that enforces property rights and contracts, this is still not enough. This point was elaborated most forcefully by Polanyi (1957), a Hungarian refugee intellectual who developed his own theoretical synthesis drawing on insights from Marxism and the German historical school. Polanyi argued that the flaw in the belief in an autonomous economy is that land, labor, and money are not true commodities; they are not things that were produced for sale on a market. Economists assume, however, that the price mechanism will equilibrate supply and demand for these fictitious commodities just as it does for true commodities. The difficulty is that when the demand for labor suddenly falls, human beings cannot be warehoused like unsold merchandise; those who are out of work must still have income. Similarly, countries that leave it to the market to determine the supply of money and credit are likely to suffer from chronic deflation when credit is too scarce or chronic inflation when it is too abundant. With labor, money, and land, a continuous governmental role is needed to make the market for these fictitious commodities work like other markets.

In short, a market economy cannot be autonomous because the state is involved intimately in three of the most important markets. What follows from this insight is that capitalism, defined as a society organized around an autonomous market in which actors seek to maximize utility, has never existed. Polanyi went on to argue that the market societies that actually exist are constituted by two opposing tendencies. The first are the ongoing efforts to expand the scope of markets—the project first announced by the classical economists. The second are parallel efforts to protect the social order from the consequences of market competition that includes regulatory efforts, social welfare policies, and other macroeconomic policies. Polanyi emphasizes that business firms participate in both of these tendencies, since they often need to protect themselves from market situations where uncertainty is uncomfortably high.

In recent years, scholars have produced a body of work that elaborates this Polanyian insight by

analyzing the existence of a number of varieties of capitalism that vary significantly in the way that key markets are organized and in the relationships between state and economy (Block 1994, Crouch and Streeck 1997, Hollingsworth and Boyer 1997). These studies represent a fundamental challenge to the assumptions of both mainstream economists and Marxists that market societies should converge towards some common pattern. At the same time, however, some commentators (Gray 1998) have expressed concern that the neoliberal rules of the global economy might have the consequence of destroying varieties of capitalism that are actually more efficient than the Anglo-American type.

3.2 Transition to a Borderless World

A second theoretical confusion has to do with the tension between a unified global market and a world of nation states. Both the classical economists and contemporary neoliberals have been motivated by a vision of a peaceful planet in which military rivalries and warfare are replaced by the competition of individuals and firms to reach higher levels of efficiency. Both have imagined a gradual withering away of the nation state as the globe becomes economically unified. While there is much that is appealing in this vision, there has been a lack of clear thinking about the actual staging of this transition to a borderless world.

Ironically, the historical periods in which this vision has been most influential were marked not by the disappearance of state power, but by the unchallenged military and political hegemony of a single power—first England and then the USA (Kindleberger 1973). The temporary dominance of a single power hardly seems a sound foundation for a transition to a world beyond nations. A closely related problem is that this transition requires that nations give up the various measures that buffer their populations from the pressures of the global economy just as those pressures are intensifying. Creating a unified global market for agricultural goods, for example, requires that governments dismantle programs designed to stabilize the income of farmers just as those farmers are becoming more vulnerable to cheaper agricultural imports. The neoliberal vision rests on the willingness of millions of ordinary people—farmers, workers, and small businesspeople to be extraordinarily flexible—to accept that years of reasonable income periodically will be interrupted by years in which their income might fall by as much as 40–60 percent. (These figures reflect income losses in Asia and Mexico in the financial crises of the 1990s.)

For the affluent, such flexibility might seem logical and reasonable; they know that years of high returns on their portfolios can alternate with periods of

negative returns. But those who lack an investment portfolio tend to resist this type of flexibility; their ability to pursue a life plan depends on some stability and predictability in their income flows. When such people are able to exercise political influence on their national leaders, they demand to be protected from extreme instability of their income. This is precisely what happened in the period from 1875 to 1900; ordinary people demanded to be protected from the costs imposed on them by global economic integration, and the result was a significant retreat from global free trade. Moreover, if governments are constrained by global power and are unable to respond to these popular demands to be protected from income instability, discontent does not disappear. It is often channeled into militant movements of the left or of the right that target both the ineffectiveness of the government in power and the foreign enemies who have imposed economic hardship on the local people. The efforts of centrist political leaders in the 1920s and 1930s to restore the gold standard and a liberal world economy were defeated by these types of movements. The deep historical irony is that the effort to create a pacified, borderless world produced exactly the opposite; extreme forms of nationalism and war on a global scale.

4. Conclusion

The period from 1973 to 2000 has seen unprecedented growth in a variety of indices of economic globalization. However, these theoretical confusions about the autonomy of the economy and the transition to a borderless world raise concerns about the sustainability of these trends. How the organization of economies and states will evolve remains an open question.

Policy Information

Information is used by governments for a wide variety of policy purposes. It can be used in the formulation of public policies, by helping to identify the need for a public policy, or to select one among alternatives. It can be used in the implementation of policies, to help target or improve programs. It can be used in the evaluation of policies, such as measures of progress toward desired outcomes, or of the intended or unintended social, economic, and environmental effects. Here, however, *policy information* is taken to mean information used in the formulation, design, and selection of public policies. It may also include information from the evaluation of public policies to the extent that effects of the policies inform consideration of alternative policies.

Policy information differs from political information, such as polls of public opinion, or of support for a policy among legislators. Policy information is objective. It may be quantitative or qualitative, but it is based on evidence, rather than opinions, attitudes, or beliefs (see Citro and Hanushek 1991). Policy information comprises both data and analysis. Indeed, it is often the result of *policy analysis*, by which is meant the objective prospective, and sometimes retrospective, evaluation of the social and economic implications of changes in public policy. For example, in considering choices among social welfare policies, decision makers typically want to know what populations would be affected, in what ways, and at what cost. Policy analysis provides answers to these 'what if' questions. In order to inform choices among policy alternatives, policy analysis involves forecasts or projections into the future. As a result, they are more uncertain than evaluations of the past. Three key ingredients of policy analysis are data; analytical models, including their documentation and validation; and effective communication of the results to policy makers, in particular of the assumptions in models and uncertainty in estimates.

1. Data

Accurate and relevant data are critical for policy analysis. Government surveys are a common source (see *Government Statistics*). Since the behavior of individuals in response to decisions of employers or government agencies is often what is being modeled, data may be needed on the interactions of individuals with organizations and institutions. For example, an individual's access to health care services will depend on providers, insurers, and government health care programs and policies. Often, however, data are available only on a single unit, such as an individual, family, or firm. In this situation, analysts must meld together data from different sources.

Useful sources of data to augment survey data are administrative records, such as health care claims, tax returns, earnings reports for social security, and case files from public assistance programs. Such data may need to be linked, or matched, to the survey data. Increased concern in government statistical agencies about possible violations of the confidentiality of survey data, however, militate against such linking. Analysts in this situation must make assumptions, the validity of which the analysts may not be able to determine without the linked data.

As important as the availability of data is, it is not sufficient. Data for public policy analysis must reflect relevant and accurate measurement. For this reason, government statistical agencies need to conduct research on concepts, definitions, and measurement, and assess the quality of their data. In the highly decentralized statistical system in the United States, however, it is not uncommon for agencies to report different measures from different surveys of ostensibly the same concept, such as income, employment status, or disability. Efforts may be made to explain the differences, or a result from one survey may be adjusted, or controlled, to agree with the result from a more prominent survey. Good policy analysis, however, requires integrated databases with the best estimates that can be developed from multiple sources.

Policy analysts, as well as other sophisticated users, cope with the lack of integrated data by performing additional adjustments to make the data suitable for modeling and analysis. But not all users have the information, much less the resources, to do so. And those that do may either duplicate efforts of others or, much worse, wind up with different results.

2. Models

Models are fundamental tools of policy analysis. *Microsimulation models* are one important type of policy analysis tool. With data from individual records, a microsimulation model simulates how the records change over time and as a result of a proposed policy. To predict the effect of a change in tax law, for example, the model processes records for people as if they were filling out their tax forms. As Citro and Hanushek (1991) note:

Models based on microsimulation techniques are conceptually highly attractive because they operate at the appropriate decision level and take into account the diverse circumstances and characteristics of the relevant population, whether it be low-income families, taxpayers, or health care providers. Such models are able to respond to important needs of the policy process for information about the effects of very fine-grained as well as broader policy changes, the effects of changes that involve complicated interactions among more than one government program, and the effects of changes on specific population groups as well as total program costs and caseloads.

Microsimulation models, however, tend to be highly complex and expensive to develop and maintain. Because of the lack of integrated data, analysts using the models must often patch together a variety of data and research results of varying, if even known, quality. As a result, often many assumptions are made; and some are unsupported. Because of these problems, some analysts may rely on simpler models, akin to accounting methods, to understand the effects of changes in a program. But the value of microsimulation models in informing a policy debate is that they can model behavioral responses to changes in policies and programs.

Many other statistical models are also used in policy analysis, from linear regression models, to simultaneous equation models, to complex macroeconomic ones. Macroeconomic models are also tools for 'what if' questions. They are often used to make unconditional forecasts, such as the rate of growth of the economy, as opposed to conditional projections. In addition to these models, a cornucopia of social science methods are also employed in policy analysis, including cost-benefit studies, risk assessments, meta-analyses, and even social experiments.

While microsimulation models seek to answer 'what if' questions, other models seek to answer 'why' questions, such as why people save, or fail to save, and to provide estimates of relationships that may be used in microsimulation models. Sometimes the research model may not be explicit, as when a database is constructed by piecing together data from different sources, in particular to determine a trend for which there is no survey-based indicator, such as the retention of children in the same grade in school. Sometimes the model may be difficult to ascertain, because political factors must also be taken into consideration; for example, in formulas used in legislation to allocate funds to school districts according to the numbers of children from families with incomes below the poverty level.

3. Uncertainty

Even when the model is explicitly clear, however, its uncertainty may be unclear. The estimates from models in policy analysis are conditional forecasts of the effects of a policy change. The effects may be poorly understood. They may be unknown or depend on unknown factors. The model relating cause and effect may be incorrect; or it may be uncertain as to which of many factors contribute to the effects. Moreover, the lack of data is a ubiquitous problem.

The understanding, however, of the effects of a proposed policy is important, if decisions on it are to balance the benefits against the costs. Key to that understanding are reasonable judgments about the quality of estimates of the likely effects of a proposed policy change. Policy makers need to understand the

uncertainty or variability in the estimates and to judge the track record of a policy analysis model. Unfortunately, they are rarely given the information to enable them to do so.

3.1 Model Validation

Assessing the quality of model estimates is a common problem in statistical research, but the problem is compounded in policy analysis, because it involves conditional forecasts. Some, if not all, of the policy alternatives studied may not be adopted. And, even for alternatives that are, data may never become available on the outcome. Yet it is crucial to understand the uncertainty in model estimates, if only to evaluate the utility of different models. *Model validation* is the process for measuring the uncertainty or variability in a model's estimates and identifying the sources of that uncertainty (Citro and Hanushek 1991).

One technique of model validation is *external validation*, in which the model's estimates are compared with the outcomes the model is forecasting. Because the outcomes may never be known, however, two variants of external validation may be used. One is *ex post forecasting*, in which one takes a policy or program change adopted in the past and, applying a model to data available then, forecasts the effects in a more recent past year when outcome data are available to compare. Another variant is *backcasting*, in which the model and current data are used to simulate the effects of a reversion to program conditions in the past, and the results are compared to measures of the effects based on data in that period.

Internal validation refers to studies of the model, its components, and how it is used, as well as of the data used. Measures of internal validity derive from the data used and model estimates obtained, without any comparison to external reality. They include sampling variability and other errors in the data or other inputs, and errors of model misspecification. Estimates of variability may employ standard sample variance calculations or more modern resampling techniques. *Sensitivity analysis* looks at the effects on model estimates of changes in one or more assumptions, specifications, or components of the model. It is used to determine the factors that most affect the results, or how robust the results are to changes in assumptions.

3.2 Documentation

Documentation of data, models, and analyses is important, not only for validation studies but also for a better understanding of the model estimates and their quality. Documentation should include information on the policy alternatives under analysis, the data and other inputs, assumptions, interpretations,

and changes made. The information should be specified in sufficient detail so that another person could replicate the results. Otherwise, the utility of the model may be limited to only a few analysts who are experienced in its use. Moreover, as models invariably grow in complexity, even experienced users may not understand the implications of underlying assumptions, or how components of the model interact.

3.3 Communication of Uncertainty

Policy analysts should include information about the uncertainty of their estimates and the sources of that uncertainty in the presentations of results to policy makers. Sampling variability is often the most straight forward to calculate and report, but it neglects errors due to model misspecification, nonsampling errors in surveys, and other factors. Efforts should be made to convey a more complete description of uncertainty through a variety of techniques, including variance calculations, sensitivity analysis, and the proven record of a model.

It is important for policy makers to understand the uncertainty attendant in model estimates, for a number of reasons. First, the information on uncertainty allows them to distinguish differences from those that could occur solely by chance. Second, they can use the information to compare the quality of different estimates. Third, the information may help them decide how much weight to give to a policy analysis, as opposed to other, political considerations.

But there is an even more important reason for agencies that are responsible for policy analysis to measure and communicate the uncertainty in data and model estimates. It is only through such measures of quality that resources to improve the data and models can be justified. For example, in the United States, many national surveys are so sparse that they are unable to provide direct survey-based estimates for all but a handful of states. National policy makers have devolved some programs to the states, such as children's health insurance and welfare reforms, and expect estimates of outcomes to hold states accountable. The estimates can be modeled, but their much larger uncertainty than that for the national average must be communicated. Not only would policy makers know if a reported difference reflects a real difference; they could see the need to invest resources to improve data or models, or both. For example, the sample size of the Current Population Survey has been increased to improve estimates, in each state, of the numbers of children covered by health insurance.

4. Organization of Policy Analysis

Agencies conducting research in support of public policies in a department of government must an-

ticipate policy issues if its research is to inform the policy debate when it occurs. As a result, a policy research agency may invest resources in research on policy issues for which it may never be asked for the results. When consideration of an unanticipated policy comes to the fore, the agency must be able to draw upon a synthesis of research or a review of extant data to provide the required policy information. For that reason, the policy research agency must develop data and research continually, and be cognizant of that developed elsewhere in the important subject matters of its department.

The national government may provide for unsolicited basic and applied research, in particular in academic institutions, but policy analysis rarely, if at all, is a byproduct of this research. Moreover, policy research conducted by private organizations with a stake in the outcome may not be objective. Effective policy analysis, therefore, can neither be delegated to academia nor to interested organizations. Government policy analysis agencies must either conduct or direct the research. In doing so, they may draw upon research conducted by a wide variety of institutions, such as quasi-governmental organizations, universities and academic research institutes, private foundations and other nonprofit organizations, and for-profit consulting firms.

Policy analysis in a department of government may or may not be the responsibility of a distinct, independent unit. For example, the United States has many units in the executive branch with responsibilities for policy analysis, such as the Office of Tax Analysis in the Department of the Treasury, and the Office of the Assistant Secretary for Planning and Evaluation in the Department of Health and Human Services, but no single unit in the Department of Transportation is responsible for policy analysis. Moreover, policy analysis need not be the responsibility of just the executive branch. The US Congress has developed policy analysis capabilities, through such agencies as the Congressional Budget Office, the Joint Committee on Taxation, and the Congressional Research Service, to counterbalance the policy analysis capabilities in the executive branch.

For government policy research agencies, maintaining independence from the political process itself is essential to the agency's effectiveness. 'Research in support of public policy depends for its credibility, in great part, on its conduct by those with a greater interest in the quality of the work than in the substance of the conclusion' (Geweke et al. 1999).

5. Conclusion

Developing information to inform debate on public policies requires data, models, and an understanding of uncertainty in the resulting estimates. By far the

most common problem and the bane of policy analysts is the lack of adequate data. When a panel of the National Academy of Sciences–National Research Council was asked by the US Department of Labor to advise on the development of models to assess policies for retirement income, the panel concluded instead that priority be given to funding data collection and behavioral research in preference to significant investments in large-scale projection models:

Generally speaking, it takes more time to collect new data and analyze them than it does to build a model to use data and research results. There are more than a few instances in the history of policy analysis when complex projection models were built in a span of weeks or months. It is rare that a critical unmet data or analysis need can be supplied in that short a time. (Citro and Hanushek 1997)

Government, the panel concluded, must take the lead in data collection, so that high-quality, comprehensive databases are available for policy analysis use in all sectors—government, private, and academic.

Policy Knowledge: Advocacy Organizations

Substantive policy knowledge is a set of beliefs that encompass perceptions of (a) the seriousness of various dimensions of a policy problem (e.g., the health impacts of air pollution, the declining quality of health

care), (b) the relative importance of various causes of those problems, and (c) the expected impacts of policy options for changing current conditions. In conflicts between advocacy organizations that pursue their interests through the policy-making process—including interest groups, corporations, administrative agencies, and associations of governments—debate surrounding the various elements of policy knowledge is often technical in nature. These debates frequently employ scientific research, technical policy analyses (such as benefit/cost analyses), and policy evaluations that follow scientific norms of data acquisition and analysis.

There are four main frameworks for examining the nexus between substantive policy knowledge and the political behavior of advocacy organizations: (a) a ‘civics textbook’ approach; (b) an ‘atheoretical skeptics’ perspective; (c) the ‘multiple streams’ approach; and (d) the ‘advocacy coalition framework.’ All vary in their attention to the political process underlying public policy debates and the potential biases inherent in substantive policy information.

1. The Civics Textbook View of the Role of Science

This is basically a normative model, derived from certain fundamental principles of democratic theory. It assigns very distinct roles to three categories of actors in the policy process:

Elected officials are responsible for making basic policy decisions in a manner which reflects the distribution of values in society. They use scientific findings to help them understand trends in various problems, the factors affecting them, and the means of alleviating those problems. Their basic role is to establish clear laws and budgetary priorities for implementation by agencies.

Governmental agencies are composed largely of civil servants who should be politically neutral (i.e., faithfully implement whatever the legislature decides) and who have a special role in fostering applied research in areas of interest to the agency. Political appointees within the agency are responsible for seeing that the agency reflects the government’s priorities—to the extent permitted by law.

Scientists are supposed to be neutral seekers of the truth. Their role is to understand the world and to present this information to policy-makers.

This is a normative model of how science *should* be used in making public policy, and many scientists involved in policy disputes do, in fact, view themselves as ‘objective technicians’ (Meltzer 1976).

According to this model, the major problem impeding communication between scientists and governmental officials is that they inhabit two quite distinct communities with different value priorities, time-frames, and methods for resolving conflict (Dunn

1980). Proposals for reform thus focus on improving communication between the two communities by exchange programs, the development of facilitating or 'translating' institutions, etc.

The textbook model has substantial limitations in practice, in large part because most actors do not behave as the model indicates they should.

Elected officials seldom pass clear laws on contentious issues with substantial technical components because very few have the expertise to obtain a decent understanding of the technical issues. Instead, they tend to pass procedural or 'framework' laws which hand over the problem to an administrative agency without clear policy priorities.

Agency officials are seldom as neutral as the civil servants in the Weberian model of bureaucracy (Knott and Miller 1987). Most agencies have a fairly clear overall mission which tells them to give priority to some values over others. Most officials who join the agency come to accept those priorities, whether out of self-selection or gradual indoctrination. Agencies are often dominated by members of a particular profession or scientific discipline who share the norms of colleagues outside the agency. Thus, most agencies can be expected to sponsor research consistent with their mission and to be skeptical of findings which cast doubt on its wisdom.

Scientists are often not neutral participants. Virtually all scientists operate within a specific 'paradigm,' i.e., a set of often implicit assumptions about basic causal assumptions and proper methods of investigation which guide research (Kuhn 1970). More importantly for our purposes, almost all scientific disciplines contain important normative assumptions which members often come to accept in an uncritical fashion. The normative assumptions behind welfare economics and benefit/cost analysis have been widely discussed (Rhoads 1985). With respect to nuclear waste disposal, Barke and Jenkins-Smith (1993) provide evidence that biologists perceive significantly greater risks than physicists, chemists, and engineers. The latter think basically in terms of dose-response curves, while biologists are more wary of the effects of *any* dose on living organism.

Moreover, scientists are often drawn to applied—rather than basic—research because they want to help solve a particular problem. Having a demonstrable effect on policy normally requires the accumulation of results over an extended period of time (Weiss 1977). The more neutral and 'apolitical' scientists are unlikely to remain interested in an issue long enough to have such an impact. Thus the most active scientists in a particular dispute are likely to be those who have been involved the longest and who are most committed to defending a particular point of view.

The end result is that scientists who have something to contribute to important policy disputes are seldom neutral (Mazur 1981). The argument does not imply that they manipulate or falsify data. Instead, disci-

plinary paradigms, the values underlying their discipline, and their desire to solve particular problems affect the topics they choose to research, the variables they focus on, the methods they utilize, where they place the burden of proof in cases of uncertainty, and how quickly they present various results. For example, wildlife biologists are much more likely than engineers to look for species in trouble because their disciplinary norms define species extinction as a serious problem. They are more likely to look to human technological interventions as a likely explanation because they tend to respect the beauty of natural systems. In contrast, engineers assume they can improve on nature. Members within each discipline will readily present results which are congruent with these assumptions, while incongruent results are likely to be interpreted as tentative and in need of further verification (Brown 1977).

2. The Atheoretical Skeptics' View of the Role of Scientists in Policy Disputes

Over the years, a number of studies have seriously questioned the textbook view that scientists participating in policy are completely neutral. First, Weinberg (1972) argued that some topics—such as risk assessments of very improbable, catastrophic events—are essentially in the realm of 'trans-science.' Second, as argued above, there is increasing recognition that the topics chosen for research, the allocation of the burden of proof in areas of uncertainty, and the presentation of results are affected by scientists' disciplinary paradigms (Stewart 1986), organizational interests (Primack and von Hippel 1974, Jasanoff 1987), and/or policy concerns (Nelkin 1971).

Although suggestive, most of these studies have suffered from two serious limitations. First, they have failed to articulate a comprehensive theory (or theories) of the role of 'advocacy science' in the overall policy process. Instead, they have usually limited themselves to identifying certain institutional/organizational features that inhibit or exacerbate the extent of advocacy (Mazur 1981). But there is very little recognition of the role of broader social norms, economic conditions, and the myriad of advocacy organizations involved in most policy subsystems. Second, almost all of this research has consisted of essays or of rather traditional case studies which (a) lack explicit theoretical grounds for case and variable selection and (b) utilize quite subjective methods of data acquisition and analysis. The result has been a plethora of interesting arguments and illustrative examples, but very little systematic, intersubjectively reliable analysis of the extent of advocacy science, the factors affecting it, and its effects on the overall policy process.

3. *The Multiple Streams Framework of the Policy Process*

Drawing upon the 'garbage can model' of organizational choice (Cohen et al. 1972), Kingdon (1984) developed an approach to agenda-setting and policy formulation that deals explicitly with the role of substantive policy information. In his view, policy-making can be conceptualized as three largely unrelated 'streams':

(a) A *problem stream* consisting of information about real world problems and the effects of past governmental interventions. This would include large databases of problem severity and causes gathered by governmental agencies and research organizations, as well as policy analyses of the benefits and costs of previous attempts to address those problems. This information is treated as relatively unbiased.

(b) A *policy stream* consisting of proposals to solve one or more problems. This is the province of policy analysts in government think tanks and consulting firms, as well as many legislative staff. Kingdon notes the tendency for analysts to become infatuated with a particular solution and then to seek to apply it to a wide variety of problems. For the past 30 years, for example, many resource economists have viewed tradeable permit schemes as the solution to virtually all environmental problems (Tietenberg 1984).

(c) A *political stream* consisting of elections, legislative leadership contests, and other openly political competition.

According to Kingdon, major policy reforms result when a 'window of opportunity' joins the three streams. The window may be opened by a 'focusing event,' such as an airplane crash or oil spill, that dramatically illustrates the potential seriousness of a problem, or it can be opened by a political election that brings a new leader with a new agenda to power. In response to the window, major policy change will result if the policy community develops a proposal that is financially and technically feasible and if elected officials find it advantageous to approve it.

The multiple streams approach has a number of promising features. It gives a prominent role to substantive policy information about real world problems and the impacts of past governmental interventions. It was one of the first frameworks that treats researchers and policy analysts in consulting firms, think tanks, and universities as potentially important political actors. And it acknowledges the role of serendipity—particularly in the case of focusing events—in the policy process.

On the other hand, it has several limitations. First, we are not convinced that the problem stream is nearly as neutral and apolitical as Kingdon suggests. Bureaucracies gather information on some aspects of a situation and not on others. The US Department of Agriculture gathers much more extensive information on crop production and prices than it does on nitrogen

runoff from fields into streams and groundwater basins. Second, the conditions creating windows of opportunity need further analysis. Third, the multiple streams framework contains virtually no falsifiable hypotheses, and thus very little has been learned about its strengths and limitations over time (cf. Kingdon 1995, Chap. 10).

4. *An Advocacy Coalition Framework of the Policy Process*

The advocacy coalition framework (ACF) starts from the premise that political elites concerned with a specific problem or policy domain—such as transportation, education, health, or air pollution—will form relatively autonomous subsystems composed of interest-group leaders, administrative agency officials, researchers, and a few legislators with a specific interest in the topic. These subsystems (or policy communities) usually involve actors from multiple levels of government. Once a subsystem is formed, policy disputes become increasingly technical and specialized as actors learn more about the complexity of problems and solutions. In such a system, the role of legislatures and political parties is primarily to aggregate the decisions made by policy specialists and to provide some general guidance.

The ACF views policy change over time as primarily the result of competition among advocacy coalitions within a policy subsystem (Sabatier and Jenkins-Smith 1993, 1999). An advocacy coalition consists of interest-group leaders, legislators, agency officials, researchers, and even journalists who share a set of basic beliefs (policy goals plus critical perceptions of causal relationships) and engage in some degree of coordinated behavior in an effort to make governmental policy more consistent with those beliefs. Conflict among coalitions is mediated by 'policy brokers,' i.e., actors more concerned with fashioning an acceptable compromise than with achieving specific policy goals. While the framework focuses on competition among coalitions within the subsystem, changes external to the subsystem (such as fluctuations in socioeconomic conditions) and stable system parameters (such as constitutional rules) play an important role in major policy change.

The belief systems of advocacy coalitions are assumed to be hierarchically organized. At the highest/broadest level, the 'deep core' of a coalition's belief system consists of fundamental normative beliefs, such as the familiar Left/Right scale, that operate across virtually all policy domains. Within any given policy subsystem, however, it is the 'policy core' and the 'secondary aspects' that are most critical. The former consists of basic positions, some of them purely normative (e.g., the relative importance of different values, such as environmental protection vs. economic development), while others are a mixture of normative

and empirical (e.g., the proper scope of governmental vs. market authority for realizing those values), that operate across most or all of the policy subsystem. These policy core positions are very resistant to change, are only intermittently the subject of policy debate, and are usually changed as a result of perturbations external to the subsystem, although long-term 'enlightenment' may also play a role (Weiss 1977). Science plays a much more important role in the secondary aspects of coalitions' belief systems, as these involve disputes over the seriousness of a problem or the relative importance of various causal factors in different locales, the evaluation of various programs and institutions, and specific policy preferences.

The ACF assumes that members of a coalition will readily accept new evidence consistent with their views and seek to discount information which conflicts with their perception of the seriousness of a problem, the relative importance of various factors affecting it, or the costs and benefits of different alternatives (Lord et al. 1979). The result is 'a dialogue of the deaf?' in which members of different coalitions talk past each other. Given that policy core beliefs are resistant to change, the composition of coalitions is hypothesized to be stable over periods of a decade or more.

The ACF explicitly rejects the assumption that most bureaucrats and researchers involved in a policy area will be neutral. Some may well have no strong policy preferences, at least initially. But the framework contends that, as conflict between coalitions increases and as the interrelationships among sets of beliefs become clearer over time, initially loose groups with amorphous beliefs will coalesce into increasingly distinct coalitions with coherent belief systems; in the process, most neutral actors, particularly university scientists, will drop out. The ACF thus contends that, in well-developed subsystems, most agency officials and researchers who are active will be members of specific coalitions in terms of sharing a set of policy core beliefs and acting in concert to some degree (Sabatier and Zafonte 2000).

Policy-oriented learning involves relatively enduring alterations of thought or behavioral intentions that result from experience and/or the assessment of new information involving the precepts of belief systems (Hecklo 1974). Learning *within* coalitions is relatively easy, as members share the same value-premises and are looking for the most effective means to those ends. Learning *between* coalitions is much more difficult, as people from each coalition have quite different values and distrust each other. Nevertheless, the original versions of the ACF hypothesized three conditions facilitating such learning (Sabatier and Jenkins-Smith 1988).

(a) *Issues on which there is an intermediate level of conflict.* Issues have to be important enough to generate sufficient research—usually by members of several coalitions, as well as neutrals. On the other hand, issues involving conflict between the core beliefs

of different coalitions (e.g., the rights of non-human beings or the ability of humans to improve on nature) generate more heat than light. Learning across coalitions is thus most likely on issues involving important secondary aspects of the relevant belief systems.

(b) *Issues involving primarily the natural sciences.* Across-coalition learning is generally easier in the natural than in the social-behavioral sciences because the theories and accepted methods are better established and the objects of study are not themselves actors in the policy debate.

(c) *The existence of a forum* that is (i) prestigious enough to force professionals from different coalitions to participate and (ii) dominated by scientific norms. The latter assures a general consensus on the appropriate rules of evidence and a minimum of *ad hominem* attacks, as well as some attention to underlying assumptions. Possibilities for professional forums include 'blue ribbon' committees appointed by the National Research Council or a professional association, studies by organizations with a strong reputation for neutral competence (e.g., the Congressional Budget Office), or, in some cases, inter-agency technical advisory committees.

The following set of conditions have been developed for successful professional forums, i.e., those in which experts from the competing coalitions come to consensus on technical and/or policy issues placed before it. In general, such forums are most useful when a fair amount of scientific/technical information on various aspects of the topic exists, but the conclusions of different studies vary and the validity of much of the evidence is questioned by members of opposing coalitions. The arguments below assume that the essential task of a professional forum is to convince coalition experts that professional norms require the alteration of one or more beliefs important to a coalition.

Composition. In order for scientists with very different points of view to come to consensus and for that consensus to be accepted by the major coalitions, the technical advisory committee should include both (a) scientists clearly associated with each of the major coalitions and (b) neutral scientists. The chair should come from the latter.

The ACF assumes that the various coalitions involved in important policy disputes have scientists (or technical experts) whom they trust, presumably because they share most of the coalition's policy core beliefs and can help the coalition understand the scientific aspects of such disputes. Many interest-group leaders, legislative personnel, and agency officials who constitute the leadership core of coalitions have an intuitive awareness of the role of values in determining the agenda of technical advisory committees and how uncertainty is treated. Thus they are very unlikely to accept the recommendations of any technical advisory committee on which their point of view has not been argued by someone whom they trust.

And, if they do not trust the committee's report—particularly in a relatively decentralized political system like that of the USA—they almost always can find some decision-making venue that will enable them to circumvent or obstruct the committee's recommendations. In short, selecting a committee composed entirely of relatively 'neutral' scientists—which we perceive to have been the strategy of the National Academy of Scientists (Boffey 1975), for example—may facilitate short-term consensus but will probably fail in the long run.

On the other hand, the technical advisory committee needs to be chaired by a neutral (and probably to include a few other neutrals) whose task is to impose professional norms on the debate regarding acceptable evidence, methodologies, etc., and to indicate to coalition experts when a professional consensus is beginning to emerge. Nonprofessionals must be excluded from these deliberations in order that scientific norms can prevail in weighing the evidence for—and the assumptions behind—different points of view.

Funding and Sponsorship. Funding must come from an institution which is not perceived as being controlled by a single coalition. This will usually require funding either by (a) a neutral foundation or (b) multiple agencies representing the various coalitions. This is important because policy participants are unlikely to trust a committee funded—and therefore potentially controlled—by their opponents. Since many agencies are perceived as being part of a specific coalition (Sabatier and Zafonte 2000), single-agency technical advisory committees will lack legitimacy in the eyes of opposing coalitions.

Duration. A forum should meet at least half a dozen times over a year or so. It takes time for scientists from different coalitions to analyze their hidden assumptions, to evaluate the evidence critically, and to begin to trust each other. One-shot committees of short duration will probably not work.

Context of Policy Stalemate. A forum will be successful only in a context of policy stalemate, i.e., when each of the coalitions views a continuation of the status quo as unacceptable. In any policy dispute, arriving at a compromise acceptable to everyone requires that all the coalitions view the status quo as unacceptable. If any should view the status quo as acceptable, then it will be much less willing to compromise and may not even participate.

The assumption thus far has been that lasting policy change requires genuine learning between/across coalitions. In a relatively open and decentralized political system, such as the USA's, coalitions that do not agree with the conclusions of a professional forum have numerous points of appeal (courts, legislatures, agencies at different levels of government) which have different biases. In more centralized systems, such as UK's, where routes of appeal are severely restricted, it may be possible for a coalition to change

policy simply by convincing a policy broker of the merits of its point of view without having to change the views of the other coalition(s).

5. Summary

This article has presented four conceptual frameworks that seek to understand the role of advocacy organizations in processing substantive policy information of a relatively technical nature in policy disputes, particularly in the USA. Both the civic textbook model and the multiple streams model view substantive policy information as being relatively unbiased, but the multiple streams has a much more sophisticated understanding of the policy process. In contrast, both the atheoretical skeptics and the ACF view substantive policy information as 'filtered' through organizational, disciplinary, and coalition lenses, but the ACF has a much more sophisticated model of the policy process in intergovernmental policy subsystems. This sophistication, however, comes at the cost of parsimony. All four perspectives in combination can be useful in generating a clearer understanding of the role of policy knowledge in the behavior of advocacy organizations.

Policy Knowledge: Census

A census is the count of the entire population of a nation, normally tabulated by jurisdictions within the nation such as provinces, districts, cities, towns, or villages. A modern census also collects social, economic, and housing characteristics as part of the population count. Census information is heavily used in state planning and in public policy. The social sciences, especially demography, sociology, history, and economics, draw from census data across a wide range of research topics: fertility, migration, race and ethnicity, economic growth, and many others. However, with a few exceptions, the census itself has not been a research subject in social science; for example, there are no cross-national comparisons analyzing differing ways in which the census is involved in social, political, and economic processes.

1. History/Definition

The archaic definition of a census is 'poll tax,' indicating its early association with the state's function of revenue extraction. Although the term census dates to ancient Rome, where it referenced the registration

of citizens and their property, the idea of a census predates Roman times. For example, *Numbers*, the fourth book of the Hebrew Bible, starts with the Lord instructing Moses: 'Take ye the sum of all the congregation of the children of Israel, after their families, with the number of their names, every male ... from twenty years old and upward.' That is, take a census of those 'able to go forth to war.'

It is probable that taxation or military conscription or both gave rise to other census operations indicated by archeological records, such as the *Nepohualco* or 'counting place' built by the Chichimecas a millennium ago. This site, near today's Mexico City, consists of stones deposited by each inhabitant of the region, an early census databank. Other archeological records from various ancient civilizations indicate similar preoccupation by the state with carrying out systematic statistical studies. In these ancient records it is difficult to detect all of the state purposes that might have been served by a census. Certainly there was interest in economic data, as is suggested by statistical records of harvest and grain storage. Ancient Chinese records, dating from the Han dynasty (206 BC to AD 220), indicate that detailed population counts were made after each harvest. Subsequent systematic census records appear throughout Chinese history, and many scholars concur that China should be credited with the first comprehensive census (Domschke and Goyer 1986).

There were attempts to establish a periodic census in early modern times, such as the ambitious seventeenth century proposal for an annual census directed to France's Louis XIV:

Would it not be a great satisfaction to the king to know at a designated moment every year the number of his subjects, in total and by region, with all the resources, wealth & poverty of each place?... [Would it not be] a useful and necessary pleasure for him to be able, in his own office, to review in an hour's time the present and past condition of a great realm of which he is the head, and be able himself to know with certitude in what consists his grandeur, his wealth, and his strengths? (cited in Scott 1998, p. 11).

In the modern period, however, it was the United States that initiated the first periodic census. The US Constitution (1787) requires that an enumeration of the population be taken every 10 years. This decennial census, first taken in 1790, served two state-building functions. One was periodically to reallocate seats in the House of Representatives, the legislative branch to which positions are allocated proportionate to size of population in each of the member states. Because the population might grow at different rates from one state to the next, provision was made to take a census every decade and then to calculate how many legislative seats would go to each state. The second nation-building task addressed the challenge of geographic expansion. The country was expected to expand into new territories, and these areas were to join the nation

on equal footing with the original states. The decennial census measured population growth and its geographic dispersion and thereby served as the mechanism regulating how territories were added to the state.

Though the US was early in establishing a periodic census, most European nations shortly followed in instituting some form of regular census to assist in nation-building and policy-making—the United Kingdom and France in 1801; The Netherlands, shortly after independence, in 1830; Sweden in 1855; Spain in 1857; Italy in 1861; the German Empire in 1871; and the Russian Empire in 1897. In nearly every instance, the postcolonial nations of Latin America, Asia, and Africa established a periodic census as an early step in nation building. By the end of the twentieth century only a handful of countries do not have a census.

2. Census and Public Policy

A wide array of public policy purposes are served by a regular official count of the population and its characteristics. Before turning to these purposes, it is necessary to distinguish between a census and a sample survey. The vast majority of state-generated statistical information comes from sample surveys, which elicit information from a part of the population in order to estimate characteristics of the entire population. A census customarily describes the effort to count everyone in the population. There is an important statistical interaction between sample surveys and the census, for the latter provides the frame necessary to draw samples for survey purposes. It also provides the basic denominator that serves as a control to determine whether a sample is demographically and geographically representative of the country. That is, does the sample have the correct proportion of age, race, ethnic, gender, and other demographic categories that have been measured in the population census, and does it reflect how the population is distributed geographically, again as measured in the census. The close relationship of a census and surveys indicates that many policy functions that rely on sample data are, in fact, drawing from a prior census.

An important distinction between the census and the survey is that the former allows estimates of population or housing characteristics to be made at comparatively small levels of geography. Policy purposes that require fine geographic detail will directly draw on census information. Policy purposes that are targeted at higher levels of aggregation tend to rely on sample survey data and thus have an indirect relation to the census.

A census supports policy-making in four broad arenas: election systems, taxation, public funding of social services, and social control.

2.1 Election Systems

When the basis of election to a legislature is size of the population being represented, census information is used to draw the boundaries of election units. As indicated above, this was the primary purpose for which a census is required by the US Constitution. It is now the practice in dozens of democratic countries, and not just for national legislatures. Election districts for city governments and other local and regional governments are frequently drawn to ensure approximate equal population size for each geographic area that constitutes an election unit.

Size is not the only population characteristic that can be taken into account in drawing election districts. Demographic traits such as ethnicity, language, and race have been used. This occurs when the state wants to ensure that the legislative body is ‘demographically representative’ of the population at large, for instance, that racial minorities have the opportunity to elect someone from their race to the legislature. Under these circumstances, census data are commonly used to monitor compliance with election laws. In the United States, for instance, census information on ancestry, gender, race, ethnicity, language spoken at home, place of birth, and year of entry into the country are critical for monitoring compliance with voting and civil rights laws.

When political party affiliations vary across different ethnic, language, or racial groups—as they often do—the use of the census to promote ethnic, linguistic, and racial balance or access will invite partisan disagreements. Census counts become the target of such disagreements, as in the events that led to the Nigerian civil war. Even census methodology can come under attack, as has happened in the United States in connection with its 1990 and 2000 census.

Basing political representation on population counts also invites jurisdictions to inflate their numbers. This incentive confronts census taking with serious methodological challenges. Unless there is a corresponding disincentive—such as basing tax rates on population size—a census can be vulnerable to strong political pressure by those with a direct stake in high counts.

2.2 Taxation

The most direct relation of a census to taxation policy occurs when taxes are collected from a jurisdiction proportionate to its population size. Thus a central government might calculate the tax obligation of its administrative units depending on the size and wealth of the unit, and use a census to make the determination.

A more indirect use of census (and survey) data occurs when the state measures the economic life of

the nation, using that information to help design a taxation system—whether to tax manufacturing activity, natural resources, individual income, property, at what rates and in what combinations. For example, population projections based on census data are used to design social security tax rates and to estimate probable social security payment levels well into the future.

2.3 Public Funding and Planning

Social welfare policies are generally targeted to specific population groups, such as families in substandard housing, children in poverty, the physically disabled, minorities historically disadvantaged or mistreated, victims of particular diseases. Assessing the size and geographic distribution of groups targeted for welfare payments or subsidies is the task of a nation's statistical system. Frequently public funding formulae are based on census counts of particular population groups (Nathan 1999). In the United States, for instance, in 1999 approximately \$US185 billion in medical, education, housing, transportation, unemployment, and other payments depend in part on census data. Similar funding formulae using census information occur in many countries with advanced social welfare systems.

When public funds are allocated to target groups based on their size, they have a strong interest in being fully counted. But these are also population groups that are difficult to reach in standard census operations, and even if reached, will sometimes resist being counted because of concerns that census information can be used against them. This situation has given rise to advocacy organizations that work with and put pressure on census bureaus to assure as full a count as possible of their particular constituencies. Where this has occurred, census taking is no longer the domain only of professional statisticians and their government minister, but becomes of much more generalized political interest.

In addition to targeted welfare spending, national governments frequently use census information for program planning across many policy domains such as public transportation, health and education services, job training, police and fire protection, sanitation and sewage disposal, and land use.

The census also plays a role in national security policy. As indicated above, since biblical times the state has relied on census information to assess the numerical strength of its fighting age population, and also at times to design and implement actual conscription. Of course, a reliable count of the fighting strength of one nation's population will be used by another nation to calculate whether that nation poses a military threat. The first US census in 1790 was declared by the nation's leaders to have missed a sizeable portion of the population, and the Secretary of State took care to announce that fact to European

powers that might otherwise have concluded that the young nation was too weak to protect its independence. Of course not just population censuses but also economic censuses help the state assess its military capacity and that of other nations.

The relative strengths and weaknesses of contending groups within a nation are also revealed by census information, and have often played a role in strategic choices that precede internal warfare. The suppression of census data in several African countries reflects a decision by the ethnic group in power to disguise the comparative numerical strength of ethnic groups challenging its rule. In the period preceding the Civil War in the United States the more rapid growth of 'free-states' compared to 'slave-states,' as revealed in the 1850 census, was a factor leading to the succession of the South from the national union.

2.4 Social Control

More generally the state uses the census as an instrument of social control, as it was routinely used during the colonial era. Great Britain, as early as the seventeenth century, introduced a census in many of its colonies in order to control more effectively its distant subjects and to assure that resource extraction proceeded smoothly. Decisions about which territories needed policing, required additional labor, could benefit from infrastructure investments, and so forth were facilitated if a reliable census could be taken. Great Britain and other colonial powers were early practitioners of what has now become commonplace. Social control policies that police borders, population movement, and even reproduction and fertility are fashioned in part on the basis of census information.

The boundary between routine social control and abusive exercise of power by the state is not easily drawn, but certainly history offers many examples of the census as an instrument of the latter. Family planning policy and fertility regulation in China and India, for instance, is often cited in this regard.

Population displacement is a further example. Census data have been used to place restrictions on freedom of movement or to force population groups to live in places they would not have chosen. An important instance of the latter is the role of US census data in the nineteenth century relocation of native American Indian tribes from their homelands to reservations. US census data were also used to facilitate the internment of Japanese-Americans at the beginning of World War Two, because they were said to pose a security risk should Japan invade America's west coast.

Census data have also been used in genocidal policies, the most tragic example being the Holocaust. Population registers or special censuses identifying Jews greatly assisted in the location of Jews and their transport to concentration and extermination camps. The 1939 German census, for example, was used to

identify specific individuals. In The Netherlands small-area tabulation of a census of religions taken in 1930 was used in dot-maps of Amsterdam to indicate the density of the Jewish population. Poland, France, and Norway offer additional evidence linking census data to Holocaust operations (Seltzer 1998).

These historical instances of gross misuse of census information have had one beneficial outcome. There is now much more professional and political sensitivity to issues of data confidentiality, the independence of statistical agencies, and related ethical considerations (Seltzer 1994).

3. Census Data and Democracy

Census information connects to politics, and especially to democratic politics, in ways other than its use by the government to design and implement public policy. Statistics and especially statistical series also advance key features of democratic politics. One purpose is helping the electorate to assess government performance and hold it accountable. Another is in providing a platform for social reform. A third is in the assertion of group interests (Prewitt 1999).

3.1 Democratic Accountability

The theory of electoral accountability holds that competitive elections offer to the electorate alternative portrayals of how well the government in power has performed or will perform against future challenges. Aspirants for political office present themselves in terms of their past accomplishments and their promises of future accomplishments in managing the economy, protecting the nation's security, and generally enhancing national well-being. Voters then elect, re-elect, or evict accordingly.

This simple model presumes that the voters have some way of assessing government performance. Statistical trends and social indicators play a major role. They indicate whether the economy is growing or stagnating, whether education or health or housing is improving, whether crime rates are down, whether the environment is being protected, and so forth. Arguments about who can take credit for improvements, or should be blamed for failure, are the common currency of competitive elections and are often advanced by citing statistical trends.

Consider, for example, the sharp political debate over immigration policy in many wealthier countries as they face heavy demands for entry from Central Asia, Northern Africa, and Latin America. These debates are framed in terms of the 'proper' balance between native population groups and newer immigrant groups, with census and related data providing the subtext. Governments are then judged in terms of how well they protect racial purity with anti-immigration policies; or, conversely, display humanitarian compassion or perhaps, as in the United States

at present, replenish the labor pool with more open immigration policy. In either instance, as in so many areas of government programming, long-term statistical trends are invoked when assessing policy.

3.2 Social Reform

Democratic theorists have long been interested in how issues get on the political agenda, especially issues that matter most to the unorganized or disenfranchised interests of society. For instance, how do issues such as child labor or male-female wage differentials become politically salient? One route to the political agenda is through social reform action that takes as its starting point statistical profiles. Since the early days of industrialization, reform groups have used statistics to document the social conditions that they were committed to eradicating (Cohen 1982). Examples are poverty laws, prison reform, child abuse, racial discrimination in education, housing, and employment. Reform activists mobilize political participation and inform public debate by transforming previously unnoticed social conditions into highly visible social injustices. In this way resource-poor groups compensate for their lack of political organization or low levels of political participation. They use state provided statistical information as a political resource (Lacey and Furner 1993).

3.3 Group Interests

Census information can be the basis on which to establish group identity. When, for instance, the census differentiates the population into its component racial, ethnic, or tribal groups, it promotes these categories in public consciousness and in public policy. To be measured is to be politically and socially visible, and this visibility can become the basis for group representation. Public policies such as affirmative action targeted to India's lower castes or racial minorities in many countries are formulated on the principle of statistical proportionality. That is, there is pressure to ensure that racial or ethnic groups historically discriminated against are represented in high status occupations or the legislative bodies proportionate to their numbers in the general population.

This process, once started, gathers momentum. More and more groups insist on being fully counted in a census. The leaders of these groups then assert political claims on the basis of the counts. A census which is judged to undercount particular groups, such as the homeless or the linguistically isolated, is attacked by advocates for the undercounted population groups. The census and even census methodology can become a political battlefield.

The increasingly central role of statistical proportionality in democratic politics and public policy is welcomed by some but resisted by others. Proponents argue that decades or even centuries of injustice can be

reversed through social policies that correct for a history of discrimination. Because this discrimination was and even remains group-based, it requires group-based measures to overcome it. Others express concern that attaching policy benefits and penalties to persons on the base of their race or ethnicity is to abandon the liberal principle of individual rights in a democracy.

The census and what it measures is of great political interest to both sides of this debate. What is unmeasured cannot easily become the target of public policy, and certainly cannot be used in policies that employ statistical proportionality to achieve social purposes.

4. The Census as a Subject of Public Policy

The census, being an instrument of nation building, policy-making, public planning, resource allocation, and democratic governance, will itself be the focus of policy. The overriding policy consideration for a government considering its census is how to strike the proper balance between accountability and autonomy. On the one hand, the census is instituted and funded primarily because it serves government purposes. If it serves no useful purpose it will be underfunded and eventually discarded. On the other hand, the census shares with other scientific enterprises the requirements of professional independence. When a government does not respect the independence of census operations, it places at risk the credibility of the counts and can easily be accused of manipulating census numbers in order to protect itself or enhance its prestige.

This tension between policy accountability and scientific autonomy plays itself out in multiple ways within the policies that govern a census. At one extreme, census results and other official statistics are only very selectively released. For example, China during its Cultural Revolution (1966–76) tended to suppress all statistics or to make them available only through highly controlled government reports. In the former USSR, the 1937 Population Census was never made public, in part to keep from public attention the magnitude of the 1932–3 famine. In less extreme instances, particular statistical series are presented in a manner designed less to inform than to persuade the public. In democracies, for example, the release of inflation rates or poverty measures can be timed to benefit the incumbent party during an election period. Practices such as suppression of data or political manipulation of its presentation and release will of course undermine public confidence in census counts and related statistics.

At the other end of the policy continuum is the assumption that the census is a public good. From this perspective, national statistics serve broad social purposes that reach well beyond the immediate needs of the government in power. This perspective, of

course, is compatible with granting considerable independence and autonomy to a census bureau staffed less with political appointees than with professional statisticians.

In most countries, census design and operations exist uneasily in a policy space that simultaneously includes close government oversight, on the one hand, and acceptance of the importance of scientific autonomy, on the other. The weight assigned to one or the other will vary depending on the ideology of the government in power. When the conservative government of Margaret Thatcher came to power in the United Kingdom, an explicit decision was taken to narrow the functions of the statistical service and make it serve specific, immediate policy needs. In the United States, a number of questions previously asked were eliminated from the 2000 census forms because they were not directly related to a federal program. This narrowing of the function of the US census dismayed demographers and sociologists who pointed out that the census was becoming less analytically useful, that is, was less of a public good.

The mission a census is expected to serve—narrow, immediate, and even secret government functions at one extreme or broad public good functions at the other—is the first-order policy issue that confronts a government as it establishes and funds the periodic census. There follow, then, a host of subsidiary policy issues. How are government statisticians expected to balance their duties as civil servants with their obligations to their professional peers? What criteria should be used to select the director of a census operation? How much autonomy is granted a census agency in its ongoing effort to improve methods and concepts, especially in redefining politically sensitive measures in areas such as race and ethnicity or income and poverty? What rules govern the timing and nature of data release? What is the appropriate tradeoff between data confidentiality and respondent privacy, on the one hand, and the society's demand for detailed information, quickly provided, on the other? Should a census agency only provide raw data, or should it have its own analytic capacity and thereby provide reports and interpretations? How can appropriate government oversight of a census operation guard against waste of public money or agency incompetency without itself being accused of partisan intrusion in the census?

All of these and other issues are the proper subject of political debate in the articulation of policies that govern the funding, organization, and implementation of a census. The issues are similar in nature to those that arise in the government sponsorship of science or the arts, each being an activity that requires a high degree of professional autonomy but each also being an arena of great political sensitivity.

With respect to a census, or statistical activities more broadly, thoughtful observers have articulated useful policy principles. In essence these principles

recommend that the statistical products should be designed to serve the needs of multiple political interests and not just those of the government currently in power, and should be sensitive to future policy issues rather than focused only on the present. Success in institutionalizing this principle will maintain both the relevance and the credibility of a census (Seltzer 1994).

5. *The Census as a Subject of Social Science*

The social sciences make heavy use of census data across a wide variety of topics. The quantitative study of society is severely hampered in the absence of census information. It is perhaps surprising, therefore, that studies of the census itself are so few. That is, though the census is everywhere the subject of public policy, it is seldom the subject of public policy analysis.

The exceptions to this general proposition are important, and should not be overlooked. There are historical treatments and case studies of particular censuses that are often rich in analytic detail (Anderson 1988, Anderson and Feinberg 1999, Arowolo and Daramola 1982, Medvedev 1989). There are studies of particular policy issues that emerge in the census context, such as analysis of confidentiality or of the census as an instrument of social control or the role of the census in revenue sharing schemes.

What is generally lacking, however, is social science theory about the emergence, role, function, and consequence of the census. It is largely assumed that the modern nation-state needs a census, else it would not have emerged in nineteenth century Europe and North America. This assumption, however, has not been subjected to investigation in political sociology. Theoretically rich treatments of nation building and citizenship (Bendix 1964) or of the state's effort to improve society (Scott 1998) provide a platform for studies of the political causes and consequences of the census, but with few exceptions (Alonso and Starr 1987) the work is yet to be undertaken.

The political economy literature is similarly deficient in its theoretical treatment of the census as an object of inquiry. It is easy to find assertions that the modern economy requires fine-grained demographic data for making decisions about labor market dynamics, location of retail outlets, types of products that will meet future consumer needs, and so forth. From this latter assertion, it is an easy step to claim that census data are a public good and to invoke microeconomic theory to explain the government's decision to fund a census. Using the United States as a case study, one sustained examination of this hypothesis reports that public good theory offers an insufficient explanation of the rise of the modern census (Kelman 1985).

Neither political sociology nor political economy has yet turned its analytic tools on the census as a feature of the modern state and modern economy.

This will likely be corrected. If metaphors about how the 'knowledge society' will replace industrial society are taken seriously, so also is the assertion that information is the emerging infrastructure for the knowledge revolution just as railroads or canal systems were the earliest infrastructure for the industrial revolution. An accurate and credible census is basic to establishing an information infrastructure and thereby requires systematic attention by the social sciences.

Policy Knowledge: Contract Research

1. 'Contractual Research' Versus 'Academic Research'

'Contractual research' as a modality of the science-based generation and production of (policy-related) knowledge is basically characterized by the commissioner/producer or consumer/contractor principle: 'the consumer says what he wants, the contractor does it (if he can), and the consumer pays' (to quote Lord Rothschild's much-referred to formula, Wittrock et al. 1991, p. 47). Hence, the 'request for proposal' (RFP) through which the commissioning agency addresses the would-be contractors (in public bidding, selective bidding, or directly), as a rule, defines and specifies the questions to be answered and the time frame. In his project proposal the would-be contractor explains his research plan within the parameters set by the 'customer' and makes his financial offer which is usually calculated on a 'personnel costs plus overheads' formula.

By contrast, academic research has traditionally hinged on the claim to institutional and intellectual autonomy of scientific work. Ideally committed to the 'search for truth,' academic (social) science research is traditionally understood as selecting its subject matter, research questions, and methodology solely by the 'free' decision of the individual researcher on the basis of 'intra-scientific' criteria. The essential frame of reference is the scientific community and its reputation system centering on peer review and peer recognition. Hence, the publication of results is an indispensable vehicle of allowing peer review as well as scientific knowledge accumulation and theory building. The classical locus of academic research is the 'research university,' based on the Humboldtian idea of the 'unity of research and teaching' as well as the (public/quasi-public non-profit) research institutes operating on a 'university without students' logic (Weaver 1989). While academic research is essentially geared to 'basic' research, it may well, through an intra-scientific search for 'relevance,' take some 'applied,' policy-related orientation. The cognitive autonomy of academic research is essentially secured by its 'independent' modalities of research funding, be it through the host institution's own resources ('untied' public money, private donations, endowments, etc.), be it through funding agencies (public or philanthropic foundations) usually operating on a competitive, peer-reviewed application formula.

At this point, it might be useful, in a side remark, to recall that recently the term and concept of 'think tanks' has been occupying the discussion on social science-provided policy-advice and its institutionalization (see Stone et al. 1998). In order to avoid the present use of the inflationary use of the term, 'think tanks' might be understood and defined as research

institutes which are institutionally and financially independent and see their task in generating and (most importantly) diffusing policy-relevant knowledge and therefore in exerting an influence on the political debate and agenda setting. 'Think tanks' that assume an explicitly ideological stance have been labeled 'advocacy think tanks' of which the Heritage Foundation in the USA and the Adam Smith Institute in the UK (both acting as neo-conservative/neo-liberal intellectual spearheads) are perhaps the most prominent examples.

This article is meant, within the limits of its space, to do two things. First, in its main body, it will take up a historical-institutionalist approach in 'mapping' the institutional landscape of contractual research (Sect. 2). Second, some conceptual (and ethical) key issues of contract research will be addressed (Sect. 3).

2. Across-countries Commonalities and Variance in Institutionalization of Contractual Research

2.1 Institutional and Cultural Factors Influencing the Institutional Profile ('Who is Who') of Contractual Research

The size and profile of contractual research in a country plausibly depends on institutional and cultural factors both of the political system ('on the demand side') and of the (social) science system ('on the supply side').

The political, governmental, and administrative demand for (external) science-generated policy knowledge may be contingent on the *institutional structure of government* (whether presidential or parliamentary), on the *political culture* (whether government seeks policy knowledge and advice primarily 'in house' in its own governmental apparatus, or at best 'quasi in-house' in governmental research institutes, or whether it is disposed to turn to external research capacities), and on the *administrative culture* (whether the administrative elites see themselves as professionally self-sufficient and secluded or whether they are perceptive for, and receptive to, external science-generated knowledge).

The supply of science-generated policy knowledge and advice may hinge on the *institutional setting of the social science system* (whether it traditionally revolves around 'research universities' (in the Humboldtian sense) or on non-university research institutes) as well as on *research attitudes and cultures* (whether university-based social scientists have the propensity to engage in policy-related knowledge production).

As some of these factors appear deeply, even in a 'path-dependency' manner, rooted in the countries' institutional and cultural fabric, they are likely to bring forth country-specific trajectories in the way contractual research has been institutionalized.

In Sects. 2.2 and 2.3 the attempt is made to elaborate (and explain) some distinct patterns and types of that institutionalization by dwelling on a number of countries as cases in point.

2.2 *Emergence Of Contractual Research up to World War II: America's Exceptionalism*

The development of the relation between university-based social science and government up to 1945 is a story of 'American exceptionalism' for a number of reasons. When the social sciences emerged at American universities, most of which were privately funded, the explicit attempt was made in the 1920s, spearheaded by the political scientist Charles Merriam at the University of Chicago, to combine the ambition to make them 'truly scientific' with an 'applied,' policy-related orientation. This applied stance of university research was fostered and supported by the early appearance of philanthropic foundations (Rockefeller, Carnegie) which made for another US American particularity and innovation. In this context the Brookings Institution was established in 1927 as a private, independently funded, policy-related institute—another American 'first'. While the federal government abstained from setting up governmental research institutes of its own, it started to draw on external, mainly university-based, social science expertise since the 1920s, opened up by President Hoover and stepped up by President Roosevelt during the New Deal (Wittrock et al. 1991, p. 39). When, during World War II, the federal government made an all-out effort to mobilize the country's entire scientific and technological potential, including the social sciences (systems analysis, psychology, etc.), 'contract research' became the decisive tool by which the federal government succeeded in catalyzing the huge technological, industrial, and intellectual resources of America's private sector which, to a large extent, include the universities (Lieske 2000, pp. 51ff.). In view of the salience of the private sector in the American institutional world it has been aptly remarked that 'contract is symbolic of the extent that it embodies and represents the values of private enterprise and the "free" market economy that have distinguished much of the nation's history' (Owens 1996, p. 249).

In contemporary European countries the development under consideration was distinctly different. On the Continent governments showed little interest in drawing on external science-generated knowledge. Instead, for instance in Germany, governmental research institutes were put in place for the (quasi in-house) provision of policy-relevant knowledge. While the university-based social sciences, in their struggle for scientific and academic recognition, accentuated their scientific profile and shunned an applied one. Sweden was an exception to this, where since the 1930s a policy-related interaction between government and

university-based social sciences has caught root. To some degree this also held true in the UK where reformist Fabians established the London School of Economics as an explicitly policy-related academic institution. It should be added, though, that in the economic field most European governments showed an early interest in eliciting and using external expertise from newly established public and private economic research institutes that were founded in Germany, France, Austria, and Sweden during the 1920s and 1930s (Gellner 1998, p. 90, Wittrock et al. 1991, p. 48).

2.3 *The Upsurge of Contractual Research After 1945: Commonalities and Variance*

In the following, the development in a number of countries will be highlighted as cases and types in point instead of venturing in a systematic overview.

2.3.1 *USA: private for-profit institutes/firms prevail in contractual research.*

Responding to the mounting policy knowledge demand which came from the post-war role of the US as the hegemonic Western power and from the ever more intensive Cold War confrontation, the US government continued to heavily draw on contractual research, at first particularly in foreign and military policies. The RAND Corporation, founded in 1948, was an institutional innovation in that it was the first private, for-profit research institute which was basically financed through governmental research contracts, in that case particularly from the US Department of Defense (Abelson 1998, pp. 112ff.). During the 1960s, contractual research experienced a tremendous upsurge. The Social Action programs under the Johnson administration and the legislative mandate to have them evaluated unleashed a contractual research money flow from the federal ministries and agencies on an unprecedented scale. At the same time, typical of the US government system, Congress built up its own evaluation capacities (GAO, CBO counting some 6000 staff members) and the federal departments too set up extended 'in-house' evaluation units and personnel (at the cost of some 1.2 billion US\$ in 1984). A huge amount of contractual money was put into external evaluation (amounting to some 460 million US\$ in 1984, Rist 1990, p. 80); thus, evaluation research became, 'in the words of Wall Street, a growth industry' (Rossi et al. 1999, p. 11). The institutional response to the contractual money market was threefold. First, linking up with their traditional applied and policy-related orientation and experience, university-based social scientists successfully sought access to the contractual research money market, sometimes operating at self-standing (non-profit) research institutes that, while remaining affiliated with their 'mother' university, were founded for the

very purpose of doing contractual research. Second, the (quasi-public or quasi-private) non-profit institutes (such as The Urban Institute, but also the time-honored Brookings Institution) got engaged in contractual research. Third and most conspicuously, a growing number of private for-profit research institutes and consulting firms, doing 'research for business,' were founded and entered the race for research contracts (such as Abt Associates, established in 1966). Sometimes ironically dubbed 'Belt Way Bandits' (after the high way around Washington, DC, where many of them are located) they have succeeded in taking the lion's share of the contractual research money market.

2.3.2 Sweden: university-based research prevails in contractual research. Among the European countries, Sweden also makes for an exceptionalist story of contractual research. Sweden's policy-making is traditionally characterized by the practice of creating, for each major piece of legislation or policy-making, *ad hoc* commissions made up of members of parliament, administrators, representatives of interest groups, and academics; in their mandate to seek agreed upon policy solutions they epitomize Sweden's traditional consensus-seeking political style (Vedung 1992, pp. 74ff.). For preparing their recommendations to government and parliament the *ad hoc* committees dispose of contractual research money to commission policy-related information and expertise. During the 1960s when Sweden experienced a (short-lived) PPBS boom and a 'scientific revolution' in policy-making (Wittrock et al. 1991), the country became one of the European frontrunners in policy evaluation, making evaluation look 'endemic throughout the Swedish system' (Levine 1981, p. 50). Thanks to the traditional policy-related interaction between government and university-based social scientists, the latter have prevailed in the conduct of contractual research.

2.3.3 Germany: public/non-profit and private/for-profit mix in contractual research. Germany presents the case of an (at first) retarded and (then) accelerated development of contractual research. Well into the 1960s, Germany's administrative (law-trained) elite adhered to the traditional belief in its self-sufficiency and, for the rest, relied on the chain of governmental research institutes (Hohn and Schimank 1990, pp. 303ff.) for informational support. At the same time, university-based research, while still absorbed by its post-war reconstruction and expansion, largely cherished its traditional dedication to basic research and continued to be wary of applied research. In the late 1960s, this traditional distance between, if not mutual neglect of, the government and the university-based social science experienced a

conspicuous rupture and reversal which was significantly the work of 'reform coalitions' formed by reformist politicians, civil servants, and university-based (social) scientists (Wagner and Wollmann 1991, pp. 74ff.). In conspicuously revamping its governmental machinery under the then dominant planning imperative and drawing, in an attempt at the 'scientification of policy making,' on social science advice on an unprecedented scale (Wollmann 1989), Germany became a European frontrunner, besides Sweden, in evaluation research (Derlien 1990, p. 148, Wagner and Wollmann 1986). The dramatic shift was evidenced by a rapid expansion of the contractual research money market with three groups of researchers competing for the research contracts. First, pursuing their new reorientation to applied and policy-related research, university-based researchers have sought and attained some access to contractual research, partly in institutional 'spin-offs' affiliated with the 'mother' university. Second, quasi-public non-profit research institutes have held a significant share in contractual research. Third, the new sector of private for-profit research institutes and consulting firms has been able to take lion's share of the contractual money market.

2.3.4 France: production of policy-related knowledge still largely in in-house or quasi-in-house manner. France can be seen as an example of the Continental European (State) tradition in which the production of policy-related knowledge has still remained largely within the government's domain in an in-house or quasi-in-house manner. France's administrative (*grands corps*) elites have retained their traditional belief in their professional self-sufficiency (Nioche 1992, p. 31). The Court of Accounts and the General Inspection of Finances constitute another barrier of traditional policy monitoring and auditing agencies. In addition, a chain of quasi-governmental research institutes, subordinated to the central ministries, has been established to provide ancillary policy information and advice. On the science system side, France has traditionally known the functional division between the teaching role of the universities and the research-focused CNRS whose close ties with the State have been seen as 'making them an integral part of the state apparatus' (Fieschi and Gaffney 1998, p. 54). Hence, France has been a latecomer to policy evaluation (Nioche 1992, p. 24); as late as in 1990 a typically centralized evaluation procedure was institutionalized, comprising, *inter alia*, a Scientific Council of Evaluation made up of academics (Duran et al. 1995, pp. 55ff.). While the contractual research money market is comparatively small, it has been dominated by CNRS institutes which quite often have teamed with university researchers. The share of private for-profit institutes and consulting firms has so far been quite modest.

2.3.5 Japan: private for-profit research institutes prevail in contractual research. While Japan's governmental bureaucracy has traditionally cherished a culture of self-sufficiency and elitist seclusion, it was also seized, during the 1960s, by a (passing) PPBS boom which resulted in the establishment of planning and analytical units in central ministries (Ide 1969) and in growing demand and contractual funding for external analyses. In 1974 the quasi-governmental National Institute for Research Advancement (NIRA) was established to initiate, coordinate, and monitor the contractual money research. On the 'supply side,' the university-based social science research has shown little propensity for applied and policy-related work (Watanuki 1991), not least because the universities have traditionally been under-equipped for research purposes. Thus, contractual research has been procured and conducted almost exclusively by private research institutes. Out of the some 225 private research institutes (as of 1992) some 40 percent are for-profit (Ueno 1998, p. 195). While the largest ones (such as Mitsubishi Research Institute and Nomura Research Institute, founded in 1970 and 1975, respectively) have been established by their 'parent' corporations, most of the smaller ones have typically been established by former (well-connected) high-ranking civil servants after their early retirement as well as by university professors who combine teaching at the university with doing paid contractual research outside.

2.3.6 European Union (EU): dynamic contractual research money market dominated by the private for-profit research sector. While EU policy-making lies largely with the European Council and the Commission, the implementation of EU policies (that is, EU regulation and EU funding) is carried out by the member states and their (for the most part regional and local) bureaucracies. Thus the EU central actors, particularly the Commission, have a 'natural' need for external policy information. With regard to EU structural funding, for instance, the procurement of such information has been secured by a technically sophisticated evaluation system consisting of *ex ante*, interim, and *ex post* evaluation and based almost entirely on external evaluation. Consequently the EU has, since the late 1980s, opened up and has massively funded a contractual research money market. The evaluation of EU policies and programs is conducted on two levels. On the EU central level the evaluation contracts (amounting to 13.5 million Euro in 1999) relate to the entire EU programs and have been won and carried out exclusively by for-profit institutes and consulting firms among which big international firms (like Anderson, Ernst and Young and the like) loom large. Another EU contractual money flow is directed at evaluating the implemen-

tation of the EU programs in the individual member countries. As these projects are smaller and require some familiarity with the national, regional, if not local, contexts, 'national' research institutes have prevailed in gaining the research contracts. The profile of the contractors differs from country to country. While, for instance, in Spain university-based research groups have the Spain-related evaluation contracts, in most other countries the majority of the contractors are private for-profit. The contractual research money flow of the EU is bound to have significant repercussions not only on the contract research scene, but also on the social science community at large. This holds true particularly in South European member countries (Greece, Spain, Portugal, and also Italy) which receive the bulk of EU funding and which, consequently, are the target area of correspondingly massive evaluation research. There is evidence that, in fact, EU contractual research funding has given strong incentives and impulses to the national research scene in these countries.

3. Contractual Research Constituting a Threat to the (Intellectual Etc.) Integrity of the Individual Researcher or Even of the Social Science Research Community at Large?

The expansion of contractual research has been accompanied, both within the contractual research camp as well as on the academic scene, by a debate about the threats which the crucial consumer/contractor constellation may pose to the intellectual (and moral) integrity of the researchers involved and beyond. It is particularly the basic commissioning and funding logic of contractual research, described in the 'Rothschild principle' as 'the consumer says what he wants, the contractor does it (if he can), and the consumer pays,' that is being suspected of jeopardizing and undermining its intellectual integrity and of translating into reality the adage 'who pays the piper calls the tune'. First of all private for-profit institutes and firms that seek and conduct research contracts as 'research for business' are seen exposed to an erosive, if not corruptive mechanism (Ham 1999, p. 276). As a spill-over from the realm of contractual research onto social science research at large, including academic research, even a 'colonization process' has been foreboded in the wake of the external setting of the research agenda, 'whereby the bureaucracies' perspective and conceptual framework (is) established as the valid epistemological framework also for scientific research' (Elzinga 1985, p. 211).

In the face of such challenges to the intellectual integrity and honesty of contractual research, initiatives have been taken, particularly among evaluators as probably the most numerous and most

professionalized group among those engaged in contractual research, to formulate and lay down standards that could guide them in their contractual work and in negotiations with their 'clients' (Rossi et al. 1999, pp. 425ff.). Exemplary are the *Guiding Principles of Evaluation* that were adopted by the American Evaluation Association in 1995. Among its five principles the maxims of integrity and honesty of research ('evaluators must ensure the honesty and integrity of their entire evaluation process') are writ large (full text in: Rossi et al. 1999, pp. 427ff.).

H. Wollmann

Policy Knowledge: Epistemic Communities

Political science and policy studies have increasingly developed an interest in the role of ideas, values, and technical understanding in shaping political outcomes, particularly under conditions of perceived complexity. 'Epistemic communities' is a concept developed by 'soft' constructivist scholars of international relations concerned with agency to understand the actors associated with the formulation of ideas, and the circumstances, resources and mechanisms by which new ideas or policy doctrines get developed and are introduced to the political process.

1. Constructivism

Constructivism analyzes the social process by which actors construct meaning of the world through the application of broad ideas and reasoning patterns. Thus, constructivists specify how actors come to

recognize interests and make choices (Ruggie 1998, Haas 1992/1997). While there has been a long-standing appreciation of the importance of ideas—the fabric with which Weberian webs of significance are spun—on politics and on choice, the mechanism by which such constructions arise and persist has long remained elusive. Epistemic communities are important actors responsible for developing and circulating causal ideas and some associated normative beliefs, and thus helping to create state interests and preferences, as well as helping to identify legitimate participants in the policy process and influencing the form of negotiated outcomes by shaping how conflicts of interest will be resolved. Attention to epistemic communities provides a way to understand agency in politics and policy formation.

Assigning context and determining appropriate behavior—and thus policy—are fundamentally political processes, both in terms of actors' efforts to directly influence the process and in terms of their distributional consequences. Most IR theorists now agree that contemporary politics and international relations are characterized by conditions of complexity, as a consequence of growing interdependence and globalization. Complexity complicates decision-making. Substantive and procedural rationality are impossible under high degrees of systemic complexity (Simon 1983).

Constructivists rely on discussions of complexity to conclude that actors are unable to easily deduce preferences and understanding of options from contemporary circumstances. States and other actors are uncertain about their ultimate goals, and how to achieve them. Even whether actors choose to apply a logic of consequences or of appropriateness is itself conditioned by their prior understanding of the nature of the political circumstances in which they find themselves (March and Olson 1998). The very nature of political strategies actors deem appropriate is a consequence of the advice and framing that actors receive about the uncertain policy environment in which they find themselves, or what John Searle calls establishing that 'x counts as y under conditions c' (Searle 1995).

For international relations, more specifically, actors are uncertain about how to achieve particular interests in given circumstances (their preferences); with whom they have to interact to achieve their goals, and by what means to do so. For instance, when first confronted with new issues political actors are typically uncertain about whether to pursue their ends unilaterally or multilaterally, through which institutions, which nests to apply, which linkages are relevant, and what policies should be collectively embraced. For the policy studies literature (Ascher 1986, Thomas 1997, Social Learning Group 2001) the principal analytic focus that results from an appreciation of complexity and the role of ideas and epistemic communities is on the stages of policy making:

framing, agenda setting, social learning, participation, policy choice, and, to a lesser extent, compliance or enforcement.

National and international politics and policy choice then becomes a matter of applying embedded and institutionalized beliefs about the nature of problems and the appropriate means of collective response as argued by many current theorists of IR (Ruggie 1998, Adler 2001, Haas 1990, 1992/1997), rather than the process of resolving rationally formulated state preferences. In this conception politics becomes a process of learning about the world.

Thus, ideas may play important roles in framing the policy debate, and in predisposing outcomes highlighted by each perspective. Epistemic communities are the cognitive baggage handlers of constructivist analyses of politics and ideas. They are invoked by Constructivist scholars to focus analytic attention on the process by which states formulate interests and reconcile differences of interest. Epistemic communities are a principal channel through which consensual knowledge about causal connections is applied to policy formation and policy coordination. States may learn through processes of international cooperation mediated by epistemic communities. As a consequence collective patterns of behavior reflect the dominant ideas initially brought to bear to understand the area of activity which is being governed.

Ruggie borrowed *episteme* from Foucault, to describe the overarching perspective through which political relationships are visualized and understood during historical eras (Ruggie 1975). The winter 1992 issue of *International Organization* on Knowledge, Power and International Policy Coordination refined the concept by restoring agency to the study of politics and knowledge, by focusing on the actors responsible for articulating and aggregating knowledge based understanding in areas of security, environment and international political economy (Haas 1992/1997). Epistemic communities are networks—often transnational—of knowledge based experts with an authoritative claim to policy relevant knowledge within their domain of expertise. Their members share knowledge about the causation of social or physical phenomena in an area for which they have a reputation for competence, and a common set of normative beliefs about what actions will benefit human welfare in such a domain. In particular, they are a group of professionals, often from a number of different disciplines, who share all of the following characteristics:

(a) Shared consummatory values or principled beliefs. Such beliefs provide a value-based rationale for social action by the members of the community.

(b) Shared causal beliefs or professional judgment. Such beliefs provide analytic reasons and explanations of behavior, offering causal explanations for the multiple linkages between possible policy actions and desired outcomes. While they need not agree on every element—in fact they are likely to disagree vehemently

about some elements—they do agree about the core assumptions and causal forces from which their models of the world derive and agree on the means by which such differences can potentially be reconciled.

(c) Common notions of validity: intersubjective, internally defined criteria for validating knowledge.

(d) A common policy enterprise: a set of practices associated with a central set of problems which have to be tackled, presumably out of a conviction that human welfare will be enhanced as a consequence.

This combination of factors—especially the socialized truth tests and common causal beliefs—distinguish epistemic communities from other types of policy networks and groups active in politics and policy-making. Unlike other organized interest groups active in politics and policy making, epistemic communities are bound by the truth tests to which they were socialized, and thus are more likely to provide information that is politically untainted, and thus more likely to ‘work,’ in the political sense that it will be embraced and followed by political authorities concerned about the need for appearing impartial, and also technically.

2. *Cognate Literatures*

The policy sciences, since Lasswell, have stressed the difficulty of applying strong rationality assumptions when conducting policy analysis, as well as advocating a neo-pluralistic approach to understanding the politics of policy making (Ascher 1986, Braybrooke and Lindblom 1963, Healy and Ascher 1995). Discursive approaches to understanding the policy sciences reinforce constructivist studies of politics and policy (Linder and Peters 1995, Stone 1989).

Similar concepts to epistemic communities were developed in other social sciences in the 1980s and 1990s to better understand the role of expertise in constructing meaning for policy makers and for developing policy usable knowledge. Knorr-Cetina, in the sociology of knowledge, coined the term ‘epistemic communities’ (Knorr-Cetina 1981, 1999), although this neologism was not read by the international relations research program until after the 1992 publication of the epistemic communities volume.

In comparative politics and policy studies complementary notions have been put forward to study networks of experts involved in policy making. Richardson coined the term policy communities (Richardson 1995). Reinicke has extended policy communities to include global policy networks (Reinicke and Deng 2000). Sabatier developed the notion of policy advocacy coalitions, which were an extension of earlier US work on iron triangles (Sabatier and Jenkins-Smith 1993). The concept of policy communities stresses the causal beliefs shared by policy analysts involved in policy development, but do not

fully develop a causal model of their development and spread. Analysts of advocacy coalitions note the presence at different points in time of people from multiple interest groups and organizations, but do not address their beliefs systematically, nor do they look at the causal role of a kernel of individuals sharing beliefs and involved in the same policy enterprises over time. Analysts of epistemic communities, with their focus on agency and the shared beliefs of a community that shares a common policy activity over time, provide the leverage for generating social science knowledge about the development and diffusion of knowledge for policy and politics.

3. *A Constructivist Model of Institutionalized Ideas*

The development and application of an epistemic community’s consensual knowledge can be best understood within a stepwise framework. Such a framework provides independent mechanisms by which new ideas are generated, selected by authoritative actors, and persist over time. It is a path-dependent model of punctuated equilibrium because many choices or decisions are largely irreversible and the array of possible choices at time (t) is causally related to decisions taken at time ($t-1$) in ways that may not be perceptible to actors at time $t+1$ (Adler and Haas 1992/1997). Ideas may exercise a causal impact later in time regardless of the reasons for their initial selection, as they continue to shape actors’ understanding and guide decisions even in the absence of original conditions that contributed to their widespread acceptance.

While actors are always constructing the world, to some extent, the challenge to analysts is to identify what constructions are likely to prevail, and under what circumstances. Since current constructions are made in the shadow of past constructions, this framework provides the means to specify which ideas will be influential and the factors influencing the likelihood that they will exercise enduring influence. Unique collective outcomes involving learning are possible with the existence and involvement of an epistemic community to focus beliefs. Otherwise, political behavior remains a matter of applying prior frames to understanding political choices and options, with conflicts of interest resolved through the application of existing institutions and power resources.

4. *Constructivist Assumptions*

A number of key assumptions underlie this constructivist model. States are key juridical actors, and act willfully. States are functionally differentiated, and vary widely according to their state/society relations

and the technical capacity of the state to formulate and enforce public policies in technical domains (Risse-Kappen 1995, Katzenstein 1977, Gourevitch 1996, Evans et al. 1993). States operate in a complex policy environment, so that information about the environment is highly valued. Yet knowledge is asymmetrically distributed within and between countries. Finally, while perceptions are socially constructed, political actors and social scientists are not subject to the same set of influences. Thus social scientists may identify social forces influencing actors' choices without being equally prone to their influence.

A number of propositions about state behavior and its explanation immediately follow from these assumptions. States are uncertain about their policy environment and how their interests are to be recognized in particular instances, and thus they exercise bounded rationality. The recognition of threats and the identification of responses are subject to socialized patterns of reasoning, rather than through formal rationality in which actors have complete information and choose the most efficient alternatives. Decision-making operates according to a satisfying model in which actors express procedural rationality, at best, subject to the time constraints and structural blinders imposed by bounded rationality (Simon 1983, 1985, March 1994). Consequently, decisions and institutions are sticky, since decision-makers do not return to issues until there is a crisis.

States make choices subject to multiple sources of influence, whose organization varies by issue area (Keohane and Nye 2001). Thus, governance varies by issue area. Consequently, policy networks, organized around specific issues become the appropriate level and unit of analysis, because the array of actors, interests, institutions, and capabilities varies by issue. Even within a particular state, the design of policy-making institutions and procedures vary by issue area. Consequently, it is not surprising that international regimes in related areas can differ widely, because the articulation of interests for each regime takes a different form.

5. Generation of New Ideas

Epistemic communities are the agents by which policy relevant information is developed and transmitted. They are likely to be found in substantive issues where scientific disciplines have been applied to policy oriented work. Thus, epistemic communities arise in disciplines associated with natural science, engineering, ecology, and even economics. They will also be most likely to emerge in countries with well-established institutional capacities for public administration, and science and technology. They are also most likely to be present in rich (measured as a high ratio as share of GDP, and with a significant number of scientists and

engineers in the country) democracies. Democracies are most likely to encourage open-ended, spirited discussions because the knowledge enterprise is independent of the state, and yet the state has the resources to access and support science.

For governments to defer to new knowledge, the presumptive knowledge claim must be regarded as authoritative. Authoritative knowledge comes from groups that command legitimacy and authority in society. Epistemic communities' reputation for authority rests on their expertise as well as their reputation for impartiality. If not seen as being impartial their advice will be widely contested and lack any independent political influence.

Such pockets of independent research are most likely to emerge when the conduct of research is seen to be far from the direct interest and influence of the sponsoring sources of the research (Dasgupta and David 1994, David 1995). Its impartiality and accuracy depends heavily on the ability to publish in peer-reviewed journals, as well as the internal commitments to truth tests by epistemic community members. A distance from research sponsors improves the actual and perceived impartiality of epistemic community members as it is less likely to be shaped by needs of the state or sponsoring agency, and will be less politically tainted. Activities most likely to be regarded as impartial are those with relatively low costs that are not directly tied to the mission of the sponsoring agency. Epistemic communities are likely to offer policy advice that will be effective, unlike the more common process of policy advice which corresponds to specific interests, because the policy proposals are developed far from the political influence of sponsoring agencies and will be more acceptable to the public when the ideas do not appear politically compromised.

6. Selection

New ideas will be solicited and selected only after crises, for crises will alert politicians to the need for action and will seek to gather information about their interests and options. Crises will trigger agenda setting and the search for new information.

Ideas will be selected by states and international institutions. However, not all states or international institutions are equally likely to consult members of an epistemic community or defer to their advice. Institutions with strong science and technology capabilities, and those representing pluralistic societies will be most likely to be in the first wave of those embracing new ideas. It is there that the scientific culture of epistemic communities will have a close affinity, and new groups will be able to quickly articulate new policy initiatives. Selection will probably take longer in non-democratic societies with technically strong

states that have a strong domestic scientific capacity because it takes longer for ideas to percolate up from society to the government outside of routinized channels.

Different styles of policy selection occur in different political systems, due to organizational and cultural differences between types of democracies (Weaver and Rockman 1993, Katzenstein 1977). In presidential systems, with multiple checks and balances, the flow of new ideas to the state will emerge from think tanks, universities, and governmental labs; and will be solicited directly by Congressional Committee staff, the judiciary and executive branch bureaucrats. In Parliamentary systems the sources of new ideas are more limited, and much more likely to emerge from party think tanks and be deployed through political parties to ministers and suitably socialized civil servants. At times ideas may go from universities and independent think tanks to mid level civil servants, but there are fewer universities and independent think tanks in parliamentary systems because of the predominant influence of political parties.

International institutions will also vary in their propensity to take on board new ideas. In a study of international institutions that selected new programmatic ideas from epistemic communities leading to a redirection of the core mission of the institution, Haas and Haas (1995) found a number of common institutional properties among them. Their governing bodies were not split by major political disagreements, they were led by skilled institutional heads, they had skilled professional staffs recruited on merit, and the institution maintained a porous connection with external sources of information. Few institutions have these properties. Those that do were created by their initial funders and sponsoring states to have such resources. The postwar settlement institutions had to reflect the geopolitical goals of the superpowers, and be consistent with overarching values and widely shared norms about economic management because decisions were made at the top levels of government in the wake of such system wide crises, and these policy makers were alert to consistencies between perceived state imperatives and institutional design. Institutions that were established in the interstices of the Cold War, when state leaders were paying less attention to perceptions of systemic imperatives, have greater prospects for flexibility when they reflect domestic sentiment in the superpowers, and they were created during an absence of widespread geopolitical schisms.

There are several alternatives regarding the likelihood of which ideas will be selected at a moment of crisis. If there is only one new candidate, there is little problem, and the new aspirant will be selected. If there are many, choices may be conditioned by calculations of relative political gain from each idea. Studies of trade policy and the use of ideas in formulating international trade regimes have offered a number of

propositions about conditioning factors influencing the selection of competing policy ideas (Odell 1990, Goldstein 1993, Garrett and Weingast 1993). Ideas that provide a potential for building coalitions will be favored over those that do not. Simple ideas that have perceived practical utility will be chosen over more complex approaches. In either case, new ideas will only endure if they are loosely commensurate with deeper-seated beliefs and do not endanger strategic political alliances.

7. Diffusion

Over time ideas will be diffused. Whereas they were selected initially by deferring to epistemic communities and recruiting their members by states and international institutions that were seeking new information, the diffusion of ideas occurs by many channels that include direct persuasion, demonstration effects, and inducements and incentives.

Diffusion may occur by institutional learning, as groups apply evolving consensual knowledge to manage institutional practices. Learning occurs directly, through interpersonal persuasion, communication, exchange and reflection, that leads to the recognition or appreciation of new causal models and shared values. Leaders are socialized to accept new views and to empower their expositors.

One other diffusion mechanism is administrative recruitment, as epistemic community members or their confidantes replace officials informed with alternative perspectives. Diffusion may also occur by other mechanisms, as actors alter their behavior subject to the influence wielded by institutions that embody the ideas (those that selected an epistemic community and its ideas earlier).

International regimes informed by institutionalized ideas promulgated by strong states and by international institutions will have the effect of disseminating the ideas to other parties in which epistemic communities were not present, and through their socialization and exposure to new ideas presented during regime negotiations.

Diffusion may also occur directly as a consequence of incentives and inducements to adopt those ideas coming from states, international institutions, and international regimes. These incentives and inducements typically take the form of technology assistance and financial transfers. These will only promote diffusion to states with weak capacity, for whom the provision of such resources would be a powerful incentive to change policy. Demonstration effects by multilateral financial institutions will induce borrowing states to adopt the policy being demonstrated.

States may draw lessons from one another's experiences, and thus borrow policies and ideas from countries that they are trying to emulate (Rose 1993). This process of diffusion is not one of learning,

though, it is one of mimesis or borrowing because the lesson drawers are not adopting the policies based on the persuasive power of reason by an advocate of the policy. Rather they are imitating the actions of someone who commands respect and appears successful.

These diffusion mechanisms will operate along different time frames. While some effects may be felt immediately through new recruitment decisions, and persuasion, broader shifts in public opinion and societal effects may occur on the order of decades. As these processes overlap, the general diffusion of an epistemic community's ideas will accelerate.

8. Persistence

Once in place, ideas are likely to persist once they acquire a taken-for-granted element and as states and their diplomats become socialized to institutionalized regimes and practices generated by the application of new ideas. Eventually ideas get converted to domestic laws, and thus become enforced out of habit and become the basis for policy enforcement by the state. It also becomes politically costly to reverse such practices as new interest groups and policy communities mobilize around them after recognizing that material gains are possible from the application of the new ideas. Ultimately new markets may form through the application of these ideas, and thus generate economic incentives for their continued adoption once economic actors associate their profits with the application of such ideas.

9. Empirical Examples

9.1 International Political Economy (IPE)

Analysts of IPE have identified ideational dynamics in the popularization and dissemination of major economic doctrines. For instance, the repeal of the corn laws occurred after the conversion of Prime Minister Peel, in the face of likely political defeat. The adoption of liberal economic policy occurred following the creation of an influential epistemic community led by Richard Cobden able to persuade top levels of government that the national interest could be advanced by low tariffs, even in the face of economic losses to a powerful political constituency expressing particularistic protectionist interests. England's hegemonic power was then deployed to convert Europe to free trade through the 1860 Cobden Chevalier Treaty, and the US through bilateral treaties, and most European governments kept tariffs relatively low in accordance with the institutionalized ideas until

the 1890s, despite a lengthy and deep economic depression.

Keynesianism spread internationally through a similar process of epistemic persuasion in a core set of countries, followed by the creation of international institutions to legitimate and create international structures based on Keynesian dictates. Keynesianism first caught on in England, then traveled to the US through academic networks of economists. After its adoption at the highest levels in the two countries, it provided the intellectual foundations for the Bretton Woods System, through which it was institutionally embedded for decades.

Structuralism and Development Economics was developed in ECLA in the 1940s, and then embedded in ECLA and UNCTAD, from where it continued to serve as development orthodoxy to a number of developing countries throughout the 1970s, as well as providing the economic justification behind the New International Economic Order reforms of the 1970s. Odell tells how a group of 'floaters' in the US treasury department influenced ending the Bretton Woods fixed exchange rates by designing its replacement (Odell 1982). The Washington Consensus on macroeconomic management has guided international public debt rescheduling during the 1990s.

9.2 International Environmental Protection

Although multilateral economic activities have been governed, since World War II, by the application of consensual liberal ideas about free trade, efforts to control the impact of economic activity on transboundary and environmental pollution has been based on non market and regulatory principles. Since 1972 an ecological epistemic community, articulating a new ecological management doctrine, has institutionalized its ideas in state policies and practices, in the programmatic activities of international institutions, and in international regimes. As a consequence of the international institutionalization of its ideas, states were caused to undertake more comprehensive styles of environmental management for transboundary and global environmental threats, leading to selective improvements in environmental quality (Haas 2001).

A new environmental management doctrine based on ecological principles emerged in the 1960s. The ideas were developed outside the scope of most state interests and are generally regarded as being relatively uncompromised by political and institutional influence, as ecology was a relatively cheap research enterprise and its subject of study was far removed from most state interests. Members of the ecological epistemic community subscribed to holistic ecological beliefs about the need for policy coordination subject to ecosystemic laws (Haas 1990). Their ideas about

ecological management were based on a systems perspective of environmental and social systems. Ecological management proposals were based on setting comprehensive environmental standards based on conservative estimates of the ability of ecosystems to sustain stress, subject to their technical understanding of the behavior of particular ecosystems. They promoted international environmental regimes that are grounded on policies which offered coherent plans for the management of entire ecosystems, sensitive to interactions between environmental media (such as air and water), sources of pollution, and contending uses of the common property resource, rather than being limited to more traditional policies for managing discrete activities or physical resource spaces within fairly short term time horizons. They proposed treaties in which bans and emission limits were set for multiple contaminants, with environmental standards for each contaminant set according to scientific understanding about its environmental impact and its interactive effects with other contaminants.

There were few ideational competitors. Resource management bodies had traditionally been staffed by neoclassical economists and resource managers, who had been discredited by broadly publicized environmental disasters and the energy crisis of the 1970s as well as the limits to growth debate, which they had been unable to predict, and attendant popular fears of widespread resource depletion.

Following the politicization of international environmental issues in the late 1960s galvanized by widely publicized environmental disasters occurring in global commons, the United Nations convened the United Nations Conference on the Human Environment (UNCHE) in 1972. As a consequence of these new domestic demands, and in order to prepare national papers for UNCHE, governments created new environmental agencies. Most state officials were unfamiliar with environmental threats and were unable to rank order environmental threats, amounts of national emissions, what would constitute safe or dangerous concentrations of possible contaminants, and what were appropriate policies to reduce emissions. Many of these national agencies recruited epistemic community members to serve as officials or as consultants.

International organizations were created as well. The United Nations Environment Program (UNEP) was established in 1973 and was staffed principally by young epistemic community members eager to put their professional knowledge to work. The UN Economic Commission for Europe (UNECE) played a strong role in managing European air pollution. The UNECE's environmental unit was led by a former UNEP official who carried the ecological management ideas from UNEP to UNECE. After 1987 the World Bank also became active in international environmental matters. Part of the environmental reforms

introduced at the World Bank was the recruitment of ecological epistemic community members and their assignment to key posts to evaluate the environmental consequences of development projects.

Diffusion occurred principally through efforts of these major environmental IOs and through environmental regimes. The IOs encouraged other IOs to internalize environmental concerns into their missions through joint projects, and encouraged governments to pursue more comprehensive environmental policies through public education campaigns, publicizing environmental monitoring findings, resource transfers, and demonstration effects.

International regimes have been even more important for the diffusion of ecological management techniques. This spread is due to the growing influence of ecological epistemic communities and the growing confidence and influence of strong international institutions informed with their ecological beliefs.

Ecological epistemic communities, often working with UNEP, helped draft international environmental regimes governing marine pollution, acid rain, stratospheric ozone protection, wetlands protection, protecting migratory species, polar bears protection, and the preservation of Antarctica. An increasing proportion of them are now based on the comprehensive ecological approach promoted by the ecological epistemic community. In 1973, three of 11 international environmental regimes were based on ecological management styles. In 1985, seven of 22 were comprehensive. In 1995, 10 of 25 were comprehensive (Haas 2001). The application of ecological management ideas to environmental regimes spanning a number of geographic areas and functional activities means that most states have accepted ecological obligations for governing a wide variety of human activities.

Ecological practices based on ecological management ideas have become locked in through a variety of mechanisms. Following ratification of international regimes, governments enforce these obligations domestically. Ecological practices get institutionalized domestically through legal precedents, bureaucratic standard operating procedures, and policy enforcement. In many countries they have acquired domestic constituencies—composed of lawyers and civil engineers who subcontract services, firms selling pollution control technologies, and environmental NGOs—that contribute political pressure for continued state enforcement of policies grounded on these ideas.

Exogenous forces have also reinforced these state commitments. A Gallup poll conducted in 1992 demonstrated new worldwide concern about the need to respond to global and transboundary environmental threats (Dunlap et al. 1992). In democratic societies public demands for environmental protection reinforce the influence of the epistemic community's ideas. International markets for pollution control technology also came into existence in the 1990s.

10. Further Research

Epistemic communities is a core concept in a progressive constructivist research program. Its application in international relations has restored agency to the study of ideas, improved the understanding of the sources of state interests under conditions of uncertainty and complexity, and expanded an understanding of regime dynamics. In policy studies it fleshes out with accounts of agency the insight that policy debates are discursive rather than rational, and thus 'best' policy analytic suggestions do not always prevail. It provides the potential for understanding the mechanisms by which knowledge change contributes to policy change.

Further work needs to be done to integrate this work into institutional studies, to better understand the character of crises that are capable of generating political upheavals and discrediting institutionalized ideas as well as how ideas become institutionalized at the national and international levels. Research opportunities beckon on the creation, mobilization and maintenance of epistemic networks. Further prospects lie in studies of variation in generation and selection of epistemic communities, and how they communicate with the public. Applications of epistemic communities' research would contribute to the development and organization of usable technical knowledge for improved policy debates on contemporary issues.

Policy Knowledge: Foundations

Private foundations, typically found in countries with strong market economies and comparatively weak states, directly fund public policy analysis by the support they provide to research projects, policy institutes, and individual scholars who investigate policy questions. Foundations also advance public policy agendas by supporting advocacy groups and social movements that in turn have policy agendas. In most countries foundations are prohibited from direct lobbying of legislatures, but they are generally free to support public education campaigns that can contribute to an environment within which different public policies will be favored or disfavored.

1. Definition/History

The private foundation is an institution that privately manages private funds in pursuit of a public good. The source of these funds is normally a wealthy individual, almost always a person whose wealth was acquired in commercial activities. Foundation funds are privately managed by self-perpetuating trustees. The requirement that foundations advance a public good derives from the law under which they are chartered. That law stipulates that the funds made available for the endowment of a foundation, being ‘tax-free,’ must be used for charitable or philanthropic purposes. Foundations operate primarily by giving grants from earnings on their endowments, though in rare instances will also use their endowed wealth for grant making.

The wealthy donor inclined to the philanthropic act as a way to perpetuate his or her name and social influence is not a recent practice. Plato bequeathed property so that his Academy would continue after his death, and in fact the Academy lasted nearly a millennium, from 347 BC to 529 AD, until it was deemed unchristian and dissolved by the Emperor

Justinian. Popes and princes became patrons of the arts to enhance their esteem in the public eye. The royal gift, especially to provide a health or educational service, is known across history and across royal regimes from China to India to Egypt to England. More than a millennium of Islamic philanthropy built libraries, universities, and mosques. Commercial wealth has generated philanthropic endeavors across the centuries, and not just since industrial capitalism. The famous Hotel Dieu in Burgundy was established in 1443 when the benefactor donated a highly valued vineyard. The University of Uppsala was similarly endowed with a gift of productive land. Philanthropy as reflected in the royal gift, the papal patronage, and even the private endowment is the backdrop to what emerged in the advanced industrial democracies, particularly the United States, toward the end of the nineteenth century.

2. Foundations and Industrial Wealth

Late nineteenth century industrial wealth became the basis for a new type of philanthropy—the private foundation. Modern foundations were a self-conscious break from Victorian era charity focused on the immediate relief of suffering and poverty. The distinction between foundation grant-making and charitable giving is often captured in the ‘root cause’ metaphor. Rather than relieve suffering, foundations see their purpose as doing something about the deeper causes that lead to suffering in the first place. The classic example is public health such as a vaccine regimen that is designed to prevent the suffering that accompanies epidemics.

Foundations also differed from the one-time gift to endow a hospital or center of learning. The private foundation, a legally immortal institution, extends the bequest and its purposes into the distant future. That is, rather than endow an institution, the philanthropic act endowed the foundation itself. There are a number of reasons for this institutional innovation, one being the sheer magnitude of the private fortunes gained by controlling a key industry (oil, steel, banking, transport) during the unregulated and largely untaxed decades of the late nineteenth and early twentieth centuries. The private foundation, then, is a place to put wealth too substantial to give away in one’s lifetime.

The twentieth century saw a vast growth in the number of private foundations, and in their aggregate asset base. There are more than 40,000 in the United States alone, and many fewer though still substantial numbers in Western Europe, Japan, Brazil, India, Mexico, and other of the wealthier nations of the world. Many foundations are comparatively small, with annual grant budgets of \$1 million or less. At the other extreme are a few substantially endowed

foundations—such as the Gates and Ford Foundations in the United States and the Wellcome Trust in Great Britain, whose annual grant-making approaches \$1 billion. There are also corporate foundations and community foundations, which together comprise about one-fifth of all foundations in the United States and a smaller percent in other countries.

There was a surge in the number of independent private foundations in the latter decades of the twentieth century, for reasons similar to the first surge that occurred a century earlier. The late twentieth century wealth gained through such new industries as electronics, information, media, and entertainment was at a scale comparable to the nineteenth century fortunes in oil, steel, and railroads. Such growth occurs in a period when the rules of the liberal economy allow, and even encourage, the accumulation of inordinate wealth in private control and which tolerate wealth inequalities at a scale thought improper if not immoral only a few decades earlier. If wealth redistribution through public policy was not in favor in the early twentieth century, neither is it in favor in the early twenty-first. The private foundation becomes, then, a means to recycle some of this wealth, though on terms largely set by the individuals who control it.

3. Foundations and the Political Culture

Social Darwinian theories favored by late nineteenth century industrialists and their apologists was particularly favorable to the emergence of the private foundation (see *Darwinism: Social*). An influential statement was Andrew Carnegie's widely circulated essay, *The Gospel of Wealth* (1889a). Carnegie acquired his vast wealth in the steel industry. He argued that industrial capitalism was providing more and more benefits to ever greater proportions of the population, but acknowledged that its workings inevitably generated substantial surplus wealth under control of the few. 'We accept and welcome, therefore, as conditions to which we must accommodate ourselves, great inequality of environment; the concentration of business, industrial and commercial, in the hands of the few; and the law of competition between these, as being not only beneficial, but essential to the future progress of the race.' (p. 656). Having acquired this wealth under the benign influence of social Darwinianism, Carnegie then concluded that it was his Christian obligation to give it away.

It was Max Weber, in *The Protestant Ethic and the Spirit of Capitalism*, who gave sociological depth to the association between Protestant asceticism and responsibility—with its emphasis on discipline, secular engagement, and deferred gratification—and the thrifty, hardworking business ethic that shaped modern capitalism (see *Weber, Max (1864–1920)*). The Protestant ethic stressed the greatest possible pro-

ductivity, but frowned on the luxurious enjoyment of the wealth so earned. If work is to manifest God's glory, the profits of work are to be reinvested in that which is productive and socially beneficial. To do good works in this life is a sign of grace. Not that salvation could be earned by good works, but doing good as well as being good was to be expected of wealth. This was a convenient doctrine for men, Carnegie notably among them, who were both devoutly religious and wealthy beyond easy measure. It is comforting to know that one can dedicate oneself to acquisition and yet be virtuous.

Although explicitly religious motives are not often cited in today's more secular culture, the Protestant ethic retains its hold. The notion that one is a 'steward' of surplus wealth still appears in explanations of the philanthropic act, as do echoes of the belief that good works in this life signal moral worth. Late twentieth century billionaires speak of an obligation to repay society for having been so good to them. They are in this respect reflecting the notion that the wealthy *because* they are wealthy are obliged to be philanthropic. Inherent in wealth is the responsibility to be responsible for the public good that one's wealth can promote.

The social Darwinian environment within which foundations emerge was compatible with another feature of, especially, American political culture—the weak state tradition. Understood as private funds linked to public purpose, the private foundation is a social invention consistent with this tradition. If wealth is accumulated in an amount that is too substantial to be consumed or given away in one's lifetime, and thought to be too great to bequeath to family members, there are a limited number of ways to dispose of it. Furthermore, if the political culture as well as law and taxation policy invite the wealthy to create private institutions that can function as an alternative to the state, there is much satisfaction to be gained by creating a foundation. In the twentieth century, then, the private foundation has become a major mechanism by which large-scale, privately held capital memorializes the donor, endows his or her philanthropic inclinations, and not incidentally substantially reduces tax obligations. In some instances it also serves to keep control of a business enterprise in the hands of a founder's family and descendants.

There is a long tradition of inquiry that sees in the establishment of foundations the intent by the donor to exercise lasting political-economic-social control. The very wealthy do not earn their fortunes without exercising economic control—of an industry, a marketing strategy, a scientific innovation, a new product. Nor are these individuals indifferent to how policies, regulations, tariffs, and taxes can help or hinder the acquisition of wealth. It is not much of a leap from these facts to presume that transferring private wealth to a private foundation is a way to extend political-economic influence.

For example, a Commission of the United States Congress (1915–16), observed that industry and wealth in the United States had come under the control of a few very wealthy persons. The Commission alleged that this small group intended to continue and extend this control by establishing privately managed funds for indefinite purposes. Here, then, is coupled the late nineteenth century anxiety about the concentration of economic power with the fear that private foundations would perpetuate the dominance of business interests in American political and social life.

Careful historical analysis needed to test this hypothesis is in short supply. There is, however, ample anecdotal evidence that donors who establish foundations have a strong inclination to see that their funds enhance particular political and economic doctrines, especially private enterprise and market capitalism. Perhaps there is an irony in the fact that the foundation results from the accumulation of substantial private wealth and yet in instance after instance declares that its mission is to improve the lot of the poor and powerless. It goes about that mission by helping to lower the barriers to upward mobility, by working to insure basic civil and political rights or by contributing to education and health for the poor. It does not go about that mission by calling into question the political-economic arrangements that allow for unequal wealth acquisition in the first place. This despite the oft repeated claim that foundations will find and eliminate the ‘root causes’ of poverty, discrimination, and illness. These root causes, however, seem not to include the economic doctrine and public policies that govern wealth acquisition.

4. The Public Policy Agenda

Based on statistics it collects from thousands of private foundations, the US based Foundation Center uses a ten-part subject-matter classification to report grant making: arts and culture, education, environment, health, human services, international affairs and development, public/society benefit, science and technology, social science, and religion. Although data collection is less systematic in other nations, these categories are generally serviceable across the private foundation world. Public policy is not its own discrete category, because policy analysis and policy advocacy can appear in each of the ten categories. Foundations have taken up arts policy, education policy, health policy, science policy, security policy, and much more.

Of course the policy interests of foundations alter with the times. To note obvious examples: the sizeable investment by American foundations in area and international studies, language training, and student exchanges is a product of post World War II conditions; the rise of environmental consciousness in the

1970s led to a marked increase in funding for environmental policy in Japan, Europe, and the US; the collapse of communism suddenly opened up opportunities in Eastern Europe and the former Soviet Union to which both European and American foundations were quickly responsive. Such examples could be multiplied over and over, indicating that the foundation mission and especially how it expresses itself in grant making is not frozen but rather adapts and evolves as the policy conditions change.

The foundation has a number of strategic choices available as it considers whether and how to confront the public policy agenda. Considered from the broadest possible perspective, foundations adopt strategies based on their notions about how social change can best be brought about. Does the foundation operate on the assumption that ideas drive history; or that technologies do; or social movements, market incentives, government interventions, moral exhortation? If ideas drive history, invest in intellectual efforts; if government interventions drive history, invest in specific policy analysis and advocacy; if exhortation drives history, invest in public education. Or, to use a metaphor much favored by foundations, grant making should seek out the point of ‘leverage’ judged to be most productive of desired social change. The point of intervention is sometimes indirectly and at other times directly linked to public policy knowledge or policy advocacy.

4.1 New Knowledge

Foundations have made major investments in universities and in research institutions, equipment, and personnel, as part of a broad strategy to advance basic human understanding in nearly every field of study imaginable: anthropology, astronomy, biology, chemistry, economics, history, medicine, music, physics, political science, and psychology, to name only the most obvious. These investments have, at times, been sustained over long periods, illustrated by the Rockefeller Foundation’s century-long involvement with medical science. And for some foundations for certain periods of their history, the search for new, fundamental knowledge defined what they were about, what they took to be their vocation. Seldom, however, was new knowledge sought for its own sake. The foundation is focused on *public* benefits and thus even an investment in basic science will always be linked to how the new knowledge is to be applied.

4.2 New Knowledge Applied

Foundations have always been focused on how new knowledge can be applied in socially beneficial ways. An example is the investment in the public health profession, viewed as a means to ensure that dis-

coveries from biomedical science will reach the broadest population possible, and especially those population groups that might otherwise be ignored. There are many other examples: basic knowledge in learning theory being coupled with school reform efforts, basic knowledge in plant physiology leading to higher yielding food crops and their dissemination in poorer countries. In this application effort, the foundations make heavy use of the social sciences more generally and policy studies more specifically. (See *Policy Knowledge: Universities*.)

4.3 Direct Policy Analysis

Foundations have had a long, close relation with studies and publications that would inform public policy. This can be seen in the heavy investment in policy research institutions in the United States, and in policy reports and white papers in European countries. In the United States the independent policy institute and the independent foundation are linked because they are responsive to the same deep strand in the political culture that prefers the private to the public sector (Prewitt 1995). Foundation funding of the social sciences, which starts before the turn of the century, has generally been motivated by the quest for improved public policy. The close relationship between foundation funds and public policy analysis underscores how privately held philanthropic resources attempt to advance public purposes. This relationship has been a complicated one, attracting its share of sharp criticism from both the political left and political right. Notwithstanding this criticism, foundations have forthrightly declared their intent to fund analysis that will lead to what they view as public policy improvements. For example, the German-based Bertelsmann Foundation articulates as one of its primary goals to provide new concepts and models for the social market economy and for public administration.

4.4 Policy Advocacy

Often in combination with policy analysis, foundations have funded a seemingly endless number of organizations dedicated to fighting for or against particular public policies: in human rights, equal opportunity, school reform, nuclear disarmament, environmental protection, free speech, children's welfare, and on and on. Although a dimension of American philanthropy early in the century (Sealand 1997), such funding gained momentum in the post World War II period as the federal government became increasingly active in areas long of interest to the philanthropic sector. If foundation funds could stimulate the government to adopt the 'right' policy in

civil rights or social welfare, the impact would be far greater than what could be accomplished with foundation funds alone. From this emerged the notion that philanthropic dollars could be taken to scale by leveraging government funds. That is, if government through its regulatory and taxation powers influences private expenditure patterns, philanthropy reverses the direction of influence by spending private funds on policy analysis and advocacy that will change government spending priorities. In earlier years, the policy advocacy groups supported by foundations largely focused on domestic policy. In recent years, however, attention has broadened to include the international arena and international actors; policies of the World Bank or the World Health Organization or multinational corporations are targets for internationally organized advocacy groups, especially in the fields of environment and human rights. The post-1989 preoccupation with what is often if not very precisely described as civil society funding is a combination of policy advocacy and social movement philanthropy. (See *Policy Knowledge: Advocacy Organizations*.)

Though overlapping with policy advocacy, social movement philanthropy is sufficiently different to merit independent mention. In recent decades, the major beneficiaries have been social movements organized around equality for women, environmental protection, and civil rights for racial and ethnic minorities. Although each of these social movements originated outside philanthropy, foundation dollars rather quickly led to their stabilization and professionalization. Support for social movements is largely a post World War II phenomena, getting its start with the activism that characterized the 1960s. This type of funding has also been internationalized, as worldwide organizations have formed to advance environmental protection or women's rights or children's welfare. What foundations refer to as support for grass-roots organizations, or community groups, is often an element of social movement philanthropy.

Closely associated with such funding is an emphasis on *social empowerment*. This term refers to the direct empowerment of individuals, especially the traditionally powerless or disenfranchised social groups. An example is micro-credit lending, which is designed to put resources directly in the hands of the powerless poor. Social movement and social empowerment philanthropy are linked in that the former has the dual purpose of empowering its adherents and changing the social landscape. But direct empowerment need not be part of an effort to create a social movement. The beneficiaries of a micro-credit lending program or a female education strategy are not viewed as members of a movement in the same way that feminists or ecological activist are. Social empowerment, of course, is a close cousin to charity—the direct relief of suffering. But philanthropy has defined itself as not about charity so much as by its intent to remove the 'root causes' that lead in the first place to the suffering

for which relief is sought. In its effort to permanently change the condition of the disenfranchised, empowerment is distinct from direct charity.

4.5 Public Education

Foundations have often tried to influence the policy knowledge of the general public. There are numerous examples where foundation funds have been used to improve public understanding as a way to correct for what are considered 'misguided' public practices. A public inclined to permit inefficient and corrupt partisan politics, for example, might be taught to appreciate the virtues of independent expertise in government and a professional civil service—and turn of the century philanthropy took up this progressive cause. Or, a public too given to racial prejudice should be enlightened to the moral worth of racial tolerance—a major philanthropic project across the twentieth century. The examples multiply endlessly—the public is inefficient in its use of energy, unclear about the dangers of population growth, illiterate about its national history, prone to unhealthy eating habits, smokes too much, and, repeatedly, is insensitive to the plight of, depending on the times, women, workers, children, the poor, immigrants, minorities, the handicapped or others from a long list that changes its emphasis from decade to decade, but is never absent from the philanthropic portfolio.

These deficiencies in public knowledge, understanding or attitude can be corrected by the selective use of foundation resources, such as introducing new elements into the school curriculum or through targeted media campaigns. More than public education is at stake, for these efforts often have a change in public policy as the goal. The anti-smoking campaign illustrates this. Foundation supported public education intends not just to discourage smoking, but also to modify public policies on, for example, where tobacco can be sold or how it can be advertised.

What are generally described as 'liberal foundations' have been especially adept at using public education campaigns to shape public opinion, though in recent decades foundations with a more conservative inclination have supported the writings of public intellectuals on what they see as failures in public education, social welfare, criminal justice, and other projects long associated with liberal foundations.

5. Entrepreneurial Philanthropy

Through the twentieth century the attention of foundations to policy knowledge and analysis focused almost exclusively on government policies. Insofar as the behaviors of business sector firms were of interest,

the strategy of choice was to affect regulation, taxation and other public policies to influence market behavior. In the latter decades of the twentieth century this exclusionary focus on government policy began to alter. Some foundations directly addressed the policies and practices of market actors. For example, in the field of public health, foundation funds were used as an incentive to induce pharmaceutical firms to invest in AIDS vaccine research and with respect to energy efficiency, foundation funds attempted to influence utility companies to give more attention to renewable energy sources such as wind and solar power. Micro-credit lending (below market loans in impoverished areas for small-scale entrepreneurs) also became a favored target of foundation funds.

With the arrival on the foundation scene of young, recently wealthy entrepreneurs from the high technology industries this form of philanthropy is likely to increase. The degree to which it will supplant rather than simply add to traditional patterns of public policy funding is unknown, but it is not likely that foundations will soon if ever exit the long-established field of public policy analysis and advocacy.

6. Conclusions

Foundations are well established in advanced market economies, especially in those countries with a comparatively weak state tradition. Over the decades a receptive network of regulatory and tax policies have emerged to make it easy to establish foundations, and thus to withdraw funds from the tax stream on the assumption that these funds will serve the public good. Foundations have used these tax-free funds to support studies of alternative public policies in areas of interest such as health, environment, education, the arts and so forth. They have contributed significantly to the growth of policy knowledge. As more and more nations of the world adopt liberal market economies, it is likely that foundations will emerge in ever greater numbers. It is also likely that public policy analysis and advocacy will remain a foundation funding priority.

Policy Knowledge: New Liberalism

New Liberalism is at its core a contrast term, designed to distinguish it from and to set it against classical liberalism, as the latter developed in the West between the seventeenth and mid-nineteenth centuries. In use internationally between the 1880s and the 1940s, the term referred to a broad-gauged movement in social knowledge, public philosophy, state policy, and social practice intended to address the 'critique of political economy' and the 'social question' that the pernicious instabilities and distributive inequities of modern capitalism had engendered, and to provide new critical thinking about the crucial relationships between *state*, *economy*, and *society*. The movement should not be taken as a total repudiation of the older tradition, with its characteristic stress on individual autonomy, private property, and limited government. Rather, new liberalism was undertaken initially as an exploration of how and where to amend the old ideals in light of what had come to be seen as negative consequences of capitalist industrialization, and as a method for helping to shape and choose among new civic and social moralities under construction in the industrializing nations of the West.

New liberals were ultimately unable to sustain their critical assessment of the classical tradition without changing quite fundamentally their understanding of the relationship between society, economy, and state. In an intricate process of reaction and inversion, these changes shifted the meaning of political conservatism in the West, gradually severing it from its basis in quasi-feudal and aristocratic precedents and reorienting it toward a defense of personal, civil, and commercial liberty as it had earlier been defined in the 'old,' classical liberalism. The account of new liberalism provided here refers mainly to the American

case, with occasional references to other (mainly the British) experiences. It identifies four phases in the development of new liberalism that aid in heightening the visibility of critical moments in its construction. These phases are: (a) market failure and the drive for new social knowledge, (b) conflicting approaches to framing the social question, (c) the 'turn' to social insurance, and (d) the social sciences, planning, and the limits of liberal statism.

1. Market Failure and the Drive for New Social Knowledge

The devastating market failures of the late nineteenth century, destabilizing waves of bankruptcies, mass unemployment, and chronic, desperate poverty produced an enormous disappointment of traditional liberal expectations regarding the efficacy of the market. New liberals recognized market failure and attendant social conflicts as evidence of a wider collapse, more disruptive to intellectual, social, and political order and more menacing to communities of a social contract based on unfettered competition between white males that had been implemented during the market revolution of the Jacksonian era. Rejecting the excessive individualism, localism, and states-rights obstructionism of that period as morally and intellectually bankrupt, they put themselves quite deliberately in the business of conceptual innovation, seeking a higher rationality that would place knowledge in the service of a more democratically constituted society, which would maintain itself in part by allotting intellectuals a special role in shaping a more vigorous, capable, developed, and purposeful national government.

Across the range of nations involved, the conceptual revolution that new liberals sought to promote was grounded institutionally in an international social science association movement that fostered transatlantic borrowing, and in critical journalism, settlement houses, and social surveys, all of them cranked up to record, analyse, and disseminate empirical data, propound theory, encourage the development of political leadership responsive to the 'teachings' of liberal social knowledge, improve the execution of policy, and advocate reforms intended to renovate and enable Enlightenment ideals of political equality and social justice. Within government, in investigative agencies such as improved censuses, labor, women's, and children's bureaus, trade boards, and bureaus of corporations, high-level civil servants such as Llewellyn Smith and Lord Beveridge in England, and Carroll Wright, Francis Amasa Walker, and Julia Lathrop, in the United States provided conduits for policy ideas from those burgeoning 'parastates' into the state. Within this 'great transformation' in social thought and political practice, crucial early players were the

academic social science disciplines, whose missions and boundaries were historically determined, differing from country to country. Academic professionalization proceeded rapidly in the American research universities, fueled by rapid economic growth, academic entrepreneurship, and the relative shortage of other types of creditable specialized intelligence.

But from the beginning, progressive academic economists, political scientists, and sociologists were interested in more than the provision of expertise; even as conservative university trustees (and at times conservative colleagues) disciplined their advocacy, social scientists saw themselves as crucial links in the interpretive processes needed to make the new political and social economy intelligible. Thus their specialized investigations and discourses were a critical factor in reworking the political agenda so that it placed prominently before policy makers and emerging, activist publics as problems urgently needing comprehension the range of issues that came to define the politics and policymaking of the new liberal era. Most prominent among these issues were business cycles and unemployment, rights and conditions of labor, wages and distribution, industrial organization and corporate reorganization, family welfare and gender roles, problems of the low-paid, exploited immigrant work force and—often with disabling assumptions rolled in—issues of race. They also addressed related issues of governance: the detection of wholesale corruption of law and government that inspired the clean government crusade, and the need for methods of building up the cognitive abilities and administrative capacities of public officials.

Strategic rhetorical steps were taken early that shaped the ties between American governance and intellectual life in the period. In the United States, Woodrow Wilson's early and generative 'Science of Administration' (1887) addressed republican fears of bureaucracy by placing a firewall between politics and administration. Reflecting distaste for the intense, tribal partisanship of Gilded Age politics, academics and bureaucrats (unlike many female social scientists and social reformers) adopted nonpartisanship as a standard description of their professional ethic. This pristine canon elevated everyday standards of disciplinary and agency practice, but it often hampered the effectiveness of social scientists as advocates for change, routing their activism through ostensibly apolitical venues such as foundations and think-tanks, which ceded partial control of research agendas to corporate elites.

2. Conflicting Approaches to Framing the Social Question

Yet despite frequent and often calculated professions of scholarly and professional neutrality, the building

of new liberalism was neither a consensual nor a non-ideological process, but rather one in which newly experienced social realities disrupted expectations and categories in different and conflicting, contested ways. Deep divisions over the substance and implications of new empirical and theoretical knowledge led to a branching of new liberalism, early in its American career, into what participants saw as two distinct new liberal movements—a *statist-democratic* strand of reform thought born in the 1880s, and an opposing, *corporate-voluntarist* analysis that came together around the turn of the century. These conflicting reform discourses, worked out in dialogue with each other between the 1880s and the 1940s, opened up greater possibilities for genuine policy innovation than existed either earlier or since.

Assessing deficiencies in the mechanisms for translating an aroused social conscience into effective social action, the statist strand of new liberalism looked in new ways and on a number of fronts to a redefinition and a principled restriction of the meaning of 'private' in many of its applications, and to a corresponding expansion of what were to be taken as proper, morally necessary functions of government. Liberal statistes sought more effective methods for mobilizing state agencies in behalf of a reinvigorated national interest, taken as something higher and more ethically compelling than the sum of the separate private, local, class, or sectoral interests.

The competing voluntarist vision rejected with equal conviction what—telegraphing their disapproval—its founders referred to as 'state interference.' Seeking ways to insulate and energize civil society, the anti-statists preferred to build new ordering strategies upon what they took to be the naturally evolving social institutions of a modern pluralist society, premier among them the corporation, and what they saw as organic, corporate bodies such as trade associations, trade unions, professions, and charitable associations, rather than around invigorated democracy, political mobilization, and a bureaucratic, regulatory state, which they represented as intrusive upon 'natural' evolutionary processes and prone to manipulation, most dangerously by social levelers who failed to appreciate the vulnerability of the investment system. More than merely Tocqueville revivalists, they were particularly interested in what could be achieved by way of ordering a chaotic, excessively competitive economy through innovative uses of the business contract, within a rich climate of information about the market, and through enlightened management. This effort culminated in the liberal-corporatist design fleshed out during the 1920s for peak-level business-government cooperation in achieving economic and social stabilization through energized philanthropy and local relief in hard times, but mainly preventively, through the development and legitimation of industrial self-government oriented toward controlling chronic instabilities such as overproduction.

The liberal statist placed greater confidence in deliberative democracy than this, and less in capitalist rationality or the unity of the corporate and the public interest. Drawing energy from heartland republicanism, evangelical Christianity, and European socialism, a leading theorist of the new liberal state, political economist Henry Carter Adams, marked out a path that two generations of unabashedly statist progressives would define as a democratic, progressive, collectivist or communitarian public philosophy—a distinctively American middle way between what they framed as the excessive individualism of the British model and the excessive statism of the German. The founding text for the liberal statist approach was Adams's classic paper, 'Relation of the State to Industrial Action,' which interrogated standing assumptions about the beneficence of competition and called into question the fundamental morality and the long-term serviceability to the public interest of the way the modern capitalist market was being constituted in its corporate phase. For those engaged in reflecting on issues of public philosophy, Adams, along with Richard Ely, Florence Kelley, Edmund James, Simon Patten, John R. Commons, and Jane Addams among numerous others, did more than establish a 'context of refutation' for socialists and die-hard believers in *laissez faire*. More important, in relation to later developments in theoretical and policy knowledge, they directed their arguments quite explicitly to new-liberal antistatists, who were forming their own intellectual identity in the 1890s as part of a corporate-voluntarist counter-attack on liberal statism.

Reflecting back on the historical construction of the ante-bellum US liberal order, Adams pointed to three deficiencies of a regime of market competition that set the initial terms on which this new, positive vision of liberalism would be built: (a) its failure to allow society to enjoy the benefits of monopolies occurring naturally in increasing-returns industries, and thus to reap the benefits of human genius enacted in advancing technology, (b) the inevitable decline of business ethics to the lowest level, absent a generally credited method for communal determination and legal establishment of labor standards, among them a right to employment, and (c) a corruption and general hollowing out of the substance and potential of representative government in a deliberate, misguided weakening of state capacities, which Adams traced to anti-statism in the Jackson period, the lack of a respectable science of public finance in the United States, the rise of powerful corporations, and a compliant legal profession bent on shaping the protections of the law to private ends.

Naturalizing certain instances of monopoly was a critical step in the modernization of civic republicanism, designed to pull that venerable tradition out of the Jeffersonian, anti-monopoly, anti-statist discourse that had assimilated it to market liberalism. The reshaping of this core category laid an authoritative

basis for state supervision of entire segments of the transportation, communication, and production systems, designed to control monopoly power. This strategic conceptual move gathered force in the regulation movements of the early progressive era, and in Theodore Roosevelt's vision of a national law of corporations, a robust national citizenship, and a muscular 'new nationalist' bureaucracy capable of disciplining the modern corporation. Classic texts such as Herbert Croly's *Promise of American Life* (1909) and the Progressive Party Platform of 1912 represented the maturing new liberal orientation to planning, in which capable, informed governance could instruct and protect a collective interest in conservation, labor standards, and consumer protection. More than merely an affirmation of the need for aggressive regulation in these regards, Rooseveltian progressivism argued for a public presence in the civic discourses and decisions regarding production, investment, and pricing. This broader vision of a deliberative process that could detect and shape the impact of American capitalism on society was later the unifying insight at work in the planning phases of the New Deal, most evident in the activities and discourses of the Public Works Administration (PWA), the National Resources Planning Board (NRPB), and the Temporary National Economic Committee (TNEC).

The Adams-Ely view was challenged immediately by procorporate academic economists Arthur Hadley and Jeremiah Jenks, close students of the sources of market failure in specific industries, and political advisers to Republican governors and presidents. Though these two extended what they saw as a natural tendency to monopoly even further than Adams did—into the whole broad range of capital-intensive industries, they considered even indirect state control of production and profit a threat to the price and investment systems that neither liberalism, capitalism, nor private morality could long endure. Conservative institutionalists such as these began constructing an alternative, more hierarchical, less democratic discourse of elite responsibility and social control, forming around the institutions of high finance and the corporation. They hoped to make the new corporate elites responsible for transclass and intercorporate cooperation, for personal growth and individual mobility along career ladders provided by corporate business, and even for community economic and moral development—to the extent that experience within a corporate culture would inculcate values of efficiency, cooperation, interdependence, and service.

This rudimentary modernization theory was the founding discourse of corporate liberalism, which down through Herbert Hoover's associative state to its full flowering in pluralist theory and liberal-corporatist public policy during the Eisenhower years equated the (properly enlightened) corporate interest with the (properly conceived and limited) public interest in sustained growth of the economy. Cor-

porate liberalism provided a systematic alternative to liberal statism, supplying a constraint on statist progressive politics in the US that was available, in anything like comparable strength, nowhere else.

More than other distinctive qualities, such as early (white manhood) suffrage, weak parties, weak labor, weak socialism, or state structure and capacities, this continuing tension between statist and corporatist discourses of the public interest, increasingly fleshed out in programmatic terms, explains—along with issues of racial exclusion that new liberals for the most part only minimally addressed—the special character of modern United States liberalism. It also helps to account for the distinctive pattern of US state formation, and particularly welfare-state development, that students of social policy, often taking the more comprehensive European welfare states as the normal path of history, have seen as tardy, insufficient, and incomplete—kept from developing by traditions of individualism and *laissez faire*.

In reality, such commitments were highly attenuated where they survived at all among the knowledge-producing classes most involved in shaping new liberalism. For democratic theorists from Adams to John Dewey, the public interest was a potent category—reclaimed from the republican past, but extensively recast to take account of concentrations of social and economic power that threatened family subsistence, community morals, responsive and responsible governance, and political, social, and economic democracy. In his seminal *The Public and Its Problems* (1927), another powerful exemplar in the new liberal ‘role of the state’ genre that H. C. Adams inaugurated for Americans, Dewey located the public interest as the place in social relations where effects spilled over from the parties to a contract to third parties, who bore the often devastating ancillary consequences of others’ private bargains.

In the construction of democratic statism, problems raised by shoddy business ethics and new, manipulative forms of ‘scientific’ management rivaled concerns about monopolistic corruptions of the corporate form. Instituting another enduring theme in new liberal reflection about the role of the state, the second ‘evil of competition’ in Adams’s treatise—pernicious insecurity, exploitative working conditions, and relentless time pressure—he proposed to remedy by labor-standards legislation based on a community moral consensus derived discursively, from detailed knowledge of the impact of industrial labor as then constituted, on the moral, mental, and civic capacities of the working class. The debilitating effect of casual labor, low wages, and chronic unemployment on working class men and women was a constant theme that women’s social investigation and reform activism also did much to develop. But this emphasis on legislated labor standards should not be mistaken for an early blueprint for the welfare state. In the formative moment, the 1880s to 1910s, American

statist progressives were looking not to compensatory welfare measures but to independent unions, fostered by public intellectuals and protected by the state, and to community moral pressure and democratic politics, as the means for achieving an ‘economic republic’ and ‘industrial democracy.’ Their vision included recognition of two inalienable rights of worker citizens—a ‘living’ wage, sufficient to support a family in reasonable comfort, and a voice in management.

3. The ‘Turn’ to Social Insurance

Underway in Europe much earlier, the new liberal ‘turn’ to social insurance came in the American case only in the second decade of the twentieth century. Growing up in social work, settlement, bureaucratic, and academic circles, it signaled the onset of a second phase in new liberal thinking, running parallel, but in important respects contrary, to the older movement for industrial democracy, which also continued to gather force through the New Deal and into the late 1940s. Several factors can be seen to have promoted the adoption of a social insurance perspective, among them the arrival of a broad environmentalist consensus on the causes of poverty, accumulating realism about distinctive constraints on labor’s capacity to organize a positive political program, and the social tensions that compelled American cities to provide relief during cyclical downturns from the 1870s onward. Once again, academic and expert knowledge played a major role as well. European reform discourses and precedents, culminating with the British adoption in 1911 of broadly accessible unemployment insurance, were faithfully catalogued in works such as Isaac Rubinow’s *Social Insurance* (1913). As class conflict accelerated, inquiries staffed by social scientists such as the famous Pittsburgh Survey and the United States Commission on Industrial Relations documented economic insecurity as the central cause, along with corporate arrogance and powerlessness to combat it in their communities, of worker unrest, suggesting an attack on inequality through aggressive labor standards reforms and state policies promoting redistribution.

Contrary to the strong government role envisaged by the USCIR and in wartime programs for improving labor standards, in the post-World War I period, with Herbert Hoover in a prominent organizing role, the Wilson and Harding administrations arranged a series of high-level conferences for planning postwar stabilization. Allied with the President’s Conference on Unemployment, Wesley Mitchell’s National Bureau of Economic Research drew in economists such as Leo Wolman and Wilford I. King for the vital statistical work and propagated new methods for understanding the pesky business cycle. This chain of policy thinking suggested alternative policy options, among them more responsible administration of credit by banks and government, enrichment of the informational climate for business decisions to facilitate a

microeconomic approach to steadying output and employment, the accumulation of reserve funding for countercyclical public works by (from Hoover's perspective, preferably local) government, and an actuarial approach to relieving unemployment through funds amassed by employers, unions, or government. In what must be seen as one of the most significant conceptual innovations in modern governance, these more conservative approaches transformed unemployment from a problem of the political order rooted in inequality into a 'risk,' the key policy decision becoming therefore how, and by whom, that risk—understood as a problem in the smooth management of the elastic supply of reserve labor accepted as an indispensable part of the capitalist process—could be insured. In the discourse manufactured in Hooverian circles, most of these remedies could be implemented by informed business decisions and enlightened labor-management cooperation.

The impulse for what from the perspective of liberal-statist, laborist, and social-feminist proposals for extensive redistribution of income and political voice became a critical retrenchment in social policy thinking arose not only from these liberal corporatist initiatives, but from at least three other, at first glance unlikely sources as well: the maternalist turn in the women's movement of the progressive era; a vision of the immigrant and non-white poor propagated in the social sciences, by the Chicago school of sociology most particularly; and the appropriation and aggressive expansion of carefully targeted forms of social provision in the private-sector, imagined by corporate liberals in business management, government, and the academy as a strategy for making the 'modern manors' of welfare capitalism reliable instruments for securing the loyalty and uninterrupted productive service of industrial employees.

As the central sites for the development of reform discourses that transported women's issues from the private to the public spheres, the women's movement and female social science were neither immediately nor exclusively committed to a social insurance perspective. Female social scientists such as Jane Addams, Florence Kelley, Alice Hamilton, Crystal Eastman, and Mary van Kleeck initially broadened the social question to include the appalling conditions faced by working class families in immigrant enclaves, conditions they traced as much to deliberate capitalist exploitation as to the relentless, patterned instability of the capitalist economy. Constitutive new liberal texts such as the pioneering social survey *Hull House Maps and Papers* (1895) and Margaret Byington's 1907 study for the Pittsburgh Survey of steel workers' families traced their poverty to the most discretionary of environmental causes—a calculated policy of exceedingly low wages and insufficient employment, yielding family incomes well below what was needed for subsistence, chosen by leading industrialists as a way to socialize much of the cost of maintaining a low-

skilled industrial work force, including a good-sized reserve labor supply.

Female reformers such as these translated their expert knowledge of the working conditions of women and children into an ethic of public responsibility that matched and complemented the initiative of academic new liberals such as H. C. Adams for finding ways of translating communal judgments regarding the 'moral plane of competition' into policy. Often promoting and then working in state and national investigative and protective agencies, rights-thinking feminists were thus among the earliest new liberal state-builders. Yet, as conservative opposition accumulated and the suffrage crusade shifted to political mobilization, important segments of mainstream feminism took on a more elitist, exclusionist cast, and the 'female dominion' of women's institutions increasingly followed a separatist course in identifying its reform goals. Leading female reformers, sociologists, and legal realists built a maternalist case for special state-based income assistance to mothers and children, special provisions for safeguarding maternal and infant health, and special protections for republican mothers in the workplace.

Maternalists helped to shape as the American pattern what women's historians have identified as a two-channel welfare state, in which one channel provided universal coverage for male workers under reasonably generous programs such as workers' compensation, unemployment insurance, and Social Security, whereas the other offered only meager, means-tested pensions for virtuous poor widows, and little assistance of any kind for most female workers and people of color. Worthwhile in themselves as strategies for meeting real needs among the 'deserving' poor, these approaches sidestepped, or confronted only indirectly, and without formulating them as such, issues of monopoly power, proletarianized, low-wage work, and obstacles to unionization for workers of both sexes that had initially been catalysts for the development of democratic-statist new liberalism.

The social sciences provided powerful legitimization for the social insurance track as an alternative to empowering the bottom ranks of the working class. Between the 1890s and the mid-twentieth century, even as institutionalists continued to fashion economic knowledge in forms that emphasized law and capitalist agency as contexts for the political and cultural creation of markets, rival neoclassical economists cultivated statistical and mathematical models of analysis that extracted economic behavior from history and culture, naturalized the workings of the market, and turned the discipline into a potent, technocratically organized form of social engineering. As Dorothy Ross's account of the rise of scientism also documents, quantitative, behavioristic and functionalist models vied with historicism and institutionalism in other social sciences as well, perhaps most visibly in two massive collaborative efforts in Hoover-

era policy knowledge, *Recent Economic Changes* (1929) and *Recent Social Trends* (1933). The dominant sociological discourse of the 1920s, the 'Chicago School' established by Robert Park, W. I. Thomas, and their students at the University of Chicago offered an alternative to the liberal-statist explanation for poverty and urban ills that took the form of a cultural theory of urban family and community 'disorganization.' Describing a succession of discrete stages—contact, disorganization, acculturation, assimilation—that accounted for the rise of problems such as dysfunctional families, juvenile delinquency, and crime, these scholars offered a vision of the immigrant, and especially the African-American migrant poor as culturally deficient—whether from environmental, or more enduring cultural causes. They uncovered 'pathologies' in Negro personality and family patterns, an alleged inability to defer gratification rooted in the experience of slavery, and a tendency toward male improvidence and female-headed families, for example, that predicted a longer than normal acculturation process for African Americans. Culminating with Gunnar Myrdall's *American Dilemma* (1944), this new cultural analysis of poverty separated the poor from the capitalist strategies that shaped their lives, and rendered those historically constituted structures less visible.

Maternalist social knowledge and the sociology of ethnic difference merged with developments in the new sciences of management to promote the development of corporation-based programs for linking carefully constructed forms of social provision to employment with specific employers. When wartime controls on the economy were quickly abandoned, corporatism flourished in the United States (as it did in different forms during the interwar period in Europe as well). Doctrines of imperfect competition, an institutionalist analysis of the modern corporation's separation of ownership from control, arts of advertising based on a new consumer psychology that legitimized desire, and theories of an administered market allowed liberal corporatists to proffer a new economy of mass consumption as a palatable alternative to nineteenth-century producerist dreams of worker control.

Resisting this trend only formally, the American Federation of Labor, along with industrial relations experts constructing a new profession in the 1920s, recognized productivity increases as the indispensable basis for increases in wages. Where company welfare programs existed, worker loyalties based on them ran quite deep. Thus the shock of the sudden collapse of Hooverian strategies for industrial self-government in the Great Depression crisis, the failure of voluntarism more generally, the welcome proliferation of New Deal programs targeting unemployment and poverty, and the aggressive organizing efforts finally unleashed by national labor-rights legislation helped to ratchet up workers' expectations of the state, and to reinvigorate impulses, largely quiescent since the im-

mediate postwar era, toward the development within government of planning capacities capable of heading off such emergencies in the future, and of democratizing both industrial governance and the political state.

4. *The Social Sciences, Planning, and the Limits of Liberal Statism*

From their beginnings in the Enlightenment and especially since the late nineteenth century, the social sciences were oriented toward planning, defined imprecisely enough to include methods all the way from enriching the informational climate of decision making to managing economic performance and shaping cultural expression. Most centrally a conservationists' discourse of efficient natural resource management in the 1910s and a welfare corporatists' discourse about the benefits of social cooperation in the 1920s, the American conversation about planning matured rapidly in the depression emergency. As critics correctly charged, stressing continuities in the development of a national planning capacity that bridged private and public, the National Recovery and Agricultural Adjustment Acts could seem like little more than surreptitious continuations of corporatist strategies for contriving scarcity under the cover of state compulsion. Yet a parallel, consciously statist movement also reappeared in the 1930s, fueled by FDR's intense commitment to planning, challenges on the left that promised full utilization of idle resources and full employment, and the recruitment to government planning agencies of a social scientists, including a large number of institutionally oriented economists, who energized and updated the democratic statist strand of new liberal thinking. When crisis suddenly opened the way for bureaucratic efforts to comprehend and combat depression, many of the plans necessarily came 'off the shelf,' as did the comprehensive programs for national old age, survivors, unemployment, and disability insurance. Yet by the mid-1930s institutional and policy innovations shifted the planning discourse toward methods of using resources efficiently over the long term, expanding public investment, crushing debilitating tendencies toward monopoly, and rekindling demand—policy goals institutionalists insisted were related causally. Social scientists in key nodes of conceptual innovation redefined planning and, within the constraints of opposition that also bedeviled Franklin Roosevelt's own narrower planning ambitions, attempted to give it an overt civic dimension. Thus, in the early leadership of the National Labor Relations Board, William Leiserson and others experimented with methods for linking the civic and stabilization purposes of the Wagner Act, which its framers intended to ensure the worker's right to organize independently, but also to equip trade unions

to play a role in redistributing income, supporting the workers' ability to consume, and democratizing industry.

Economists' knowledge and planners' leanings toward infusing market structures with civic purposes also blended in agencies such as the venerable Bureau of Agricultural Economics, the path-breaking, community-reconstruction oriented, ultimately disappointing Tennessee Valley Authority, and the Farm Security Administration, which addressed the issue of chronic farm surpluses, but also the economic and social marginality experienced by people at the bottom of rural hierarchies. A major study by TNEC of the concentration of economic power steered by Thurman Arnold and Leon Henderson referred the stickiness of prices, excess saving, and the slow pace of investment back to the monopoly power that allowed large corporations to administer markets and perpetuate extreme maldistribution of income and wealth.

The meaning of planning was shifted most decisively by theoretical, institutional, and practical innovations generated by the NRPB, as that New Deal agency's role was enlarged by Roosevelt from resource management to guiding government efforts to achieve recovery, and later to maintain prosperity and promote economic democracy after World War II. A body of economic knowledge produced in the early 1930s by economists such as Edward Chamberlain, Joan Robinson, Alvin Hansen, and John Maynard Keynes explained how a stubborn equilibrium, well below the level of full employment of the factors of production, could have been reached and sustained over nearly a decade. Building upon this, economists at NRPB and the Federal Reserve zeroed in on underconsumption as a factor in the slow and uneven pace of recovery and pointed to gains to be achieved by more aggressive deficit financing of public expenditures in the form of worthwhile civil works. By the definition of planning that flowed from this new thinking, the state became responsible for continuously monitoring and occasionally dramatically augmenting or shifting investment flows in socially constructive directions not attractive to the private capital markets, and for limiting entrenched corporate power over prices and redistributing income to support consumption. Among the most advanced elaborations of New Deal statism, *Security, Work, and Relief Policies* (1942) conveyed NRPB's synthesis of three related but discrete government roles: guaranteeing work for the segment of the population securely attached to the labor market, financing and extending social insurance to care for those unable to participate in the work economy, and underwriting a still highly contested version of industrial democracy through the NLRB and the self-organization of labor. Through its promotion of this triad, the NRPB enunciated a liberal statist's vision of a new social contract.

New Deal planners managed only a partial and temporary fulfillment of the moralizing role Henry

Carter Adams had charted for knowledge-based civic discourse back in the 1880s, implemented in limited ways through the Fair Labor Standards Act and the Fair Employment Practices Commission. The NRPB's interest in postwar planning was one of the factors that led to the unceremonious termination of the agency in 1943, a milestone in the history of new liberalism and in the history of the social sciences as well. The commitment of New Deal planners to full employment proved untenable in the face of rising opposition to the New Deal. Though the Council of Economic Advisers authorized by the watered-down Employment Act of 1946 lacked the authority to trigger government spending at a level needed to achieve full employment, the agency continued at least through the Truman era to press for a major government role in the postwar expansion of the economy, and to jawbone against monopoly as an obstacle to growth.

Meanwhile, opponents of planning clustered around nodes represented by the resurgent free market liberalism of Frederick Hayek and by concerns among business conservatives and Southern industrialists, fanned by legal activism and the uproar created by *American Dilemma*, that federal government controls might invade local prerogatives regarding labor and race. The most influential opponents of government authority in these regards were undoubtedly corporate elites and corporate liberal thinkers who considered the associative vision of business-government cooperation a better method longterm. Herbert Stein, Allan Brinkley, and others have located a 'fiscal revolution' in economic policy thinking, underway by 1937, in which a competing body of policy knowledge suggested that the measured use of fiscal and monetary levers would enable macroeconomic stabilization without intrusion into capitalist decision-making processes or extensive interference with labor markets, which in this view could safely be left to private management in the context of 'commercial Keynesianism' and a compensatory state.

Whereas the first generation of American liberal-statist social scientists had reconstituted government as a knowledgeable, morally responsible regulator, and the second generation of planners had modeled the state as social insurer and mediator of class antagonisms, the third, New Deal generation of planners conceived a state role not well captured as state capitalism. It was closer to older Hamiltonian and Whig models of a development state responsible for liberating and energizing community efforts and for facilitating the balanced economic and civic development of the commonwealth. Policy discourses of the 1950s, developed around Cold War internal security issues, an increasingly consensual growth-oriented commercial Keynesianism, modernization theories exported from the United States as technologies for liberal internationalism, and domestic discourses of racial and gender identity, challenged the

assumptions of new liberal social science, fostered new methods for interpreting modern social relations, and inaugurated a new ideological era. But embodied in resilient structures of disciplinary knowledge formation, in durable habits that demand grounding of political argument in social empiricism, and in a chastened but resilient Enlightenment tradition of political obligation, the legacy remains—indeed, in important though little recognized ways, recurs in the dialogue between contemporary liberals and communitarians. Absent the polarizing tendencies of a world divided for half a century between capitalism and state communism, and given now the resurgence over recent decades of libertarianism and free market ideology, it becomes ever more obvious that the critical decisions in democratic governance in the West, and beyond, will henceforth be—as they were in the new liberal era, 1880s to 1940s—hard choices between variants of liberalism.

Policy Knowledge: Nonprofit Institutions

The complexity of advanced industrial systems requires governments to acquire an enormous range of specialized knowledge and administrative expertise with which to order their affairs. Uniformity in demand, however, has not produced uniformity in the character and supply of knowledge for government purposes. There are significant variations, related to diverse cultural traditions in the means of acquiring knowledge and applying methods of expertise. For example, central government bureaucracies in Western Europe and Japan directly provide many more sources and opportunities for the development of policy expertise than they do in the USA, which in modern times has relied heavily on private research organizations operating outside government bureaucracies for functional expertise. As the federal role in economic and social policy expanded in the post-World War II era, increased federal funding did not produce a commensurate increase in the size of government. Instead, it strengthened the complicated network of relationships among the federal government, state and local governments, and private groups, including nonpartisan research institutes (Alchon 1985, Critchlow 1985, Ricci 1993, Smith 1991).

In this policy system, the federal government operates indirectly, through intermediary organizations in state and local government, and in civil society (Heclo 1980). This reliance on private, nonpartisan research organizations imparts a unique quality to the acquisition and use of knowledge by the administrative state in modern America.

The vast size, complexity, and expense of this system of acquiring knowledge by government in the USA suggests the pluralistic nature of the American polity, deeply rooted in its republican distrust of centralized government. This distrust of centralized government found expression in the nation's constitution, drafted

in Philadelphia in 1787. Its famous beginning 'We the people' asserted that the source of its authority rested in the people rather than state or centralized government. This distrust of centralized government found expression in the antistatist Jeffersonian–Jacksonian tradition that emerged early in the nation's history.

1. Social Investigation in the Nineteenth Century

In the environment of relatively weak centralized government prior to the US Civil War, the craft of social investigation developed within a middle-class subculture of reformers, many of them women, who documented the plight of slaves, the poor, prisoners, and the insane. The affinity of antebellum social reform and feminism became evident in reports issued by American abolitionists who documented the conditions of slave life, as well in reports on the care of prisoners, the indigent, and the insane. In the 1840s, social reformer Dorothea Dix issued a series of groundbreaking reports to state legislatures calling for the humane care of the mentally ill. This tradition of empirical research into social problems conducted by private individuals associated with reform movements was extended late into the nineteenth century (Marshal 1937, Nelson 1992, Leach 1989, Daniels 1968, Dupree 1957).

By the outbreak of the Civil War, state legislatures in the most populous states regularly received detailed narrative and statistical reports on dependency, crime, public health, labor conditions, and economic development. These reports relied more on democratic and humanitarian sentiments associated with moral reform than they did on claims of science and disinterested expertise. Female reformers, as suggested by the role of Dorothea Dix, played an especially important role in this early endeavor to bring social knowledge to state legislatures and the public (Furner and Lacey 1993, Ross 1991).

While the capacity for social knowledge grew on the state level, the role of the federal government's activities in the pursuit of knowledge remained limited generally to surveying, land exploration, and modest technological development through private contracts. This relative institutional impoverishment reflected a unique antistatist tradition in America, reinforced by sectional politics of the period. The major institution in Washington for the gathering and accumulation of scientific and social knowledge remained the Smithsonian Institution, which opened in 1846 at the instigation of the individual for whom it was named. In the decades following the Civil War, the Smithsonian Institution became a center for people such as Francis Walker, John Eaton, John Wesley Powell, and Carroll D. Wright, who took leading roles in establishing a rudimentary infrastructure of social investigation in the nation's capital. These individuals served

as conduits for a transition from moral reform to scientific reform.

2. The Twentieth Century

By the beginning of the twentieth century a large resident class of scientific and professional civil servants had emerged in Washington. In 1904, the US Bureau of Census reported that 3,919 civil servants fell into the classification of 'professional, technical and scientific' workers. Within this group, nearly 1,100 people were described as 'special agents, experts, and commissioners,' while another 300 or so were designated simply as 'scientific experts and investigators' (Lacey 1993, pp. 127–70, Ross 1991, Blumer et al. 1991, Keller 1977, Skowronek 1982, Wilson 1909).

Many of the early organizers in the Smithsonian Institution played a critical role in the establishment of the American Social Science Association (ASSA) in 1865. The ASSA sought to serve as a clearinghouse of social knowledge in order to promote reform in education, public health jurisprudence, finance, and social economy. Directly influenced by the achievements of the Sanitary Commission during the Civil War and modeled on the British National Association for the Promotion of Social Science, the ASSA attracted commercial elite groups interested in promoting sound fiscal and monetary policy; lawyers, doctors, ministers, and teachers who sought professional affirmation; and middle-class reformers who combined humanitarian moral reform with the new scientific spirit. In this way, the ASSA, and other professional organizations that arose during this period, paved the way for a new liberalism, grounded in social empiricism (Haskell 1977, Furner 1975, 1993).

These reformers called for new measures of efficiency and economy in voluntary charity organizations and in public administration. Behind this concern with efficiency and economy lay a deep conviction that the polity was threatened by corruption of partisan political machines serving special economic interests. These political machines, run by local and state political bosses, consistently manipulated the mass of voters to maintain political power in flagrant disregard of any notion of public morality or efficiency and economy in government. Thus progressive reformers called for new social knowledge to help restore political order and representative government to American society. Beneath the catchphrase 'efficiency and economy'—the rallying cry of reformers—lay strong antimajoritarian values fused with antiparty perspectives (Critchlow 1985, Alchon 1985, Karl 1974).

This movement for efficiency found early expression in late nineteenth-century charity endeavors. Amid concern that relief was being wasted on the undeserving poor, new professionals were brought into charity organization to centralize recipient roles,

provide vouchers for relief funds to be distributed to recipients, institute periodic checks on recipients, and implement budget systems within agencies to keep a close watch on funds. Essential to this reform was the use of data gathering through statistical measures and new accounting procedures. Behind this movement lay a sentiment expressed by industrialist Andrew Carnegie, who declared, 'One of the most serious obstacles to the improvement of our race is indiscriminate charity.' Carnegie's infatuation with the new social sciences would lead him to create a number of new nonprofit philanthropic institutions concerned with the gathering of public knowledge (Lagemann 1989).

At the vanguard of this movement for efficiency and economy in government were university trained and highly specialized social scientists. In the latter half of the nineteenth century, the basis of social science research was transformed from deductive reasoning derived from natural law into inductive procedure founded on historical analysis and empirical research. This new methodology allowed social scientists to mask any preoccupation with political matters in the terminology of scholarly objectivity and empirical research. The transformation of political impulses into the quest for public knowledge and administrative solutions reflected the aspirations of a new professional class anxious to gain influence in a highly industrialized society through expertise. They sought reform by placing 'the best people'—objective-minded experts—in government (Ross 1991, Haskell 1977).

The call for efficiency and economy in government, and the need to develop new public agencies for the gathering of public knowledge essential to restoration of representative government, began on the municipal level first in New York with the creation of a Bureau of Municipal Research in 1905, organized by social scientists and civic-minded philanthropists and businessmen. Municipal research bureaus would be established in several other US cities. Central to these municipal research bureaus was the creation of executive budget systems that allowed a strong executive office, public officials, and the general electorate to track how public funds were spent. Essential to the functioning of an executive budget was the creation of an agency staffed by nonpartisan experts who would prepare and analyze budgetary finances and expenditures (Critchlow 1985, Karl 1974, Smith 1991).

This demand for an executive budget system reached the national level under the administration of William H. Taft in 1910. When Taft assumed office in 1909, the federal budget stood at over a billion dollars and the federal debt had reached disturbing proportions, largely as an aftermath of the 'Panic of 1907.' In these circumstances, Taft was able to persuade Congress to appropriate \$100,000 for a commission on efficiency and economy in government. To staff the commission, Taft called on the best social scientists in the country. After two years of painstaking work, the Taft Com-

mission came out with its report, *The Need for a National Budget*. Yet, because the proposal was made in an election year, a recalcitrant Congress refused to enact an executive budget system. The failure of the Taft Commission did not dismay reformers, however. In 1915 they created the Institute for Government Research—the predecessor to the Brookings Institution. Only in 1921 during the Harding administration would budget reform be enacted in the Budget and Accounting Act of 1921.

Taft's successor, Woodrow Wilson reflected in many respects the deep ambivalence that middle-class Americans felt about the state during the early twentieth century. An array of new government agencies was now involved in conservation, consumer protection, corporate regulation, trade practices, and monetary and financial policies. Yet Wilson, in his pioneering essay on public administration warned that the model of Prussian administration should be avoided in America. He declared that European bureaucratic practices would have to be adapted to fit the highly decentralized form of government in the USA. If the European model is to be employed in the USA, he told his fellow reformers, 'We must Americanize it ... We must learn our constitutions by heart and we must get the bureaucratic fever out of its veins' (quoted in Cuff 1993, p. 390).

Until America's entry into the war in April 1917, neither the federal government's defense department nor civilian departments had considered mobilization tasks. As a consequence, private planning proceeded public planning. Financial and manufacturing firms such as J. P. Morgan and Du Pont Corporation, by receiving Allied war orders, were among the first to assess the financial, technical, and labor requirements of munitions production (Brownlee 1993).

War, however, forced the enormous administrative expansion of the federal government in the short period between April 1917 and November 1919. New government agencies appeared in haphazard fashion, drawing corporate and academic personnel into government management. This involvement led many to the belief that the capacity for public knowledge and for effective social action rested in the mobilization of private, public-spirited professional and business groups willing to work in cooperation with a sympathetic state. The war demonstrated for these individuals how to forge a uniquely American combination of state-society relations.

Herbert Hoover sought to put this insight into practice as Secretary of Commerce in the Harding and Coolidge administrations, and later as president, by using the techniques of private-public cooperation he had learned as a wartime administrator. Hoover sought to develop state-voluntary cooperation in the collection of specialized data required for rational decision-making in both the private and public sectors. For Hoover and others concerned with public knowledge, the war revealed just how essential government

knowledge was for economic and social planning. Through the development of an administrative state he sought to develop new mechanisms for collecting public knowledge without the coercive element of state power (Hawley 1974).

In keeping with his views about the credibility of privately financed researchers, Hoover arranged for the Rockefeller Foundation, founded in 1913, to fund a comprehensive survey of social changes in American life between 1900 and 1930. The three-year study resulted in the massive 1,600-page *Recent Social Trends in the United States: Report of the President's Research Committee of Social Trends* (1933). This study presented the full panoply of available knowledge for public purposes (Karl 1974, Hawley 1974, Alchon 1985).

Although state capacity for gathering public knowledge expanded dramatically during the Great Depression era, World War II, and the postwar period, the federal government continued to rely indirectly on intermediary organizations in state and local government, and in civil society, for the accumulation of knowledge. The commensurate increase in the size of the federal government led to the creation of fluid networks of policy specialists, who operated in and between government and the private sector, identifying policy issues, generating 'solutions' to policy problems, and overseeing and evaluating the implementation and administration of policies within their specific areas of competence (Heclo 1980).

3. Role of the Think Tanks

Essential to these policy networks are private policy research institutes or 'think tanks,' a peculiarly American social invention. By the 1990s there were an estimated 1,200 non-government think tanks of various descriptions. World War II and the postwar continuation of a large defense program, as well as expansion of federal social programs, was a watershed in the evolution of the American think tank.

At the end of World War II, Americans made a political decision to have government train, subsidize, and regularly consult a sizable population of civilian experts on such issues as defense, welfare, health, and economic stability. Of the major think tanks, only the Brookings Institution (1916) and the Carnegie Endowment for International Peace (1910) were founded before World War II. The American Enterprise Institute was founded during the war in 1943 (Critchlow 1985, Smith 1991, Lagemann 1989, Dickson 1971).

Although think tanks are ostensibly nonpartisan, in many instances they function as extensions of state power, their influence rising and falling with changes in governments and shifts in the ideological climate of the country. In other cases, think tanks function more independently, questioning and monitoring state strat-

egies and structures. For example, the Rand Corporation of the 1940s and 1950s was designed to strengthen the programs of the US Air Force, whereas the Institute for Policy Studies (IPS) has been a major center of criticism of US foreign policy, domestic social programs, and policies in the areas of civil rights and poverty.

Often the ideological orientation of these think tanks reflected changes in the historical context and political climate, as indicated by the dominant trends in high and popular culture, changes in voting behavior, and shifts in political leadership (Ricci 1993).

The course of the Brookings Institution from the New Deal through the end of the twentieth century reflected these ideological currents. While Brookings studies in the early 1930s criticized New Deal programs, the Brookings Institution under its president Harold Moulton tried to avoid becoming directly involved in partisan politics. By 1937, however, the institution had emerged as a vociferous critic of New Deal fiscal policy.

In response to the new postwar environment and the reluctance of foundations to fund an institution they perceived as ineffective or out of touch, Robert Calkins, former head of the General Education Fund at the Rockefeller Foundation, agreed to head the institution. Calkins reorganized Brookings and recruited social scientists with liberal credentials and government experience. This new group had close ties with government, and unlike the devotees of the earlier nonpartisan ideal, aligned themselves closely with presidential administrations. In 1965, when Calkins retired, Brookings was representative of mainstream Keynesian economic thinking, and its growing influence was reflected in renewed foundation support, especially from the Ford Foundation. Under Calkins' successor, Kermit Gordon, Brookings' reputation as a liberal Democratic think tank was well entrenched. As a result, the institution became a major research center and a holding area for policy experts who were temporarily out of office. In these years, the Brookings Institution became a major center for policy innovation in welfare, healthcare, education, housing and taxation policy (Critchlow 1985, Smith 1991).

Divisions over foreign and domestic policy opened cracks in the liberal consensus in the early 1970s, however, leading many observers to see the institution as isolated from large segments of business. In 1976, the board of trustees appointed Bruce MacLaury to head the institution. A former regional Federal Reserve banker and Treasury official, MacLaury successfully courted business support, increased corporate representation on the board of trustees, and moved the institution toward a more moderate ideological stance.

By the 1970s, the Brookings Institution confronted competition from other major policy research institutions, especially the American Enterprise Institute and the Heritage Foundation—both viewed as conserva-

tive research institutions close to the Republican Party.

The American Enterprise Institute (AEI), which was founded in 1943 as the American Enterprise Association (AEA), illustrates the experience of a conservatively oriented research institution that expressed deep ambivalence about the post-World War II policy consensus (Critchlow 1985, Smith 1991). The key figure behind the establishment of the AEA was Lewis Brown, chairman of Johns-Manville Corporation. Brown realized that the New Deal had changed the political environment for business and, although he expressed anxiety about the level of government intervention, he accepted much of the New Deal program. From the start, the AEA reflected a conservative bias.

In 1954, A. D. Marshall, head of General Electric, assumed the institution's presidency and immediately hired William Baroody Sr. and W. Glenn Campbell, both staff economists at the US Chamber of Commerce, to head the research program. Under their guidance, AEA was gradually built into a modern research institute under its new name, the American Enterprise Institute. Principal support came from private foundations and major corporate sponsors. The institution's reputation was enhanced when the Nixon administration called upon a number of AEI associates to fill government positions. The AEI also emerged as a successful proponent of economic deregulation.

In 1977 Baroody retired and his son, William Baroody Jr., took over the presidency of the institution. To improve its standing in the academic community, the AEI assembled an impressive staff including Melvin Laird, William Simon, Robert Bork, Michael Novak, and Herbert Stein. The tenure of William Baroody Jr., however, ended abruptly in the summer of 1987, when an increasingly restive board of trustees forced his resignation because of cost overruns and declining revenues. Moreover, despite the large number of AEI staffers who held appointments in the Reagan administration (30 left AEI to join the administration in its first two years alone), members of the New Right, suspicious of what they considered the centrist orientation of the institution, voiced bitter criticism of the AEI.

Baroody's successor, Christopher DeMuth, bolstered the conservative orientation of the institute by bringing on board several former Reagan administration officials with strong rightist reputations.

The founding of the Heritage Foundation in 1973 revealed a new ideological climate in the analysis of public knowledge (Edwards 1997, Peschek 1987). Founded by Edwin Feulner and Paul Weyrich to provide rapid and succinct legislative analysis on issues pending before Congress, the Heritage Foundation sought to promote conservative values and demonstrate the need for a free market and a strong defense. The Heritage Foundation's articulation of conserva-

tive values in social policy, education, and government activities placed it at the forefront of New Right activity. Although sympathetic to the Reagan wing of the Republican Party, Heritage's commitment to conservative economic theories and social values allowed the institution to be critical of both Republicans and Democrats. The Heritage Foundation remained relatively small in its early years, but the election of Ronald Reagan to the presidency in 1980 enhanced the institution's prestige. By the mid-1980s the Heritage Foundation had established a solid place in the Washington world of think tanks as a well-organized, efficient, and well-financed research organization that called for the turning over of many government tasks to private enterprise, a strong defense, and a cautious approach to Russia and China.

During these years, myriad other think tanks emerged in Washington representing a range of ideological positions and specialized policy interests, including the left-oriented Institute for Policy Studies (1963) and the libertarian-oriented CATO Institute (1977). Think tanks concerned with national security included the Center for Strategic and International Studies (1962) and the Center for National Security Studies (1962) affiliated with the American Civil Liberties Union (Friedman 1997).

These private institutions served to supplement social research conducted by federal agencies and institutions. By the 1990s the number of personal and committee staff of Congress exceeded 11,000, with a further 20,000 people responding to the information needs of the legislature from the Congressional Budget Office, the Office of Technological Assessment, and the General Accounting Office (Lacey 1993). The executive branch commands far greater numbers. By the 1990s the scale of spending by the federal government for the acquisition and application of public knowledge was massive. Funding is currently routed through an estimated 180 bureaus and agencies. This research includes a mixture of 'in-house' research conducted by career civil servants, and a larger body of research conducted by outside parties via grants and contracts on a 'for profit' basis and some of it by university-based scholars on a 'not for profit' basis. An estimated third of this research activity is supported by the federal government to meet its needs, while the remaining two-thirds is authorized for state and local government, school systems, policy forces, welfare agencies, and industrial and agricultural groups. In addition, a vast array of trade and professional organization and 'public interest' groups conduct research in the areas of environmental policy, consumer affairs, civil rights, and foreign policy issues (Critchlow 1985). While the government relied on think tanks for policy innovation, program review, and policy assessment, the federal government relied on nonprofit service providers to implement social programs. In this way, the expansion of the welfare

state in the 1960s and 1970s created a seeming paradox that remains apparent in the contemporary regime: the rapid growth of the nonprofit, voluntaristic sector occurred at the same time that federal social policy became increasingly centralized and active. The parallel development of the centralized welfare state and the voluntary sector was no coincidence. The growth of federal social programs mobilized the nonprofit sector, while in turn the nonprofit sector, through policy innovation and program implementation, helped legitimize the modern welfare state.

Thus, as the traditional federal system that had existed since the founding of the nation eroded in the 1960s, when the federal government extended its powers at the expense of state power, the nonprofit sector was called upon to help design, implement, and administer social programs that had once been within the jurisdiction of the public sector (Hall 1992, Kameran and Kahn 1989, Salamon 1992). As a consequence, the nonprofit sector expanded in the 1960s at the very time that the federal government enlarged its powers over the states. The result produced an unusual phenomenon—government centralization produced greater nonprofit sector voluntarism (Critchlow 1999).

4. The 'Mixed' Welfare State

Between 1965 and 1980 the American social welfare state underwent a significant transformation, with government spending on social welfare increasing by 263 percent in inflation-adjusted dollars (Gilbert 1983, Critchlow 1999). The expansion of the welfare state promoted the emergence of a government–nonprofit partnership. Increasingly in the 1960s, the federal government generated the funds but then turned over the delivery of services to other public state and local organizations, and private nonprofit organizations. The private, nonprofit sector became a major beneficiary of this system of services. By the 1980s, the federal government alone provided \$40 billion in support to the private nonprofit sector, while state and local governments provided additional amounts from their own resources (Salamon 1992).

Federal demand enabled the nonprofit sector to grow by leaps and bounds. In 1940 there were only 12,500 charitable, tax exempt organizations. By 1990, there were over 700,000, with most of this growth taking place after the 1960s (Salamon 1992, Hall 1992, Critchlow 1999). While the federal government centralized social policy through congressional mandates, administrative and legislative regulations, and new funding arrangements, the delivery and implementation of these programs were placed in the hands of state and local governments and nonprofit organizations.

The emergence of the 'second welfare state' in the last three decades of the twentieth century—contrary

to the concerns of those who feared that government would replace the nonprofit sector altogether—created a vibrant nonprofit sector. Government, in turn, came to rely on this sector to design and implement programs, undertake demonstration projects, contract with other private agencies, and provide outside consultation and independent review agencies and activities.

As this second welfare state emerged, the nonprofit sector was called upon to fulfill a number of distinct functions. Nonprofit organizations served as *funding intermediaries* distributing funds to other parts of the nonprofit sector, *service-providing organizations* involved in healthcare, education, counseling, adoption assistance, and *political action agencies* supporting particular pieces of legislation or candidates for political office (Salamon 1992). By providing public services, these nonprofit organizations developed a symbiotic relationship with the federal government. By 1990, government grants, contracts, and reimbursements accounted for 31 percent of nonprofit service organizations' income. Just 18 percent of the total income that nonprofit organizations receive comes from private giving (Salamon 1992, Hall 1992).

The proliferation of government and nonprofit institutions involved in public policy marshals expert against expert, testing the credibility of each and enriching the information environment in which policy discourse occurs and decisions are taken. Indeed, on highly technical issues, opposing experts often directly contradict one another. Yet the growth of public and private agencies involved in collecting public knowledge allows for a more democratized policy process—much closer, in a sense, to the Jeffersonian–Jackson vision of an open, competitive democracy.

Still, two qualifications are in order: neither Jefferson nor Jackson envisioned a world of competing experts representing various interests and ideological positions; and secondly, this contemporary world of competing institutional research is not equally open to all comers. Access to financing is one limitation, and access to those in power is another.

The proliferation of expertise and the expansion of government knowledge that has arisen in response to the demand for more policy inquiry have not necessarily improved the information base on which political decisions are made. The emergence of more complicated patterns of political mobilization by a larger and more diverse array of interests and groups has necessarily politicized the nature of policy knowledge and thereby redefined the nonpartisan ideal espoused at the beginning of the twentieth century. Competition for attention to research places heavy demands on the time and attention of legislators and policy-makers who, in a value-laden universe, are left, ultimately, to decide what information counts for them on the basis of their own values. A widespread acceptance of relativism, embodied institutionally in public and

private research organizations, has irrevocably altered the process of social investigation and the uses of social knowledge.

Policy Knowledge: Universities

All civilizations have needed higher education to train their ruling, priestly, military, bureaucratic, and other service elites. However it was in twelfth-century Europe that an institution recognizable as a university came into being, as a school of higher learning combining teaching and scholarship and characterized by a corporate autonomy and academic freedom. This institution of higher learning has survived in varying forms down to the present day, while evolving a flexibility which has permitted it to serve the needs of enormously different societies in every part of the world. One of those common societal needs which universities in recent years have striven to serve is that of public policy, that can be defined as national policy which is at some level an expression of the public will. Universities have come to interact with the policy process in multiple ways.

The idea of the practical application of thought to the solution of technical and social problems is virtually timeless and universal. However the direct and total involvement of the corporate universities in social and economic activity is of relatively recent origin. It is identifiable in the later stages of the Industrial Revolution and in the Europe of the nineteenth century, when the direct relevance of scientific and intellectual thought was generally discussed and debated in public. However, it was only after World War Two had dramatized the life-saving significance of knowledge production and application that in the second half of the twentieth century a clear relationship to public policy can be discerned: 'The systematic attention of universities to social reconstruction and economic innovation to all aspects of economic development—financial, industrial, entrepreneurial, organizational, managerial—its concerns for the urban infrastructure, epidemiology, family welfare and schooling, the enhancement of life chances and the encouragement of vertical and horizontal mobility, are changes occurring within living memory' (Rothblatt 1995).

1. The Foundations of the Relationship Between Universities and Public Policy

That issues of social and economic development and policy claimed the attention of the university was a combined consequence of developments within the institution itself and in its external political context. The great nineteenth-century development within the university was the emergence of a new paradigm of the institution, in which research was added to teaching as an equal part of its mission.

Twentieth-century universities have systematically developed structures that allowed them to add the function of generating knowledge to the previous ones of preserving and transmitting it. This was followed by

the rapid development of the empirical social sciences as an expanding part of university curricula. Thus research and the production of knowledge emerged as a service to society and the social sciences arrived as a science of society. The potential of both brought the university into a systematic engagement with public policy.

Outside the university in the second half of the twentieth century came the solidification of political systems that derived more fully than before from the wishes of the national public, and required technical and research-based knowledge to satisfy those wishes and to inform policies. National competition to produce new knowledge made universities the key institutions of postindustrial society.

Historically there has always been interplay between what happens inside universities and what goes on in society outside. In the twentieth century this bond became close. The kind of people who work in universities, the type of topics on which they work and the theories, methodologies, and knowledge which they produce all have relevance to the solution of policy problems and improved social wellbeing. As problems became increasingly complex and multidimensional, cross-disciplinary and multidisciplinary concentrations began to develop within universities as a way of responding to the different problems. Specific techniques, such as survey research, manpower planning, opinion polling, rate of return analysis, and systems theory are a few among the techniques and vocabularies of social analysis which universities developed and exported, to societies wishing to digest and utilize knowledge, and to policy-makers anxious for a scientific base to their choices. There was, in the second half of the twentieth century in Europe and America, a social demand from the policy arena for the kind of knowledge, ideas and techniques which trained people within universities tend to produce.

2. Autonomy and Relevance

The extent of this demand created a dual temptation: within the academy for faculty members to direct their work towards perceived policy issues and, outside it, for governments, with the power of the purse, to put pressure on universities to create specific policies backed by suitable academic rationales. The result was a tension between the traditional autonomous role of the university and the demands of partisan government for knowledge that would make policies competitive.

In this situation the critical issue becomes the institutional relationship between the university and the government, which has taken over the formulation of public policy, and the nature of government's claim on the ideas and people producing them, in a context where the essence of the university ethos is autonomy. In the USA and Europe, where concepts of university autonomy are relatively well established, this auton-

omy was protected in large measure by a *de facto* hiving off of the policy function to independent policy research institutions. Often physically close to universities, they are staffed mainly by former university academics who focus on specific policy issues in the company of like-minded scholars.

A dense network of such institutions has grown up in the USA addressing a wide range of policy issues and there is a constant two-way traffic between them and the universities, and between both these and the government and the private sector. With regard to public policy, individuals from universities who had developed strong knowledge and skills in particular policy areas would be recruited for policy positions and consultancies in government. In the USA, Henry Kissinger, Daniel Patrick Moynihan, and Joseph Stiglitz are no more than the better known among the many who took that route in the current era. The critical point here is that they were recruited because of their individual competence and interest, not because of a particular position reflected by their university. Universities as institutions in general try to avoid espousing specific public policy positions and make a virtue of eclecticism. The guiding, albeit unstated, principle by which universities diffuse the tension is that they do not make policies but rather see themselves as enlarging the knowledge base on which policies can be made. The balance is sometimes hard to hold as when, for example, a policy philosophy becomes so strong that it is associated with the institution itself, and, in this connection, the reputation and influence of the so-called 'Chicago School' in the 1960s comes to mind. Other forms of encroachment of the policy-making function on university autonomy become controversial when the policy institute and the university appear synonymous at least to the outside eye, or when the university takes government money for training for research related to debatable policy purposes.

3. The Internationalization of the Social Sciences

Outside the USA and Europe the postwar era of independence in Asia and Africa, and before that in Latin America, led ultimately to the internationalization of social science and hence the university's role in relation to public policy. First, it became clear that theories derived from industrialization and market behavior did not automatically apply in rural settings, imperfect markets, or centralized and state-controlled economies. Policy-making required more contextual understanding derived from history, anthropology and cultural studies and to develop a theory of problem-solving. The content, theories, and techniques available for policy consideration were enriched. Second, the issue of autonomy and relevance, as encapsulated in the relationship between government and universities, took very different expression in developing countries than in the industrialized west.

Instead of a dense array of public policy institutes, policy and research units existed as full and functioning parts of what were to begin with often single national universities. In this period the relationship between university and government was so close that either through a honeymoon sense of postindependence common purpose, i.e., to take control of the foreign-dominated state policy-making apparatus, or because a single party regime did not see much room for university autonomy in the sense of expressing views contrary to national policy, there was little call for independent policy institutes. In many such situations in Africa the universities came close to becoming part of the civil service with a responsibility to develop and present public policy, solve problems, and in so doing be relevant.

The tension between autonomy and relevance comes to the fore and becomes more acute to the extent that the university's role in producing new knowledge and a workable science of society is supplemented by additional social demand for relevance from universities, where relevance is defined not simply in terms of the institution's ability to train its students for jobs but also to define and support specific public policies. This tension was contained by a sense of common purpose between government and universities in Africa for a period but, in Latin America, autonomy was an early casualty to conformity and the independent and knowledge-producing function moved out into independent centers which in essence became the source of alternative policies that in Africa during the same period emanated from the universities.

However, with the end of the Cold War, sweeping international forces transformed the situation and created conditions permitting a new kind of relationship between universities and the policy-making process. Economic liberalization, political democratization, and administrative decentralization all created a favorable environment for genuinely autonomous universities. Universities could now redefine their relationship with the policy-making process in a context of autonomy and chose to favor coexistence with separate policy institutes in line with the Western pattern. This move was strongly promoted by the World Bank, anxious as it was to have recognizable partners for policy dialogue in an economic context increasingly dominated by debt ratios. At the end of the twentieth century the pattern worldwide is for research centers, institutes, and think tanks to multiply on the periphery of universities while university faculties and departments are becoming the place for the provision of teaching.

4. Universities and Public Policy in the Twenty-first Century

Universities were never the sole producers of knowledge for policy consideration but they were para-

mount, and they are perhaps the only institutions with the objectivity and neutrality to train and make provision for the public good dimension of public policy. However, as they enter the twenty-first century they face global forces and technological change which promise a massive transformation and significant reduction in their paramount role. They are being required to function in a larger, more complex environment than existed when they became basic knowledge producers after World War Two. Knowledge production and dissemination, research and teaching will no longer be self-contained activities but will involve integration with a far wider variety of knowledge producers than before, including industry. As always, the universities are being required to respond to external change.

The biggest single source of change in the relationship between universities and the policy process is the emergence of the Internet and the pace of change in information technology. It is influencing enormous changes in the nature of knowledge production, the corresponding role of the university and its relationship to other actors in the informing of public policy. At the same time, globalization and economic pressures of international competition are dissolving the boundaries between national institutions and disciplines and creating widely dispersed knowledge production systems in which universities are a part but have many partners.

Universities have traditionally organized their work into disciplinary science structures. Such structures will retain a privileged place in knowledge production but they will no longer be alone. The disciplinary structure of the production of knowledge is itself changing, as we witness the emergence of a new model in which knowledge is produced in the context of its application rather than in a single theoretical disciplinary structure and is becoming heterogeneous and more socially accountable. Research done in the context of application and global distribution means that 'science' cannot remain easily within the confines of a university department or academic center. The emergence of a host of new institutional arrangements linking government, industry, NGOs, and private consultancy groups will arrange knowledge production in new forms of organization that erode the traditional place of the university.

To the extent that research is cutting loose from disciplinary structures and generating knowledge which does not seem to wish to institutionalize itself in university departments and faculties, universities will be forced to pay more attention than before to links with the new institutions and centers where the research is being generated. Coalitions, partnerships, and networks are becoming more important than institutions. In terms of their relation to policy, the old division of labor in which universities focused their knowledge production on government, and industry on private application, is less relevant and the re-

lationshps which count are those with the host of diverse and globally scattered institutions which now have a voice and a hand in the production of policy-related knowledge.

Policy Networks

Although the concept of policy network has taken on a variety of different definitions since its first appearance as an analytical term in the late 1970s, gradually a consensus has appeared on its meaning. A policy network refers to a set of informal and formal interactions between a variety of usually collective

public (state) and private actors, who have different, but interdependent interests. Operating in a more or less institutionalized setting, these actors are engaged in horizontal, relatively nonhierarchical discussions and negotiations to define policy alternatives, or formulate policies, or implement them. This definition suggests that policy networks vary along two core dimensions: the structural pattern according to which public power is shared among the members and the degree and patterns of integration among the members. These two dimensions developed along distinct conceptual routes, only merging into a unified concept in the mid-1990s.

1. The Changing Context of Policy-making

This definition of policy networks signals a change in the way political decision-making has been conventionally understood. It contradicts the standard notion of a clear separation between state and society, with the state being seen as the highest center for social and political control. As Mayntz (1993) observes, social modernization has brought more importance to formal organizations in all areas of society and with their strengthened position comes an increasing fragmentation of power. Policy networks represent one response to the escalating functional differentiation of social subsystems. With the state no longer being the sole entity capable of organizing society, there is a dispersion of expertise and competence, a multiplication of channels for mediation and agreement, and the involvement of different levels of decision-making from the local to the supranational (Jouve 1995). Consequently, public policy is much less likely to be produced by a unitary state with adequate control over all the resources necessary for implementing decisions in the public interest.

Rather, public policy is more likely to result from strategic interaction among several or many policy actors, each with a particular understanding of the problem and its own individual or institutional self-interest (Scharpf 1997).

1.1 Historical Development

The sharing of political power between public and private actors became the first avenue of enquiry that led to the development of the policy network concept. In the mid-1970s, Schmitter and Lehmbruch (1977) suggested the concept of corporatism be reconsidered as a conceptual tool for understanding the particular relationships between public and private actors that had emerged for the management of macroeconomic policy in several European democracies. The revitalization of the corporatism concept coincided with

other suggested new concepts for capturing the changing patterns of power sharing between private and public actors: 'corporate pluralism' in Scandinavia, 'issue networks' in the US (Hecklo 1978), 'policy communities' in the UK (Richardson and Jordan 1979), and 'policy networks' (Katzstein 1978).

The early focus in each of these concepts was on broad, macro characteristics of the political system. As these concepts became more familiar, however, a number of scholars noted their potential relevance for understanding private-public relations in more restricted sectoral policy arenas. Drawing on a growing number of empirical studies, these scholars began to develop typologies of different structural patterns of public-private interaction at the sectoral or meso level (Atkinson and Coleman 1989, van Waarden 1992), prompting a certain spate of definitional disputes. By the mid-1990s, however, sectoral and state corporatism, pressure pluralism, clientelism, issue networks, and state-directed networks generally were accepted as core structural types.

In addition to patterns of power sharing between public and private actors, a second line of inquiry developed focusing on the degree of integration among the various actors involved in these horizontal policy-making settings. Rhodes (1990) and Rhodes and Marsh (1995) targeted the degree of integration as their key variable and outlined a typology of different types of 'policy networks' that ranged from fairly tightly integrated 'policy communities' to very loose and open 'issue networks.' The prevalence of large organizations in horizontal arrangements in policy-making also triggered the interest of political sociologists interested in patterns of communication between large organizations. Laumann and Knoke (1987) sought to identify network structures by examining how information was transmitted between policy actors, the nature of the resource transactions between actors, and the relative openness of boundaries in various policy domains. These studies employed quantitative social network analysis developed in sociology. By the mid-1990s, this quantitative approach had incorporated insights from other policy network writings (Pappi and Henning 1998).

1.2 Current Views on the Concept

When speaking of the degree of integration of the policy network, it is usual to employ a concept that refers to the aggregate of actors involved. The term 'policy community' is utilized most commonly for these purposes, but terms like 'policy domain' or 'policy subsystem' are also used. Research has established a number of factors that are related to integration:

(a) Openness of the policy community. The more open deliberations in the policy community tend to be, the less integrated it is likely to become.

(b) Size of the policy community. The larger the number of members of the policy community, the greater the obstacles to high integration.

(c) Frequency of interactions among community members and the degree to which these interactions become institutionalized as opposed to remaining *ad hoc* and fluid. Institutionalization normally enhances the degree of integration.

(d) Membership stability. The more changeable the membership of a policy community, the less integrated it will be.

(e) Density and structure of information exchange. The denser the ties for information exchange and the more direct relationships are, the more integrated the policy community.

Another, particularly important, factor affecting the level of integration of a policy community is the degree to which its members share basic beliefs, values, and norms. Some actors within a given policy community may come to share a set of deep normative core beliefs and from these develop basic strategies and policy positions (Sabatier and Jenkins-Smith 1993). These 'advocacy coalitions' create 'spaces of meaning' within the policy community that provide a framework for political action. The degree of integration of the policy community will be affected by how many distinct spaces of meaning it holds. Sabatier and Jenkins-Smith suggest that policy communities will normally contain two to four advocacy coalitions. They add that the number will likely be higher when the policy community is newly formed, and may dwindle to one dominant coalition as policy-making becomes routinized. The concept of an epistemic community developed in international relations has certain properties in common with Sabatier and Jenkins-Smith's advocacy coalition (see *Policy Knowledge: Epistemic Communities*). All or part of an epistemic community may act as an advocacy coalition. When this development occurs, these epistemic communities often provide important links between policy communities, whether in other nation-states or at the transnational level.

Different types of policy networks may be distinguished depending on whether state actors share political power and on the relative resource balance between private and public actors. State actors may share political power by inviting private actors to participate directly in the formulation or implementation of policy (see *Authority: Delegation*). Here private actors become policy participants. Corporatist and clientelist networks have this feature. Or, state actors may monopolize policy formulation and policy implementation, while listening to, or receiving submissions from, private actors. In this relationship, private actors perform as policy advocates. Pressure pluralism is the most common network with this feature, but it also occurs in issue networks and state-directed networks. The decision by state actors to share political power affects the overall balance of

resources between public and private actors in the policy network. Resources may be relatively balanced, they may favor the state actors, or they may advantage civil society actors. Both pressure pluralist and sectoral-corporatist networks feature a balanced relationship. Private actors have the stronger position in clientelist and issue networks while public actors dominate in the state-directed and state-corporatist types.

2. Theoretical Status of the Concept

Although definitional disputes surrounding the concept have gradually been resolved, the overall theoretical status of policy networks remains subject to debate. Two fairly fundamental criticisms have been directed at the concept. First, Dowding (1995) has charged that the concept is nothing more than a metaphor and will thus fail to produce theories of the policy process. Second, the concept is said to have limited relevance because of an apparent lack of suitability for explaining policy innovations and policy change.

2.1 Policy Networks as Metaphors Only

Dowding has argued that the attempts to provide a middle range theory of policy-making utilizing the policy network concept are bound to fail. He suggests that the driving force of the explanation, the independent variables, are not characteristics of the network as such, but of the components within the networks. Variables such as the relative openness of a policy network are cast as a mere redescription of policy phenomena. Related criticisms argue that policy network studies have failed to explain both the mutual dependence of public and private actors and the conditions under which particular policy networks arise (Thatcher 1998). Critics also lament the lack of specificity of the hypotheses that do exist, a failing bound to render any empirical testing rather unconvincing.

Although useful for spurring discussion and reflection, there are several reasons why these criticisms may be premature. First, the criticisms undervalue the descriptive utility of the policy network concept. One of the most difficult empirical problems faced in the analysis of public policies is determining specifically who the consequential actors might be in any policy domain. Although one might be able to begin to specify these actors by utilizing a good understanding of formal institutions and of the persons occupying key positions, such a specification is almost inevitably bound to be incomplete. Policy-making is replete with informal relationships and the operation of subtle, somewhat opaque norms that empower certain actors in unexpected ways. Accordingly, the methodologies developed for delimiting a policy network have a

broader use in policy analysis. By identifying the central actors in policy-making, they assist the analysis of the processes by which policy ideas are translated into particular policy proposals through interchanges between an identified set of actors. This identification process becomes particularly helpful in policy areas featuring multilevel governance as Peterson (1995) has argued in referring to the European Union. This argument also has relevance to such patterns of governance as they emerge in policy areas where globalization has a decided impact.

Second, numerous empirical studies subsequent to the publication of Dowding's critique have provided convincing evidence of relationships between variations in policy networks and policy outcomes. Josselin's (1997) study of the negotiation of core directives for a single market in financial services in the EU evaluates the extent to which different network types facilitate or hinder the promotion of member-states' interests in EU-level negotiation settings. She shows that a relatively closed corporatist network at the national level is a decided asset in promoting a unified position at the EU level. Conversely, however, a more fluid issue network makes such unity more difficult, while providing additional degrees of freedom in the fluid decision-making arenas that exist at the supranational level. Similarly, Daugbjerg (1998) relates the relatively closed character of corporatist networks to patterns of political change. The more closed and cohesive the network, the more incremental the pattern of change and the more stable the utilization of policy instruments. Coleman's (1996) study of the impact of globalization on the regulation of financial services at the domestic level traces relationships between particular types of policy networks and the varying adaptation of countries to these globalizing pressures.

Finally, Dowding's critique is addressed by some scholars who are using more formal models. Pappi and Henning (1998) elaborate a complex model that suggests direct relationships between network types (pluralism, corporatism, clientelism, state-direction) and policy outcomes. Scharpf's 'actor-centered institutionalism' introduces network-based negotiation settings as one of several core types of forums for policy-making. Drawing on game theory, he sets out a series of propositions that provide a basis for modeling negotiations between actors in such networks and deriving likely differences in policy outputs based on general welfare and distributive justice criteria. Both of these theoretical approaches would appear to hold considerable promise for the development of middle level theory where policy networks will be an important independent variable.

2.2 Policy Networks and Policy Change

Policy networks have been conceptualized primarily using structural variables. Such structural character-

istics are helpful for building descriptions of the policy process at a particular point in time and, more recently, for positing testable explanations of variations in policy outcomes. Dowding (1995) questions, however, whether these same variables are sufficient for explaining how and why policies change and why networks themselves change. Two avenues of investigation have been pursued for addressing these criticisms. The first focuses on the relationship between policy ideas and policy networks and the second draws on an analysis of boundary rules.

Sabatier and Jenkins-Smith (1993) argue that policy networks include one or more advocacy coalitions that are composed of actors who share deep core beliefs, near core policy beliefs, and secondary beliefs about the use of policy instruments. Changes in the relative dominance of advocacy coalitions in a policy network may prompt policy change. Or members of coalitions may negotiate adjustment of secondary beliefs that, in turn, open the door to policy change. Paralleling Sabatier and Jenkins-Smith's work, Jobert (1995) argues that a 'political forum' and a 'scientific or expert' forum exist alongside a policy network. When politicians begin to experience problems that cannot be addressed well within a policy network, they begin to reach to these other fora for advice. To the extent that this advice is acted upon, the policy network may be dissolved, with new arrangements taking its place.

What both these theoretical arguments stress is the importance of looking at the interaction between policy ideas and who shares which ideas within a given policy network. Coleman et al. (1996) follow up on these insights by arguing that the degree of sharing of policy ideas in a given policy network will determine the approach to policy negotiations among actors in the network. They hypothesize that the more ideas are shared, the more policy discussions will take on aspects of what Scharpf (1997) has called 'positive coordination' or a 'problem solving' decision-making style. They suggest that positive coordination is more likely in closed networks like corporatism than in more open networks such as pressure pluralism. By coupling policy network structures to policy ideas, they then trace out different patterns for how policy change occurs. Scharpf's work stresses the importance of looking at actor preferences and cognitive orientations in studying policy processes. The richness of his theoretical work offers further opportunities for improving theories of policy change.

The second avenue for improving explanations of policy change focuses on different types of boundaries within policy communities. In their retrospective on policy network analysis in the UK, Rhodes and Marsh (1995) note that a policy community can have several policy networks. These, in turn, may operate at two levels; a central level whose members dispose of considerable resources, and a peripheral one composed of those with few or no resources. Changes in

the actors at the center of a policy community and thus in the dominant policy network, or movements from the peripheral networks to the dominant one, will be crucial intervening variables in explanations of policy change. Similarly, new actors may build peripheral networks over time and then come to contest the exclusivity of the existing dominant policy network. To the extent that new actors enter an existing policy network, they may bring about a change in its structure. For example, entry of new actors into a previously closed corporatist network may foster sufficient dissent that the state refuses to involve private actors any longer in policy making. Once such actors are excluded, the network takes on pressure pluralist characteristics, altering, in turn, the policy process and perhaps policy outcomes (Coleman et al. 1996).

3. Methodological Issues

The empirical analysis of policy networks has centered on two variables: the degree of integration of policy communities and the division of power between state and civil society actors. Scholars have approached these empirical issues from a variety of methodological standpoints. Among these, the use of quantitative network analysis, elite interviews, and close examination of documents and archival materials are the most commonly used. The use of these methods varies depending on the particular empirical task in question.

3.1 What are the Boundary Rules of the Policy Community? Who Belongs?

Determining the boundaries of a policy network is one of the more difficult, yet more important empirical tasks in this approach. Understanding who belongs and who does not provides key information about likely political demands and patterns of political influence, factors, in turn, important to explaining policy outcomes. In addition, as noted above, observations of changes in policy network membership may be crucial to approaching the explanation of political change. Accordingly, boundary questions must be approached diachronically, with Sabatier and Jenkins-Smith (1993) suggesting a time perspective 'of a decade or more.'

Those working in the public policy field have tended to approach boundary specification by looking at relationships and then at activities and events. In the relational approach to boundary specification, they seek to identify the actors involved in the formulation and implementation of policies in selected policy domains. With these relationships in focus, they then examine variations in the organizational attributes, political ideas, and degree of participation of these actors in selected activities and events. A mix of

quantitative network analysis and qualitative techniques are used in these studies. The relationships of concern are usually determined using 'snowball-sampling' techniques to set up the right set of elite interviews. This methodology does have its weaknesses in that reliance on elite interviews is costly both in time and in money and it is difficult to replicate these interviews over time to get a dynamic perspective on boundary change.

3.2 Does the State Share Power Directly With Policy Community Members? What is the Balance in the Distribution of Resources in the Policy Community?

The answers to these questions provide the empirical base for determining the type of policy network in place in a given policy community. In beginning, to assess the nature of the policy network, it is essential to understand well the organizational attributes of the actors in the policy community. One of the crucial empirical legacies of the corporatist literature were some empirical guidelines for assessing such policy capacity.

The policy capacity of interest associations and of associational systems may be evaluated by looking successively at three types of phenomena. First, it is useful to assess whether associations in a policy network compete with one another for members and are part of a more comprehensive associative order. The development of an associative order is evaluated by examining the degree of horizontal and vertical integration among associations. Second, some evaluation of the internal resources of the associations is useful for assessing likely policy capacity. Frequently, however, these kinds of analysis are still insufficient, particularly for determining the degree to which associations participate in policy-making. Normally, before final determination of the structure of a policy network, it is useful again to turn to elite interviews for additional information on the extent to which civil society actors participate directly in policy formulation or implementation.

4. Future Challenges

The concept of a policy network was designed in the first instance for the analysis of policy making at the national and more local levels. As globalization has increased the internationalization of many policy areas, however, the likelihood rises that several policy networks will be interacting with one another across different levels of decision-making. Future research, therefore, will need to focus on improving understanding of the relationships between policy networks.

Some of these networks will have the additional property of being transnational in character, that is, they will include actors from both the nation-state and the international levels.

The concept of policy community mediators offers one avenue for research on the relationships between policy networks (Coleman and Perl 1999). In many internationalized policy domains, boundary rules will create overlapping memberships between policy networks, with mediators emerging from among those actors with joint memberships. Mediation can take place at two levels. First, a mediator may operate as a pragmatic policy broker who looks for opportunities to lessen conflict within and between policy networks in order to move the policy process forward. Second, perhaps even more important, mediation takes place on an intellectual plane, involving the 'translating' of policy ideas and policy paradigms between policy networks. Drawing on Kuhn's work on scientific paradigms, Schön and Rein (1994) suggest that translation is crucial to resolving conflicts between different policy paradigms or frames. Mediators construct a new view of the world that has a place for the policy concerns of both networks and that provides a language and set of norms that enable them to speak to one another.

Success in this second role requires that the mediator be accepted as legitimate in both policy communities. Legitimacy will derive from having both adequate expertise and a socialization experience that permits straddling the boundaries of the communities concerned (Jouve 1995). Research on linkages between policy networks and on the role of policy mediators will be crucial to further theorizing on policy networks in this globalizing era.

Policy Process: Business Participation

While business firms play an important role in policy process in all capitalist societies the extent, nature, and impact of this participation varies both over time and among countries. Business political participation has changed significantly in the USA since the 1970s, and to a lesser extent in Europe. However the degree of political power exercised by business remains an important point of contention among scholars.

1. Business Political Participation in Comparative Perspective

A critical factor underlying differences in national patterns of business–government relations is the extent and scope of government intervention in the economy (Shonfield 1965). The greater a government's impact on the direction of national economic development—measured by spending, government ownership of industry, and control over capital allocation—the closer are the political ties between business and government. In capitalist nations characterized by extensive government intervention, the government will often promote the formation of business associations in order to facilitate policy coordination both with and within the private sector. The way business is organized politically also tends to mirror the structure of the public sector: the more governmental decision-making is centralized, the greater the breadth of business political associations.

On both dimensions, the USA is distinctive: government economic intervention has historically been relatively limited and public policy making is relatively fragmented. Accordingly, there is no American counterpart to 'peak' associations such as the German Federation of Industry, Confindustria in Italy, the Comité National du Patronat in France, the Keidanren in Japan, or the Confederation of British Industry—organizations which both represent and are able to speak for business as a whole (G. Wilson 1981, 1985).

In many capitalist nations, trade associations negotiate with the government on behalf of all firms in a particular sector. Such arrangements are often characterized as corporatist (Schmitter and Lehmbruch 1979). By contrast, trade associations in the USA rarely enjoy official or quasiofficial status and they tend to be much weaker and less inclusive than their counterparts in other capitalist nations. More generally, while business firms have become much more politically active in the USA since the 1970s, business is still less politically organized than in other capitalist nations.

The nature of the interaction between business organizations and government officials also differs in

the USA. Firms in the USA typically influence public policy through 'lobbying,' a term which connotes an arms-length relationship between business and government. Corporations typically need to engage in pressure group politics to gain access to policy makers and shape the policy process. But outside the USA, business and political elites are more likely to come from similar social backgrounds and there is considerable movement of personnel between the two institutions. There are numerous opportunities for both formal and informal interaction between business and government officials and firms can expect to be closely consulted about policies which affect their interests. There is less need to 'lobby' because business organizations are themselves either a quasiofficial or official part of the public policy process.

2. Changes in Business Political Participation in Europe

However, business political participation has changed in Europe. In many capitalist societies a growing portion of firms are subsidiaries of multinational corporations whose headquarters are outside national borders. Such firms are less likely both to identify their interests with those of the nation in which their business is located and to lack the kind of informal access to policy makers enjoyed by domestic firms.

In addition, the role of government in managing the economy has declined in almost all capitalist polities: the importance of national industrial policies which required close business-government cooperation has diminished while a substantial number of government-owned firms have been privatized, thus creating a more independent and pluralist business community. Both of these developments have diminished the historically close ties of business and government in a number of European countries and made the structure of business political representation more fragmented.

Within Western Europe, the increasing importance of the European Union has had a significant impact on business-government relations (Mazey and Richardson 1993, Wallace and Young 1997). The Single European Act (1987) not only significantly expanded the regulatory role of the EU, but ended the unanimity rule of the Council of Ministers. The latter constitutional change meant that each member state was no longer able to exercise a veto power over EU legislation. Accordingly, firms and trade associations could no longer rely on their influence with their national governments to protect their interests in Brussels.

The result has been a substantial increase in business political representation in Brussels. Many European-wide trade associations have been established to represent business interests in Brussels. At the same

time, many large multinational firms have established their own independent lobbying operations in Brussels. The interests of 80 American firms with subsidiaries in Europe are represented by the EC Committee of the American Chamber of Commerce. In addition, many national trade associations have shifted part of their political efforts to Brussels.

In some cases, the more stable corporatist arrangements which characterized business-government at the national level have been undermined and firms and industries no longer enjoy the privileged access they had when policy making took place at the national level. The result has been an EU policy process which often resembles the American pattern of 'disjointed pluralism' and fluid issue networks (Streeck and Schmitter 1991). This, however, is not true of all policy areas, many of which continue to be characterized by stable policy communities which usually privilege producer interests.

2.1 Contemporary Changes in Business Political Participation in the USA

The degree and forms of business participation have significantly changed in the USA since the 1970s. During the 1950s and 1960s, business devoted relatively few resources to influencing public policy in Washington. Few large firms had Washington offices and these were typically thinly staffed. An exhaustive study of business lobbying on foreign trade policies during the 1950s found most business lobbies to be poorly financed, ill-managed, and at best only marginally effective. Indeed, only a minority of either large- or medium-sized firms regularly communicated with Congress (Bauer et al. 1993).

Certainly, many firms and industries received considerable benefits from government. For example, defense contractors benefited from procurement policies, agricultural interests received substantial price support, and the oil and textile industries, and also much of American agriculture, were protected from import competition. Many industries, such as housing and energy, received important tax preferences and a substantial portion of the American economy was regulated in ways that limited price competition and stabilized markets. However, because business enjoyed considerable public support, and nonbusiness constituencies were poorly organized, business did not need to engage in extensive political activity to enjoy a wide array of economic privileges.

2.2 The Changing Political Environment of Business

The political environment of business began to change in the late 1960s. The social activism of the latter part of that decade reflected and contributed to a decline of

public confidence in all institutions, including the large corporation. It also spawned a new political force: a loosely allied network of consumer and environmental organizations who began to pressure for expanding government regulation of business. Led by skillful political entrepreneurs such as Ralph Nader, and enjoying extensive and for the most part favorable press coverage, the public interest movement had a major policy impact (Berry 1997). From the late-1960s through the mid-1970s business experienced a series of major political defeats in Congress. New laws were passed which expanded the regulatory role of the federal government in environmental protection, consumer protection, and occupational health and safety.

Unlike previous patterns of government intervention, which had primarily affected only specific industries, the impact of the new social regulation was much broader: now, for the first time, virtually every firm faced a large and complex array of federal rules that mandated or prohibited a wide range of business decisions. The additional costs of complying with these regulations also became more burdensome following the economic downturn of the mid-1970s, which also led to a substantial increase in public hostility toward particular industries, most notably the oil industry.

2.3 Implications for Business Political Strategy

Business-government relations had previously been dominated by 'insider politics': corporations had secured benefits primarily by making low-visibility appeals to key legislators and administrators. But social regulation was dominated by 'outsider politics': it was often driven by highly visible, often emotional appeals to both public and elite opinion. To counter effectively the appeals of activists and their supporters, companies had to adopt to the 'outsider' strategies of their political opponents. Moreover, within Congress power became more decentralized and party discipline weakened. This meant that business could no longer rely on a handful of influential politicians or party leaders: they had to learn how to influence the votes of 535 individual legislators.

This decade also witnessed a substantial change in the regulations governing campaign contributions by business. Since the beginning of the twentieth century, corporations had been forbidden to contribute funds to candidates for federal office. However, the investigations surrounding the Watergate break-in revealed that a large number of firms had responded to pressures from the Finance Committee to re-elect the President by making illegal contributions to President Nixon's re-election campaign. Ironically, Congress 'cleaned up' federal campaign finance by providing a legal vehicle for corporations to solicit funds from their executive employees and shareholders. The 1974

Federal Campaign Act Finance Amendments permitted corporations, and also other organizations, to establish political action committees (PACs). Corporations were allowed to pay the costs of establishing and administering PACs, although they still could not contribute to them

2.4 New Forms of Business Political Participation

As a response to these developments, business political activity both increased and became more visible (G. Wilson 1981). Between 1968 and 1978, the number of corporations with public affairs offices in Washington grew from 100 to more than 500, while many other firms employed full- or part-time lobbyists. All told, by the early 1980s nearly 2,500 business firms had some form of political representation in Washington (Vogel 1989, J. Q. Wilson 1996).

The number of trade associations also grew substantially, and many moved their headquarters to Washington in order to more effectively monitor and influence national policy. Some, such as the Chemical Manufacturers Association, the Semiconductor Industry Association, and the Health Insurance Association of America, proved highly effective. But the typical industry trade association declined in importance. This was largely the result of structural changes in the American economy which made firms more diversified. With investments in a wide variety of different industries, their interests could no longer be effectively represented by an industry-based interest group. Accordingly, many large corporations developed an independent capacity to monitor political developments and to advance their political interests (Ryan et al. 1987, Harris 1989).

In order to advance its collective interests, the business community engaged in coalition building—the identification and mobilization of large numbers of companies and trade associations who shared a common interest in a particular issue. This became a highly effective strategy to maximize the political influence of substantial segments of the business community, since it enabled many firms and trade associations to pool and coordinate their political resources. Such coalitions were often difficult to establish since many firms were reluctant to commit scarce political resources to lobby on issues in which their stake was either modest or not readily apparent. But those that were establishing were often politically effective.

Many coalitions were *ad hoc* in nature: they were formed to lobby on a particular issue—and then disbanded when the issue was resolved or disappeared from the political agenda. However, some business coalitions became institutionalized (Levitan and Cooper 1984). One of the most important new 'peak' business organizations was the Business Roundtable.

It was established during the early 1970s from a merger of three *ad hoc* coalitions which had been primarily formed to lobby on issues affecting labor. Exclusively composed of the chief executive officers of approximately 200 of the nation's largest corporations, it relied on the 'unique mobilization of the talent and prestige of the nation's top corporate heads' to lobby government officials (Vogel 1989, p. 198).

Other more established business organizations representing large numbers of firms and industries also grew in importance. Of particular significance was an increase in coordinated political activity on the part of smaller firms. Between 1970 and 1979, the membership of the National Federation of Independent Business (NFIB), which represented smaller firms, grew from 300 to 600,000. The NFIB frequently took positions opposed to those of the Business Roundtable, which many small firms viewed as too willing to accommodate itself to liberal political pressures for government expansion.

Another dimension of business political participation focused on mobilizing the 'grass-roots.' By the late 1970s, corporations and trade associations were spending an estimated \$850 million to help their supporters throughout the USA to communicate with, and thus influence the votes of, their representatives and Senators. Much of what Washington lobbyists now did was to identify strategies for influencing particular legislators, rather than lobby them directly. Business associations representing large numbers of smaller firms such as the National Association of Independent Businessmen and the Chamber of Commerce made particularly extensive use of grass-roots lobbying.

2.5 The Politics of Ideas

An important component of business participation in the policy process focused on changing public attitudes toward business in general and specific policy issues in particular (Blumenthal 1986). Corporations and trade associations made considerable use of 'advocacy advertising,' a specialized form of institutional or corporate advertising whose purpose is to influence the public's attitudes on issues of public policy. During the 1970s, more than 35 corporations and trade associations launched public advocacy campaigns and by the end of that decade, major corporate advertisers were spending about one-third of their advertising dollars on campaigns aimed at the public in their role as citizens rather than consumers.

The oil industry made extensive use of this advertising strategy during the 1970s to explain its position on antitrust policy, government regulation and industry profitability—all issues then much in the public spotlight as a result of the energy crisis. Steel firms purchased advertising space to explain their

positions on import restrictions and pollution controls, the American Electric Power Company ran a multimillion dollar campaign opposing the use of scrubbers and the Caloric Control Council employed advocacy advertising to build a successful grass-roots campaign to enact legislation overruling the Food and Drug Administration's ban on saccharin. During the 1990s, the Health Insurance Association of America waged a highly effective television campaign against the Clinton Administration's proposed health care plan.

The business community and its supporters also sought to influence the terms of public debate by funding research on public policy. Financial support from corporations and conservative foundations played a critical role in creating and expanding private research centers that issued and sponsored books, studies and reports that challenged liberal and left of center views on public policy. In contrast to advocacy advertising, these efforts were aimed at influencing the views of elites such as politicians, government regulators, academics, and journalists.

The Heritage Foundation, a conservative policy research institute, employed several dozen policy analysts who worked closely with the staffs of sympathetic members of Congress, tracking the progress of particular policy proposals and preparing detailed positions papers on them. The American Enterprise Institute, which became a kind of right-of-center counterpart to the more liberal and older Brookings Institution, released scores of studies, held numerous conferences, and prepared several analyses of legislative proposals—in addition to publishing seven journals and newsletters—primarily focusing on government regulation and tax policy. This research helped contribute to a more skeptical attitude about the role of government and a more positive attitude about the role of markets—first among elites and then among the public as a whole. More liberal research institutes also became more sympathetic to business perspectives.

3. The Debate Over Business Power

During the 1950s and 1960s, the scholarly consensus within both political science and sociology regarded business as an interest group which did not pose any distinctive problems for democratic governance (Truman 1951, Epstein 1969). There were dissenters, but they were a minority voice (Bachrach 1967). During the 1970s and 1980s the intellectual center of gravity of both disciplines began to shift: a considerable body of scholarship now judged 'the large corporation's concentration of resources and wealth (to be) an anomaly that upsets the balance between democracy and capitalism' (Menninger 1985, p. 210).

According to the critics of pluralism, business political influence has two dimensions, one structural

and the other instrumental. Structural power refers to the ability of business to shape both the terms of political debate and political outcomes by virtue of its privileged position within a capitalist system. This privileged position in turn has two roots. One is the central role of business in shaping the rate and direction of economic development. According to this analysis, if public policy does not furnish firms with sufficient inducements to invest, or alternatively if it imposes too many restrictions on their ability to accumulate capital, firms will reduce their rate of investment, thus resulting in an economic downturn. Consequently, politicians, knowing that their reelection will be adversely affected by a slowdown in economic growth, will be reluctant to support policies that might antagonize corporate investors.

Since a critical dimension of political power involves control over the political agenda and the ability to define the terms of public debate, the privileged political position of business in capitalist societies also has an ideological dimension. According to this analysis, a capitalist society is characterized by a prevailing ideological consensus that places a wide array of issues and policy alternatives off the political agenda, such as the autonomy of corporate managers, the prevailing distribution of wealth, and private ownership of the means of production—all of which protect business privileges.

While the structural dimension of business power is often exercised in subtle ways, the second, instrumental dimension of business power is more visible. It is reflected in the disproportionate resources that business has available to shape the resolution of issues that actually do come before the political process—resources which give business political advantages enjoyed by no other interest group, or the public as a whole. This dimension of business power became substantially more visible in the 1970s and 1980s as firms devoted increased resources in order to both shift the terms of public debate and affect political outcomes.

3.1 Is Business Privileged?

The claim that business enjoys a privileged political position is closely associated with Charles Lindblom, whose book *Politics and Markets* represents one of the most important and influential analyses of business political power published since the 1970s (Lindblom 1997). As he argues, capitalism in the USA enjoys considerable legitimacy: no political movement in the USA has seriously questioned private ownership or challenged the central role of markets in distributing wealth and privilege. However, while business certainly benefits from this characteristic of American society, it is not responsible for it. The hegemony of the 'liberal tradition in America' is deeply rooted in popular American culture—a culture that has long

valued individual self-reliance, limited government, and private property—and which predates the rise of the large corporation (Hartz 1955, McClosky and Zaller 1984).

At the same time, American culture also contains a strong populist dimension, which, although not anti-capitalist, has periodically been expressed in considerable public hostility to the large corporation. During the twentieth century, the USA experienced four reform movements—Populism, Progressivism, The New Deal, and the public interest movement, each of which has effectively challenged a wide variety of corporate prerogatives. Moreover, in other capitalist nations, anticapitalist movements and political parties on both the left and the right have received considerable public support, which suggests that capitalism does not enjoy equal legitimacy or hegemony in all capitalist societies.

Scholars have challenged Lindblom's thesis with reference to the USA by citing the ability of non-business constituencies to challenge effectively a wide array of corporate prerogatives during the 1960s and 1970s (Vogel 1987, G. Wilson 1981, J. Q. Wilson 1996). The effectiveness of the challenges to corporate privileges that have surfaced periodically in the USA implies that corporations, like any group of interests, must engage in interest-group politics in order to defend and advance their interests. Sometimes their efforts will be successful and other times they will not. But this does not distinguish them from any other group of interests.

Vogel claims that the power of business has varied considerably over time: it was relatively substantial in the 1950s through the late 1960s, declined through the late 1970s, and then subsequently experienced a resurgence (Vogel 1989). These fluctuations in business political influence are primarily attributed to shifting public perceptions of the performance of the economy: business tends to be more influential when the economy appears to be performing relatively poorly and is less influential when it is relatively prosperous. While this analysis does help account for many of the changes in political influence from the early 1960s through the late 1980s, it cannot account for the 1990s—when economic performance was extremely strong and yet business was able to successfully resist the efforts of the Clinton Administration to increase public social spending and expand medical coverage.

Plotke (1992) argues that the slowdown in growth and the decline in profits during the 1970s was not by itself sufficient to mobilize business politically. What was also required was an alternative vision of political economic relations which both attributed the nation's economic difficulties to the expansion of government intervention and proposed an alternative model of economic growth and development. This ability to redefine the political agenda provided a referent for business interest formation that in turn made possible the mobilization of large numbers of disparate firms

and industries. An important contribution of this perspective is to emphasize the contingent nature of business political preferences, as well as the extent to which business influence both affects and is affected by the terms of public debate.

Mucciaroni (1995) analyzed the factors that affect the ability of particular sectors or firms to maintain the benefits they receive from government. Focusing on developments in four policy areas, namely trade policy, agricultural subsidies, tax expenditures, and economic regulation, over two decades, he concluded that producer-group fortunes have varied considerably both over time and among issue areas. In three of the four policy areas, producers experienced reduced benefits due to changes in both public policy norms and the structure of political decision making.

3.2 Corporate Campaign Contributions

The number of business-sponsored political action committees grew substantially in the 1970s and 1980s. While there were no corporate PACs in 1971, there were more than 1,700 in 1992 and they gave a total of \$64 million to congressional candidates. Thanks to the wealth of data available due to federal reporting requirements, few dimensions of business political participation—and power—have been studied as extensively.

One focus of this research has examined the effect of campaign contributions on the voting of legislators, from which different conclusions have been drawn. A series of studies have found that business contributions affected roll-call votes on minimum wage legislation, the debt limit, the windfall profits tax, wage and price controls, trucking deregulation, and legislation affecting auto dealers (Conway 1991). However, a comprehensive study of a number of PACs and congressional voting behavior over an 8-year period found contributions to be rarely related to congressional voting patterns.

According to Wilson, ‘a fair summary of the existing studies (reveals) there is no consistent and systematic evidence showing that PAC contributions, independent of other factors (such as constituency pressures, legislator ideology, and party affiliation), have a significant impact on voting in Congress. Some studies find some effects in some areas, other find no effect in other areas’ (J. Q. Wilson 1996, p. 430). These findings suggest that corporations often make contributions as much to gain access as to influence votes. However, other studies reach a very different conclusion, arguing that campaign contributions do represent a critical source of business power and privilege (Clawson et al. 1992, Ferguson 1995).

The extent to which firms share similar policy preferences, and are able to cooperate to achieve them, has been an important focus on scholarly debate over the political significance of business campaign spend-

ing as well as over business political influence in general. Business campaign contributions are often coordinated. For example, in the 1984 election, business contributions went overwhelming to only one candidate in almost every race, while in three out of four congressional races, large corporate PACs have given at least nine times as much to one candidate as the other (Clawson et al. 1992, p. 160).

3.3 The Extent and Significance of Business Political Unity

This coherence, in turn, reflects not only their common interests, but also a common culture and the extent of structural ties among firms, such as loans from the same banks, sales and purchases from each other, and interlocking boards of directors. ‘Business power derives in part from this ability to achieve political unity on most issues’ (Clawson et al. 1992, p. 160). Another study found economic leverage between industries to be associated with similar patterns of donations (Mizuichi and Koenig 1986). Moreover, the American business community has numerous mechanisms that facilitate cooperation and coordination, especially under the leadership of large firms (Useem 1984).

Other scholars, by contrast, emphasize that while ‘corporate class consciousness’ does exist in the USA, it only emerges sporadically under unusual circumstances: the American business ‘community’ is more often a community in name only (Vogel 1978). The structure of the American economy is highly fragmented with firms having multiple sources of capital. Moreover, the American system of corporate governance encourages managers to support public policies that directly benefit their firms—even if such policies may not be in the interest of business as a whole. While companies may not typically give to opposing candidates, they nonetheless frequently do have opposing interests.

Many important public policies, such as trade policy, tax policy, health policy, environmental policy, and economic deregulation, divide the business community. A particularly important and long-standing division is between large firms and small businesses, with the latter often frequently opposing the more liberal policy preferences of ‘big business.’ Martin’s study of the politics of human capital investment, including the bitter debate over the expansion of medical coverage in the early 1990s, reveals sharp divisions between large and small firms which precluded the enactment of reforms that arguably would have benefited business as a whole (Martin 2000).

Ironically, the politicization of business that took place during the 1970s has exacerbated the centrifugal tendencies within American business. Because firms have become more politically sophisticated and both able and willing to devote substantial resources to

influencing public policy, corporate political strategy has become more closely linked to business strategy. Firms now frequently seek to gain competitive advantages through the use of non-market strategies, which in turn increases the likelihood of policy differences among them (Baron 1995).

4. Conclusion

The latter part of the twentieth century has witnessed a substantial increase in both scholarly and popular studies of business political activity in the USA and the European Union, in large measure because this activity has become more visible. There have also been a few comparative studies of business political participation (G. Wilson 1985, 1990, Bottomore and Brym 1989). However, there remains a dearth of comparative studies of business political power and influence. Scholars who assert that business enjoys a privileged position usually assume that business is equally influential in all capitalist societies, while most empirical studies of business political influence tend to focus on only one country, or even more narrowly on specific policy areas. An important challenge of future scholarship is to compare systematically patterns of business political influence in different capitalist societies.

Politeness and Language

1. What is Politeness?

If, as many have claimed, language is the trait that most radically distinguishes *homo sapiens* from other species, politeness is the feature of language use that most clearly reveals the nature of human sociality as expressed in speech. Politeness is essentially a matter of taking into account the feelings of others as to how they should be interactionally treated, including behaving in a manner that demonstrates appropriate concern for interactors' social status and their social relationship. Politeness—in this broad sense of speech oriented to an interactor's public persona or 'face'—is ubiquitous in language use. Since, on the whole, taking account of people's feelings means saying and doing things in a less straightforward or more elaborate manner than when one is not taking such feelings into consideration, ways of being polite provide probably the most pervasive source of indirectness, reasons for not saying exactly what one means, in how people frame their utterances.

There are two quite different kinds of feelings to be attended to, and therefore there are two distinct kinds of politeness. One kind arises whenever what is about to be said may be unwelcome, prompting expressions of respect, restraint, avoidance ('negative politeness'). Another arises from the fact that long-term relationships with people can be important in taking their feelings into account, prompting expressions of social closeness, caring, approval ('positive politeness'). There are many folk notions for these kinds of attention to feelings—including courtesy, tact, deference, demeanor, sensibility, poise, discernment, rapport, mannerliness, urbanity, as well as for the contrasting behavior—rudeness, gaucheness, the making of social gaffes, and for its consequences—embarrassment, humiliation. Such terms label culture-specific notions invested with social importance, and attest both to the pervasiveness of notions of politeness and to their cultural framing.

2. How Can We Account for Politeness?

Since politeness is crucial to the construction and maintenance of social relationships, politeness in communication goes to the very heart of social life and

interaction; indeed it is probably a precondition for human cooperation in general. Politeness phenomena have therefore commanded interest from theorists in a wide range of social sciences. Three main classes of theoretical approach to the analysis of politeness in language can be distinguished.

(a) *Politeness as social rules*. To the layman, politeness is a concept designating 'proper' social conduct, rules for speech and behavior stemming generally from high-status individuals or groups. In literate societies such rules are often formulated in etiquette books. These 'emic' notions range from polite formulae like *please* and *thank you*, the forms of greetings and farewells, etc., to more elaborate routines for table manners, or the protocol for formal events. Politeness is conventionally attached to certain linguistic forms and formulaic expressions, which may be very different in different languages and cultures. This is how the 'person on the street' tends to think about politeness, as inhering in particular forms of words.

Some analytical approaches to politeness are formulated in terms of the same sorts of culture-specific rules for doing what is socially acceptable, for example, the work by Ide and others on Japanese politeness as social indexing or 'discernment' (see Watts et al. 1992). In these approaches, politeness is a matter of social norms, and inheres in particular linguistic forms when used appropriately as markers of pre-given social categories. This approach is most appropriate for fixed aspects of language use—the more or less obligatory social marking of relatively unalterable social categories.

(b) *Politeness as adherence to Politeness Maxims*. Another rule-based approach derives politeness as a set of social conventions coordinate with Grice's Cooperative Principle for maximally efficient information transmission ('Make your contribution such as required by the purposes of the conversation at the moment'), with its four 'Maxims' of Quality, Quantity, Relevance, and Manner (See *Pragmatics: Linguistic*). Lakoff (1973) suggested that three 'rules of rapport' underlie choice of linguistic expression, rules which can account for how speakers deviate from directly expressing meanings. Choice among these three pragmatic rules ('Don't impose,' 'Give options,' 'Be friendly') gives rise to distinct communicative styles. Leech's more detailed proposal (1983) is in the same vein. Complementary to Grice's Cooperative Principle, Leech postulates a Politeness Principle—'Minimize the expression of impolite beliefs,' with the six Maxims of Tact, Generosity, Approbation, Modesty, Agreement, Sympathy. As with Grice's Maxims, deviations from what is expected give rise to inferences. Cross-cultural differences derive from the different importance attached to particular maxims.

The conversational maxim approach shares with the social norm approach the emphasis on codified social rules for minimizing friction between inter-

actors, and the view that deviations from expected levels or forms of politeness carry a message.

(c) *Politeness as face management.* A more sociological perspective places ‘face work’ at the core of politeness. Goffman (1967) considered politeness as an aspect of interpersonal ritual, central to public order. He defined face as an individual’s publicly manifest self-esteem, and proposed that social members have two kinds of face requirements: positive face, or the want for approval from others, and negative face, or the want not to offend others. Attention to these face requirements is a matter of orientation to Goffman’s ‘diplomatic fiction of the virtual offense, or worst possible reading’ (Goffman 1971 pp.138ff.), the working assumption that face is always potentially at risk, so that any interactional act with a social-relational dimension is inherently face-threatening and needs to be modified by appropriate forms of politeness.

2.1 Universal Principles of Politeness

Brown and Levinson (1987, henceforth B&L) introduced a new perspective by drawing attention to the detailed parallels in the construction of polite utterances across widely differing languages and cultures, and argued that universal principles underlie the construction of polite utterances. The parallels they noted are of two sorts: how the polite expression of utterances is modified in relation to social characteristics of the interlocutors and the situation, and how polite utterances are linguistically constructed. At least three social factors are involved in deciding how to be polite: (a) one tends to be more polite to social superiors; (b) one tends to be more polite to people one doesn’t know. In the first case, politeness tends to go one way upwards (the superior is less polite to an inferior); in the second, politeness tends to be symmetrically exchanged. In addition, (c) in any culture there are norms and values affecting the degree of imposition or unwelcomeness of an utterance, and one tends to be more polite for more serious impositions. In language there are also parallels, the linguistic structures for realizing particular kinds of politeness show remarkable similarities across languages. The politeness of solidarity is characterized, for example, by use of intensifiers, in-group identity markers and address forms, exaggerated intonation patterns, forms for seeking agreement and avoiding disagreement. Avoidance-based politeness is characterized by self-effacement, formality, restraint, deference, with the use of honorifics, hedges, indirect speech acts, and impersonalizing mechanisms like pluralization of pronouns, nominalization, and passive.

Why then are these kinds of detailed parallels across languages and cultures to be found in the minutiae of linguistic expression in socially analogous contexts? Explanations in terms of social norms or rules can

account for politeness in a particular social group, but not the cross-cultural patterns, which seem to require a strategic account in terms of what people generally are trying to do when they are being polite. B&L (1987) proposed an abstract model of politeness wherein human actors are endowed with two essential attributes: *face* and *rationality*. Face consists of two specific kinds of wants: positive face (i.e., the desire to be approved of, admired, liked, validated), and negative face (the desire to be unimposed upon, unimpeded in one’s actions). The second ingredient in the model—rationality—provides for the ability to reason from communicative goals to linguistic means that would achieve these goals. From these two assumptions—face and rationality—and the assumption that speakers mutually know that all speakers have these attributes, B&L developed a model of how speakers construct polite utterances in different contexts on the basis of assessments of three social factors: the relative power (P) of speaker and addressee, their social distance (D), and the intrinsic ranking (R) of the face-threateningness of an imposition. P, D, and R are seen as abstract social dimensions indexing kinds of social relationship (P and D) and cultural values and definitions of impositions or threats to face (R).

B&L (1987) distinguished five general types of strategies of politeness, ranging from avoiding a face-threatening act (FTA) altogether, to carrying it out but ‘off record’ (indirectly). On-record realization of an FTA can be done without any redressive action at all (‘baldly’). It may be carried out with positive redress, which is essentially approach based, addressing the hearer’s positive face wants by emphasizing closeness and solidarity. Politeness may also be carried out with negative redress, which is essentially avoidance based, addressing negative face wants for distance, deference, freedom from unexpected impositions. Speakers are assumed to choose the linguistic framing of their utterance from this set of strategic possibilities according to the weightiness of the FTA, which is assessed with reference to the three contextually dependent social factors P, D, and R. For low levels of FTA-threat, bald-on-record, or positive politeness is most appropriate and cost effective; for higher levels, negative politeness is required; for the highest threats, indirectness is the safe option.

The claim, then, is that, however culturally variable the kinds of social relationship and kinds of face threat might be, underlying them are pan-cultural social dimensions (relative power, social distance, ranking of face threateningness) which universally go into the reckoning—and the interpretation—of strategic language choice, and hence one can derive the cross-cultural similarities in choice of linguistic realizations of politeness strategies that empirically seem to be in evidence. B&L (1987) claimed further that this model of politeness universals could be applied in particular cultural settings as an ethnographic tool for analyzing the quality of social relationships. Stable social

relationships are characterized in part by stable patterns of language use, which may distinguish particular societies or social groups.

2.2 Criticisms of the B & L Model

The goal of B&L to formulate an 'etic' set of concepts in terms of which politeness can be analyzed in 'emic' terms for any particular society was ambitious. Critics of the B&L model reveal several major points of contention about how a theory of politeness should be formulated.

2.2.1 The universality of face. Many critics have challenged. B&L's formulation (via Goffman and Radcliffe-Brown) of positive and negative face wants, as a valid way of conceptualizing the universal underpinnings of politeness. Negative face, in particular, considered as wants for freedom from imposition, appears entirely too embedded in Western individualism to sit well with conceptions of face in some other (e.g., Asian) cultures. In part, this is due to a misconstrual: the B&L face wants are abstract, they do not necessarily correspond clearly to conscious emic notions. What B&L (1987) claimed that *underlying* very diverse folk notions is a core of two interactionally relevant wants (for ratification, and freedom from imposition) which seem to be cross-culturally applicable, as desires concerning one's public self-image in the context of the moment which are *assumptions oriented to in interaction*. Other theorists (e.g., O'Driscoll 1996, Arundale 1999) have argued for notions of positive/negative face that are even more abstract, in terms of merging/individuation or closeness/separation, as the universal heart of politeness.

Challenges to the universality of the model also extend to the proposed hierarchy of increasing politeness (from bald-on-record to positive to negative to indirectness). Assessments of the P, D, R factors are situationally and culturally very variable, it is possible to accumulate different strategies in one utterance and to balance elements of negative politeness with positive politeness in one act, and indirectness is not always seen as the most polite option. These observations have led some researchers to argue against the possibility of identifying any kind of universal basis for polite behavior; politeness is simply incommensurate across societies. Those who take this extreme relativistic line can have no explanation for the observable cross-cultural parallels in patterns of language use, for how people manage (sometimes) to understand others from culturally different backgrounds, or for cross-linguistic parallels in the diachronic sources of honorifics from politeness strategies.

2.2.2 Politeness as communicated or taken for granted. In contrast with rule-based approaches, B&L

(1987) insist that politeness inheres not in words or in sentences *per se*, but in utterances uttered in a context, by virtue of the successful communication of a polite attitude or intention. Polite utterances are not necessarily communicating 'real' feelings about another's social persona, but expressing contextually-expected concern for face. This concern is an 'implicature,' an inference of polite intentions, not a feature inextricably attached to particular linguistic forms. Politeness is ascribed to a speech act, or to an interactional move (if you prefer), not to a strategy or its linguistic realization *per se*.

In other approaches (for example, Fraser's (1990) 'conversational contract,' Watts et al.'s (1992) 'politic behavior'), politeness is taken to be the expected *background* to interaction; it is normally not communicated but consists in following expectations as to appropriate behavior.

2.2.3 Broad vs. narrow scopes for politeness theory. A narrower view takes politeness to be strategic orientation to potential face threats; there are some situations (e.g., task-oriented ones) where politeness may be subsumed to other goals, and there are many reasons for being indirect in speech other than politeness (e.g., humor, irony, rhetorical farce). Many motivations other than politeness guide human behavior. A more inclusive view sees politeness as orientation to the social-relationship dimension of every interaction, with attention to face taken to be an omnipresent necessity. The whole continuum from extreme politeness through a quite neutral level of politeness (maintaining the status quo, 'discernment') to rudeness (outright intentional threat) then needs to be brought into the theory.

2.2.4 Politeness from the point of view of the individual, the dyad, or the social group. The B&L model takes the interacting dyad as its unit; it is about how interlocutors make inferences of politeness from one another's deviations from Gricean efficient communication, and how stable patterns of strategies characterize dyadic interaction, providing an index to the quality of the social relationship. Many politeness strategies are quintessential examples of 'inter-subjective perspective-taking'—putting yourself in the others' position. A major goal of B&L (1987) was to insist on the centrality of social interaction as a significant level of social life, intermediate between the individual and society, where social/cultural facts (status, role, values, norms, rights, and obligations) are integrated with individual ones (goals, plans, strategies).

Yet the Gricean foundation of the theory and the speech-act based formulation of the B&L strategies have made many see the model as purely psychological (how a speaker calculates how to frame an utterance).

Arundale (1999), for example, argues for a theory of how face is *jointly constituted* in ongoing interaction. In fact, we need both perspectives: face is indisputably interactionally created and manipulated. Nevertheless, it can be considered from the point of view of the individual speaker or hearer (as B&L do in their production/comprehension model), or of the society or social group (as 'face constituting theory' and most sociolinguists do).

2.2.5 The indeterminacy problem. The usefulness of the B&L (1987) model as an ethnographic tool for analyzing the quality of social relationships in any society is undermined by the contextual dependency of ratings of the social factors. The problems of the mixing and ordering of strategies are compounded by the indeterminacy of context-dependent P, D, R assessments, which make it hard to code levels of politeness in any concrete situation. This is a problem with any theory in terms of actors' intentions when applied to empirical data; as both interactors and conversation analysts know, it is not always possible to be certain what interlocutors' intentions are at a particular point in natural interaction.

The B&L model of politeness as originally formulated clearly needs elaboration and revision. Nonetheless, it retains its centrality in research on politeness, largely because it provides a coherent set of concepts for analytically dissecting polite speech in different societies and contexts. It is also the only theory that begins to provide an account for the detailed cross-cultural parallels in polite speech.

3. Conclusions

Politeness has attracted an enormous amount of research attention since the 1970s, and continues to be a major focus for research in disciplines concerned with social interaction. The study of politeness phenomena can provide insight into widely differing issues; foci of interest correspondingly differ widely. They include, for example, analyses of the sequential development of politeness in natural interaction, the study of cross-cultural pragmatics and misunderstanding, the ethnography of speaking of face and politeness in different cultures and contexts, politeness strategies as providing the stylistic coherence of particular types of interaction (e.g., gender differences in speech style), politeness as a functional motivation for linguistic structure, the social psychology of face management and interpersonal perception, politeness theory applied to the analysis of formal ritual and to a view of culture as 'rhetoric,' or forms of effective expression.

Research on politeness has, however, been much weaker on the theoretical front. A major limitation is the kinds of data used in analyses. A large proportion of studies take as their data people's conscious

evaluations of politeness expressed in sentences, judgments which tend to be both prescriptive and stereotypical. Far fewer studies use as data recordings of situated conversational exchanges to explore how politeness is achieved sequentially in naturally-occurring discourse, and only a handful provide the crucial kind of evidence necessary to test the universality of any theory of politeness: for a particular society, an 'ethnography of speaking' providing evidence across different contexts to show how politeness is modulated in relation to social factors (P, D, R and others) in that society.

The emphasis in research has been largely on cross-cultural *differences*, with insufficient attention addressed to the cross-linguistic/cross-cultural parallels which tend to be taken for granted when they are not disputed. But politeness has a significance far beyond the P's and Q's of appropriate behavior and speech. The wider significance of politeness is in the interactional, communicative, day-to-day basis of social life, and the conduct of social relationships. Any work in this area needs to be based in a theory of social interaction that takes account *both* of our common human nature (and ability to communicate cross-culturally) and of our cultural differences (which makes us sometimes misunderstand one another), to anchor research on politeness—this is the great weakness in butterfly-collecting approaches.

Political Advertising

Political advertising has been the subject of intense scholarly investigation for nearly a century. Two agendas underlie this strain of social science inquiry.

The first agenda seeks to measure how political advertising, and campaigns generally, produce votes. Candidates' campaign advertisements are a major source of information about electoral choices that voters face. The intellectual origins date to Gosnell's studies of voting in Chicago in the 1920s (Gosnell 1927, 1935). How much and how do advertisements influence election outcomes? The answers to these questions have very practical uses for political practitioners, who seek information that can guide campaign strategies, and for social scientists, who seek to explain how elections are won. Many social scientists question whether political advertising has any influence on elections, because elections are readily forecasted using indicators of peace and prosperity. Key writes in *The Responsible Electorate* that 'The hullabaloo of a presidential campaign so commands our attention that we ascribe to campaigns great power to sway the multitude. Campaigning does change votes and it does bestir people to vote. Yet other influences doubtless outweigh the campaign in the determination of the vote' (1966, p. 9). On election forecasts, see Rosenstone (1983).

The second agenda concerns the extent of voter autonomy. Are votes hollow echoes of campaign messages, or does political discourse enable voters to reach reasonable decisions that reflect their own preferences and values? Electoral reform motivates much research on advertising and voter autonomy. If political advertising easily misleads voters, then restrictions on campaign advertising or some sort of

'political consumer protection' may be necessary in order to make democracy work. To the extent that there is a scholarly consensus on this matter it is that concerns about voter autonomy are overdrawn. Behavioral research in a wide variety of settings indicates that advertising has modest but important effects on election outcomes: advertising can make a difference in a close election, but it does not appear to persuade large numbers of voters to turn against a candidate or party that is well-known, well-liked, and represents the voters' interests.

1. Advertising and Vote Production

Political advertising covers a wide range of media that candidates use to mobilize supporters to turn out or to persuade people to vote for them. Commentary on political advertising often equates it with television advertising, as, for instance, when European commentators decry the 'Americanization' of their politics. But even in the US there is, in fact, much less television in politics than is often supposed. Campaigns for the US House of Representatives, for instance, use as much direct mail as television advertising. And in local campaigns candidates use little television but a vast range of other media, including mail, billboards, lawn signs, telephones, and door-to-door canvassing (Key 1966).

Campaigns' usage of different media appears to follow the same principles that apply to firms. Candidates choose what media to use based on the productivity of the media and their relative prices. Variation in the mix of media used at different levels of office suggests that there are economies of scale to different sorts of advertising. Personal contact is reputed to be the most effective mode of political communication and it is a staple of local elections everywhere. But it is impossible to spend 15 minutes with each of the millions voters in a national election.

Mass media are most cost-effective at reaching broad constituencies. Evidence of the rational use of media comes from US House races. The average household in the typical House district receives about two pieces of mail and sees at least two television advertisements. However, candidates choose a mix of advertising media based on the prices and productivity of those means of reaching potential voters (or consumers). Campaigns for the US House in districts with expensive broadcasting media (such as Los Angeles and New York) spend \$2.50 on mail for every \$1 broadcasting, or three pieces of mail and 15 seconds of advertising per person. House campaigns in districts with inexpensive broadcasting (such as Dayton, Ohio and El Paso, Texas) spend \$10 on broadcasting for every \$1 on mail, or one piece of mail and 8 minutes of advertising per person. (For details see Ansolabehere et al. 1999a.) To my knowledge, similar sorts of

calculations have not been conducted for other countries, though it is evident from patterns of media usage that parties and candidates in Europe, Australia, and elsewhere are similarly responsive to media prices. (See, for example, Blumler 1983 and Australian Election Commission 1997.)

Social science research has focused on how voters respond to the overall volume and different sorts of campaign advertising that they receive. The estimated effects depend in part on the methods used.

Three different approaches have been taken to the study of advertising. First, laboratory and field experiments have been used to gain precise measures of the effects of advertising exposure in specific campaign settings. Such studies control what messages individuals receive and then measure differences in opinions or behaviors in response to different sorts of messages (e.g., Gosnell 1927, 1935, Ansolabehere and Iyengar 1996, Gerber and Green 1999, Norris 1999).

Second, studies of aggregate data correlate the observed vote to levels of campaign spending. Some of these studies design their inquiries around 'quasi-experiments' which exploit factors that change levels of spending (such as personal wealth) in order to measure the effect of spending on the vote. The seminal work in this vein, for both American and European researchers, is Jacobson (1978). Subsequent research has improved on this model; see, for example, Gerber (1998). Races involving three or more candidates pose statistical problems in estimation of vote production functions, for which widely accepted statistical models have not yet been developed. Third, surveys associate reported vote or political attitudes with reported or recalled exposure to messages. Almost all research outside of the US relies on survey methods. For a discussion of the problems with survey based measures of campaign effects see Ansolabehere et al. (1999b). Analogous with the aggregate studies, instrumental variables can solve such problems.

Experiments, which offer high internal validity, show a remarkably consistent set of results about the capacity of advertising to produce votes. Researchers observe exactly what messages citizens see and can design the study so that other factors do not confound the effect of the experimental manipulation. Perhaps the earliest experimental study of political advertising and campaigning took place in the 1920s in the US. To measure the mobilizing effects of direct campaigning, Gosnell (1927) sent a cadre of graduate students out to canvass a set of blocs of the city of Chicago in an effort to manipulate the levels of voter contact. They found higher in turnout ranging from 4 to 7 percent in the areas that the students canvassed over the areas that they did not canvass. Fast forward to the 1990s. Gerber and Green (1999) replicated Gosnell's study in several towns in southern Connecticut. They found increases in participation similar to those reported in the Chicago studies 70 years earlier. They also found increases in vote shares of candidates in the neighbor-

hood of 4 percentage points for two pieces of mail. In a series of laboratory experiments conducted in Los Angeles from 1990 to 1993, Ansolabehere and Iyengar (1996) found strikingly similar results for television advertising. Exposure to a 30-second television advertisement raised the percentage of viewers who intended to vote for a candidate by 4 to 10 points. These and many other experiments show substantial effects of political advertising on candidates vote shares. Those who see a broadcast message, receive a mailing, or talk to a campaign worker are between 4 and 10 percent more likely to support the candidate being promoted.

Aggregate studies of campaign spending yield similar, albeit lower estimates of the effectiveness of campaign advertising. Using fairly complicated, and controversial, statistical models, researchers have attempted to measure the marginal effect on the vote of spending an additional campaign dollar. Such techniques yield estimates ranging from miniscule effects of a dollar spend on the vote to estimates of approximately \$10 per vote. The key papers in this subfield are Jacobson (1978), Green and Krasno (1988), and Gerber (1998).

Such estimates are in the right ballpark, but the wide range of estimates in the literature on campaign spending suggests that additional work finding valid statistical models is in order before we can put much confidence in the estimates emerging from this literature.

The problem is that it is difficult to sort out cause and effect in aggregate electoral data. Consider, for example, two similar legislators: one holds a highly competitive seat and the other holds a very safe seat. The legislator in the competitive seat must spend large amounts of money to win re-election; the legislator in the safe seat is unlikely to be challenged and if they are they do not need to spend much to retain the seat. In this example the correlation between spending and vote shares is negative! To fix this problem researchers have taken a 'quasi-experimental' approach, using factors such as candidate wealth, which affect directly how much candidates spend and in turn affect their vote shares. Improving such statistical models remains an important research challenge.

Survey research has presented the most modest estimates of the effectiveness of advertising. A long line of studies report minimal effects of campaigns in general and of advertising in particular on the vote (in the US, see Campbell et al. 1960; in the UK, see Norris 1999). Serious problems of question validity lead to serious doubts about these research findings. In the laboratory setting, Ansolabehere and Iyengar (1996) document that survey-based measures of advertising exposure miss one exposure for every one that they detect. This degree of misreporting is sufficient to explain why surveys often produce insignificant findings or even estimates in the 'wrong' direction. Quasi-experimental techniques analogous to those used in

aggregate studies can correct measurement problems (Bartels 1993).

Beyond differences in media and methodologies, a further theme in the study of political advertising is the mechanism through which messages become votes. There are three. Advertising may solidify an uncertain vote (reinforcement), it may stimulate a supporter to vote (mobilization), and it may lead a voter to change their mind (conversion). This typology is due to Berelson et al. (1954). Although political observers often talk of 'swing' voters and movement in the polls, there appears to be relatively little evidence in experiments or surveys of conversion. Few Republicans decide to vote Democrat and few Democrats decide to vote Republican in response to political advertisements. Perhaps the strongest evidence against conversion, though, comes from nonpartisans. Nonpartisans, especially low information independents, are the least responsive to political advertising.

Reinforcement appears to be the dominant mechanism in political communication. For instance, in the experimental research reinforcement produces the clearest effect on the vote. Nonpartisans and viewers of the opposite party as the sponsor of the ad showed no statistically significant response to a candidate's ads. Low information partisans of the same party as the sponsor showed by far the strongest favorable response to political advertising. That effect shrank, though it remained statistically and substantively large, with the partisan's level of information and interest in politics (Ansolabehere and Iyengar 1996). This pattern suggests that political advertising fits neatly into the more general model of information acquisition developed by Zaller, in which both predisposition to believe a piece of information and prior levels of knowledge determine responsiveness to new information (Zaller 1992).

Mobilization has proved the most controversial of the three mechanisms. Experimental research on political advertising has called into question the long-standing belief among political scientists that campaigns are inherently stimulating affairs. Berelson et al. (1954) describe the process in detail. This is essentially the model behind retrospective voting developed by Key (1966) and widely used to understand elections in the US, Europe, and elsewhere. A large number of experimental studies have demonstrated that not all viewers are stimulated to vote by political advertisements. For example, nonpartisan and low information viewers exposed to negative advertising express significantly lower intentions to vote than others. As a result, negative campaigning can produce lower turnout among the key group of 'swing' voters and an electorate that reflects two ideologically opposed groups.

The demobilizing effects of negative advertisements on non-partisans underscores the difference between reinforcement and mobilization. Negative advertising might win the highest vote share, mainly by reinforcing

partisans, but it can lead to lower overall participation.

One important caveat about the state of social science research on political advertising is in order. The bulk of the research on the effectiveness of political advertising has been conducted in the United States. Many of the findings about mobilization and reinforcement likely depend on the electoral system, which influences the number of parties or candidates. The dynamics of campaigns and the consequences of advertising appear to be quite different in races involving more than two candidates. Johnston et al. (1992) provide excellent examples of political communications having complicated effects on competition in Canada's multi-party system. Careful experimental research on multicandidate and multi-party races, though, is in its nascency.

2. Voter Autonomy

The central problem for democratic theory in modern societies is that people apparently know little about the choices they face and they have little incentive to seek new information. Candidates and parties, then, have very strong incentives to provide information to voters at little or no search costs: candidates try to reach us, rather than us, them. As a result we are highly reliant on what politicians choose to say in their advertisements.

This is the problem of voter autonomy. By one telling voters have abdicated to political elites the important jobs of choosing what issues will be discussed, what elections and therefore government will be about, and even what we will think as people walk into the voting booth. From this view, people are highly susceptible to false or deceptive advertising and will vote for the candidate whom we see the most rather than the one we think is best representative. Regulation of the volume and content of political advertising may, therefore, be necessary.

The counter argument is that voters, even though they do not know much by way of details, have a clear sense of what they themselves value or prefer, and, in order to win elections, politicians must adjust their messages to what the voters want. In crafting their advertisements, a candidate selects issues on which he or she can make electoral gains, because the voters care about it, because the candidate has a strong record, or because the candidate has have taken the more popular position. This leads to majoritarian biases in what is discussed, but that is the essence of elections.

Voter autonomy presents a much more difficult set of research questions. In order to say that people are or are not misled by political communications, we must establish what it is that they prefer or value *a priori*. The effects of advertisements must then be judged against that baseline. Two questions are central.

First, do advertisements lead people to choose a candidate who is less good for their interests or values? Research showing strong reinforcement and few conversion effects suggests that the answer to this question is probably no. In both survey and experimental data it appears that people who lean toward a party become more solidly in favor of that party as the campaigns progress (Ansolabehere and Iyengar 1996, Chap. 4, Gelman and King 1990). An important variation on this arises from tactical voting in Britain, Canada, and other countries. As campaigns progress, voters supporting a candidate or party in third place or lower might vote for the second place candidate if they prefer that candidate over the front-runner. This seems to have happened in the 2000 Mexican election as support for Cardenas fell over the course of the campaign and support for Fox, who was in second place most of the race, rose.

Nonpartisans tend to move very little, and tend not to vote. The immediate political implication is that campaign discourse is polarizing: it ultimately pits Democrats against Republicans, Conservatives against Labourites. The low amount of conversion suggests, however, that people fundamentally are not misled.

Second, can advertising set the public agenda, or are people mainly responsive to what they themselves care about? While agenda setting effects have been widely documented in other areas of study, they have received surprisingly little careful study in the field of political advertising. Early evidence of agenda setting is provided by Berelson et al. (1954, Chap. 12). Two careful studies stand out. Jamieson's (1992) *Dirty Politics* documents how the Republican and Democratic strategists use their advertising and the news media to magnify their own agendas, especially Republican's usage of crime and race. Johnston et al. (1992) demonstrate that the debate over free trade completely transformed the Canadian voters' priorities, without changing their preferences on free trade itself.

Reinforcement and agenda setting can hold conflicting implications for voter autonomy. Partisan reinforcement suggests that there is little evidence that people vote against their expressed preferences; agenda setting suggests that people are vulnerable to what the campaigns choose to discuss. There may, however, be no contradiction here. It may indeed be the case in each of the examples discussed that voters were simply very receptive to new agendas, and that elections gave voters an opportunity to change public policies on trade, affirmative action, and other issues from those set decades earlier.

3. New Directions

Political advertising poses both methodological and normative challenges for social scientists, and our understanding on both levels has advanced consider-

ably over the last two decades. Advertising has important effects on election outcomes, but it does not appear to lead people to vote for candidates with whom they fundamentally disagree. It, therefore, does not on the whole undercut the normal workings of majority rule in democratic elections.

In terms of methods, a high priority for further inquiry is bridging the gaps between experimental, aggregate, and survey methods, and developing more powerful quasi-experimental approaches to correct measurement and simultaneity problems. To this end, research on vote production, which has relied mainly on quasi-experiments in aggregate data, should make greater use of experiments to map out features of the vote production function more fully, especially the effects of repeated exposures to messages and interactions between the messages and the viewers preferences.

In addition, there is considerable need for research on political advertising outside the US. The American focus of campaign research stems in part from existing regulations on elections and media. The US imposes few limits on how candidates and parties raise and spend campaign funds, on their access to media, and on what can be said on the various media. As a result, the US has proved a rich field to study advertising effects. Research on campaigning in European countries has placed a much greater emphasis on electoral laws, political parties, and tactical voting. There is, however, growing interest in campaign effects in European political science.

Beyond methodological differences, there is the matter of why. Reinforcement and mobilization are a sufficiently well established phenomenon that it is worth opening up the black box. Why are these the routes through which political advertising works, and why not conversion? The highly inductive approach of empirical researchers is likely to pay the biggest dividends, as political theory has yet to produce a powerful model of why people vote.

Political Anthropology

1. Definitions

Political anthropology is a subfield of sociocultural anthropology and as such is concerned with the comparative, fieldwork-based study of politics in a broad range of social and cultural contexts. If sociocultural anthropology is above all a comparative discipline, concerned with the full variety of human social and cultural life, the existence of a coherent subfield of political anthropology presupposes a relatively clear definition of what constitutes ‘the political.’

Classic studies in political anthropology in the 1940s and 1950s concerned themselves with the maintenance of order and the regulation of force in societies apparently lacking the institutional forms of the modern state. In contrast, more recent studies in the anthropology of politics are as likely to be concerned with issues of citizenship and exclusion, democracy and nationalism, law and violence, but they coexist with a whole corpus of work which identifies and analyzes the workings of power in all social contexts.

There are three overlapping ways in which anthropologists might tackle the definitional issue. One would be formal: political anthropology is the study of ‘political behavior,’ wherever and however encountered, which in turn may be defined in various ways—for example, in terms of the pursuit of power, of strategizing, or of instrumentality. A second way would be to concentrate instead on function: the political refers to institutions and practices which perform political functions—the maintenance of social order, the succession to positions of power and authority, the settlement of disputes. The third would be substantive and based on a recognition that ‘the political’ is not a universal category of experience, but is a product of a certain history: it emerged in Western Europe after the Reformation, alongside the modern idea of the state, and as part of a move towards recognizably modern forms of mass politics based on the institutions of representative democracy. Insofar as such a category now also exists across the spectrum of postcolonial and postsocialist states, political anthropology is the study of whatever it is people in those places believe politics to be.

These three approaches to the anthropology of politics are further complicated by the relationship between political anthropology and other disciplines concerned with the same topics. Both the formal and the functional versions of political anthropology have obvious affinities with political science and political sociology, but less apparent overlap with political philosophy and political theory. In the early days of political anthropology, there was a reaction against philosophical accounts of human political capacities, such as social contract theories of the state, which relied on evolutionary speculation about the primitive origins of contemporary political institutions. Political anthropology’s affinity for political science and hostility to political theory also stemmed from political theory’s tendency to combine and confuse the ideal and the actual, accounts of how things *are* with speculations on how they *ought* to be (Fortes and Evans-Pritchard 1940, p. 4). However, in the latter half of the twentieth century, anthropological accounts of politics have become less confident about the reliance on observed behavior and the appeal to dispassionate science. In particular, since the 1970s, the influence of the work of Michel Foucault has focused attention on the alleged ubiquity of power, while opening the way for an empirical reexamination of the language and

claims of liberal political philosophy. At the same time, the recognition that the anthropological science of 'observed behavior' was almost always a colonial science has shifted attention from the comparative study of politics to a reflexive concern with the political constraints that have shaped the emerging discipline of anthropology. This double concern—with the anthropology of politics *and* with the politics of anthropology—animates Vincent's recent authoritative overview of the subject (Vincent 1990).

Translated into more conventional historical terms, there is a tale to be told of the rise, fall, and partial resurrection of political anthropology. Between the 1940s and 1960s the comparative study of political institutions became a central anthropological interest, especially for social anthropologists in the European tradition. From the early 1970s political anthropology swiftly fell out of fashion, before a number of political themes—power, nationalism, resistance, the state—returned to the anthropological agenda in the mid 1980s. Even so, many anthropologists who studied obviously political topics, but not in the style of 1960s political anthropology, were reluctant to identify themselves with the label of 'political anthropology.'

2. From Function to Process to Form

A comparison of three key works from the early years of political anthropology provides a better sense of the strengths and weaknesses of canonical political anthropology. In 1940 Edward Evans-Pritchard published his monograph on *The Nuer*, subtitled 'A description of the modes of livelihood and political institutions of a Nilotic people' (Evans-Pritchard 1940). Evans-Pritchard had conducted his research among this group of people in the 1930s at the request of the colonial government. His book found the key to Nuer political order in the field of kinship, specifically in the structure of dominant lineages, and the systematic way in which segments of the population would unite in antagonism to structurally equivalent segments. The result was an extraordinarily neat and coherent account of the emergence of political order in the absence of a unitary ruler. Key issues in Evans-Pritchard's account—such as the ordered exchange of violence in the institution of the feud, or the structure of so-called 'segmentary lineage systems'—generated their own specialist literatures, and inevitable critiques, in the years that followed.

Fourteen years after Evans-Pritchard's Nuer study, Edmund Leach published an analysis of highland Burma of comparable intellectual ambition (Leach 1954). Like Evans-Pritchard, Leach concentrated on a group of people on the further fringes of colonial power. As his title suggested, Leach was also concerned with the idea of the political system, or in this case *systems*, and, like Evans-Pritchard, he rooted parts of his analysis in the everyday structures of

kinship and marriage. But Leach was also concerned to historicize his account, and to insert a dynamic element. Dissatisfied with the conservative assumptions of functionalist anthropology, Leach attempted to problematize the idea of a system in equilibrium, by showing how, over a relatively wide area and a relatively long period of time, the same people could oscillate between an egalitarian and a hierarchical political structure, each of which was inherently unstable and contained within itself the germ of its opposite.

The same concern with the dynamic working through of internal contradictions could be found in Victor Turner's (1957) analysis of village micropolitics in what was then Northern Rhodesia (now Zambia). Eschewing the more geographically and historically ambitious vision of Evans-Pritchard and Leach, Turner concentrated on the meticulous analysis of specific cases of conflict within a specific village. Pattern and form were to be found not so much in a social structure, apparently frozen in time, but in the orderly sequence of events within what Turner described as his 'social dramas,' while the shared symbols in village ritual bound people together, even as political conflict drove them apart.

The studies of Evans-Pritchard, Leach, and Turner assumed canonical status in the emerging subdiscipline of political anthropology, and together they can give a fairly good idea of what kind of work political anthropologists of the 1950s and 1960s might be expected to do. First, and most obviously, political anthropologists were relatively unconcerned with the political institutions of the modern nation state, and, although all three authors were working within the political structures of late colonialism, European rule was not a central concern of their work. Their empirical focus was on relationships of kinship, marriage, and residence, and their intellectual goal was to locate the principles of local order in the details of everyday conflict and show the structural consequences of those principles as they applied across a wider social field. Yet, as we move from one author to the next, two related changes emerge, and one unresolved dilemma is left hanging. The two changes were the shift—evident in the contrast between Evans-Pritchard and Leach, and further developed in Turner's work—from a concern with *structure* to a concern with *process*; and the parallel move from relatively large-scale models of social structure to what Turner described as 'diachronic micro-sociology' (1957, p. 328). The unresolved dilemma concerned the cultural content of politics.

The 1960s were the subdisciplinary heyday of political anthropology, and many of the edited collections and monographs of this period celebrate this shift towards a processual view of politics, and evince a growing concern with the microstudy of political behavior (cf. Swartz et al. 1966, Bailey 1969). In the terms set out at the start of this article, if political

anthropology had started out as the study of political *functions* in societies apparently lacking modern political institutions, it gradually became the *formal* study of political behavior in all kinds of society. But the formal definition often rested on a hostility to the cultural meaning of politics. In *African Political Systems*, Fortes and Evans-Pritchard had insisted on the need to ignore culture for comparative purposes: 'A comparative study of political systems has to be on an abstract plane where social processes are stripped of their cultural idiom and are reduced to functional terms' (1940, p. 3). In *Political Systems of Highland Burma*, cultural differences became mere tokens in the political games analyzed by Leach (1954, pp. 16–17). Yet this antagonism to the cultural meaning of politics was never simple and complete: Turner concludes *Schism and Continuity* with a recognition of the binding force of ritual and symbols—paradoxically, a point also acknowledged by Fortes and Evans-Pritchard (1940, pp. 16–22)—and the promise, richly fulfilled in his subsequent work, of more analysis in the future of 'the cultural aspects of Ndembu ritual' (1957, p. 331).

3. After Formalism: Domination, Resistance, and the Nation

The emphasis on formal models of political behavior owed much to the prevailing positivism of political science, especially North American political science, but was increasingly out of joint with the anthropological *zeitgeist*. The 1960s and 1970s saw a major shift away from the formal, typologizing type of work found in political anthropology, and towards the more humanistic style once characterized by Evans-Pritchard as the 'translation of culture.' In Europe, this shift was given theoretical impetus by Lévi-Strauss' structuralism, which directed attention to the study of myth and ritual; in North America, the same role was played by the cultural analyses of Clifford Geertz and David Schneider, with their roots in Parsonian theory, and their concern with culture as a system of symbols and meanings. By the early 1970s, a leading political anthropologist described an intellectual landscape unhelpfully divided between those he characterized as the 'thought structuralists' and those interested in power relations (Cohen 1974). The task, ever since, has been to attempt some sort of *rapprochement* between anthropology's symbolic wing, concerned with the explication of cultural meaning, but often at the expense of any concern with social context and social process, and its political specialists, who had been increasingly identified with a rather narrow and culturally arid formalism.

One area of convergence that emerged in the 1980s was in the anthropology of power and resistance. This represented a development of themes that had first emerged in the feminist and Marxist work of the

1970s. To what extent are marginal or oppressed people—women, the poor—mystified by the ideological representation of their own position? Is culture a source of such mystification, or is it a resource for resistance? Is culture internally homogeneous or, as the slogan of the times put it, is it 'always contested'? Theoretical answers to these questions were found in a range of new sources—Marxist and post-Marxist theorists of culture like Raymond Williams, Antonio Gramsci, Pierre Bourdieu, and Stuart Hall; feminists like Judith Butler and Gayatri Chakravorty Spivak; the radical South Asian historians of the Subaltern Studies group; and, perhaps above all, Michel Foucault. Empirically, instances of resistance might be found in everything from changing domestic consumption patterns, to agricultural workers' self-conscious footdragging, to participation in new religious movements. From a considerable distance, it might be possible to discern a strong continuity with the 1960s analysis of local micropolitics, but the antipositivism and self-conscious poststructuralism of many writers on resistance left them reluctant to acknowledge too strong a kinship with the political anthropology of a previous generation.

A second area of convergence between anthropology's symbolic and political tendencies was in the study of nationalism. The wave of decolonization in the decades after World War II provided anthropology with an obvious area of research. But despite interesting attempts at interdisciplinary enquiry, such as Chicago's Committee for the Study of New Nations, the anthropology of nationalism failed to take off in the 1950s and 1960s. The publication of a provocative essay by a highly 'anthropological' political scientist, Benedict Anderson's (1983) *Imagined Communities*, put nationalism back on the anthropological agenda, and the emergence of ethnic and nationalist conflict in the years after the collapse of Soviet hegemony in Europe provided further impetus. However, while the new anthropology of nationalism has produced a great deal of important and imaginative empirical research, it has been somewhat less theoretically impressive. Some of the most impressive anthropological work has been on the experience of ethnic and nationalist violence, but this has been overwhelmingly studied from the point of view of the victims, rather than the perpetrators, of violence (e.g., Das 1990). The big political mystery of the twentieth century, mass mobilization in the name of the nation, remains as problematic for anthropology as for the other social sciences. In the face of the breakup of the Soviet empire and the war in former Yugoslavia, political anthropology's key contribution in the 1960s—instrumental analyses of the politics of ethnicity—now looks dangerously reductionist. The major theoretical gain from the anthropology of nationalism has been a new attentiveness to the political history of anthropology's central concept of 'culture,' and a reflexive awareness of anthropology's potential complicity in

nationalist interpretations of culture and cultural difference (Handler 1988).

4. Towards Complexity

Although the label 'political anthropology' still retains some of the stigma of 1960s formalism, the study of politics has returned to the center of sociocultural anthropology since the 1980s. There are two obvious and related reasons for this. One is an increased openness to interdisciplinary collaboration with historians, political scientists, and political theorists as anthropologists grapple with the spatial and temporal limitations of the ethnographic method. The other is a renewed critical interest in the received vocabulary of modern politics, obviously dense and complex ideas like 'the nation' and 'the state,' but also concepts of 'citizenship,' 'civil society,' and 'democracy.'

Ethnographic enquiry itself has changed, opening up new potential issues for political anthropology. A study like James Ferguson's *The Anti-Politics Machine* (1990) exemplifies what is now possible. Ferguson's book is based on an ethnographic investigation of a large and unsuccessful development project in Lesotho. It involves at once a critical examination of the 'development discourse' that informs projects like these, and a description of the systematic ways in which potential political issues, like the sources and consequences of social inequality, are swept aside in the path of the project, while all the while the reach of state power is extended into the countryside. Theoretically, Ferguson's work owes a great deal to Foucault's critique of liberal complacency, but empirically it combines local ethnographic detail with broader understandings of the translocal processes and institutions that are so characteristic of the age of development.

In some ways, the new anthropology of the state represents a return to the founding suspicion of political philosophy in *African Political Systems*. In the Preface to that volume, Radcliffe-Brown had dismissed the idea of the state as 'a fiction of the philosophers.' In a series of provocative essays, Michael Taussig has raised the issue of the productive potential of this 'fiction': the—mostly symbolic—ways in which people are subjected to the 'state effect' (Taussig 1997). In a collection of critical studies of African politics, John and Jean Comaroff (1999) subject the notion of 'civil society' to a similar process of empirical scrutiny. Thomas Hansen's (1999) study of Hindu nationalism, combines history, ethnography, and Lacanian theory, and locates the rise of politicized Hindu identity in the peculiar postcolonial trajectory of Indian democracy. These studies represent an especially interesting departure in the relationship between political anthropology and political theory. They focus on central concepts in liberal political philosophy but, rather than viewing that philosophy

as a potentially universal and neutral idiom, treat it as one more folk theory of government, better viewed as an object of ethnographic enquiry than a source of wholesale explanation.

Political Communication

Political communication is an interactive process concerning the transmission of information among politicians, the news media, and the public. The process operates downward from governing institutions toward citizens, horizontally in linkages among political actors, and also upward from public opinion toward authorities. The literature in political

Figure 1
Systems model of political communication process

communication can be subdivided into three major categories, using a simple systems model of the process illustrated in Fig. 1 to distinguish between production, contents, and effects.

1. Production Processes

Work on the production process focuses on how messages are generated by political actors like parties and interest groups, and then transmitted via both direct channels like political advertisements and indirect channels including newspapers, radio, and television. Many studies have focused on the increased professionalization of political marketing campaigns in the postwar era, including the rise of the class of political consultants, pollsters, advertising executives, and their coterie, and the consequence of this process for strategic communications by political parties and interest groups. A large literature, particularly within Europe, has also studied the changing structure of the news industry, notably the economic basis of the newspaper industry and the legal structure regulating broadcasting and the press. Comparative studies have also commonly analyzed the news culture, especially the values that journalists, broadcasters, and editors employ as 'gatekeepers' in deciding 'what's news,' as well as the organizational structure of newsrooms. Recent work within this area has generated a growing body of research on the rise of new communication and information technologies, and use of the Internet by parties, new social movements, and the news media.

One of the major challenges in this subfield is to widen the scope of comparative research on a sys-

tematic basis so that we move from studies of the structure of the political communication process within particular nations to conceptual typologies, broader theories, and empirical generalizations that can be tested across different types of societies. Much of this work has traditionally focused upon postindustrial nations, particularly the USA and Western Europe, although in the 1990s increased attention has been paid to new democracies in Central and Eastern Europe, Latin America, and Asia, as well as, to a lesser extent, to the role of the news media in authoritarian regimes like Burma, China, and Cuba where the role of the free press and opposition movements remain severely restricted.

2. Contents

Another related mainstream research tradition has examined the content of the messages that are produced by this process, such as the amount and tone of political reporting presented in television news, the partisan balance in the press, the coverage of election campaigns and particular events, the agenda-setting reporting of policy issues, and the representation of social minorities in the news media. The most common forms of comparison are between different media, for example, differences in the messages conveyed during an election campaign in paid political advertisements, party press releases, newspaper columns, and TV news stories.

Other forms of comparison examine trends over time, such as the coverage of political scandals or social minorities in recent decades. More rarely, collaborative teams have attempted comparison

across nations, for example, concerning a specific period or event in selected major newspapers. Work in this tradition has drawn largely upon systematic forms of content analysis of a representative random sample of stories among different media, although alternative qualitative techniques for deconstructing textual and visual messages are also common. Moving beyond systematic description, which is valuable but limited, the main challenges in this area are to relate the content of the messages to either the production process (to examine their possible causes) or to their potential impact (to understand their effects).

3. *Effects*

Lastly perhaps the largest body of research, certainly in the USA, has focused at individual level on the study of the potential effects of exposure to different types of political communication messages. The most common method has been to draw upon cross-sectional or panel representative surveys or, more rarely, experimental methods. The key issues have focused upon analyzing the potential impact of exposure to different type of mediated messages (such as watching an advertisement or news story) upon either political knowledge and opinions (such as awareness about an issue, civic knowledge, or recognition of political leaders), political attitudes and values (such as support for a particular party or issue), and political behavior (such as voting turnout). Most work has focused upon the impact of the messages on the mass public or particular subgroups, like women or undecided voters, although some studies have also analyzed the effects upon middle-level elites involved in the policymaking process.

The primary challenges are threefold: (a) to expand generalizations beyond the USA, to see how far they continue to hold up within very different contexts; (b) to move beyond cross-sectional surveys, which cannot determine issues of causality, toward more dynamic designs such as panel surveys and pre-post experimental designs; and (c) to link studies of the individual-level analysis of effects to both what we know about the structure of the news industry and the contents of the messages, generating multilevel and multinational research designs. This work has made considerable progress as the study of political communications has moved increasingly into the mainstream within political science since the 1980s, but nevertheless the subfield remains predominantly US and European, and the process of internationalization in what is increasingly a global society is only starting to produce more systematic cross-national and multilevel research.

Political communication has, therefore, always been central to the electoral and policymaking process but since the 1990s certain important structural develop-

ments have fundamentally altered this process, particularly postwar trends in the mass media moving from the traditional world of newspapers, radio, and television broadcasting toward the Internet. The rest of this article outlines alternative interpretations of the nature of these trends and reflects on their consequences for the process of socioeconomic and political development around the globe.

4. *Postwar Trends in Newspapers*

Concern about traditional standards of journalism has been fuelled by major changes in the newspaper industry during the postwar era. In the USA the daily press has experienced dwindling readership and sales, especially among the younger generation, a loss of advertising market share to the electronic media, and growing concentration of ownership in larger multiple newspaper chains or a few multimedia conglomerates (McManus 1994, Baker and Dessart 1998). All these developments have had a major impact upon the profitability and economic viability of the print sector in the USA, particularly for smaller outlets (De Bens and Ostbye 1998).

Yet although the demise of newspapers has been widely predicted for decades, we should not underestimate their continued popularity and technological adaptation to new forms of production and distribution. If we compare postwar trends in circulation, controlling for population growth, the evidence shows that sales of the daily press in most postindustrial societies has not been affected by the growing availability of electronic media. The long-term trend in newspaper sales in OECD countries, per 1,000 population, has proved fairly stable. Average circulation in all OECD states was 271 newspapers per 1,000 population in 1950, rising modestly in 1980, before subsiding slightly to 263 per 1,000 in 1996 (UNESCO). In postindustrial societies, despite the massive surge in the availability of television since the 1950s, about one quarter of the population continues to buy a daily newspaper, and readership figures are even higher. The electronic media have therefore increased the choice and diversity of news outlets and formats, but at the same time they have not killed sales of the printed press. Given growing educational levels and affluence characteristic of postindustrial societies, consumption of news has not proved a zero sum game.

Moreover there are considerable variations among societies in use of the traditional mass media. Figure 2 illustrates the penetration of newspapers and TV sets per 1,000 population worldwide. The pattern confirms how far newspaper and TV penetration levels are associated with basic patterns of socioeconomic development; use of the mass media is related to a more affluent and educated population with greater leisure

Figure 2
Worldwide distribution of newspapers and TV sets, mid-1990s. (Sources: Newspapers: UNESCO Statistical Yearbook 1997; TV sets: World Bank 2000; Type of democracy: Based on the Freedom House classification of political rights and civil liberties.)

time. Postindustrial societies tend to be the heaviest consumers of the mass media; nevertheless the pattern also shows considerable variations among these nations. Some outliers like the USA and Canada prove far more television-oriented than average (along with Southern Mediterranean Europe and much of Latin America), while others nations like Norway and Sweden (along with much of Northern, Central, and Eastern Europe) remain more newspaper-oriented.

It remains unclear whether systematic trends in the newspaper industry have changed traditional journalism, producing an increased focus on crime, sex, and entertainment, as is assumed by some critics. What seems equally plausible across OECD countries is an expansion of both lowbrow and highbrow news media in recent decades, representing a diversification of the market. A recent review of the comparative literature by Kees Brants concluded that the few available content analysis studies provide an ambiguous and sometimes contradictory picture of the growth of 'infotainment' news in different countries, rather than showing a uniform pattern: 'Where for the European countries as a whole we might see a slight tendency towards the popularization of news, there is little evidence that politicians and politics are more

dramatically personalized and sensationalized than before' (Brants 1998).

Brants found that the available content analysis shows a mixed picture of the growth of 'infotainment' news in different European countries, rather than a uniform trend. Frank Esser concluded that there were marked contrasts between Germany, the UK, and the USA in the popularity of tabloid news, and that the nature and degree of competition in a particular media market is the decisive factor explaining the degree of tabloidization (Esser 1999). Moreover systematic research on long-term trends in British newspapers from 1952–97 found that the amount of political coverage in the tabloid sector had not declined over time, as many critics assume. Instead, the tabloid press in the UK has expanded its coverage of entertainment but also maintained its political news over this period (McLachlan and Golding 1999, McLachlan 1999).

Therefore across all postindustrial societies newspaper circulation levels have remained largely stable during the postwar era, yet at the same time the range of papers published in these states has contracted. The number of daily newspapers published in OECD nations fell on average by 15 percent during the postwar era, from 160 per country in 1960 to 130 in

1996, producing greater concentration of readership in fewer outlets. Many countries have introduced measures to maintain press diversity, on the assumption that we need diverse outlets for an effective civic forum. Antitrust regulations have attempted to insure competition in the ownership of the press, for example, limiting the proportion of cross-media ownership by a single company, administered by fair trade bodies like the British Monopolies and Merger Commission or the German Federal Cartel Office. Other societies like Sweden and Norway have used press subsidies as a policy instrument to protect the financial viability of the more vulnerable sectors of the press (McQuail and Siune 1998). Countries with provincial and localized newspaper markets like the USA and Germany proved particularly prone to media mergers and acquisitions, reducing pluralism and competition in many cities. Papers in smaller countries like Austria and Belgium also often experienced takeovers or closure because of a limited domestic market and imports from neighboring states with a shared common language.

Concentration of ownership in the hands of a few multinational corporations with multimedia empires has become increasingly common, notably Rupert Murdoch's News International, and the vast holdings of Bertelsmann in Germany, or Fininvest in Italy (Tunstall and Palmer 1991, Smith 1991, Sanchez-Tabernero 1993). Hence Rupert Murdoch, who started with two small Australian newspapers, built an empire in News Corp. that includes 20th Century Fox films, the Fox TV network, a number of US stations, 50 percent ownership of Sky TV, a majority interest in the STAR Asian satellite, ownership of *The Sun* and *The Times* in the UK, additional television stations in Latin America, and the book publisher HarperCollins, as well as investments in Internet companies. In the USA, Time Warner's purchase of Turner Broadcasting Systems Inc (including CNN) in 1996 created the largest media firm in the world with strong print, cable, and programming divisions. Walt Disney Company's acquisition of Capital Cities/ABC Inc for \$19 billion in 1995 created the second largest media conglomerate with movie, television, cable, and Internet interests, although the purchase proved costly since ABC's profitability moved sharply into the red four years after acquisition. Conrad Black's acquisition of Southam in Canada in 1996 gave his company, Hollinger Inc, control of two-thirds of the newspapers in that country.

What will be the consequences of these developments? Many commentators like Ben Bagdikian (1997, see also Bogart 1995) fear that media mergers have concentrated excessive control in the hands of a few multinational corporations, who remain unaccountable to the public, and that only greater economic competition can change this situation. Recognition of this problem has arisen from the understanding that economic controls can constrain the media just as significantly as political controls. There is nothing new

about this concern, which was often expressed during the interwar era of the press barons when proprietors like Beaverbrook and Rothermere actively intervened to further their political ambitions. Yet others like Robert Picard (1988, 1998) remain more sanguine about recent developments, arguing that we need to distinguish between concentration defined by considering the number of media outlets held by dominant firms and concentration defined by dominance in a clear geographical market. It is the latter—which can harm consumers by producing fewer choices, poorer services, and higher prices—which is important for the availability of alternative sources of political information in a democracy.

Monopolies in the local market for ideas can be harmful for pluralism. Nevertheless it must be recognized that we need to look beyond any single media sector to establish the harmful political effects of concentration, since consumers use and have access to multiple sources of news and information, from newspapers to radio, television, and the Internet. Moreover the trends toward greater concentration are not universal, as some OECD countries have seen a significant expansion in the circulation and range of daily newspapers being published in the postwar era, particularly states like Mexico and Greece where educational and literacy rates have been rising sharply, as well as more modest growth evident in newer democracies like Hungary, the Czech Republic, and South Korea.

5. Trends in Broadcasting

Just as there are serious concerns about the future of newspapers, so many believe that in recent decades traditional standards of television news and public affairs have come under threat from technological and economic developments. The critical factors transforming broadcasting include the proliferation of channels on terrestrial, cable, satellite, digital, and now broadband services, fragmenting the mass audience; the crisis of identity and funding facing public service television, which once enjoyed a monopoly throughout most of Europe, following the rise of myriad commercial competitors; and lastly the more recent technological convergence with the digitization and compression of images, sounds, and data which has produced a new multimedia environment breaking down the traditional boundaries between telecommunications, the audiovisual industries, and computers.

These trends have affected all OECD countries to different degrees although their impact and timing has been strongly mediated by the existing communications landscape. In the Thatcherite 1980s, deregulation and privatization had the most profound influence on public service broadcasters throughout Western

Europe (Achille and Ibanez Bueno 1994). Following the fall of the Berlin Wall, the transition to democracy in the early 1990s produced an even more radical jolt to public television in Central and Eastern Europe (O'Neill 1998). Meanwhile in the USA the long-standing rule of the three major networks experienced an equivalent coup d'état, cut down in the 1980s by myriad competitors on cable and satellite (Kimball 1994). Despite the long-standing contrasts between the commercially dominant major networks in the USA and public television in Europe, in recent years both have faced a strikingly similar multiplication of outlets and fragmentation of television audiences, raising new concerns about the standards of programming.

Despite the deluge of commercial alternatives, the public channels remain popular; on average across all OECD states public channels maintain a 42 percent share of the television audience. This varies substantially, however, by country. Public television RAI1 and TVE1 remain market leaders in Italy and Spain, while NRK in Norway and SVT in Sweden had most of the best-rated shows in their countries. In contrast public TV has a far smaller share in some other societies such as PBS (3 percent) in the United States and NHK (18 percent) in Japan (Mediametrie 1999). OECD states can be classified into three major types: those that remain predominately *public* systems (based on an audience share of public channels of 60 percent and above), *mixed* systems (with a public share of 40–59 percent) and predominately *private* systems (with a public share of less than 40 percent). Where there is comparable data, only three OECD nations can be categorized as predominately public (Austria, Denmark and Hungary), 11 represent mixed systems, while 10 can be classified as predominately private systems. Therefore although there has been growing transatlantic convergence over the years, nevertheless broadcasting systems continue to bear the distinct imprint of their origins with radio in the 1920s, and public television continues to remain popular in many countries, rather than being swamped by commercial services.

6. The Rise of the Internet

Since the early 1990s the most important change to the political communication process has occurred through the rise of the Internet, particularly in postindustrial societies that are at the forefront of the information society such as the USA, Australia, and Sweden. Networked computing and computer-mediated email have existed for the scientific elite since the early 1960s but the number of users was too small to monitor through mass surveys. The key historic development transforming the Internet into the world's favorite virtual reference library, post office, and shopping

mall was a series of rapid innovations: the birth of the World Wide Web (in 1990) and the launch of popular browsers to access materials including those by Mosaic (1993), Netscape Navigator (1994), and Microsoft Internet Explorer (1995) (see Berners-Lee 2000). Subsequent technological applications, like the easy transfer of .mp3 music files and video formats, and WAP-enabled digital telephony, while representing important innovations, cannot yet claim to have had an impact equal to the basic invention of point-and-click browsers.

As yet no official government statistics on the online population are collected by international agencies like UNESCO and the International Telecommunications Union (ITU), although many indirect measures of technological diffusion are available, including investment in scientific Research and Development, the spread of computer hardware, and the rate of telephone density. The most comprehensive worldwide guide estimating the size of the online population is provided by NUA. This organization regularly monitors and collates survey results conducted by different market research companies in each nation. The surveys ask a representative sample of the public in each country about use of the Internet from home, work, or elsewhere during the previous three months. NUA's database 'How Many Online' (<http://www.nua.ie>) currently collects data from 179 countries, covering 5.7 billion people.

The NUA evidence highlights the dramatic rise in popularity of the Internet in recent years: between 1995 and 2000 the total number of Internet users surged from about 26 to 377 million worldwide, an explosive jump within the space of a few years. The Internet became a truly global phenomenon as more and more users came online from around the world and the proportion of Americans in the online community dropped from 70 to 40 percent in 1995–2000. Despite this remarkable expansion, about one in 20 of the world's population was online in 2000, with highly uneven diffusion globally.

According to NUA estimates, in Spring 2000 Scandinavia and North America led the world in rates of Internet penetration, with one-third or more of the population online, followed by Western Europe, with about one in 10 online. Central and Eastern Europe, Asia, the Middle East, and South America fall below the world average, all with less than one in 20 online, while minimal diffusion is evident in Sub-Saharan Africa, with only 36 users per 1,000 people. In terms of levels of human development, there are stark contrasts between rich and poor nations. Most of the world's online community (87 percent) lives in highly developed nations, as measured by the UNDP index (see UNDP 1999). In comparison, the 35 societies classified by the UNDP with low levels of human development, like Nigeria, Bangladesh, and Uganda, contained only 5 percent of the online population, although home to half a billion people.

A finer-grained comparison of countries ranked by the online population reveals a pattern of widespread adoption in four clusters of societies:

(a) Throughout the smaller Nordic social democratic welfare states, especially Sweden, Norway, Iceland, and Finland;

(b) In larger Anglo-American and English-speaking nations including the USA, Canada, Australia, and the UK;

(c) In the Asian 'tiger' economies of Singapore, South Korea, and Taiwan, as well as Japan; and lastly,

(d) In a few smaller European nations with above-average Internet use such as the Netherlands, Belgium, Switzerland, Slovenia, and Estonia.

At the bottom of the national rankings, with less than 0.5 percent of the population online, few Internet users are found throughout most of the poorer countries of sub-Saharan Africa (with the exception of South Africa), as well as in many states in central Europe, the Middle East, Asia, and Latin America.

Yet at the same time if technological diffusion can be achieved in poorer societies, and it is a big 'if,' then many observers hope that the Internet will provide multiple opportunities for socioeconomic and democratic development. Digital networks have the potential to broaden and enhance access to information and communications for remote rural areas and poorer neighborhoods, to strengthen the process of democratization under transitional regimes, and to ameliorate the endemic problems of poverty in the developing world. With connectivity as the umbilical cord, enthusiasts hope that the Internet will eventually serve multiple functions as the world's favorite public library, school classroom, and medical database; post office and telephone; marketplace and shopping mall; channel for entertainment, culture, and music; daily news resource for headlines, stocks, and weather; and heterogeneous global public sphere. In the heady words of the G-8 Okinawa Charter:

Our vision of an information society is one that better enables people to fulfill their potential and realize their aspirations. To this end we must ensure that IT serves the mutually supportive goals of creating sustainable economic growth, enhancing the public welfare, and fostering social cohesion, and work to fully realize its potential to strengthen democracy, increase transparency and accountability in governance, promote human rights, enhance cultural diversity, and to foster international peace and stability." (G-8 Okinawa Charter on Global Information Society 23 July 2000. <http://www.g8kyushu-okinawa.go.jp/w/documents/it1.html>)

The Internet may allow societies to leapfrog stages of technological and industrial development. On the production side, if Bangalore companies can write software code for IBM or Microsoft, and if Costa Rica can manufacture chips for Intel, then potentially entrepreneurs can offer similar services from Malaysia, Brazil, and South Africa. The Internet encourages market globalization: small craft industries and

the tourism industry in Bali or the Maldives can deal directly with customers and holidaymakers in New York and London, irrespective of distance, the costs of advertising, and the intermediate distribution chains of travel agents and retail businesses (International Telecommunications Union 1999, p. 7, Dugger 2000).

The Internet also offers promise for the delivery of basic social services like education and health information across the globe, a function that may be particularly important for middle-level professionals serving their broader community (Hayward 1995, Wresch 1996). Potentially, local teachers or community officials connected to the digital world in Lagos, Beijing, or Calcutta can access the same electronic journals, books, and databases as students at the Sorbonne, Oxford, or Harvard. Distance learning can widen access to training and education, via open universities in India, Africa, and Thailand, and language websites for schools (Arunachalam 1999). Net works of hospitals and healthcare professionals in the Ukraine, Mozambique, and Stockholm can pool expertise and knowledge about the latest research on AIDS. Peasant farmers using village community centers can learn about storm warnings and market prices for their crops, along with employment opportunities in local towns. Where peripheral regions lack access to the traditional media, the convergence of communication technologies mean that potentially the Internet can deliver virtual local newspapers, streaming radio and television video, as well as other services.

Numerous examples can be cited to show the potential of digital technologies for fostering new opportunities for development in societies around the world (World Economic Forum 2000). Many South East Asian nations seek to emulate the Japanese model of development in the postwar era of reconstruction, and the knowledge-based economy in Singapore, South Korea, and Taiwan. In Malaysia, for example, the Multimedia Super Corridor has been developed to bring investment from telecommunications, multimedia, and electronics companies, and the production of silicon wafers and software. The corridor has attracted major players such as Microsoft, Sun Systems, and NTT (Japanese telecom). Under the 'Vision 2020' plan, Malaysia now boasts cellular telephone penetration rates of one in every 10 people, more and more wired schools, and 21 Internet hosts per 1,000 people. Revenue generated by the production of information and communication technology goods, like office equipment, telecommunications, and consumer audiovisuals, shows that the USA leads the world but many Asian countries are close rivals, including Japan (second), Korea (third), Singapore (fourth), Taiwan (seventh) and Malaysia (eighth) (OECD 2000, p. 24, Table 2).

Southern India is most often cited as an important area of software development, producing an estimated \$3.8 billion in revenues, with this figure doubling in the

last years of the 1990s. Over one-half of India's software services are exported to the USA (OECD 2000). The Bangalore area has attracted inward investment from many major corporations, not least from the diaspora of the Asian dot.com entrepreneurs thriving in California's Silicon Valley and Cambridge's Technology Park (for a discussion see Yourdon 1996). In rural Bangladesh many isolated communities lack landline telephones. An innovative program by Grameen Telecom supplies cellular mobile phones to village women, who rent calls in their community to repay the loan and sustain thriving micro enterprises. (By Spring 2000, over 1,000 phones had been provided, serving 65,000 people, and the eventual target is 40,000 phones. See Richardson 2000, see also <http://www.grameenphone.com>.) With this service, local communities benefit by direct links to job, weather, and health information, as well as more efficient markets for their produce. Village telecom centers are being developed with email and fax services, along with computer literacy projects in selected schools.

In Central and Eastern Europe, Slovenia, Estonia, and Slovakia have made great strides in moving their populations online, moving well ahead of Portugal, Greece, and Austria in levels of connectivity. Hungary's ambitious Schoolnet program has allowed students in two-thirds of all secondary schools to browse the Web from their classrooms, with extensive teaching resources, interactive discussion forums, events, and competitions (see <http://www.SuliNet.hu>). In the Baltic, the Estonian government has provided public access points for the Internet throughout the country, using schools, post offices, community centers, libraries, police stations, and health clinics. The program has been highly successful; today more than one in 10 Estonians is online, with personal computer ownership well above average for Central and Eastern Europe (UNDP 1999, p. 64).

Progress has been slower in Africa, but nevertheless plans have been announced by Global Crossing, Lucent Technologies, and Africa One for an ambitious \$1.9 billion project to link up the whole continent by 2002 through a high-speed underwater fiber optic cable, with interior countries connected through terrestrial cables, microwave, or satellite facilities, overcoming many of the current problems of the inadequate telephony infrastructure (Wired News 2000. For further details see www.AfricaOne.com). Given a high-speed backbone, and market liberalization of telecommunication services, African nations may also be able to 'leapfrog' stages of industrialization through new technology by investing in fully digitized telecommunications networks rather than outdated analog-based systems. Cellular telephony is rapidly expanding as an alternative to conventional network services; the number of subscribers in the OECD region reached almost one-quarter of the population in 1998 (OECD 2000, p. 81). This growth has had even greater impact

in the developing world. In postindustrial economies there were 20 times as many mobile phones in 1998 as there were in 1990, and in developing economies there were 160 times as many, an astonishing rise (World Bank 2000, p. 299). Over a third of all telephone subscribers in Cote d'Ivoire, Cambodia, and Paraguay, for instance, are now connected via mobiles, a far higher proportion than in the USA (International Telecommunications Union 1999).

7. The Consequences for Democracy and Democratization

What will be the political consequences of changes in the traditional news media and the subsequent rise of the Internet? In many ways it remains far too early to say (for a detailed discussion, see Norris 2001). The Internet has generated deeply contested alternative visions about the future. Luddites fear for the worse, but technophiles hope for the better.

The most positive perspective is held by cyber-optimists who emphasize the Panglossian possibilities of the Internet for the involvement of ordinary citizens in direct democracy. In its more utopian manifestations, this view has been dubbed 'technoromanticism' (Coyne 1999), expressed in earlier eras in response to Samuel Morse's electric telegraph, Alexander Graham Bell's telephone, and Guglielmo Marconi's wireless radio (see, e.g., Rhodes 1999, Pursell 1995, Lubar 1993). In this account, digital technologies hold promise as a mechanism facilitating alternative channels of civic engagement such as political chatrooms, electronic voting in general elections and for referenda issues, and the mobilization of virtual communities, revitalizing levels of mass participation in public affairs (see Barber 1998). The use of the Internet by groups and social movements is often believed to exemplify digital politics.

The more utopian visions of the Internet suggest a future society in which virtually unlimited qualities of information become available, civic society flourishes, government decision making becomes more open and transparent, and nation-state borders are eroded as people build virtual communities for work, learning, and leisure spanning traditional boundaries of time and place. Although still in its adolescence, the core transformative capacities of the Internet include its potential for radically shrinking communications and information costs, maximizing speed, broadening reach, and eradicating distance. Compared with radio, television, and newspapers, controlled by editors and broadcasters, the World Wide Web facilitates a virtually unlimited choice of information and communication one-to-one (e.g., via email), one-to-many (e.g., via a personal home page or electronic conference), many-to-one (e.g., via an electronic poll) and, perhaps most importantly, many-to-many (e.g., an online chatroom), with a minimal role for gatekeepers or

government censors (see, e.g., Shapiro 1999, Weare 2000). Internet messages have the capacity to flow further, faster, and with fewer intermediaries.

As a result many hope that recent developments, especially the spread of new information and communication technologies, will serve to undermine authoritarian regimes, creating a 'dictators' dilemma' in countries like Burma, China, and Cuba (Drake et al.). Leaders in these nations want to facilitate economic development through the Internet and yet at the same time they seek to restrict political access. It is also believed that the Internet will have major consequences for electoral democracies, countries like Russia, Taiwan, and Mexico that are seeking to consolidate democratic political institutions.

Yet as the Internet evolves, a darker vision has been articulated among cyber-pessimists, who regard digital technology as a Pandora's box unleashing new inequalities of power and wealth, reinforcing deeper divisions between the information rich and poor, the tuned-in and the tuned-out, the activists and the disengaged. This account stresses that the global and social divides already discussed mean that Internet politics will disproportionately benefit the elite (see, e.g., Golding 1996, 1998, 2000). In this perspective, despite the potential for technological innovations, traditional interests and established authorities have the capacity to reassert their control in the virtual political sphere, just as traditional multinational corporations have the ability to reestablish their predominance in the world of e-commerce (see, e.g., McChesney 1999, pp. 182–5). In this view, so far the potential of the Internet has failed to have a dramatic impact on the practical reality of 'politics as usual,' for good or ill, even in countries at the forefront of digital technologies (Margolis and Resnick 2000). There are fears that continued inequalities in the spread of new technologies will exacerbate the traditional North–South divide evident in access to the traditional news media like newspapers, radio, and television. As such, while some developing countries may manage to leapfrog earlier technologies in the race towards the information society, other poorer societies may drop even further behind.

The debate between the cyber-optimists and pessimists continues and as the Internet continues to evolve over the first decade of the twenty-first century, then the impact of new technologies will become evident, whether for good (as some hope) or ill (as others fear). What is certainly clear is that political communications via the old world of newspapers and television is in the process of fundamental change and this process holds both threats and promises for the future of socioeconomic and political development.

Political Culture

At the broadest level, political culture refers to the meanings attributed to politics. All aspects of meaning, subjective and intersubjective, related to politics are included in this broad perspective—including the definition of what constitutes or determines the boundaries of the political. A central concern is the role of political culture in the transformation of power into authority, and in challenges to authority. Political culture constitutes the socially constructed and tenuously shared meanings which endow or challenge legitimacy in the political institutions, offices, and procedures of a polity. At the cognitive level, political culture defines and explains or questions the rules of the political game, and at the normative level it justifies or denies the authority of those who play it and of the institutions within which the players interact. Political culture is employed to establish or contest the legitimate boundaries of collective identity. It defines a 'we' against a 'them' and marks the centrality and marginality of various groups within the social unit. At any given historical period, a political culture will likely be characterized by a fairly limited repertoire of particularly salient themes that express the values and goals most sacred to the collectivity through key symbols, myths, rhetorical strategies, and rituals accessible through the analysis of discourse. Most contemporary approaches to political culture consider a consensus on values unlikely to occur and unnecessary for the viability of polities. The public need only resonate to common symbols to which they may ascribe radically different meanings. Even in the best of circumstances the shared meanings of political culture are highly tenuous. Like a fragile spider's web, its symbolic themes are stretched in multiple directions through contested interpretations. Political culture, for all its fragility, is essential for the survival of society and civilization.

1. The Politics of Culture and the Culture of Politics

Contemporary approaches to political culture derive from two Western intellectual traditions. One emphasizes politics—viewing it as a neutral adjudicator of conflicts including those in the realm of culture. The second tradition, descending from Montesquieu and de Toqueville, views politics and governance as cultural constructs. The first tradition is expressed by Harold Lasswell's (1960) inquiry into who gets what, when, and how. The second is illustrated by Michel Foucault's (1966) concern with multiple ways in which power is implicated in the constitution of all areas of social life. In this second tradition the definition of the political and the location of its boundaries is framed as a fundamental cultural question. Political culture

encompasses both approaches—the politics of culture, and the culture of politics. Although the term ‘political culture’ is used primarily by political scientists and historians (Gendzel 1997), interest in the relationship between politics and culture—including the investigation of the extent to which each constitutes an autonomous realm—is of interest in fields in which the practitioners use the term less frequently; for example, anthropology, sociology (Swidler 1984), and cultural studies.

2. *Components of Political Culture*

Symbols are the threads from which the web of culture is spun. Sherry Ortner (1973) distinguishes between elaborating and summarizing symbols. The latter, deriving their power primarily from their emotional resonance, tend to be sacred (in the broad sense)—acting as objects of reverence. The national flag is treated with such reverence as to constitute a fetish in American civil religion. The Western Wall in Jerusalem, a place of sacred centrality in Israeli political culture, and the Black Madonna of Czestochowa in Poland constitute powerful summarizing symbols.

Elaborating symbols work in the opposite direction. They provide vehicles for sorting out complex and undifferentiated feelings and ideas, thereby making them comprehensible, communicable, and translatable into orderly action. Given their cognitive nature, they play a more dominant role in ideology. Root metaphors have conceptual elaborating power. Their value derives from providing categories for comprehending order in the world. ‘Exile’ from and ‘return’ to the ‘Holy Land’ provide the root metaphor of Zionism—the dominant discourse (master narrative) of Israeli political culture (Aronoff 1989). Key scenarios are specific guides that provide maps for socially valued action. The Horatio Alger myth is a such a guide to achieve the idealized American success story.

The myths that endow power with legitimacy are challenged constantly by iconoclasts who call them into question and undermine them, thereby tearing the web of cultural meanings. Old truths are constantly reinterpreted as political realities change, and new cultural traditions are invented by myth-makers who repair the web and drape emergent groups with the mantle of authority. Political myths are narratives which rely on the nonrational for their emotive power. Myths present more lucid and compelling images than do more abstract principles. The more compelling the image, the more powerful the myth’s appeal. Because a myth makes hidden connections between disparate ideas based on unconscious premises, public discourse in mythical form is relatively immune from rational criticism that points out its logical contradictions, or evidence which disconfirms it. When such a pattern of discourse dominates a polity, it is usually a powerful force constraining political change. Yet, political myths also play crucial roles in times of crisis and can

be used—especially in rituals through which myths are enacted—to achieve even revolutionary change (Kertzer 1988). Solidarity and the Catholic Church utilized the Pope’s visit to Poland effectively to orchestrate public rites and political rituals which undermined the hegemony of the Polish People’s Republic (Kubik 1994). Political rhetoric, as in the case of the Pope’s sermons, also constitutes an important component of political culture.

Collective memory and amnesia are molded and expressed through invented traditions which are revitalized cultural forms, such as nationalism, portrayed as continuations of more ancient customs. These elements of political culture articulate a society’s self-definition and destiny. Political cultures are effectively reified when the ‘reality’ they define becomes taken for granted by their publics as natural or divinely ordained. This ‘reality’ explains and justifies (or challenges) ideologically the allocation of resources, prestige, and power in the polity. Ideologies are more concrete and rationalized versions of the general political culture articulated by groups to give legitimacy to their identities and to justify their goals. The endurance of dominant (hegemonic) political cultures at any point in time varies depending on their effectiveness in providing models for dealing with societal problems. Political cultures are dynamic because they are embedded in changing historical, social, economic, cultural and political environments that shape them, and which are in turn shaped by them. The relationship between these variables is dialectical, making the determination of causality highly problematic.

Political cultural divisions can be understood as competing temporal and spatial perceptions. Contested interpretations of myths of origin and aspects of history forgotten and remembered selectively reveal contrasting imaginings of political community. Analysis of the relationship between the cultural construction of past, present, and future, and political ideology reveals the link between contested collective memories and competing visions of nationhood. Temporal and spatial perceptions vary within and across political cultures. Social and political boundaries are related to, but not always identical to, actual geographic frontiers of the state (Lustick 1993). Alterations of the physical borders of a state, filtered through temporal cultural frames, shape citizens’ senses of personal and collective security, which in turn influence their political sentiments and positions.

3. *Disciplinary and Interdisciplinary Approaches*

At the apex of the post-World War II behavioral revolution, the first systematic multinational comparative study of political culture based on the new research method of sample surveys was published. Gabriel Almond and Sidney Verba’s *The Civic Culture* (1963) had a major impact on the comparative study

of political culture, leading to replications, adaptations, extensions, and criticisms of both theory and methodology. By the 1970s and early 1980s, the role of the political culture approach had diminished considerably in political science. Since the mid-1980s the concept has regained stature, during a time when the role of culture in the social sciences and humanities has undergone far-reaching reinterpretation.

At the analytical level, rational modes of thought can be attributed to the cognitive dimension of political culture, and nonrational modes relate to the normative. Most political scientists, including some students of political culture, assume the rationality of political actors and essentially ignore the nonrational dimension—with notable and important exceptions. Rational choice and formal modeling approaches have strengthened this bias, making many political scientists unreceptive to cultural approaches. Reactions against attempts to make the rational actor paradigm hegemonic in the discipline, however, and the resurgence of identity politics—most dramatically in the manifestations of xenophobic nationalism and ethnic cleansing—have contributed to the renewed interest in the role of political culture. David Laitin (1998), who shows how political culture is part of an equilibrium in a coordination game, is one of several scholars who combine rational choice and political cultural approaches. The revival of interest in political culture is most apparent in the field of comparative politics (Ross 1997), but the concept has also gained importance in international relations, particularly in the areas of conflict resolution and strategic culture (Katzenstein 1996).

The two major approaches to political culture are semiotic (via anthropology) and cognitive (via social psychology). Richard Wilson (2000) subdivides them into five approaches. Hermeneutics, influenced by the work of Clifford Geertz, is an important bridge between traditional and postmodern approaches. The interpretative semiotic approach (characterized in the introduction to this article) has been very influential in the social sciences and humanities—the boundary between these two having become increasingly blurred in recent decades. James C. Scott (1990) utilizes this approach to investigate the boundaries of the political. The culture theory approach builds upon the work of Mary Douglas. Developed by Michael Thompson, Richard Ellis and Aaron Wildavsky (1990), it postulates a universal division of politics into four ideal-type subcultures based on two criteria. Analysis focuses on the contestation within politics between competing subcultures, and explains change in terms of their different competencies and biases.

Social character is the third approach influenced by anthropology, but it also draws heavily from social psychology. It emerged from studies of culture and personality, and national character. Personality variables are analyzed in terms of types of significant value orientations, including attitudes toward and depen-

dence upon authority, fear of disorder, and various religious and ideological positions. These studies generally are based on the analysis of the relationship between norms and behavior in specific cultural contexts. Although a few scholars define types of broad civilizations, most, like Robert Putnam's (1993) influential study of civic traditions in Italy, focus on selected case studies. The social learning approach, based more directly on psychological theories, utilizes social surveys to analyze values and beliefs to explain the role of socialization in determining values and behavior. Ronald Inglehart's (1997) work on the relationship between generational change and post-materialist values illustrates this approach well, following the tradition of *The Civic Culture*. Other cognitive approaches incorporate Piaget's theories and conceptualize value orientations very differently from social character studies. Analysis focuses on the reciprocal relationship between individual development and social life. In some of this work moral reasoning and development is at the center of analysis.

Ironically, although political science borrowed the concept of culture from anthropology, contemporary perspectives in anthropology challenge the utility and integrity of the concept, and either avoid the term culture or bracket it with quotation marks to signal its problematic nature (Brightman 1995). Postmodern approaches deconstruct political culture by defining all cultural phenomena in terms of domination and contestation for power. Many practitioners of cultural studies use euphemisms for culture to explore the relationship between power and the imaginative expression of culture. Much innovative work on political culture crosses disciplinary boundaries.

4. *Changes in Focus and Recent Developments*

Contemporary understanding of political culture builds on the foundations of Karl Marx's notion of reification, Max Weber's analysis of legitimation, and Michel Foucault's insights into the cultural definitions of the political and his analysis of power in institutional discourses. Many scholars utilize Antonio Gramsci's conceptualization of hegemony, Eric Hobsbawm and Terence Ranger's formulation of the invention of tradition, Pierre Bourdieu's notions of habitus, doxa, and cultural capital, which reveal how power is inscribed in the scripts of everyday life, and Jurgen Habermas's concept of the public sphere. Feminist theory has also influenced contemporary formulations by calling attention to the gendered aspects of political culture. Volumes edited by Nicholas B. Dirks, Geoff Eley, and Sherry B. Ortner (1994) and by Victoria E. Bonnell and Lynn Hunt (1999) are excellent examples of such contemporary, cross-disciplinary approaches. Their appearances in two of the half dozen important interdisciplinary series on politics and culture established by major university presses are indicative of this trend.

Although there are important exceptions to these broad generalizations, traditional and contemporary approaches can be contrasted in several major respects. Traditional approaches define political culture in terms of attitudes and values, whereas more contemporary approaches view culture in terms of scenarios and discourses. The former conceive of political culture as reified, holistic, discrete, clearly bounded, coherent systems; while the latter view boundaries as fragmented, tenuous, and contested. Older approaches view traditions as objective or 'natural' and assume continuity, while newer approaches perceive traditions as 'invented' social constructions and assume they are dynamic because actors have (limited) options. Some traditional approaches were ahistorical, while most contemporary approaches ground analysis in historical contexts. Contemporary students of political culture examine the mechanisms of transmission of political culture and strategies of boundary maintenance. Traditional approaches focus on goals, while contemporary approaches focus on strategies of action and the incompatibility of strategies of various actors. The analysis of limited repertoires of cultural options available to actors seeks to conceptualize the dialectic of system and practice.

5. Current Areas of Research and Future Directions

An important area of research is state and society relations (Migdal 1989). The disintegration of the Soviet Union and the emergence of the new states of Central and Eastern Europe give renewed currency to interest in civil society, democracy, state and institutions, political communication and meaning, and collective action (Berezin 1997). The ongoing attempt to determine whether there may be certain cultural prerequisites for democracy has been chastened by postmodern and postcolonial critiques of the Western biases in such investigations. More culturally informed reformulations of traditional areas have resulted in the study of New Social Movements and the New Institutionalism (Powell and DiMaggio 1991).

Interest in civil religion and in the relationship between religion and politics (including fundamentalism) has increased. Benedict Anderson's (1991) notion of the nation as an imagined community is one of the many publications on collective identity which, in addition to nationalism, examine ethnicity, race, gender, and sexual preference. Studies of political rituals, rhetorical strategies, strategic discourse, commemorations, museums, political funerals—including the reburial of the remains of previously buried 'heroes'—are areas of considerable innovation. The study of the cultural dimension of processes of globalization and localization (including migration) is another frontier for the study of political culture from its increasingly interdisciplinary perspective. The con-

ceptual threads connecting the different approaches to political culture are as tenuous as the webs of meaning constituting political culture. Yet, the fragility of both does not lessen their importance.

M. J. Aronoff

Political Discourse

1. Introduction

Discourse in general is a way of organizing human experience. It establishes frames of meaning by the recounting and interpreting of events and situations. It constructs systems of order. Political discourse applies such frames to the exercise of power—including principles of hierarchy, representation, and accountability. It deals with the narrative interpretation of events and ideas, logical and mythic, and establishes criteria and contexts for comparing and evaluating political systems. In these terms, political discourse is as old as politics, its pedigree going back at least as far as Plato for whom discourse took the form of a *dialectical logic*. Plato used this method to derive a model system composed of appropriate connections between truth, knowledge, virtue, and justice that he used to evaluate and rank different polities. Plato made explicit what might best be referred to as the relationship between discourse as rationality and rationality as discourse. But he also recognized that there were limits to the role and place of rationality in human affairs. Where the rational leaves off, he invoked a revelatory higher power, religious, mythic, magical, numerological—a Pythagorean idea of myth, (Cassirer 1946). One can say that Plato defined political discourse in terms of a *mytho-logic* that he regarded foundational for the functioning of any political community. For Plato the state, or better, the city, is a discourse community.

For Aristotle political discourse was an emergent teleological process embodying final causes, the shape, purpose, and meaning of the polity. This established a basis for a purposeful history of ideas—a narrative realizing itself in the evolution of democracy of which

there are several versions. One starts with Athenian democracy as a defining and classic polity, Rome representing natural and positive law (with interpretive exegesis by Glossators and Commentators). The Schoolmen raised the issue of revelation, ecclesiastical law vis-à-vis natural law. Medieval corporatism established the principle of conciliarism (and the kings ‘two bodies’) (Kantorowicz 1981). Social contract theorists, from Hobbes, Locke, and Mill, defined a political spectrum, which at one end was autocratic, the other democratic. Another version uses ages: classic, ecclesiastical, enlightenment, romantic, democratic. The end of history is modern, secular, democratic government. Which makes a better story than a good history.

Although hardly a corpus or a stable body of knowledge, modern political discourse theory is composed of a variety of concepts and ideas from many disciplines. As a form of critique it tries to penetrate below the surface of the good stories that people tell themselves about politics. Discourse theories may differ but they are all concerned with what it is that people come to believe about power and its exercise, and how they come to think that way. Political science and sociology analyze different ideologies, dogmas, and belief systems in terms of their content and the extent and intensity of their support to understand threats and opposition to democracy and democratic principles.

As with Durkheim’s treatment of social facts, political beliefs are no different from any political perceptions and preferences, loyalties and affiliations. Examining them requires operational techniques, quantitative analysis. Belief systems are amenable to survey methods, questionnaires, and statistical techniques (Lane 1962, Converse 1964; Putnam 1973, Tilly 1978, Sidney Tarrow 1994).

In contrast, several other disciplines break up concepts like ideology, belief systems, or culture into components on the grounds that they have become ‘overkill’; that by explaining too much they explain too little. How political discourse establishes order and control and organizes and mobilizes social groups and organizations requires more differentiated categories and more interpretive knowledge. How is it that words can kill? When does ecclesiastical belief lead to murder in the cathedral? How much was Nazi ideology the cause of the Holocaust? How and when does ethnicity, religion, language, or other differentiating social criteria that establish exclusivity define ‘others’ in negative terms—the extreme consequence being genocide? Similarly, when do such circumstances reverse themselves? When do the same defining characteristics constitute pluralism, multiculturalism, or diversity? How does confession within the framework of legal discourse connect guilt with justice, and by so doing change the contours of the permissible? How was Apartheid in South Africa, with its biblical racism, its Boer myths of a chosen people replaced by a Truth

and Reconciliation Commission? These and similar questions have led to a virtual explosion of concepts, categories, and theories: structuralist, phenomenological, linguistic, psychological.

Despite differences among approaches, all favor the analysis of events as more than chance, i.e., as coherent and meaningfully and internally connected. In terms of political discourse theory, events are *social texts*. They can be read as *language* including words, of course, what people say about each other and their condition, but also as *signs, symbols, rhetoric*—as *semiotics*. Discourse theory addresses the problem of how best precisely to read events. It is less concerned with the content of particular ideologies than ‘the content of the form’ (White 1987) and the ‘narrative construction of reality’ (Bruner 1991).

Political discourse theory occupies a position on a continuum, the opposite end of which is political economy and rational choice. Like those approaches, it responds to a calculus of costs and benefits, losses and gains. Unlike them what is exchanged is outside the normal range of interest competition and bargaining—*symbolic* rather than economic capital. If so, then an important purpose of political discourse theory is to identify the coin by which different rationalities are measured.

While the substance of political narratives varies widely, they follow certain fairly standard trajectories, including the *recounting* of events in the form of *retrievals* and *projections*. Events serve as *signifiers* and *metaphors* in which meanings are transmitted in terms of past and similar situations, real or fancied; and as *metonymies* in which the event is a fragment or representation of some larger logical theoretical or revelatory belief system. By this means the past provides evidence for a projected and transcending state of affairs, including millennial outcomes, promised lands, states of grace, or a condition of political virtue or justice. This suggests a central question: when does political discourse lead away from a politics of give and take associated with rational economic behavior and when does it generate *symbolic capital*? (Bourdieu 1977). It is this question that will be discussed here.

First the intellectual pedigree of political discourse will be examined, indicating ways that discourse affects the way people think about politics, act on what they think, and, as a part of such action, how they form discourse communities using symbolic capital, in contrast to those predominantly organized around economic and political exchange followed by a critique and assessment of future trends.

2. An Intellectual Pedigree

Modern concern with political discourse might be said to begin with the *semiotic* revolution. To name only a few contributors (and leaving out forebears like Peirce,

Saussure, Wittgenstein, and others), one might include linguists like Roman Jakobson, Dell Hymes, and Umberto Eco; sociologists like Basil Bernstein, Erving Goffman, and Herbert Garfinkel; philosophers like Alfred Schuetz, John Austin, Ernest Gellner, and John Searle; anthropologists such as Claude Levi-Strauss, Clifford Geertz, Victor Turner, Mary Douglas, and Jack Goody; historians such as Robert Darnton, Pierre Nora, Le Roy Ladurie and of course many others. Political scientists include Benedict Anderson, David E. Apter, and James Scott. In literary theory there is a very large cohort concerned with *narrative* and *interpretation* (Mitchell 1982): Kenneth Burke, Roland Barthes, Hayden White, Frederic Jameson, Terry Eagleton.

Which brings up the question of the range of concepts that such thinkers apply to the analysis of political discourse theory. Walter Benjamin, examining the relation between memory and the crafted story, the potentiality for what might be called the *fictive use of recounting*, implies the significance of the *imaginary real*. Levi-Strauss laid out the structural properties or better, the isomorphic ordering properties of *myth* and *theory* in the form of binaries which literally compose the order of the universe, providing rules of appropriate *intermediation*: between man and the cosmos, men and women, kin and family, earth and sky, land and water, etc. (Levi-Strauss 1955). Similarly in Umberto Eco’s theories of semiotics, with their emphasis on *codes* and *codex, signs* and *signification*, and what he called *sign production*.

In a more literary vein Hayden White refers in his analysis of narrative to the *poetic troping of the facts* in which certain events become in effect what Eagleton called *drenched signifiers*, images and metaphors so symbolically powerful that they become incentives to action. Foucault examines the way certain *discursive codes* establish authority and power. For François Furet political discourse becomes a *nonscientific representational strategy* or a structure of time, or *time consciousness*. Ricoeur emphasizes discourse as *sin, confession, and purification, negative poles and overcoming* and the uses of metaphor. Henri Lefebvre deals with space as *terrain* and jurisdiction as *agora*—a theater of intersection between *addressor* and *addressee*. For Baudrillard an appropriate discourse produces *symbolically dense* miniaturized versions of state and society, encampments, staging areas, fortresses, neighborhoods, which form the moral center for what is yet to be. Guy Debord emphasizes political discourse as theater, drama, *spectacle*.

While each of these and many other thinkers contribute in very different ways to political discourse theory, it is possible to identify one common and underlying concern. People make stories out of events. They do so individually and collectively. Recounting individual stories makes for sociability. Collective stories have political consequences when, as myths they purport to be history, as history they are

reinterpreted as theories, and as theories they make up stories about events. Theories that become stories create *fictive truths*. Since in politics, truth-telling and story-telling are part of the same process, it becomes possible to interrogate the past in order to transform the future.

There are of course many ways to examine such matters. A useful place to begin is with the actual ways and circumstances in which individuals recount their own stories. As a process, this becomes politically interesting if such stories are *collectivized*, systematized, and formed into what have been called *master narratives*. For this purpose *agency* is required, a public figure able to play the special role of 'story-teller' whether in the form of philosopher-kings, cosmocratic figures, politicians, soothsayers, diviners, or others (Benjamin 1969).

Agency, a form of authoritative recounting, begins with some benchmark, a state of grace which then defines a *negative pole*, loss, suffering, struggle, on the basis of projecting an *overcoming project*, a preferred goal. Such recounting is intrinsically *dramatic*—exceptional experiences punctuated by *promontory events*. Events may be tragic, including suffering, torture, betrayal, murder, and death. They can also result in superior *insight*, knowledge through *struggle*, *purification*, and *redemption*. Recounting renders the unimaginable manageable. It builds into the narrative *imaginary reals*, necessary fictions which establish boundaries and borders, affiliations and loyalties, terrains and jurisdictions, defines insiders and outsiders, separates the good citizen from the pariah. The narrative establishes *boundaries* and *clienteles*, identifying relevant *markers*, ethnic, religious, racial, kin, clan, and class, or other categories. It locates *surrogates*, *negative* (but redeeming) *others*, Genet's thief, or homosexual, Fanon's colonial African, Foucault's madman or prisoner, etc. (Foucault 1979).

It deals too with *ritual endowments*, insignia, votary paraphernalia that go with them, flags, and uniforms. It emphasizes the theater of the absurd, or the solemn occasions, the mass, the funeral, the parade, votary ceremonies, candle light parades, pistols, whips, massed guns and technology; anything which permits *symbolic intensification*. Ordinary terrain, transformed into sacred space, serves as metaphors or better *simulacra* for the national patrimony (old and new Jerusalems). Politics is the stage on which leaders perform, recapitulating historical events as theater and choreography (Plant 1992).

Time becomes crucial, especially in *disjunctive* and *transformational moments*, when leaders propose a fresh start. The French revolution tried to reinvent the calendar in its desire to start the world all over again. Time foreshortened becomes space, a *geomancy of space*, enclosure as architecture, the placement of buildings, squares, parks, transportation, homes, meeting places, amphitheaters all taking on new meaning as potential rallying ground, or as Agora's or

forums, staging areas, embattled zones, etc. So too with monuments, statues, shrines, graveyards, jails, public buildings, this pub, that hideout, this square, street, neighborhood. Virtually any ordinary thing can take on significance, disrupting the daily or routine business of commerce, its taken-for-grantedness, in favor of the exceptional moment in the exceptional space (Lefebvre 1986).

Similarly with clothes, uniforms, medals, gestures (verbal and other), hair, Jacobin hats, red flags, insignia, swastikas. These emphasize the body as reference point; exaggerated posture, sexual affronts, cross dressing, racial inversions. The body politic takes on the characteristics of the individual body. It can be violated, penetrated, tortured, mobilized, transformed.

Opportunities for such *recounting* include the founding of new nations and states, revolutionary and redemptive *breaks*, a turning of the world upside down. In effect, political discourse helps produce such breaks. It also capitalizes on them when the opportunity arises. In such moments political discourse creates its own rationality, defining sharply what it is against and what it is for. It contains within itself a disordering effect in rejecting established political beliefs and institutions, and an ordering principle designed to negate and transcend the disordering condition it helped to create.

Political discourse then is bound up with history as conflict and struggle. Typical circumstances are one or other form of *inversion*; *revolutionary*, *ecclesiastical*. A classic device is some variation on Hegel's *master and slave*, or, more redemptive, the *last* becoming *first*. One can find both in the speeches and texts of early church fathers, fifteenth century mystics, and radical political revolutionaries from the Jacobins, to the Levellers and Diggers, not least of all including what Hobsbawm called *social banditry* (Hobsbawm 1959). Such situations lead to exceptional acts of daring and devotion. They involve a tension between *purity* and *danger* such that the words of the recounted narratives resonate.

Recounting is thus a way of both periodizing the past and incorporating it within a series of performances in which singular and distinctive individual events and actions stand out, the whole inspiring urgency, martyrs and heroes not to speak of loyalty, obligation, and what Bernard Yack has called political 'yearning' (Yack 1986).

Narrative is half the process. *Text* is the other. Both are required if political discourse is to become an active ingredient in political life. Required of texts in relation to symbolic capital is that they provide exegetical opportunities. *Textualization*, the transition from *orality* to *writing*, requires not only a narrator but a writer. Both are essential if those documents designated as sacral are to serve as symbolic centers of power, complete with their coterie of interpreters devoted to locating hidden meanings, logical and

magical, thus providing those esoteric nuances that make a discourse community unique and which give it its moral center. Text and coterie, with the agent at the center, suggest truth as insider knowledge. They create an *iconography of words and objects* worthy of worship and respect. So virtually all societies and social movements have certain texts which become canonical, whether they take the form of a constitution or a 'little red book.'

Whether as Marxist texts or canonical or biblical texts, the word as written embodies both logical truths and mythic or fictive ones. Some are enshrined in sanctuaries. Others as authorizing documents are on suitable display (as for example the constitution in the United States or the Magna Carta in Britain). Hence, one might say that political discourse involves the alteration of original meanings by means of mythic retrieval and logical projection, what Roland Barthes and Claude Levi-Strauss referred to as 'mytho-logics' (and what Malinowski called a mythic charter).

Which returns us to the question raised above. How can history as a representation of symbolic events become simply history—exceptional moments becoming unexceptional? Or, to put it differently, how can symbolic capital be converted into normal interest competition and bargaining within a framework of constitutional authority and law? It is a question that comes up in the context of wars, nationalist, separatist, and revolutionary movements, the rise of cults, persistent and organized protest—matters which if anything are more important today than ever before. In this sense one can say that political discourse is about how to change the world by reinterpreting it, and political discourse theories are about how to interpret the interpretations.

3. Applications and Implications

The twentieth century has perhaps been more witness to powerful and consequential political occasions than any previous one, not least of all because of the connection between terror and utopianism. If one includes the power of nationalism, the mobilization of its rhetoric, which accompanied the decline of colonialism and the founding of new states in Asia and Africa, one thinks too of a virtual explosion of political *agents* like Nkrumah, Senghor, Sekou Toure, and Nyerere, leaders all of whom, in the name of anticolonialism, nationalism, and independence, created their own political vernacular texts, doctrines by which they claimed exceptional and continuing political privileges (emulated by their putative descendants). In these terms too political discourse was very much a phenomenon of such populist dictatorships as Peron's Argentina not to speak of De Gaulle's myth of a glorious (and largely fictive) France.

Perhaps the exemplary defining event or historical moment, or disjunctive break, was the Russian

revolution with Lenin its agent, surrounded by a band of intellectuals forming a coterie. In the texts so formed the strong elements are *orality* and *textuality*. Dramatic public spaces were carefully selected for delivery. What began in speeches was translated, that is, words became converted and modified in the form of writings many of which became canonical. As the redemptive and prophetic figure of the revolution, he wrote the bible of revolutionary principles and tactics, not simply for his own followers but subsequent generations and putative descendants. Perhaps the most significant of these disciples was Mao Zedong who 'rewrote' China's history in the form of three narratives: long, intermediate, and short; each fitted inside the other, *contextualizing* in the form of radical revolution and militant nationalism, converting time into immediacy, forming a *fictive/factual* basis for *revolutionary discourse* (Apter and Saich 1994).

Political discourse not only precipitates conflict and foreshortens time but also can extend the disjunctive moment and keep it alive. Examples of conflicts of the long *duree* include the IRA in Northern Ireland, and between the Israelis and Palestinians (where two diasporic populations remain locked together in their hostility). In both cases the parties are divided by their discourses, their retrievals of the past determining their view of the future, and so making mutual accommodation difficult as long as their territorial claims are to the same physical space. Each discourse has the same contours as the other, similar themes of loss and displacement. Each makes salvational, redemptive, and recuperative national claims. For one side to give way to the other is considered betrayal.

There are innumerable examples. The rise of fundamentalism or integralism enables the preaching of the word as *scripture*, something to be pored over and through a process of *exegesis* made to reveal hidden, deeper, and higher meanings. For some such words will be profound, for others ritualized, both appearing to offer magical depth, a common sensibility. By this means, the individual is linked to the state or sect and by multiple references and *reciprocities*. Virtually any categories will do, religion, ethnicity, clan, family, or region, village, town, or cult, political program, ideology, etc. All potentially are *condensed symbols*, complex, with multiple references and signifiers, providing opportunities for *exegetical bonding*—establishing boundaries in the mind that constitute boundaries on the ground.

There are certain recurrent themes: an original and negative condition to be transcended, a mythical past to be redeemed, a frame within which certain primary symbols are characteristic, loss, defilement, sin, stain. Grievance is converted to intentionality, time into space, and space into particular places, symbolically endowed terrains. By this means individual stories are collectivized and conveyed as master narratives to a group as a whole. Hence the narrative process itself creates political leaders acting as agents who validate

preferred outcomes embodied in texts. Such narratives contain a story within a story, the storyteller or agent figuring in his or her own story. Prototypical exilic figures are Odysseus or Moses. Forced to suffer the loss of the patrimony, wandering far from their homes, they learn to outwit enemies. By means of knowledge gained from experience, they regain the power necessary to reclaim the patrimony in the first instance or a Promised Land in the second.

The more cosmocratic the impulse, the larger than life the *principal agent*, the greater the moral density of the text, the more likely are the doctrines to intensify differences, separating believers and nonbelievers; the saved and the damned, divided by a potential millennial accomplishment. Some are privileged at the expense of others. A chosen people will claim superiority, whether by class, ethnicity, religion, nationality, race, or doctrinal persuasion. Each such group becomes both *surrogate* for higher truths and a symbol or representation of them. Loyalty is thus moral obligation, affiliation deep seated, binding groups together. Hence political discourse theory constitutes as its subject matter all those cleavages of human *association*, which especially in a context of violence acquire durable properties reinforced rather than undermined in subsequent events. In these terms, discourse communities generate their own objects, symbolic capital possessing its own *exchange value*.

There are certain serious weaknesses to political discourse theory so considered. It works best in conjunction with intensive case studies in depth. It depends on depth interviewing or political anthropology. It is not very amenable to operational techniques, survey, path analysis, and other statistical methods. Its relativism is less concerned with the content of ideologies, the conventional interest of political scientists, than in the structure of beliefs, what forms them, and how they become adopted. There is also a bias that over time rationality will triumph over nonrationality, logic over revelation, theory over myth, facts over appearances.

However one approaches it, discourse theory is not likely to disappear in the foreseeable future. It has moved in several different general directions: toward *postmodernism* in the connection between *narration and legitimation* (Lyotard 1984); *cultural studies*, with respect to the symbolization of violence and the state (Bhabha 1990); *sociolinguistics*, itself divided into three main strands, psychological, linguistic, and sociological (Giglioli 1982); towards an intermediate position between comprehensive structural theory and the concrete explanations (or justifications) people give for their actions and beliefs—what has been called ‘critical hermeneutics’ (Habermas 1979). Finally, for those interested in politics, power, and rational choice theory, some attention is now being paid to how symbolic capital fits into much the same framework as economic capital, using narrative to show how the two represent different forms of the same rationality (Bates

et al. 1998). Indeed, if ‘money’ is itself the symbolic form of utility *influence* is the consequence of symbolic capital. If so, rational choice theory and discourse theory instead of occupying opposite ends of the same continuum may come to constitute their own hermeneutic circle.

Political Economy, History of

The term 'political economy' first appeared during the early seventeenth century in French texts that considered the contribution that trade, agriculture or manufacturing might make in augmenting the powers of the sovereign and rendering their subjects more prosperous. It is linked to the rise of the early modern state: it assumes that the interest of the monarch lies in a strong state, and that the path to a strong state leads via the augmentation of a population, and the extension of their means of subsistence. The interests of sovereign and subject therefore coincide—the strength of a state is founded upon the well-being and numerosness of its population. During the seventeenth and early eighteenth centuries an extensive literature on the contribution of trade and agriculture to the welfare of people and ruler developed in the English, French and German languages. The diverse practical propositions encountered in such writings were systematized in the course of the eighteenth century, first through the work of François Quesnay (1694–1774) and the Physiocratic 'School' with which he was associated, and subsequently through Adam Smith's (1723–1790) critique of Physiocratic and 'mercantilist' schools of 'political economy.' Smith's *Wealth of Nations* (1776) provided the foundations for a new 'principled' science of political economy, the chief architects of this new science being Thomas Robert Malthus (1766–1834) and David Ricardo (1772–1813). The 'classical political economy' which these and their contemporaries represented elaborated a limited set of economic principles turning on the proposition that, ultimately, the exchange value of a commodity was reducible to

the amount of labor embodied in it. Price, therefore, inhered in the good, rising or falling according to the cost of labor. By the 1830s an independent American literature was developing on this basis, and in the final two decades of the century Dutch, French and English texts began to be read in Japan. In continental Europe Jean-Baptiste Say's (1767–1832) reception of Smithian principles was extremely influential; his writings laid the basis for the transformation of 'political economy', during the last third of the century, into a new 'economics' in which value was a product of subjective choices, and price the outcome of the degree of scarcity which these choices created.

1. The Derivation and Evolution of the Term 'Economy'

Although the discourse of political economy first emerged in early modern Europe, the term derives from Aristotelian beliefs concerning social and political order. Aristotle's *Politics* outlined two forms of human association: the *oikos* and the *polis*. The first, the household, was instituted for the satisfaction of private daily needs; the second, the domain of political association, structured public life. Aristotle introduced this distinction in response to Plato's argument that the art and technique of government was everywhere the same; much of *Politics* is therefore taken up with the different ways in which public life could be structured. By contrast, only one form of organization was foreseen for the household, whose head ruled over its members like a monarch over its subjects, securing the proper employment and maintenance of property and persons. Elsewhere in his *Nicomachean Ethics* Aristotle had argued that the virtuous man set no store by wealth, hence it could be no part of virtue to deliberately increase the wealth of a household. The purpose of the household was therefore the provision of an ordered material existence to its members through the allocations made by the household head. Beyond the household, in the public domain, merchants engaged in trade and money-getting, but this was activity governed by no definite conceptions of virtue or order, subordinated to the superior principles of government.

Vestiges of this way of conceiving social and political relations persisted into the eighteenth century, especially in English, French and German treatises which adumbrated the proper management of farm and field. However, in the early seventeenth century 'économie politique' adopted the central householding tenet of the Aristotelian model outlined above, projecting it into the public domain, hence creating a new 'political oeconomy'—which sought to identify the most expedient manner in which the interest of ruler and ruled might be reconciled within a state conceived as a giant household. Although this

naturally involved proposals for the augmentation of population and the means of their subsistence, the pursuit of wealth for its own ends had no definite place in this new order. In France, *commerce* was the term assigned to activity related to trade, finance, and money; literature related to this aspect of economic activity developed quite separately to that of a political oeconomy primarily focused on agricultural, subsistence activities.

2. The Sources of Power and Plenty

In the context of a European economy recovering from the ravages of the Thirty Years War, vulnerable to epidemics on the one hand and periodic poor harvests on the other, the priority given to agriculture as the foundation for any increase in numbers and welfare requires little elaboration. Overseas trade could make a small country like Holland rich, but both Britain and France were simply too large for trade to have such an impact. When in the early nineteenth century David Ricardo outlined the benefits of international trade he chose as his examples English wool against Portuguese wine—products that both countries had in abundance, of course, but where the increase in welfare consequent upon exchange had little impact upon the central issue of subsistence. And in fact the overseas trade of Britain throughout the eighteenth century facilitated the import of sugar, tea, coffee and spices, luxury goods whose significance in turn became part of a debate on the implications of the production and consumption of such goods. Not until the end of the century did grain imports exceed exports, and this reflected both an increasing population and a shift in the structure of production that formed the origins of the industrial revolution. This new pattern of international trade—in which domestic employment and a rising population increasingly depends on the export of manufactured goods in return for which food and raw materials are imported—first emerged in the nineteenth century.

States with ready access to the sea—Spain, France, Britain, and the Hanseatic cities—had the opportunity to develop overseas trade and fisheries, and an associated literature developed which both urged the extension of trade as the path to wealth, and outlined the practicalities of successful trade and commerce. Where access to the long-distance trade that the oceans offered was limited, arguments that herein lay the route to wealth and power had little force. Moreover, the profitability of merchant ventures seemed to depend upon risk and chance, not upon the wise investment of capital, the proper management of resources, and the judicious use of labor that typified a flourishing agriculture. The rhythm and progress of production in this sphere of economic activity lent itself to the conceptual framework of political

oeconomy and could without serious modification be extended to manufacturing activities. German texts of the eighteenth century routinely countered *Landwirtschaft* to *Stadtwirtschaft*, the town economy to the country economy, signifying manufacture in the former and agriculture in the latter—even though much early manufacturing actually took place in rural locations. But the contrast set up in this manner simply excludes serious consideration of trade and finance as significant elements in the welfare of the state.

3. The Enlightenment Science of Political Economy

In the mid-eighteenth century a ‘new science of political economy’ was created, based upon a conception of the ‘natural order’ of society in which agricultural activity was the unique source of a ‘net product.’ The systematic analysis of production and circulation that was developed by the so-called ‘Physiocrats’ between 1760 and 1780 owed much to contemporary enlightenment rationalism, but it was also prompted by the growing problems of the French economy, and the increasingly parlous nature of the state finances.

Physiocratic political economy identified the natural foundations of economic activity, and at the same time implied that proper management of the economy required that the ruler not ‘govern too much,’ that excessive interference would impede the formation of wealth. The source of wealth was agriculture, whose net product circulated through the various classes of society; the greater this net product, the stronger the circulation and hence the greater the wealth. Improvements required investment, which could only take place if the net produce was not in the course of its circulation diverted into unproductive ends, such as the production of luxury goods for landed proprietors. Special taxes and duties were impediments to the free circulation of goods; and since all taxes were ultimately funded by the net product, all state revenue should be drawn directly from the sole source of this net product, agriculture.

Quesnay illustrated his ideas with a circulatory diagram, the *Tableau Économique* (1758–9), depicting the flow of net product from its agricultural source, through the hands of the landlords, thence to the ‘sterile class’ of manufacturers, and then, through the agricultural purchases this last group made, back again to the source. This clear diagrammatic representation of three economic classes and the flows of goods and payments between them is now seen as the original conceptualization of circular flow in an economy, but the originality of this drew little contemporary attention. Criticism of the Physiocratic system isolated two central tenets: the proposition that

non agricultural employment was unproductive, and that a single tax upon agriculture was viable, practically or intellectually. The most prominent criticism of this system can be found in Smith's *Wealth of Nations*.

4. The Smithian Critique of the 'Mercantile' and 'Agricultural' Schools

In Book IV of *Wealth of Nations* Adam Smith arranged his intellectual forbears into two (fatally flawed) schools of thought. The first of these was the 'commercial, or mercantile system,' which, he argued, sought to enrich one state by impoverishing others, imposing duties and a range of restraints of trade designed to attract money and gold into the land. In part a rhetorical exaggeration designed to highlight his own 'system of natural liberty,' and in part a willful misreading of an extensive and varied literature more sophisticated than he would allow, his remarks laid the foundations for a critique of 'mercantilist' policy that has survived up to the present day.

The other school to which Smith addressed critical remarks was the 'agricultural' school. He rejected the idea that agricultural labor was the sole source of wealth, and that other labor was unproductive; but he warmly supported the Physiocratic representation of the annual flow of goods as the source of wealth, and the proposal that this flow should be as little impeded as possible. These were indeed central principles of Smith's own work, together with a redefinition of what counted as 'productive' as against 'unproductive' labor.

Smith defined the 'wealth' of a nation not as an accumulation of gold, nor as simple populousness, but as the annual produce of its (productive) labor. Productive labor was that embodied in capital; it left a physical trace, unlike a service (no matter how useful or vital to the state that service might be). This could be augmented through the extension of the division of labor; labor could be made more productive by subdividing tasks and rationalizing the production process. There were two provisos attached to this: the first was that this process of the increasing division of labor had greater potential in manufacturing than in agriculture; and the second was that the degree to which it could develop was limited by the extent of the market. From this it follows that the most rapid increase of national wealth would result from the augmentation and rationalization of labor applied to manufacturing, within an economy which was both internally and externally freed from impediments to trade.

Smith was writing in the context of an economy whose structure and rhythms were dominated by agricultural production. This was not only the major economic sector; it was the immediate source of food

and was prone to annual fluctuations in output and associated variations in prices. Since foodstuff represented such a major part of expenditures on the part of a majority of the population, the achievement of a low and stable price for grain was a crucial political problem throughout the eighteenth century for European governments.

Broadly speaking, there were two opposed solutions to this question. The first option was to encourage home production of grain by protecting domestic producers: high tariffs on imported grain would prevent the flooding of the market with cheap food in good years, undermining home production which would then be unable to provide adequate supplies whenever the sources of foreign grain diminished, or even dried up altogether. This option therefore secured whatever the level of home produce might be to domestic consumers, albeit at a high price. The second option also encouraged home production, but did so by permitting free import and export of grain. According to this, the availability of a market greater in extent than that offered by the national economy would stimulate domestic producers, consequently rationalizing their activities so that cheap foreign grain would not appear to be such a constant threat to domestic production. This second option proposed that the domestic population would be best served by a supply of cheap food based not upon the protection and control of the home market, but rather upon their access to an international market in foodstuffs. Smith's argument that the division of labor was a powerful engine of economic growth, and that it was limited only by the extent of the market, was therefore an argument for the benefits of free trade in all goods, augmenting the welfare of all states through the extension of the international economy.

5. The Principles of Classical Political Economy

Malthus' *An Essay on the Principle of Population* (1798) was conceived as a critique of contemporary conceptions of human betterment, and it certainly played a part in discrediting the conventional association of large populations with economic wealth and national progress. But his demographic arguments presupposed a closed agricultural economy, enjoying none of the benefits of commerce outlined by Smith. Some five years before the publication of the first edition of the *Essay* Britain had, however, become a net importer of grain. Henceforth, exported manufactures would pay for the imports of food required to subsist a large, increasingly manufacturing, population. Expanding (free) trade and commerce was to provide the solution for the 'Malthusian problem.'

Nonetheless, during the first two decades of the nineteenth century the elaboration of the classical theories of production and distribution presupposed

the conditions of an agricultural economy, producing a staple crop through the joint contribution of laborers, farmers and landowners. These three economic classes received wages, profits and rent, respectively, and the question which political economists sought to resolve was the relation between price formation and the distributive shares received by each class. Smith had assumed that prices were simply the sum of distributive shares; political economists sought a systematic explanation of the level of each of the elements within a framework that supposed that human labor was the sole creator of value.

Debate over Britain's Corn Laws during 1814–5 provided the occasion for the systematic linkage of the pattern of domestic income distribution to the trade regime. Malthus composed three pamphlets during this period which argued the benefits of limited protection, and suggested that rising rents were a reflection of human progress, since he regarded rent as a payment made subsequent to the settlement of wages and profits. Ricardo in his own pamphlet, known as the *Essay on Profits*, dissented from Malthus' protectionist sentiment and assumption that rising rents were part of the progress of wealth. Since he assumed that wages were fixed, he argued that there was an inverse relationship between rent and profits. High rents, therefore, meant low profits, they furthermore meant high prices for grain and hence increased the wages that manufacturers must pay their own workers. Since he also assumed that the rate of agricultural profit determined the rate of profit in general, protection for the landlord and high rents depressed the rate of profit in the economy as a whole. The solution to this prospect, he argued, was free trade in grain, which would force agricultural rationalization and lower the average price of grain, the basic foodstuff for the majority of the population. Ricardo's *Principles of Political Economy and Taxation* (1817) elaborated these points, and established a core of theoretical propositions that survived until late in the century, John Stuart Mill's *Principles of Political Economy* (1848) providing a lasting synthesis of classical principles in a manner that made the science accessible to an informed public readership.

6. The Diffusion of Political Economy

Smith's *Wealth of Nations* was by 1800 acknowledged everywhere as the canonical text of political economy, but nineteenth century English writing had relatively little impact outside English-language areas, and at this time anything written in French had a far bigger readership than texts written in English. Jean Baptiste Say had been greatly influenced by his reading of Smith, and in 1803 he produced his own *Traité d'Économie Politique*, followed by a number of new editions, a 'catechism' in 1815 and a new six-volume 'complete course of political economy' in 1828–9. Say conceived political economy as a significant part of an

education for republican citizenship, and his writing was deliberately directed to a large popular audience. Since his texts were readable and in French they were quickly taken up outside France, with the result that, after Smith, Say became the most widely recognized political economist of the first half of the nineteenth century.

Say is remembered today for his 'law,' that 'supply creates its own demand.' In fact, this is a travesty of his argument on 'effective demand,' that whatever the general demand for a good, the political economist was only concerned with the demand of those with means to purchase, which means had themselves been gained from previous sales of their goods or services to others. He also argued that the process of production and distribution involved utilities, not goods, and that what the process of consumption destroyed was the utility of a good or service, and not the good or service itself. When combined with his principle of effective demand, this shifted the emphasis of his work away from the (production-oriented) English Classical Political Economy and towards the sphere of consumption. In these and other respects Say's political economy laid the path which led to the new subjective, marginal economics of the 1870s.

Political Economy in Anthropology

While in the history of economics, political economy is a widely accepted description of the general style of analysis of national wealth and international trade that emerged in the early nineteenth century in the writings of classical economists such as Adam Smith and David Ricardo, the term has come to be used in anthropology to refer to a variety of theoretical approaches that developed in the 1970s and shifted the focus of anthropological analysis away from isolatable local systems and toward 'large-scale regional political/economic systems.' In this shift, research now took 'the form of studying the effects of capitalist penetration upon these communities' (Ortner 1984, p. 141).

Although the term is sometimes applied only to developments within North American anthropology, it is misleading to see political economy in this sense as a description of a distinctively American 'school' limited to the 1970s. At least some practitioners had examined such broader links much earlier. Moreover, at around the same time, anthropologists elsewhere were also beginning to investigate more closely the links between global capitalism and the local social systems they had been trained to analyze. Doubtless American efforts in this direction were distinguishable because of their greater debt to the work of Andre Gunder Frank and the sociologist Immanuel Wallerstein on the capitalist world system, as well the influences on them of earlier materialist tendencies within American anthropology.

But, particularly in France and Britain, and often under a rather different set of theoretical influences—most notably from contemporary Marxist theorizing—anthropologists were also reexamining the relationships between capitalism and what were often described as various precapitalist modes of production or social formations in Asia, Africa, and Latin America. Any assessment of this general move on the part of anthropologists from the 1970s to engage with global economic factors and their influence on the local groups anthropologists were more used to studying must then examine both of these developments.

1. Political Economy, Anthropology, and Global Capitalism

The development of political economy in North American anthropology was linked to a more general

intellectual and cultural challenge to America's imperial expansion, itself stimulated by opposition to the war in Southeast Asia. Consequently, political economy in the American context was on the one hand theoretically somewhat eclectic, and on the other, concerned primarily with issues of global capitalism. Given the tendency of anthropologists to engage with regions, societies, and cultures outside or on the margins of North Atlantic capitalism, much of the energy of political economists in America was devoted to analyzing the impact of capitalism on individuals and communities on what was sometimes called the 'periphery' of the capitalist system. This global emphasis in their approach to more traditional anthropological concerns, moreover, made American political economists less likely to classify these marginal individuals and groups as *precapitalist*. They were consequently also less interested than their French counterparts in any attempt to develop a general theory of modes of production, seeing this as being of little relevance to the concerns of social and cultural anthropologists doing field studies in the present.

Materialist analyses were well established in American anthropology some time before the emergence of political economy, although it could hardly be argued that these were based on any genuine engagement with, or even sympathy for, the work of Karl Marx himself. This materialist current is commonly associated with the name Leslie White, who is assumed to have been familiar with work in the Marxist tradition, if not with Marx's own writings, although he was prevented from acknowledging the link explicitly because of a generalized American hostility to Marx. Marvin Harris was an influential advocate of materialist analyses from the 1960s, although, unlike White, he was openly hostile to Marxist theorizing, preferring a form of techno-ecological determinism that was rather nearer to that of White.

Closer to the interests of the new generation of political economists was the work of Julian Steward. Steward had formulated a more open, 'multilinear' theory of evolution. He also headed the Puerto Rico project, unusual for the ways it tackled issues to do with social change and colonial history as central concerns of anthropology.

But more than anyone else, a group of anthropologists studying in New York in the 1940s—including subsequently well-known figures such as Eric Wolf, Sydney Mintz, Elman Service, and Stanley Diamond—became the key figures in anthropology's direct engagement with colonialism and global capitalism from within a materialist perspective, an engagement that subsequently attracted the label 'political economy.' Wolf and Mintz in particular became increasingly concerned with the implications of European global expansion for the anthropological analysis of peasant communities in the Caribbean and South America. Both wrote anthropological monographs that were unusual for their discussion not only of local

systems of culture, kinship, and social organization, but of the formative links established in the long history of European colonization between local communities and the centers of the world economy in Europe and North America. Later, both also produced influential general works on the development of a world capitalist system, paying particular attention to the interconnections established in this process between Europe and North America on the one hand, and the only apparently isolated peoples on its periphery on the other (Wolf 1992, Mintz 1985).

Others, from both the New York group and outside it, contributed, if less directly, to the development of political economy. Unlike many materialists in American anthropology, Stanley Diamond made important contributions in Marxist theory, founding the journal *Dialectical Anthropology* in the 1970s, and working on a critical/phenomenological Marxism that contrasted rather sharply with contemporary Marxist theorizing in France. Eleanor Leacock made her own contribution, both to the development of a Marxist anthropology, through a pursuit of themes of kinship, family, and gender raised in Engels' *Origins of the Family*, and to political economy in some important work on the impact of the fur trade on indigenous North Americans.

Two further influences served to broaden the popularity of such analyses in American anthropology by the early 1970s. First, there was the publication of the very influential early works of the dependency theorist Andre Gunder Frank and, shortly thereafter, the sociologist Immanuel Wallerstein (see Frank 1969, Wallerstein 1974). What this work brought in particular was a more sophisticated understanding of the imperatives of the global economy, and the compatibility, indeed even functionality, within it of apparently noncapitalist economic and political forms. Anthropologists such as Jane Schneider and Peter Schneider, Katherine Verdery, Gavin Smith, Carol Smith, William Roseberry, and others associated with the new political economy 'school' did not necessarily accept wholeheartedly the 'capital-centrism' of these more global approaches, but instead entered into a sustained and fruitful debate with them over the global versus the local determinants of socioeconomic systems in what Wallerstein called the 'peripheries' of the world capitalist system.

The second formative influence, particularly on materialist anthropology in America in this period, was the growing movement against America's military intervention in Indochina. This contributed greatly to the radicalized political and intellectual atmosphere on North American campuses, where a new generation of anthropologists was being trained. But it also has specific implications for anthropology, raising as it did the possibility that the discipline itself could be implicated in the project of imperial. In 1968, in an article that generated a heated debate, one anthropologist went so far as to describe anthropology

explicitly as a 'child of imperialism' (Gough 1968). Similar concerns led to significant conflicts within the professional anthropological body itself (the American Anthropological Association), which debated at its annual meetings the involvement of anthropologists in covert operations.

2. The French Marxist Heritage

If in North America the main parameters of political economy were laid down by the engagement of anthropologists with a predilection for materialist explanation with issues arising out of the development of a world capitalist economy, in Europe the situation was somewhat different. This is not to say there was no interest in the relationship between global capitalism and local socioeconomic organization. On the contrary, this central concern in American anthropology found important parallels, especially in France and Britain. Here, however, the debates were informed by a far more theoretically sophisticated attempt to develop a Marxist theory appropriate to the analysis of anthropological materials, a level of theoretical concern largely absent in contemporary American anthropology. And the center of this reworking of Marxism was to be found in France.

Developments in French anthropology were subject to three distinctive influences. The first was the opening up of the Marxist left, in part spurred by the developing Marxist critique of Stalinism which, among other things, produced a space for Marxist intellectuals, both inside and outside the Communist Party, to criticize the kinds of mechanical and evolutionist interpretations of Marx that up to then were the only versions permitted by Marxist parties. Second, and related to this, the Sino-Soviet conflict inspired at least some Marxist intellectuals and political activists to search for alternative models of both socialism and the ways it could be achieved. Third, unlike the case in America, French anthropology was dominated by the imposing intellectual figure of Claude Lévi-Strauss, and thus it is not surprising that when French anthropologists turned to the work of Karl Marx for inspiration, they developed a structural version of Marxism highly critical of the existential and humanist Marxism whose best-known exponent in France was Jean Paul Sartre. It is not especially surprising that the two main 'schools' in French Marxist anthropology—the first associated closely with the theories of the communist philosopher Louis Althusser, and the second with the structural Marxism of Maurice Godelier (a student of Lévi-Strauss)—while being critical of mainstream 'mechanical Marxism,' should both also have been equally if not more critical of the main alternative. While these ideas may have been influential in the wider student movement, Althusser's anthropological admirers, most notably Emmanuel Terray and Pierre Philippe

Rey, along with Godelier and his students, all sought to reformulate a Marxism that was 'scientific,' based on Marx's 'mature' work, and avoided what they took to be the pitfalls of an approach based on humanistic assumptions about a universal human subjectivity thwarted by capitalism.

As this suggests, for structural Marxists, rethinking the Marxist heritage meant going back to the work of Marx on capitalism, and what they found in doing so was the beginnings of a general theory of historical materialism within which anthropology could play a very significant role. That role was to be the formulation of a general theory of modes of production, and the laws of transition from one to another. Contra some of their critics, this was not seen as a mere exercise in antiquarianism, since such a theory would provide, it was argued, the theoretical basis for a political practice aimed at stimulating not just a transition to communism, but the shaping the nature of the communist future as well.

It is suggested that there was no single Marxist approach in French anthropology, but instead a collection of competing and often antagonistic camps. And yet, in spite of differing allegiances—to Althusser, to Godelier's version of structuralism, etc.—at least when viewed from the outside, French Marxist anthropology did seem to constitute a fairly unified discursive field for debate.

French Marxist anthropologists made important contributions to a number of areas of concern to both Marxism and anthropology (for an overview, see Kahn and Llobera 1981). A good example is provided by the debates over the nature of lineage-based societies in Africa that were sparked off by the early publications of Claude Meillassoux (see, for example, Meillassoux 1964, 1967). Scholars, including most centrally, Meillassoux himself, Emmanuel Terray, and Pierre Philippe Rey (both former students of Louis Althusser), as well as Maurice Godelier, Arienne Deluz, Pierre Bonte, and others, used Meillassoux's material on the Gouro of the Ivory Coast, as well as ethnographic data on other uncentralized African societies, to debate the nature of most of the basic concepts of historical materialism—class, mode of production, productive forces and relations of production, exploitation, articulation, social formation, patriarchy—as well as the central theoretical tenet of historical materialism—economic determinism (or what one participant called Marx's hypothesis of economic determinism in the last instance). This important debate, more than any other, serves to illustrate much of the potential theoretical benefits, as well as some of the main pitfalls, of the project of a Marxist anthropology as it was conceived by these scholars, namely a project to recover, by means of a careful reading of Marx's own work, his 'mature' theoretical project, and to examine its more general validity in situations largely unknown to its originator. Moreover, the debate added considerably to the

understanding of more traditional anthropological problems to do with the nature of authority and social cohesion in kinship-based societies, and societies without centralized political systems.

3. *Marxism, Articulation, and Political Economy*

From the perspective of the study of the linkages between global capitalism and local social and economic systems, the most important effect of these debates was in contributing to the formation of a theory of what some participants called the 'articulation of modes of production.' Drawing on the theoretical work of Althusser, Etienne Balibar, and Maurice Godelier, anthropologists, and others with an interest in the concerns of political economy, produced analyses of the relations between the local and the global understood as an articulation of capitalism with different precapitalist modes of production. It is not often unappreciated that exploring this relation was always a central concern of Meillassoux's in a series of publications, including his early monograph on the Gouro. A sophisticated Althusserian analysis of articulation is to be found in the work of the brilliant Marxist anthropologist, Pierre Philippe Rey (see especially, Rey 1973). And other important contributions to this project were made in Britain by a variety of scholars influenced by French structural Marxism, including Ernesto Laclau, Barry Hindess, Paul Hirst, Talal Asad, and others, and by a group associated with the journal *Critique of Anthropology* including Felicity Edholm, Olivia Harris, Joel S. Kahn, John Gledhill, Josep Llobera, Stephen Nugent, and Maila Stevens. Mention needs also to be made of the important work of Jonathan Friedman on Marxist theory, anthropology, and globalization.

4. *Beyond Political Economy*

The central concerns of political economy have certainly not disappeared in anthropology. But it would be fair to say that in general within the discipline there have been significant shifts at the level of theory and analytic style, as well as at the level of the selection of problems and issues for research, so that very few anthropologists could now be described as political economists. The reasons for this declining popularity of political economy are varied. There has certainly been a recognition that earlier attempts to theorize the relationship between the global and the local in either a dependency/world systems mode or by means of a concept of the articulation of modes of production suffered from problematic theoretical tendencies. These include an overly functionalist understanding of the needs of capitalism, a unidimensional economism, an inattention to the spheres of meaning and agency, and so on. Political economists have, like many others,

been criticized for their eurocentrism, and for failing to appreciate that race, culture, and gender are not mere epiphenomena of social systems. Like those of many others, the truth claims of political economists have been subjected to wideranging critique by scholars influenced by poststructuralism, postmodernism, feminism, and postcolonialism.

Social and cultural anthropology has been affected profoundly by the critiques of those associated with the so-called 'writing culture school.' This has undermined claims about the reality of those other lives constructed in anthropological texts, by the demand for greater degrees of reflexivity, and by the placing of problems of cultural, religious, gender, racial, and national identity at the forefront of issues for investigation. Political economy which, despite the name, doubtless focused on economic issues more than any other, naturally was affected by these shifts. Finally, European versions of political economy, precisely because of their greater concern with issues of (Marxist) theory, have been damaged by the general intellectual and political rejection of Marxism, particularly since the late 1980s.

While political economy in the various forms that it took in Europe and North America in the 1970s and early 1980s will probably not regain the central role it once had in the discipline, for better or worse it would be misleading to pronounce it dead and buried. The tendency to see in the rise of Foucauldian and poststructuralist paradigms a complete rejection of, particularly, the basic conceptions of structural Marxism, is probably misleading. It is possible to argue that these merely take the structural Marxist project one step forward, from a critique of ideology, to a critique of discourse *tout court*.

Certainly, some of the central concerns of political economy have reemerged in more recent attempts by anthropologists to theorize the phenomenon of globalization. An anthropology seeking its roots in a variety of new social movements is very much on the agenda of anthropologists styling themselves as 'radical' and/or 'committed.' Some of the concerns of an earlier generation of political economists are evident in more recent feminist anthropology, as well as in various attempts to construct an anthropology of human rights. Recent attempts to forge a link between critical social theory and anthropology through various reworkings of the concept of modernity may be seen as an attempt to correct the economistic and unidimensionalist failings of the structural version of Marxism. There are even apparently once again calls to return to Marx. It remains to see how these will develop in anthropology in coming years.

Political Elites: Recruitment and Careers

The question of who rules is always central to political science precisely because power is never evenly distributed. At any given time, some individuals and subgroups in society will have more power than others. While most non-Marxist theorists tend to agree that concentrations of power are inevitable, their understandings of how individuals or groups gain, maintain, and distribute influence differ widely. Further, despite the common usage of the term elite, theorists fail to agree on an appropriate definition.

Some descriptions of elites focus on the role and effectiveness of a society's leaders. Suzanne Keller, for example, defines elites as 'a minority of individuals designated to serve a collectivity in a socially valued way' (1963, p. 4). Alternatively, Eva Etzioni-Halevy (1993), following in the tradition of Lasswell (1936), Lasswell and Kaplan (1950), and Sartori (1976), grounds her definition of elites in terms of distribution of resources, explaining that 'resources are mostly (though not exclusively) accumulated in organizations, and elites are thus mostly (though not exclusively) people who control such resources through incumbency of certain top positions in organizations' (p. 221). Taking still another tack Dogan and Higley define political elites as 'the holders of strategic positions in powerful organizations including dissident ones, who are able to affect national political outcomes regularly' (1998, p. 15, Dogan 1989). In their view it is elite adjustment and compromise which creates stable political orders, even under conditions in which the population as a whole is characterized by

sharp ethnic and cultural divisions, a perspective which is shared by Luther and Deschouwer (1999).

Etzioni-Halevy's definition, which we follow in this article, allows analysts to include among elites, movements which are attempting to change the structure of leadership in the social and/or political order. Thus African Americans holding important positions in, say, the National Association for the Advancement of Colored People (NAACP) will be included among political elites.

1. The Study of Elites

Vilfredo Pareto (1848–1923), Gaetano Mosca (1858–1941), and to a lesser extent, Roberto Michels (1876–1936) developed the underpinnings of modern elite theory. In part they were reacting to a Marxist analysis which insisted that, in bourgeois society, basic divisions occurred between two social classes, the bourgeoisie and the industrial workers (Pareto 1935, Mosca 1939, Michels 1915). Politics and political power were perceived as effects of these arrangements. Formal or nominal political leaders of all societies were agents of the dominant class and were not free to act on their own in any but matters of relatively little consequence. By the late twentieth century, Marxists had changed their orientation somewhat, allowing the state and political leadership some freedom to act upon a few important matters, but Marxist theory, even in its present tattered form continues, basically, to urge the dominance of economic class and the mode of production as the prime moving forces (Sitton 1996).

Both Mosca and Pareto insisted that political elites play an independent role in determining the nature of regimes. They argued that all societies are hierarchical, dominated at any given time by one or more elites which, eventually, will be replaced by others. Dominant elites are political elites and will remain in power as long as they retain their unity and character.

Elite theory has changed a great deal since its initial formulation but many of the same arguments continue. Thus populists and quasi-Marxist analysts such as C. Wright Mills (1959) and William Domhoff (1990) (see also Zweigenhaft and Domhoff 1998) continue to insist that America and other capitalist societies are ruled by powerful socioeconomic groups (capitalists and the military for Mills; WASP capitalists and their dependents for Domhoff). More recently feminists and race theorists have maintained that gender or race in conjunction with class are the dominant forces in society, and consequently political elites' thoughts and behavior emerges from their economic, or racial, or gender status (McClain and Garcia 1993, Carrol and Zerilli 1993).

Alternatively, scholars like Robert Dahl (1982), Nelson Polsby (1980), Theda Skocpol (1979), Evans et al. (1985), Gabriel Almond (1978), Etzioni-Halevy (1993), Dogan (1989), and Keller (1963) argue that the

political order and political elites play a significant, independent role and are not merely the captives of class, gender, or racial patterns. Indeed as noted earlier, Dogan and Higley (1998) and others go so far as to argue that it is the character of political elite conflicts and settlements which determine the nature and stability of the social order.

A number of social scientists, including Robert Putnam (1976), Samuel Eldersveld (1989, Eldersveld et al. 1995), Eric Carlton (1996), and Ronald Ingelhart (1997), have conducted empirical studies of elites around the world and through time. Their work permits some generalizations based on the evidence but does not resolve key issues concerning the structure of power. There is still little agreement as to the role of political elites as compared with other elite groups, or to what extent gender and race need to be brought into the analysis of elite organization and power.

2. What Kinds of Elites?

While Marx and Engels' notion of an anarchic, communal, totally egalitarian society at the dawn of history, in which women played key social and political roles, seems to have little basis in fact, the earliest groupings of human beings were members of relatively egalitarian, though male dominated, segmented societies. With little societal power available, power differentiation was, almost by definition, limited (Service 1975). Historically, the next human developmental stage involved the creation of pyramidal systems of social organization. This pattern characterized the most advanced societies down to the fourth or third millennium BCE and generally involved a number of groups or villages loosely organized under the authority of a paramount chief. Such chiefs often emerged as charismatic leaders who were successful in the hunt and/or war and whose power waned as they aged.

A new step in societal evolution, generally associated with the further development of agriculture and its consequent population growth, was the emergence of patrimonial societies, dominated by one individual (king or chief) whose authority was generally based on tradition supported by religious myths (Weber 1978). Such societies often attempted to institutionalize succession by hereditary right as a means, theoretically, of overcoming succession crises, and ensuring that the present chief or king could pass authority on to his male heirs. Historically, however, the hereditary mechanism for choosing rulers has not been very effective in maintaining social peace (Burling 1974).

Patrimonial kingdoms also took the first steps in the differentiation of political institutions with at least some authority devolving to subordinate officers whose positions were based on lineage and/or personal or contractual fealty. The expansion of power

available to the new social organizations led to greater asymmetries in the society. It is in patrimonial kingdoms and, even more so, in the great bureaucratic empires of the ancient world, i.e., China, Egypt, Rome, etc., that one can begin to analyse issues in terms of mutually supportive or competing elites (the army, the bureaucracy, religious elites) who shared at least some power with the ruler (Eisenstadt 1963). These societies, too, selected leaders on hereditary principles for the most part, though rulers were not infrequently deposed by the military or bureaucrats. Indeed military control of the succession came to characterize the Roman Empire by the third century CE. Military or bureaucratic leaders seized power to improve their own status and that of their clan or family. It was partly for this reason that Chinese and Byzantine emperors often assigned eunuchs to key bureaucratic and military roles in the empire (Balch 1985). Since they lacked direct descendents, eunuchs were considered more reliable instruments of the ruler.

3. Political Elites in the Modern World

In the modern world societies become more differentiated and patrimonial orders based on traditional authority gradually give way to authority derived from the beliefs in the legitimacy of 'rational laws' in the Weberian sense, agreed to by the people. Not only does the emergence of democratic structures (polyarchies to use Dahl and Lindblom's (1953) felicitous expression) increase the number of power centers and the complexity of power relations, but the issue of how power should be distributed becomes more central to political discourse. At the same time patterns of recruitment to and career development in elite institutions change dramatically.

Some groups which traditionally held political power lost it. For example at one point religious leaders had to be counted among political elites. Today religious leaders may still play a significant role on the political scene though, in the Christian world, their impact on political outcomes is far more limited than it once was. Indeed the process of secularization has proceeded in Europe, and, even the more religious United States boasts a fairly strict separation of religious and political institutions. In some Muslim countries religious leaders play a much more significant role. However, they are not, with the exception of Shi'ite Iran, members of the political elite *per se*, with the power to formulate and enforce policies (Tschirgi 1994, Zartman 1980).

There are today, also, a few patrimonial regimes dominated by particular lineages: Saudi Arabia, Jordan, and the Gulf Emirates come to mind as well as a few small African kingdoms. As traditional authority has come to be replaced by the notion that governments should be based on the rule of the people (which emerged in Europe as part of the liberal tradition),

most regimes, even when not democratic, pretend to be so, basing their authority on mass parties, often dominated by charismatic leaders such as Hitler or Mao Zedong and his successors. Charisma plays an even more important role for leaders who have not institutionalized their power. One clear example is Fidel Castro, who rules directly like a traditional Latin American *caudillo* (chief), eschewing a mass party (Aguila 1990).

Military leaders, who emerge from time to time claiming to speak for the people, and/or 'to restore order' continue to play an active role in such countries as Myanmar (formerly Burma), Pakistan, Turkey, Indonesia, and a number of African and, from time to time, Latin American countries. In Turkey the military considers itself to be the inheritor of the policies of Mustafa Kemal Atatürk and has intervened in politics on a regular basis to preserve a secular state, usually withdrawing once the crisis was over. It is currently highly suspicious of a Muslim revival with important political overtones (Gole 1997). The military has played a similar role in other Muslim countries, such as Algeria, where it has been the prime competitor of fundamentalist groups. Of course the military plays an influential role in such countries as China and North Korea though not officially part of the governing structure of either regime. Military influence and indirect connection to policy making is more likely today than direct military rule over a political system which, when it occurs, typically does not last too long. In long-established and strong parliamentary regimes (as in Europe and the United States), the military role in political decision making is very limited.

4. Elites in (Mostly) Modern Democratic Systems

In relatively polyarchic systems with successfully functioning parliamentary or presidential regimes, legislatures elected by the populace play key roles in making binding decisions about the distribution of resources. In such societies election to office is mediated by political parties and the character of the electoral system is important. In both parliamentary and presidential regimes the key elite players tend to be lawyers and other professionals such as teachers and retired bureaucrats and politics becomes a full-time profession, replacing the old English notion of the amateur politician (King 1981). In presidential regimes the chief executive (whatever the formal title) exercises considerable power independent of the party to which he/she is attached and has, in the past, based more of his authority on charisma. Indeed, in the United States, the president, while not independent of his party, draws much of his authority from his unique relation with the mass media. Arguably the political roles of American political parties have substantially diminished in the face of the media revolution.

In parliamentary regimes, however, chief executives (prime ministers, premiers) are selected from within the party and generally are leaders of a group of almost equals and exercise less personal power than presidents. Of course this depends partly on the particular nature of the party system. Within the framework of a relatively disciplined two-party system, party members are more likely to adhere to the party line than in regimes characterized by multiple, usually weaker, parties and coalition governments. Exceptionally, during their heyday, the Communist parties of France and Italy were, despite multiparty systems with relatively weak political parties in each country, quite able to retain control over party members. Even in parliamentary systems with relatively disciplined parties, the role of the media has heightened the charisma and power of the party leader (especially when in office) above that of his closest associates. This results in greater identification of the Party with the leader (Dogan 1989, Kamarck 1995, Linz and Valenzia 1994, Mainwaring and Valenzuel 1998, Patterson and Mughan 1999, Trend 1997, Yesilada 1999, Riggs 1988).

Political parties are present even in authoritarian regimes such as the People's Republic of China. They were the preferred mode of political organization in most other Communist countries and in many African states. Generally, such parties have been instruments of mobilization and control allowing relatively little freedom. They have also been the central loci of power in the society. There have been some partial exceptions. In Mexico the PRI (The Party of the Institutionalized Revolution) effectively dominated politics but opposition was permitted and the party did not attempt to control the whole society. The Mexican system has further opened up in recent years and the one-party system is probably in a state of terminal decay. Also, the Soviet Union and its former satellites have, at least temporarily, transformed themselves into more open societies often with a substantial circulation of elites. Under the Soviet regime, and still in China, advancement in political power required working one's way up through the party with the aid of powerful patrons whose fall from favor could seriously affect one's career (MacFarquhar 1993, Li and Bachman 1989, Lane 1995).

In well-established parliamentary regimes the success of those seeking elite status depends on party position, seniority, and effectiveness in parliamentary work including the give and take of debate. Party loyalty generally remains the requisite condition of advancement in parliamentary regimes with disciplined party systems. Loyalty is less important in the American presidential regime. There power in the legislature is partly a function of seniority, good committee assignments, service to constituents, and a good relationship with the media.

In most of Europe, party organizations are relatively weak and the number of active party militants small.

In less developed countries parties are even weaker and mostly quite short-lived. Parties often are the personal vehicles of individual charismatic leaders. After the leader passes from the scene, such parties usually fall apart to be replaced by still another 'personal' party. Political power in such countries is actually heavily dependent upon 'clientelist' relationships among various political families.

In modern democracies politics has increasingly become a career in which those aspiring to office start early and remain long, often beginning in local government (Eldersveld et al. 1995). With the passing of distinctly working-class socialist parties in Europe, political leaders are even more likely than they were in the first half of the twentieth century to come from middle-class backgrounds and to boast college or university degrees (Dogan 1989, Putnam 1976).

Money plays a relatively important role in elections in capitalist societies even when stringent limitations are placed upon the amounts parties are permitted to raise. However, individual wealth has not provided a passport to office, even in the United States where considerable freedom in the use of personal and contributed funds is permitted. Middle- or lower-middle-class aspirants to office can usually obtain financial support from backers who, for one reason or another are willing to bankroll them.

Among the unique elements of modern, relatively large complex societies is their heavy dependence upon highly differentiated bureaucracies. Despite important elements of bureaucratic structure in traditional empires, bureaucracies of the modern type never developed in these countries. High level bureaucratic officials, as Weber pointed out early in the twentieth century, are among key political elites (Weber 1978). They have played especially important roles in societies such as the Soviet and Chinese Communist regimes whose theoretical goal was to eliminate them. Indeed as late as the 1960s Mao Zedong's cultural revolution was designed to abolish or at least sharply reduce bureaucratic power. Mao had a point. Bureaucrats were blunting the cutting radical edge of the Chinese revolution for, as Weber argued, bureaucrats tend to routinize decision making. Mao did not succeed, for Weber was also correct in asserting, when many social theorists thought otherwise, that socialism could only increase the size and power of bureaucracy.

Weber, however, was wrong in implying the modern political order would eventually be dominated by bureaucratic elites. It is true that carrying out legislative mandates always involves administrative discretion. However, bureaucracies have never completely dominated a political system, with the possible exception of Japan in the decades after World War II (Van Wolferen 1989).

The influence of bureaucracy is heightened when the technical training of an elite corps of bureaucrats emphasizes their authority and power in the state. The

second empire in Germany (1870–1918) was characterized by the very significant role of the bureaucratic elite as was France under the Fourth Republic (1946–58). In the latter case the substantial power of the bureaucracy was partly a result of the inability of the party system to create a stable executive (Koh 1989, Peters 1978, Suleiman 1984, Farmer 1992, Thakur 1981).

For different reasons England and the United States have never created a bureaucratic elite of the continental European type. In the US, especially, the courts have added a layer of control above that created by Congressional oversight and presidential authority, and have insisted, in many cases, upon public consultation in bureaucratic decision making. Indeed, the role of courts has become so significant in many countries (though not as significant as in the United States) that some scholars now speak of the 'judicialization of politics.' Such judicialization has strongly affected bureaucratic decision making (Vallinder 1994).

In many modern political regimes, e.g., France, Japan, England, etc. higher level bureaucrats are recruited directly from the university for bureaucratic careers and often retire early to enter business or run for political office. High office in the United States federal bureaucracy is more permeable through in-house promotion and lateral recruitment. This gives American bureaucratic recruitment a more democratic cast than that of most other advanced industrial nations.

5. *Issues for the Present and the Future*

Political elites in advanced industrial societies do exercise more power in the sense of producing desired outcomes than do those in less developed countries. Elites in the poorer countries of Latin America, Africa, and parts of Asia often behave as if they are creating new public policies and yet nothing changes. This occurs because the organizational capacity of the society is limited and thus there is simply not sufficient power to carry through new initiatives. Promising beginnings frequently end in failure, too often frustrating, and eventually corrupting, those elites who begin as sincere reformers. Individuals or political groups may dominate the political orders of poorer societies but frequently they can change very little because the population lacks the capacity to respond effectively to new initiatives. Similarly efforts by richer more powerful nations to assist in or compel change are usually unsuccessful.

In general the role of women in public affairs has been very limited. In western Europe and the United States increasing numbers of women are becoming part of the political elite, though their role remains relatively small except in the Scandinavian countries.

In most of the rest of the world their role is still smaller. Indeed the representation of women in official governmental organs dropped when the regimes in Communist states were overthrown. However, the offices they had held in various ineffective legislative bodies did not entail real authority so that the loss is more symbolic than real.

The distribution of power among racial and ethnic groups in increasingly multiethnic societies is very likely to be a major source of conflict in the twenty-first century. How such conflicts are to be handled is an issue which, except in a few cases, has not been dealt with effectively.

Political Geography

Political geography is a field of inquiry concerned with the nature and implications of the evolving spatial organization of governmental regimes and formal political practices around the world. It is a widely recognized sub-discipline of geography, and it is increasingly an interdisciplinary pursuit as well. Political geography investigates why politically organized areas emerge in the places they do, and how the character and configuration of those areas both reflect and affect the social and environmental contexts in which they are situated. Whereas a political scientist or political sociologist might focus on the politics and social structure of a political entity, a political geographer would likely emphasize how and why a particular piece of the earth's surface came to be

organized as a discrete political unit, and what that unit represents and means for the peoples, institutions, and places affected by it.

1. *Development of Modern Political Geography, 1890s–1970*

The origins of political geography are often traced to Aristotle's effort to describe the ideal state in terms of its territory, population, and internal geographical structure (Kasperson and Minghi 1969). Its modern roots, however, lie in the writings of the German geographer, Friedrich Ratzel (1844–1904). Ratzel sought to analyze states in terms of their environmental characteristics, arguing that an understanding of the political world needed to be rooted in the human and physical character of the concrete territorial spaces occupied by states. He is most known, however, for his Darwin-inspired organic theory of the state, which treated states as competitive territorial entities vying with one another for control over parts of the earth's surface. He set forth his theory in a seminal book, *Politische Geographie* (1897), which marked the formal beginnings of the modern sub-discipline.

Ratzel's organic state theory attracted attention in both Europe and the United States (Glassner 1996). The Swedish political scientist, Rudolf Kjellén (1865–1922), used Ratzel's ideas about the territorial dynamics of state growth to develop an elaborated vision of the state as an organism, in the process giving birth to the term 'geopolitics' (see *Geopolitics*). Contemporaneously, the American naval historian Alfred Thayer Mahan (1840–1914) published an influential set of works arguing that control over sea lanes and adjacent land areas was critical for the maintenance and expansion of political power. This was soon followed by an alternative, more widely circulated geopolitical vision from the geographer-director of the London School of Economics, Sir Halford Mackinder (1861–1947). He emphasized the importance of the interior of the Eurasian landmass (the heartland) for the maintenance and spread of political power.

Given the relevance of these geopolitical contributions, and the interest they attracted, it is not surprising that the political geography of the early twentieth century was strongly identified with geo-strategic thinking (Claval 1994). Ratzel and Kjellén's work became the foundation for a school of geopolitics (*Geopolitik*) in Germany led by Karl Haushofer (1869–1946), which eventually was appropriated by the Nazi war machine. In other parts of Europe and the United States, debates over the relative merits of Mahan and Mackinder's conceptualizations attracted considerable attention in both academic and policy circles, and led to yet other geopolitical visions, most notably those of the Dutch-born, American-educated international relations scholar, Nicholas John Spykman (1893–1943), who focused attention

on the importance of the so-called rimland (coastal fringe) of Eurasia.

Despite the importance of geopolitical theorization in the early history of the sub-discipline, the first half of the twentieth century also saw expanding work on the geographical characteristics of individual states (Hartshorne 1954). The specific configuration of the world political map was undergoing substantial changes that required investigation and analysis. Geographers were being called upon to provide background on boundary disputes, the internal divisions within empires, and the impacts of new transportation technologies on political areas. World War I was a particular catalyst to such work. Indeed, the director of the American Geographical Society, Isaiah Bowman (1878–1950), was a member of the American delegation to the Paris Peace Conference where a new European political map was forged, one that reflected a combination of prevailing geopolitical visions influenced by Mackinder and understandings of the particular geographical characteristics of state territories.

During the interwar period, the study of political geography expanded modestly in colleges and universities, although relatively few geographers defined themselves primarily as political geographers. Those who did emphasized the historical territorial development and contemporary geographical characteristics of individual states. Bowman produced the first systematic political geography text of the post-World War I political order. It concentrated on the territorial problems of the new countries of the world, particularly those in Europe. Richard Hartshorne (1899–1992) saw this work as an extension of Ratzel's concern with the environmental character of state areas; his own influential work focused on the integrative and disintegrative potentials of differing state territorial characteristics and founding territorial ideologies (summarized in Hartshorne 1954).

World War II spawned increased interest in political geography offerings in some colleges and universities in the United States and parts of Europe, yet it did not lead to any fundamental reorientation of the sub-discipline. The one exception concerned the geopolitics wing of political geography, which fell into wide disfavor in some places because of its association with Nazi efforts to justify claims to territory. For decades the Soviets opposed any use of the term political geography, and in Germany itself the sub-discipline ceased to be taught altogether. In the English-speaking world, the most influential writings of the succeeding two decades dealt with geographical influences on the functional character of individual states through the study of their morphology, internal organization, social and physical homogeneity, relative location, and boundaries (e.g., Hartshorne 1954, Prescott 1965, East and Moodie 1968). Some innovative work came out of these studies, highlighting critical connections between geography and political decision making (e.g.,

Cohen 1963). For the most part, however, political geography became somewhat disconnected from conceptual and empirical developments in other parts of geography and beyond. Moreover, the positivist turn of the discipline of geography during the late 1950s and 1960s left little room for the consideration of political matters. By the end of the 1960s, these circumstances had placed political geography in a somewhat marginalized position.

2. *Political Geography in the Late Twentieth Century*

Political geography did not remain marginal for long. An important edited compilation from the late 1960s (Kasperson and Minghi 1969) provided a useful framework for teaching and research, and geographers trained in quantitative urban and economic geography began to turn their attention to the role that politics plays in the distribution of services, people, and wealth. The latter development spawned work focused at local and regional scales. Kevin Cox's (1973) seminal book on the politics of urban services gave rise to an influential set of studies in 'welfare geography' (see *Welfare State, Geography of* and *Locational Conflict (NIMBY)*) that drew on diverse theories ranging from Marxism to public choice theory. In the process, political geography came into contact with emerging 'political economy' perspectives.

A somewhat different influence on political geography came from a group of urban and economic geographers with a quantitative bent who saw the potential for the quantitative analysis of election data. Extensive work on the spatial organization of elections, voting patterns, and the geography of representation made electoral geography a widely recognized sub-specialty within political geography beginning in the 1970s (Taylor and Johnston 1979). The methods and theories of electoral geography were not closely aligned with other work in the sub-discipline (Taylor 1985), but the developing field of electoral geography widened the scope of political geography and attracted interest among a new generation of geographers. At the same time, the different scales and issues on which votes are taken encouraged a broadening of political geography's prior preoccupation with the scale of the state.

By the early 1980s, political geography was clearly emerging from its formerly marginalized status. Having shed its positivist orientation, politics was back on the agenda of geography as a whole, and political geography could therefore no longer be dismissed as peripheral to the discipline. Moreover, new work on urban, regional, and electoral themes was attracting increased attention to political geography and connecting it to issues and concerns being taken up by other social sciences. Even more tra-

ditional themes were taking on new life, with expanding interest in shifting cold-war geopolitical relations and the emergence of new regimes of control in the world's oceans (see Glassner 1996). The founding of a new journal, *Political Geography* (originally entitled *Political Geography Quarterly*), in 1982; the establishment of major research and study groups in the International Geographical Union and various national geographic organizations; and the founding of a boundary research institute at the University of Durham signaled the growing importance of the sub-discipline.

At the heart of political geography's revivification was the effort to develop a more sophisticated theoretical foundation for the sub-discipline (Reynolds and Knight 1989). Impetus for the theoretical turn came from the combination of insights being offered by the new, theoretically informed literature on urban social conflict and a growing frustration with the lack of connection between research initiatives outside political geography and more traditional work in the sub-discipline. Explicit engagement with theory took two overlapping, but sometimes conflicting forms: a concern with developing a theory of the state and a concern with theorizing the nature of the state system.

The work of Gordon Clark and Michael Dear (1984) is particularly associated with the effort to theorize the state in political geography. They promoted consideration of a variety of theories of the state and themselves advanced an approach that drew on Marxist ideas on the role of the state in the maintenance and expansion of capitalism, but which argued that the state is also the product of the institutionalized political-economic patterns and arrangements that are produced through specific state structures and functional hierarchies. Their work helped to foster wide-ranging inquiries into the spatial dimensions of state policy initiatives, as well as studies of the 'local state' and its relationship to the national state. The latter was also heavily influenced by the writings of David Harvey (e.g., Harvey 1985), who focused attention on how the capitalist accumulation process was linked to the political production of spatial inequalities within cities and sub-state regions.

Although those writing on the nature of the local and national state looked to the role of large-scale structural forces, their work focused on communities existing within states (see Reynolds and Knight 1989). Some political geographers saw this as seriously limiting, arguing that intrastate processes could only be understood with reference to the dynamics and norms of the international system of states. They also argued that political geography would have little to say about international relations if it did not confront the nature and meaning of the state system. The writings of Peter Taylor—particularly his important text, *Political Geography: World-economy, Nation-state and Locality* (Taylor 1985 and later editions)—were influential in advancing this argument.

Drawing on the world-systems work of Immanuel Wallerstein, Taylor sought to situate analyses of the changing political geography of the modern world in the context of the territorial dynamics of the emerging capitalist world economy. He argued that the forms and functions of national and sub-national units are derived from the positions territorial states occupy in the global political-economic order. Taylor's particular use of world-systems approaches was not widely emulated, but his writings helped to put the very nature of the system of states at the center of the political geographic enterprise.

The new theoretical perspectives coming into political geography during the 1980s influenced both the types of issues being studied and how they were studied. The relationship between political geography and uneven development became a particularly significant focus of attention (see Smith 1984). Political geographers also turned their attention to processes of nation-building and substate nationalism, seeing these as predicated in significant ways on the nature of the state and the system of states (e.g., Johnston et al. 1988). Even some studies in electoral geography began to look at the relationship between spatial structures of power and electoral outcomes (Johnston et al. 1990).

The closing decade and a half of the twentieth century saw the emergence of new theoretical influences and a broadening of the scope of political geography (Agnew 1997). The growing influence first of structurationist, and then of post-structuralist, theories in the social sciences had clear impacts on political geography. The concern with the relationship between structure and agency that was part of the structurationist critique prompted political geographers to focus more attention on the ways in which political contexts are created through the interplay of large-scale forces and local practices. In his influential volume *Place and Politics*, John Agnew (1987) argued that political studies are generally based on the assumption that, in the modern world, local and regional identities are being replaced by national communities segmented by socio-economic differences, not by geographic sectionalism. Yet Agnew showed that this 'nationalization thesis' failed to account for the enduring impacts of local context on social and political behavior. In the process, he made a compelling case for taking the concept of place seriously in political geography (see also Johnston 1991).

The structurationist literature also brought with it growing interest in the spatial structures and arrangements that circumscribe social and political life. This offered a potential bridge between new currents of thought and longstanding efforts to analyze the development and meaning of the world political map (Gottmann 1973). An important element in building that bridge was Robert Sack's work on *Human Territoriality* (Sack 1986). Sack argued that a critical

component of human social behavior was the effort to influence people and ideas through the control of specific geographical areas, and that a concern with 'human territoriality' could therefore provide important insights into social and political processes. Sack's work directly challenged the dominant tendency to treat political territories as *a priori* spatial givens, in the process opening an important theoretical window for political geographic work focused on the nature and meaning of specific political-territorial developments.

Work on the politics of place and on territoriality has developed in conjunction with themes from the post-structuralist literature to open new vistas for political geography. The very centrality of politics and political relations to post-structuralist thought has greatly abetted this process (Painter 1995). Indeed, at some level much of human geography as currently practiced is about politics, making it difficult to establish exactly what constitutes political geography *per se*. Yet, as Agnew (1997, p. 3) has argued, 'there is nevertheless still the need for an area of study of the more formalized and institutionalized arenas of power such as the spatiality of states, interstate geopolitics, the geographies of political and social movements, and territorial conflicts involving national and ethnic groups.' These are the matters that continue to be most closely associated with the sub-discipline of political geography, and they are not particularly confining. Indeed, the recent political geography literature addresses themes that range from the role of political geographic arrangements in the constitution of gendered identities to the implications of new telecommunications technologies for the territorial integrity of states.

3. Contemporary Approaches and Themes

The contemporary practice of political geography echoes the diverse elements that have contributed to its development. Textbooks and research literature reveal approaches that are traceable to (a) political geography's tradition of describing the spatial configuration, geographic character, and boundaries of politically organized areas; (b) the quantitative turn of political geography in the 1960s; (c) the influence of political-economy perspectives on the sub-discipline in the 1970s and 1980s; and (d) the recent interest in post-structuralist theories of society (see Agnew 1997 for a variation on this typology). Some studies can still be neatly classified in one or another of these analytical traditions, but there is also considerable blurring among them. Nevertheless, tensions persist among proponents of these different perspectives, the most acute of which is between those who posit a world of 'real' political spaces/arrangements that we can try to comprehend through some combination of empirical and critical analysis, and those post-structuralists who

view reality as unknowable outside of the individuals and societies that construct it. The opposition between these positions has created a dualism in the political geography literature that is only beginning to be addressed (Agnew and Corbridge 1995).

The substantive topics on which political geographers are working are a product of the more general effort to make sense of the rapidly changing political, social, and economic environment of the late twentieth century. The following subsections highlight the topics that are receiving the most attention. There is considerable overlap among and between these topics, but each has a core literature attached to it.

3.1 *Political Geographic Assumptions of Social and Political Theory*

There is a pervasive tendency in the social sciences to frame analyses of social and political developments in terms of the political territories in which they are situated. Yet the territories themselves are usually treated as little more than locational referents for whatever is being studied. A body of work in political geography seeks to expose the theoretical shortcomings of this state of affairs. Much of that work focuses particularly on the importance of understanding what is hidden and what is revealed when the modern territorial state is treated as an unproblematic spatial container for social and political processes. John Agnew in particular has argued that this creates a 'territorial trap' in which critical historical and geographical processes are ignored because the nature and meaning of territory are not problematized (see Chap. 4 of Agnew and Corbridge 1995). A number of political geographic studies support this line of reasoning by showing how the political organization of space is itself implicated in social and political processes, even shaping the very concepts of identity on which political communities are based. Work in this arena is thus tied to the larger effort to bring concepts of space into social theory.

3.2 *Geopolitics and Interstate Conflict*

Geopolitics is clearly back on the political geography agenda, as evidenced by the publication of a spate of recent books and the founding of a new journal, *Geopolitics*. The recent literature on the subject reveals some continuing interest in the development of formal geopolitical models, but recent work has concentrated on the changing geopolitical environment for interstate relations and on the world views and political/military priorities of key political actors. Particular attention has been paid to the emergence of the modern world economy and its impacts for the

conceptualization and pursuit of geopolitics (e.g., Agnew 1998). Political geographers have also examined the locational components of conflict itself, studying where conflicts have occurred and why some areas have experienced more conflict than others (e.g., O'Loughlin and van der Wusten 1993). The interest in discourse as a window into geopolitical motives is the focus of a new literature on 'critical geopolitics' (see Ó Tuathail 1996). Influenced particularly by deconstructionist ideas, this increasingly influential literature looks at the discourse of geopolitical practice to gain insight into the ways in which spatial understandings have been developed, deployed, and manipulated in the pursuit of particular political and military objectives.

3.3 *The Changing Role of the Territorial State in the Modern World*

There is a lively debate in political geography and beyond about the degree to which the traditional role of the state is being undermined by the increased mobility of capital and labor, the growing power of multinational corporations, the advent of transportation and communications technologies that decrease or eliminate the friction of distance, and the rise of extra-state trading blocs and political organizations (see generally Painter 1995). Within political geography this debate finds concrete expression in studies focused on the ways in which these developments have altered the internal spatial organization and territorial character of states. Political geographers are raising questions about the changing nature and function of boundaries; the distribution of powers among and between substate, state, and superstate political-territorial entities; and the means by which governments at different scales are seeking to integrate and defend their territories. Research on such matters has been spurred by concrete changes in the world political map: the rise of the European Union; the break-up of the Soviet Union, Yugoslavia, and Czechoslovakia; and the devolution of substantial powers to substate regional authorities in countries such as the United Kingdom and Spain.

3.4 *Ethno-national Challenges to the Prevailing Territorial Order*

Closely related to the prior theme is research focussed on the often discordant relationship between the map of territorial states and the territorial claims of different ethno-national groups. Political geographers have long argued that the concept of the nation-state is more an aspiration than a reality. The rise of so many visible instances of ethno-national conflict over the

past few decades has moved this issue to the center of the political geography agenda. Political geographic research has focused on the competing territorial ideologies and strategies of majority and minority groups, the ways in which the political organization of territory affects intergroup interaction and intragroup identity, and the particular notions of citizenship and nationalism that have been forged in differing historical-geographical contexts (see, e.g., Johnston et al. 1988). The infusion of post-structuralist ideas into political geography has also promoted interest in the use of cultural symbols in the pursuit of territorial strategies, as well as the ways in which meanings develop around particular territories and nationalized landscapes. Work on the political geography of ethno-nationalism has highlighted the overlapping senses of territory that exist among many ethno-national groups and the need for policy approaches that recognize this state of affairs.

3.5 The Political Geography of the Environment

One of the clearest obstacles to the effort to confront environmental problems is the fragmentation of the planet into political spaces, few of which are meaningful ecological units. The problem is not just that ecological and political boundaries do not coincide; the very roles that territorial states play in the international state system and the world economy frequently work against collective action in the interests of the environment (Johnston 1996). Building on a tradition of examining the relationship between spaces of governance and environmental geographies, political geographers are increasingly turning their attention to environmental questions. Recent work has focused on new transnational regulation regimes and the special issues presented by environments that do not lie within the territories of individual states: the world's oceans and Antarctica. At smaller scales, political geographers have examined the circumstances giving rise to the emergence of an environmental politics in particular places, the problems and prospects of collective resource management in different political contexts, and the use of environmental strategies in the pursuit of political-territorial objectives. Some of this work is closely aligned with the emerging field of political ecology, with its focus on the role of large-scale political-economic structures in the production of local environmental outcomes.

3.6 The Quest for Political Power and Influence

Studies in electoral geography have long focused on the spatial dynamics of a particular type of quest for political power: that which takes place in formal elections. The geography of elections continues to attract significant attention among political geographers, but a variety of other political movements

are commanding attention as well. This is a product of the increased visibility of such movements and the success of some of them in challenging long-standing political arrangements. Work in political geography has focussed on the political-territorial contexts that give rise to political movements, the spatial character of movement support, and the impacts of movement objectives on the political organization of space. A significant body of recent literature has considered how the economic, social, and political character of individual places is implicated in the rise and success of different types of political movements (Staeheli 1994). The focus on places, however, is not at the expense of larger-scale influences. Instead, many political geographers treat individual places as the product of the interaction between large-scale political and economic structures and local cultural, social, and material circumstances (Johnston 1991).

3.7 Political Place and the Construction of Social Identity

Closely related to the prior theme is a strand of work in political geography concerned with the ways in which social identities are shaped by the political-territorial construction of place. The plethora of new social movements that have come together around social categories such as race, gender, sexual identity, and ethnicity have attracted growing attention throughout human geography, and the recognition that such identities are rooted in territorial practices and arrangements has provided an important bridge between work in political geography and the literature of economic, social, and cultural geography (see Wolch and Dear 1989). The concept of place—as politically and socially constructed—is once again at the center of this area of research because identification with place is so often at the heart of social identity (Johnston 1991, Agnew 1997). Yet place is not necessarily presented as a benign incubator of social identity; a considerable body of literature has focused on the ways in which dominant interests create spaces/places of marginalization that reflect and reinforce existing power relations and social prejudices.

3.8 The Emergence of New Political Spaces

The sweeping economic, political, and technological changes of the late twentieth century are associated with the development of new political spaces that coexist, and sometimes compete, with territorial states. Many of these new spaces are derivative of the map of states in that they are either collections of states (e.g., the European Union) or sub-state regions that have recently achieved greater autonomy (e.g., Catalonia). Yet activities within and among these new state-derived political spaces are creating political spaces of

a completely new sort. These include new political spaces of cooperation along international boundaries and geographically distant political communities that are forging links outside the framework of states. Behind many of these developments is the explosion in communications and information technologies, which is fostering an increasingly deterritorialized politics that nonetheless has concrete territorial implications. The emergence of far-flung political communities united by ideology and technology poses new theoretical and empirical challenges for an area of inquiry concerned with the spatial dimensions of politics.

4. The Way Forward

Political geography has emerged as one of the most vibrant, active areas of inquiry within the discipline of geography, and it is likely to remain so. The political-territorial upheavals of recent years show no signs of abating. Moreover, it is likely that growing challenges to the role of the state will bring into question the tendency throughout the social sciences to treat the map of states as a static frame of reference, and will direct attention to the nature and meaning of the changing spatial organization of politics. The interdisciplinary character and impact of political geography are likely to grow with the recognition that political practices and outcomes cannot be divorced from the changing geographical spaces and contexts within which they are situated.

A. B. Murphy

Political History (History of Politics)

Political history is the study of how legitimate power has been defined, distributed, and justified in the past (see *Power: Political*). Two imperatives, both with ancient roots, link historiography and politics. The first is the need to affirm the identity of the political community by uncovering its roots in the past. This search for historical identity engaged both the Hebrews and Greeks at the very beginning of European culture; it moved the Romans to search for the sources of their state and prompted succeeding generations to study the history of their cultures, religions, and nations. 'No question,' wrote Jean Bodin in the sixteenth century, 'has exercised the writers of histories more than the origin of peoples' (Kelley 1998). The second link between history and politics is the desire to

find lessons in the past that might help solve the political problems of the present. 'I shall be content,' Thucydides remarked in the first chapter of *The Peloponnesian War*, 'if (this history) be judged useful by those inquirers who desire an exact knowledge of the past as an aid to the understanding of the future' (Thucydides 1996).

1. From the Ancient World to the End of the Middle Ages

Political history in the West begins with two masterpieces: Herodotus's history of the Persian wars, written between 445 and 425 BC and Thucydides's history of the long conflict between Athens and Sparta, which he began in 424 BC and left unfinished when he died a quarter of a century later. Products of the extraordinary burst of cultural energy that transformed fifth and fourth century BC Greece, Herodotus and Thucydides combined a deep sense of the importance of their own age—Herodotus wrote about the recent past, Thucydides about events in which he himself had taken part—with an awareness of the historian's responsibility to establish the truth about the past. Both men reflected on the problems of historical research, the reliability of eye witnesses, and the necessity of critically analyzing source material. More than any particular way of writing history, this was their most significant legacy for future historians (see *Historiography and Historical Thought: Classical Period (Especially Greece and Rome)*).

The study of history was more important in Rome than it had been in Greece, perhaps because Romans were always conscious of their complex historical relationship to the Greek culture that they had both vanquished and absorbed. Roman historians examined the problem of politics from a variety of perspectives; they wrote about leadership and institutions, military strategy and court intrigue, republican virtues, and imperial ambitions. But behind these disparate approaches was a common theme: the origins, triumph, and—eventually—the decline of the Roman state, which, as republic and empire, dominated the public life of the Mediterranean world for 700 years and then continued to haunt Europeans' historical imagination until well into the nineteenth century.

The emergence of Christianity and its adoption as the Roman Empire's official religion transformed all of western culture, including both politics and history. Christianity's most immediate contribution to political historiography was to pose the problem of church and state, which would decisively shape the theory and practice of European politics from the end of the Roman empire to the beginning of the twentieth century. Unlike the pagans whom they displaced or the Hebrew traditions upon which they built, Christians created religious institutions that were connected

to, but not coincident with, the sources of political authority. 'Spiritual and secular power,' Ranke (1962) wrote, 'could approach one another and be intimately related, but they could be fused only under exceptional circumstances and for a brief period of time. Their relationships and conflicts provide one of history's most important themes.' From Eusebius's history of the church, which reflected the triumph of Constantine's conversion at the beginning of the fourth century, to Otto of Freising's twelfth-century chronicle, *The Two Cities*, which described the conflict between empire and papacy, to Ranke's own history of the popes, which bore the marks of nineteenth-century's struggles between church and state, historians searched the past for clues to the proper relationship between God and Caesar, pope and emperor, altar and throne, religious autonomy and secular authority (see *Historiography and Historical Thought: Christian Tradition*).

2. History and the State

Beginning in the 1490s with the French invasion of the Italian peninsula, a series of international, constitutional, and religious crises disrupted European politics and helped to create a new subject for political history. This subject was, in Quentin Skinner's (1978) concise summary, 'the concept of the state—its nature, its powers, its right to common obedience'. The concept of the state emerged from the dissolution of two closely-connected assumptions that had shaped European political thought since Augustine: first, that the secular realm of politics had to be seen as part of a sacred order; and second, that Europe's components—its free cities, ecclesiastical states, and various monarchies—were part of a single polity, governed by the universal laws of the church and sustained by the institutional legacies of imperial Rome. A good deal of medieval political theory and practice had been devoted to reconciling these assumptions with the stubborn realities of political life; in the first decades of the sixteenth century, Europeans began groping their way towards new ways of thinking about politics—and, therefore, towards a new kind of political history.

One of the first signs of this can be found in the work of Niccoló Machiavelli. As a Florentine who had been forced into exile by the collapse of his city's constitutional order, Machiavelli (see *Machiavelli, Niccolò (1469–1527)*) felt the political crisis of the early sixteenth century at first hand. In *The Prince* and *The History of Florence*, Machiavelli sketched a political world that Thucydides would have recognized immediately, a world driven by struggles for power, beset by violence, subject to forces that are often beyond human capacities to control. A similar picture emerges in the work of Machiavelli's fellow citizen and contemporary, Francesco Guicciardini, whose histories

provide an even darker picture of instability and violence. But however limited people's ability to control events, history, for both Machiavelli and Guicciardini, was a totally human enterprise, untouched by the hand of God, unfettered by a transcendent order.

Machiavelli wrote about 'the state,' but without giving it a clear institutional definition. This would be the great achievement of sixteenth- and seventeenth-century legal humanists, whose study of the law provided a new foundation for both politics and history. Of course law had always been an important part of European culture, but scholars like Guillaume Budé, Jean Bodin, François Baudouin, and François Hotman combined philological methods and historical analysis to create a new science of jurisprudence that enabled them to establish the origins, nature, and limits of the state's authority. Bodin, for example, provided the classic definition of sovereignty as the supreme source of law within a commonwealth, exercised by, but clearly independent from, the ruler's person. The work of these scholars stands at the source of one of political history's richest traditions: the study of legal institutions and constitutional development, which includes among its practitioners such giants as Montesquieu, Savigny, and Maine (Kelley 1970).

Law was also important to those who sought a vision of the international order to replace medieval universalism. Hugo Grotius, for example, who wrote during the Thirty Years War in the first half of the seventeenth century, argued that the international order was based on natural laws, which were divinely ordained but could be discovered by examining the past; like the French legal humanists, Grotius regarded the study of law and history as part of a single enterprise. By the end of the eighteenth century, under the influence of a new set of crises generated by the French revolution (see *French Revolution, The*) and Napoleonic conquests, a number of scholars searched for an international system that was no longer based on God-given laws but was still subject to underlying principles that the historian could discover. Heeren (1834), for instance, wrote that the 'essential property' of the European state system was its 'internal freedom, that is, the stability and mutual independence of its members. To set forth how this was formed, endangered, and preserved ... is the great object of the historian.'

The historical image of a world of independent states struggling for existence within an international system was given its definitive formulation in the middle decades of the nineteenth century by Leopold von Ranke, perhaps the greatest political historian of the modern era (see *Historiography and Historical Thought: Modern History (Since the Eighteenth Century)*). Von Ranke is best known for his archival work and his insistence on the critical use of primary sources. But inseparable from Ranke the great empiricist was Ranke the moral philosopher of statehood, who

regarded states as the 'ideas of God' that move through the historical order 'like celestial bodies.' His work, which combined scholarly rigor with stylistic grace, was read widely and admired throughout Europe; his methods of teaching and research were adopted everywhere (see Krieger 1977).

3. History and the Nation

Of all kinds of history, the history of the nation has the deepest roots and the most widely extended branches (see *Nation: Sociological Aspects*). Its first and most persistently influential expression was in the Hebrew Bible, which recounts the archtypical story of a nation's origins, defines its special historical mission, traces its survival in the face of terrible trials, and promises its eventual triumph. Their story, the Hebrews' historians insisted, is a story like no other—among the many ways in which national histories resemble one another, none is more striking than their insistence on being unique. As for so many other nations without states, this national history sustained the Jewish people's sense of collective identity through centuries of dispersal and oppression. And once the Jewish nation finally had its state, the story of the national past became—and this is also characteristic of the genre—the site of political debates about the nation's present identity and future direction (see *Historiography and Historical Thought: Jewish Tradition*).

Although national history has a genealogy that extends to the dawn of western culture, its most intellectually vigorous and politically potent versions were written in the nineteenth century when, for the first time, political history became virtually synonymous with the history of nations and nation states (see *State, History of*). The nineteenth century was, of course, the great age of historical writing, a time when historical consciousness touched virtually every aspect of European culture, from art and literature to philosophy and the social thought and even the natural sciences. For most nineteenth-century intellectuals, to think about the world was to think about historical origins, evolution, and identity. This was a time when statesmen—men like Guizot and Macaulay—wrote history and when historians—Bancroft, Droysen, Treitschke—were active in political affairs. And this was also the era when the institutional foundation for modern historical scholarship—document collections, libraries and archives, journals and reference works—was created, much of it by, and often for, national governments (see *Historicism*).

While every nation has a story to tell about itself, every national story is different, shaped by the political imperatives, cultural climate, and institutional arrangements of each national community. Nineteenth-century French historians, for instance, whose state had a unusually long and apparently uninterrupted

existence, were able to imagine a single national history. Their problem was how to find a place in this history for the trauma of revolutionary upheavals and prolonged warfare that engulfed France after 1789. For almost two centuries, French historiography was shaped by political struggles over the revolution's legacy, just as French politics was influenced by historical struggles about the revolution's character and significance. Among the works engaged by this project are such classics of political historiography as Tocqueville's *Ancient Regime and the French Revolution* and Michelet's *History of the French Revolution* (see Tocqueville, Alexis de (1805–59)). It was not until the 1970s that François Furet could declare that the French revolution was finally over, by which he meant that it had lost its central place in the nation's political discourse and public memory.

Each national experience poses a distinctive ensemble of questions for its historians to confront. In Britain, these are most often questions about institutional continuity rather than revolutionary ruptures. In the US, the central historical issue is the question of identity itself, which was addressed in works like Frederick Jackson Turner's classic study of the frontier in American history (see *Frontiers in History*). The problem of identity also dominated German historiography in the nineteenth century: before the creation of a German nation state, this meant a competition between different versions of the national past, after national unification, it involved demonstrating that the nation created by Bismarckian 'blood and iron' was the only authentic destination for the German people's long historical journey towards political unity. In the twentieth century German history was shaped by efforts to locate the catastrophe of National Socialism in the national past: was National Socialism, as some claimed, the destination of Germany's 'special path' (*Sonderweg*) to modernization, or was it a particularly toxic example of a broader crisis within modern culture and politics (see *National Socialism and Fascism*)?

An important element in the public life of every nineteenth century state, history was even more significant for those national communities that did not have a state of their own. For the Poles, the Irish, the Czechs, and, in the course of the twentieth century, for the peoples of the world colonized by Europeans, a shared history was the surest source of present cohesion and the brightest hope for future nationhood. After all, what else did these nations possess besides their belief in a common ancestry? Often enough, this belief had to be constructed from the scattered remnants of an imagined past—literary works discovered and transcribed by patriotic scholars, ancient sites unearthed by archaeologists, memories of lost greatness brought to life in poems and plays and popular histories. Often enough the character of the national past was bitterly contested—by Czechs and Germans in Bohemia, Protestants and Catholics in

Ireland, conservatives and liberals in partitioned Poland, Muslims and Christians in the Balkans. In these parts of the world, the historical significance of John Hus, whether the town was called Derry or Londonderry, the meaning of the Polish uprising of 1863, or how to commemorate the battle of Kosovo could swiftly become matters of life or death. Every national history reflects ideological divisions and political conflict, but in nations without states, the seam between politics and history was nearly invisible, so that it was usually impossible to determine where the one began and other ended.

4. Subversive Histories

Although historians have often been the servants of those in power, there is also a long, rich tradition of subversive historiography, written by scholars who turned to the past in order to question the established order and suggest new paths for the future. In the nineteenth century, at the same time that historians were drawn into the service of the nation state, subversive historiography was given its most influential formulation by Karl Marx. For him, the political movements that had interested Thucydides, Machiavelli, and Ranke are surface phenomena, reflections of the deeper social conflicts from which history takes its shape and direction. Politics is merely an instrument of the ruling class, a way of justifying and defending its hold on the means of production. Traditional political historians, therefore, view the past through a distorting lens that turns the world upside down, obscuring the essential sources of change with their concern for artificial conflicts, empty slogans, and trivial events. The Marxist historian's purpose is to substitute for these ideological distortions the radical clarity of scientific materialism, which will reveal to the proletariat the roots of its oppression and thus help prepare them for their revolutionary role in history cosmic drama. From the last decades of the nineteenth century until the end of the twentieth, Marxism—in all its many forms—remained the most influential form of subversive historiography (see Marx, Karl (1818–89); *Marxist Social Thought, History of*).

Well before the final collapse of international communism in 1989, Marxist historiography had begun to lose its intellectual attraction and political influence. In part this was because of the diminution of ideological energies both in the communist regimes of eastern Europe and in labor movements throughout the world. Moreover, by the 1970s, the political passions that had drawn intellectuals to Marxism during the struggle against fascism in the 1930s and against colonialism in the 1960s had cooled. The Marxist view of history was also undermined by a growing skepticism about all grand narratives, a turning away from the aspiration to grasp the meaning

of human history as a whole. And finally, Marxism declined because it could not explain very well the subjects to which more and more historians now turned, especially problems of ethnicity, race, and gender, which did not fit into the categories defined by the means of production. Not surprisingly, the form of Marxism that remained most influential in Britain, the US, and most of western Europe was associated with historians like E. P. Thompson, who tried—not always with success—to fuse class analysis with a concern for culture and politics (see *Social History*).

Since the decline of Marxism, the subversive impulse in historiography has been fed from many other sources of which the most important, at least in the last two decades of the twentieth century, was certainly the work of the French philosopher and historian, Michel Foucault (see *Boserup, Ester (1910–99)*). Like Marx, Foucault's enemies were oppression and inequality, his goals, freedom and community. But unlike Marx, he did not propose an alternative view of history or a critical science of society. Foucault's project was willfully fragmented; he called his approach to the past a genealogy rather than a narrative history. Deeply concerned about what he regarded as the repressive power of organized knowledge, he was nevertheless unwilling to abandon efforts to understand and subvert the existing order of things. Above all, this meant to understand and subvert power, which was exercised not only by the agents of the state but rather was diffused 'in the multiple forms of subjugation that have a place and function within the social organism.' Emancipation, therefore, required a struggle against all of what Foucault regarded as the 'polymorphous techniques of subjugation' (Dirks et al. 1994).

Marx (and also, if much less influentially, Freud) had sought to subvert traditional political history by showing that politics was really a reflection of deeper social (or psychological) conflicts (see *Psychohistory*). Foucault subverted the conventional image of politics from the opposite direction, that is, not by showing that politics should be reduced to something else, but rather by insisting that everything—including what was once thought of as the most intimate spheres of private life—is politically charged. Both perspectives are useful since both can illuminate new problems and neglected connections. Whether they can—and should—lead to the abandonment of the subjects that have concerned political historians since classical times is much more open to question.

5. *The Varieties of Political History in the Twentieth Century*

Scholars' interest in the past has always been influenced by contemporary crises. Thucydides was moved to write his history by the Athenians' disastrous war with Sparta, Josephus recorded the destruction of

the Jewish people by the Romans, and Augustine composed his universal history under the shadow of the Vandals' sacking of Rome. In the modern era, the French revolution inspired Tocqueville, the Bolshevik revolution, Trotsky, the rise of Italian fascism, Salvemini, Nazi totalitarianism, Arendt, the world wars, Churchill—the list might easily be extended to include many other occasions when, to borrow Hegel's phrase, men's hopes were destroyed on history's slaughter bench.

The war that shattered the world order in 1914 dominated the study of international political history for a quarter of a century (see *First World War, The*). Basing their work on the documents published by all of the belligerents, historians examined both the immediate causes of the war and its deeper roots in the great power rivalries of the nineteenth century. Some of this work was obviously partisan, written to absolve the historian's own nation of responsibility; but much of it sought to strike a balance between commitment and detachment. A notable feature of this historiography was the participation of American scholars. Responding to the hopes and disappointments that attended the failure of Woodrow Wilson's vision of a conciliatory peace, these scholars—Sidney Fay, Robert Binkley, William L. Langer, Raymond J. Sontag, and many others—played an active role in controversy over the causes and consequences of the war. By the 1930s, there was a rough scholarly consensus that no one power was responsible for the war, which was thought to have come from a series of miscalculations by several different governments. In the 1960s, this consensus was shattered by the work of Fritz Fischer and his students who attempted to blame the war on Germany's reckless bid for world power. Fischer's view was bitterly attacked and then widely accepted, but no new consensus has emerged to explain what George Kennan, himself a distinguished student of international history, once called 'the great seminal catastrophe of the century' (Stevenson 1997).

In contrast to World War I, the causes of World War II did not attract much scholarly attention; virtually everyone agreed that this was Hitler's war (see *Second World War, The*). But the war's character and consequences generated an enormous historical literature, including some great works by participants such as Winston Churchill and Charles DeGaulle. Historical controversies surrounded issues such as the air war (especially the decision to use atomic weapons against Japan), wartime diplomacy, and the role of resistance and collaboration in the territories occupied by Germany and Japan. Among the historical questions about the war in Europe none are more painfully complex than those surrounding the mass murder of European Jews, conventionally known as the Holocaust. Was it, as some scholars believe, tied to a distinctive sort of German anti-Semitism? Or did it arise within the climate of violence created by the war itself? Is it best seen as a problem of German

history? Or of modernity as a whole? Could it have been prevented or at least diminished by the action of Germany's enemies? Central to the historical self-understanding of both perpetrators and victims, the Holocaust has become the century's exemplary disaster (Marrus 1987) (see *Holocaust, The*).

The origins of the Cold War, the global geopolitical rivalry between the Soviet Union and the US that dominated international politics from 1945 to 1989, were a matter of intense scholarly controversy throughout its long history. Was the Cold War, as some claimed, a defensive response by the western powers to communist aggression and expansionism? Or, as the so-called 'revisionists' argued, did the US over estimate, perhaps even manufacture, the communist threat in order to advance its own aims throughout the world? Until the collapse of the Soviet Union, both sides in this controversy depended largely upon sources from the western powers, but after 1989, the empirical basis of Cold War historiography was transformed by the opening of archives in both the former Soviet Union and its eastern European allies. As a result, historians have begun to create a new picture of international history in the second half of the twentieth century (Gaddis 1997).

Among the great themes of world history is the expansion of European power which began in the late fifteenth century and ended during the second half of the twentieth century, when the colonial states either abandoned or were expelled from their overseas possessions (see *Colonization and Colonialism, History of; Imperialism, History of*). European expansion was the subject of many important historical studies, including the analyses by J. A. Hobson and V. I. Lenin that inspired several generations of anti-imperialist writers. Decolonization also had a lively historiography, stimulated in part by the traumatic wars fought by France in Algeria and by the US in Indo-China. In the 1990s, historians became interested in what became known as postcolonialism, that is, the persistent and reciprocal relationship between colonized and colonizer both during and after the colonial experience itself. While many postcolonial studies take up issues that seem far distant from conventional political history—for instance, questions of gender, sexuality, and cultural identity—they are all connected to the ways in which political power is defined and distributed.

In the last decades of the twentieth century, political historians have become increasingly aware of the importance of regional and local allegiances and institutions. A number of recent works on the revolutions of 1848, such as Jonathan Sperber's account of the Rhineland, have shown how tensions between central and local authorities affected both the origins and outcome of the revolution. Historians have also become sensitive to the historicity of the national state: Eugen Weber, for instance, has described the long and uneven process through which the French

state imposed its values in the countryside, while Linda Colley, among many others, has uncovered the way in which Britain became a focus of people's interests and loyalties. The upheavals that destroyed Yugoslavia in the 1990s produced a cluster of new works on the historical sources of ethnic identity and changing nature of nationalism in the twentieth century (see *Nationalism: General; Nationalism, Historical Aspects of; The West*). In these studies traditional questions about state power and politics are enriched by a new concern for ethnicity, culture, and identity.

6. Conclusion: Political History in the Twenty-first Century

Although it no longer has the unquestioned historiographical primacy it once enjoyed, the history of politics remains a vigorous and remarkably diverse enterprise. For the general public, political history is a source of apparently endless fascination. Each year a staggering number of books, especially biographies and battle narratives, are published about subjects such as the American Civil War and World War II. Among professional historians there are signs that political history may have recovered some of the ground lost to social and cultural history in the 1970s and 1980s. An increasing number of scholars are now seeking to apply social scientific methods and concepts to the study of both domestic and international politics (see *History and the Social Sciences*). At the same time, insights from cultural anthropology (see *Anthropology and History*) and literary criticism have raised interesting new questions about the nature of political power and identity.

The history of politics is important because individuals' lives are shaped and limited by political institutions, while the very existence of their communities depends on how political power is exercised and restrained. The illusion that politics does not matter is a luxury that only those fortunate enough to live in a rich and orderly state can afford. Moreover, while the importance of national history may have declined in western Europe, for much of humanity the question of national identity remains vitally relevant; in many places people are still willing to die—and to kill—in behalf of their own version of the national story. And the emergence of a new set of problems and opportunities from the wreckage of the Cold War system (see *Cold War, The*) will certainly raise a new set of questions about the past and future of the international politics.

Does knowledge of the past help us, as Thucydides and Machiavelli and so many others believed, to master our own political problems? To be sure, few now share the confidence expressed by Lord Acton in his inaugural lecture of 1895 that 'the science of politics is the one science that is deposited by the

streams of history, like the grains of gold in the sand of a river; and the knowledge of the past, the record of truths revealed by experience, is eminently practical, as an instrument of action and a power that goes to making the future' (Acton 1957, pp. 25–26). And yet the impulse to extract lessons from the past seems irresistible; historical references and analogies are everywhere a prominent part of political discourse. If nothing else, the study of past politics should help to assay the ore left by the stream of history and to recognize the fool's gold so often on display in the rhetoric of public life.

Political Lawyering

Scholarship on lawyers and politics falls into two broad classes. On the one hand, as in most theories of professions—most notably functionalist and market control theories—any politics is largely absent. In a very different way, studies of lawyers' participation in the state and political institutions, where lawyers take for granted the rules of the political game, conceal the collective action of lawyers toward a common definition of the public good. There are, however, two theoretical perspectives that engage lawyers' politics: political lawyering and cause lawyering. The first approach demonstrates that lawyers have mobilized collectively, at critical points of political transition, to advance the institution-building of liberal political regimes. The second approach indicates the impact of those lawyers who pursue political agendas in direct response to perceived inequity or injustice, and in reaction to repressive or arbitrary legal and political regimes. This article briefly reviews the first class of scholarship and then analyzes in more detail political lawyering and cause lawyering.

1. The Avoidance of Politics

1.1 Functionalism and its Critics

Functionalism dominated the sociology of professions, including law, during the years 1950–70. Since functionalists sought to understand the link between knowledge and social needs—or, more precisely, to study the social control of knowledge—the logic of the profession solved the intractable problem of the balance between esoteric, dangerous knowledge in the hands of a potentially egoistic few and democratic control of those few which could in itself be destructive. Functionalists found a solution in the logic of a profession where (a) specific social structures (socialization, ethics, rewards, etc.) oriented the use and the development of knowledge in order to produce a relationship of service between professionals and society, and (b) society delegated to a 'community' a set of duties which were dominated by 'institutionalized altruism' and whose dedication to those duties was appropriately compensated by high social rewards (self-government, prestige, power, and some-

times wealth). Yet the constellation of questions and concepts that were used to study lawyers, as a specific profession, did not refer either to politics or to collective action. History was not considered as the product of social action, but rather as the change to which a profession was compelled to adapt.

Although Talcott Parsons (1964) was the central figure of functionalism, he recognized that, due to its specific 'interstitial' position in the social structure, the legal profession cannot escape the political system. Through the different choices they make, lawyers, as intermediaries, facilitate or impede the task of political authority and favor or not transformations in legal interpretation. Yet even this analysis remains rather limited, because the terms that orient lawyers' action—political authority, law, clients—are given, and because, with some room to maneuver, the legal profession is fundamentally defined by an integrative function.

In the 1970s, functionalism (among other theories) became the target of a critical sociology that leveled three charges against the sociology of professions:

(a) theory (in this case, the functionalist theory of profession) was nothing more than the reproduction of professional ideologies and a mask for gaining or keeping symbolic and material rewards;

(b) the so-called 'service relationship' was only a social mystification and, like the ideal of independence, was not justified by the quality of the service; and

(c) sociologists, therefore, were servants, unwittingly or not, of the professional elite.

Critical sociology rejected ahistorical studies, demanded realism about professional interests, and raised new questions about power, effectively anticipating the rise of market control theory.

Magali Sarfatti Larson opened up a new research program in the late 1970s. Devoted to the comparative and historical study of several professions in the United States, *The Rise of Professionalism* (1977) brought together two intellectual traditions: the European tradition, centered on Marx, Weber, and Polanyi; and the American tradition. It combined a historical framework with collective action (the mobility project), and it integrated the transformation of the market and the change of the symbolic systems through a very original analysis of the role of universities in creating legal service as a new commodity. An interpretation of Larson's book became the central resource of a new school—market control theory—whose simplified thesis posited that lawyers are rent seekers who, to maximize their profit, use two complementary strategies: to reduce the supply of legal services by excluding competitors, and to increase demand for legal services by influencing the state. All the established and distinguishing characteristics of the legal profession—self-government, professional mortality, independence, controls over entry to the profession, moderate internal competition, and so on—still exist, but only as tools to extend market control and thus to increase

economic and social profit. This perspective, which received its most expansive application in Abel and Lewis's *Lawyers and Society* (1988a, 1988b, 1989), ignored politics, took for granted the capacity of professions to mobilize collectively, and assumed the ability of professions to impose their self-interested wills on legislatures and states. It directed scholarly attention away from lawyers acting collectively for reasons other than market control. Although erudite and fruitful in many other respects, Abbott's jurisdictional theory of professions has a similar result. While Abbott (1988) offers acute insights into ways that professions mobilize knowledge in their scramble for control over work, he does not classify either the political processes by which professions secure and maintain jurisdictional control, or the activities of professions beyond control of work domains.

1.2 Institutionalized Politics

Originating primarily from political science and studies of political recruitment, many studies since the 1960s have sought to understand the significance of a widely observed phenomenon—the overrepresentation of lawyers in the legislatures of many liberal democracies, e.g., the USA, India, Canada, Venezuela, Australia, and the Netherlands (see Miller 1995). What are the effects of background and networks on legislative process? Does the prominence of lawyers in legislatures make a difference to policy outcomes?

Studies of the compositional or recruitment politics of lawyers show limited results. Lawyers' actions in legislatures are rarely the expression of any collective professional orientations. Lawyers as legislators do not evince as a whole a coherent or distinctive substantive politics. They distribute themselves across political parties, so there is rarely a clear affinity with party ideology.

At least in the United States, the strong overrepresentation of lawyers in legislatures leads not to substantive outcomes but to a peculiarly lawyerly way of dealing with issues. According to Miller (1995, p. 174), who summarizes several decades of research as a context for his own findings on Congress and state legislatures, 'the numerical dominance of lawyer-politicians in US political institutions produces a government that is preoccupied with the procedurally-oriented, incrementalist myth of rights, instead of with broader substantive questions of public policy.' Thinking like a lawyer leads to reaction against radical change, it privileges procedural rationality over substance, and it produces a rights-focused approach to the solution of public problems. Policy-making alternatives are defined more narrowly and institutional parameters are largely taken for granted. Similar patterns may be observed elsewhere. Ledford's (1996) study of German lawyers in the last quarter of the nineteenth century finds that, through their partici-

pation in national political movements and parties, lawyers were actively committed to the building of the *Rechtsstaat*, a rule-of-law society that would implement the protection of civil rights. But he also found that this procedural orientation faltered when faced, a half-century later, with the substantive challenges posed by National Socialism.

2. Political Lawyering

Sociologists, historians, and legal scholars have demonstrated that, in Europe and North America, legal professions, acting collectively, have been periodic but by no means consistent agents of political liberalism at particular times and places from the seventeenth century onwards. These scholars generally define political liberalism along three dimensions:

(a) a moderate state, which is an amalgam of the rule of law, strong intermediate associations that exist between the state and the individual and will defend the latter against the former, a balance of national and local political authority, and an institutional separation of powers between the executive branch of government and the judiciary;

(b) a civil society, which combines the existence of voluntary associations, religious institutions, and publics, which do not owe their existence to the state and can stand against it; and

(c) citizenship, most notably the civil element of citizenship, in which individuals gain legal rights and personality.

These scholars identify historical episodes in several countries in which political lawyering has facilitated the construction of the moderate state, civil society, and civil citizenship. The findings of these studies may be summarized in five propositions.

2.1 *The Autonomy of the Judiciary and the Autonomy of the Bar are the Principal Conditions for the Fight of Lawyers on Behalf of a Moderate State*

Autonomy from the state has relevance for legal professions for two reasons. First, some independence of the judiciary from executive power is not only critical for establishment of a rule-governed state; and second, autonomy of the profession itself is the key element in this establishment, for without it no independent collective action will be possible. The fight for judicial autonomy can be found in eighteenth-century France where the *parlements* (sovereign courts with judicial and legislative functions) sought to enlarge their powers and control the person of the king and power of the royal court. Lawyers were the *parlements'* most faithful allies. They supported the independence of the *parlements* by urging effective general strikes which brought the justice system to a

halt, and by becoming the political thinkers of the struggle. Lawyers articulated the foundations of the moderate state with such slogans as 'Laws are veritable contracts between those who govern and those who are governed.' Since the 1870s, the bar in the USA has strenuously exerted itself to immunize federal and state courts from control by presidents or governors, congress or state legislatures, and federal, state and municipal bureaucracies. In Germany, where the judiciary was subordinated to the state, the lawyers' campaign for a 'free bar' began in the 1830s with the aim of obtaining the institutional separation of judicial and administrative authority and the autonomy of law through adherence to judicial precedent. This movement reached its zenith in the Imperial Justice Laws of 1877–79, only to decline thereafter until the advent of National Socialism.

Seen from the vantage point of political liberalism, the autonomy of lawyers may be one of the key distinguishing features of a liberal political society. In England, the autonomy of the bar long preceded the emergence of an English state in the sixteenth and seventeenth centuries. It thus became a pillar of English constitutionalism, and was therefore able to resist effectively the attempted incursions of Charles II and James II on such 'little commonwealths' and 'little republics' that existed independently within the English body politic. In France, that autonomy grew consistently with the nurturance of the *parlements* from the seventeenth century to the present, with short interruptions during the Revolution and 1822–30. It was the absence of long-established, independently-secured autonomy in Germany, coupled with internal and external conflicts, which ultimately brought the bar under National Socialist control in 1933 and rendered it quite unable to defend judicial autonomy.

2.2 *Lawyers' Struggles to Institute and Extend Citizenship are Diverse*

Lawyers' orientations towards the extension of citizenship can be distinguished along two dimensions: first, between substantive and procedural rights; and, second, among civil, political, and social concepts of citizenship. French lawyers have been the champions of substantive rights, such as the eighteenth-century efforts to defend the religious rights of Jansenists and to obtain property rights for peasants in Burgundy, or the nineteenth-century efforts to transform the courtroom into a political forum to fight against emergency laws, attacks on a free press, and limits on individual freedoms. In contrast, German lawyers in nineteenth or twentieth centuries did not press directly for substantive individual rights, but rather pursued them indirectly through proceduralism—which opened them to seduction by antiliberal sentiments in the 1920s and 1930s. In the United States, fringes of the

profession variously championed substantive civil rights and rights to representation on behalf of the poor, but the central tendency of the profession has been to valorize procedural limits on state authority, as in the McCarthy period of anti-Communist purges.

2.3 Lawyers' Collective Defense of Civil Rights Does Not Extend to Struggles in Favor of Economic and Social Rights, or to Fights Against Racism, Xenophobia, or Gender Discrimination

With surprising continuity across history and nation, lawyers have been strongly defined by a 'pure' civil rights model. Lawyers are not to be found collectively on the barricades of expanded welfare rights, of national political issues such as the universal ballot, or of the restriction of racism. During the civil rights era in the United States (1950s and 1960s), a few professional associations took collective action. In nineteenth-century France, few lawyers mobilized to defend the working class. Lawyers are limited liberals, most especially in relation to citizenship.

2.4 The Forms of Lawyers' Political Action are Principally Reactive and Rely on the Authority of the Public or Civil Society

Compared to social movements, lawyers react against arbitrary or illegal actions by governments and repudiations of individual rights through trials that become '*causes célèbres*.' In Britain and France, use of the courts as forums came to constitute the political public sphere. Radical barristers in eighteenth- and nineteenth-century England used the courts to rail against corrupt government, to publicize causes, and to champion rights. French barristers used their freedom of speech in the *ancien régime* to create extended legal briefs that effectively became political tracts. Not only did they stimulate debate within the enlightened public, but they claimed for themselves a representational role as the voice of the public. By contrast, lawyers in the United States used the institutions of civil society, which were well developed, to mobilize publics. In Germany, lawyers were able neither to constitute publics as an autonomous sphere, nor to mobilize the institutions of civil society, which barely existed.

2.5 Contradictory Movements Entangle Economic Globalization with Political Globalization on Behalf of Liberal Institution-building

The market has contradictory effects on political globalization of liberal political institutions. On the

one hand, the global market has homogenizing effects on nation states at the same time as it stimulates national reactions against it. The extension of the global market also introduces more contradictions within segments of legal professions and thus inhibits their capacity to act collectively. On the other hand, the conditions of financial stability and global trade require institution-building, such as the rule of law, independent courts, and private professions. Thus, differing segments of legal professions come to constitute liberal politics through institution-building that will facilitate global commerce, and through advocacy on behalf of human rights and environmental responsibility among other fields.

3. Cause Lawyering

Cause lawyering is a form of doing politics (Sarat and Scheingold 1998, 2001). Whereas legal elites separate law from politics, and legal skills from moral calling, cause lawyers seek to 'reconnect law and morality.' Unlike the classic image of the lawyer as 'hired gun,' prepared to serve a client whatever the merits of the client's case and however wide the gap between the values of lawyers and clients, cause lawyers usually identify with the values and causes of their clients. They may even join with clients in political and social movements to advance a common goal. Thus, cause lawyers have a substantive vision of the good society and they use their legal skills to produce it.

If political lawyering is defined by the defense of political rights construed narrowly, the range of causes can be enormously variegated, encompassing pay equity, animal rights, capital punishment, Bedouin land rights, struggles against military repression, women's rights, peasant movements, and human rights, among a multitude of others. (See the case studies in Sarat and Scheingold 1998, 2001.)

Scheingold (2001) shows that cause lawyering is both constant and contingent, and that cause lawyers must choose between frequently uncomfortable alternatives. There is a constancy and coherence that transcends time and place for, while 'cause lawyering is frequently directed at altering some aspect of the social, economic, and political status quo,' (Sarat and Scheingold 1998, p. 4) cause lawyers are everywhere caught between two visions of democracy—of legal and political rights versus social and economic rights. They lean towards the latter and its emphasis on 'egalitarian values and redistributive policies.' Since they face an enormous variety of political regimes (totalitarian, colonial, authoritarian, repressive, liberal democratic, neo-corporatist) with quite different sets of resources, and since their causes are highly diverse, the expression of cause lawyering and its efficacy is highly contingent.

3.1 Strategies of Cause Lawyers

Cause lawyers must usually choose between two broad strategies, although these frequently blur in practice (Scheingold 2001). To follow a *legal strategy* means operating within the very mainstream of professionalism, with which cause lawyers constantly struggle. Thus Israeli civil rights lawyers defend Palestinian 'terrorists' against Israeli security officials within Israeli courts. This may be somewhat effective on narrow grounds but leaves the larger status quo intact. To follow a *political strategy*, and to identify with the cause of clients, may take the form of a political advocacy through social and political movements that extends well beyond legal constraints, as evidenced by many cause lawyers in Latin America. This allows much greater scope of advocacy, but reduces the scope of professional collective action since it marginalizes the cause lawyers.

Similarly, cause lawyers must choose between distance from the state versus close proximity to the state. On the one hand, a close relationship with the state, through cooperation with state authorities, such as maintained by cause lawyers in post-Apartheid South Africa, may yield results while significantly constraining the scope of action, for lawyers are bound by the limits of state institutions. Yet many of the ideals advocated by cause lawyers cannot be achieved without the exercise of state authority, as in the extension and enforcement of new rights, or the complicity of state officials. On the other hand, an adversarial relationship to the state may mobilize public opinion and social movements, but it is a high-risk strategy. The closer to the state, the more the cause lawyer will be compelled to moderate the cause and compromise his or her objectives.

3.2 Resources of Cause Lawyers

Cause lawyers must often rely on resources quite different from those available to the elite or core of the profession. When cause lawyers seek to mobilize, they may be heavily resource-dependent in at least five areas.

(a) *Money*: since little funding for cause lawyers comes from third world governments, they rely heavily on western governments, development agencies and churches (see Ellman in Sarat and Scheingold 1998);

(b) *Media*: publicity, including widely distributed articles, books, print and media interviews and stories, even public demonstrations and courts, increases the impact of otherwise isolated cause lawyers (see Bisharat in Sarat and Scheingold 1998);

(c) *External validation*: in Third World countries, funding by international foundations, partnerships with international non-government organizations (INGOs), and recognition by distinguished professional bodies, cannot be underestimated;

(d) *Professional solidarity*: where cause lawyers can ally with professional legal elites or law schools, they can obtain sponsorship, protection, and legitimation at the local level; and

(e) *Churches*: in some countries, such as Brazil during the military regime of the 1970s and 1980s (see Meili in Sarat and Scheingold 1998), the church and its human rights centers offer institutional solidarity to cause lawyers (Halliday 1999).

The cause lawyering perspective also perceives an ambivalent relationship with globalization.

'For cause lawyers ... globalization and state transformation may be a mixed blessing. In some contexts it may help to provide a political structure wherein minimal rights claims and legal defenses against abuses of state power become meaningful. In other contexts, it may erode support for the kinds of social changes which these lawyers, and the movements with which they are affiliated, seek to advance' (Scheingold 2001, p. 384).

4. Conclusion

Although they have quite different theoretical origins, the two principal approaches to lawyers' politics show some convergence. Political lawyers have been studied more in the past and cause lawyers more in the present, but in fact both can be found in every period. In both cases, three questions are central: how to explain the relationships between political orientations and lawyers' involvement; how to understand the collective construction of a defense or a cause; and how to produce collective action that will change institutional rules. The main difference between political and cause lawyers lies in the conditions which facilitate or hinder the sharing of a common political vision. Cause lawyers are usually individuals or groups defending a specific case in the context of an indifferent or hostile profession. If cause lawyering is very much a creature of, and a contributor to, legal-liberal forms of democracy, cause lawyers do so as a deviant strain within the legal profession and by making appeals for support of their cause outside the profession. By contrast, political lawyering is the expression of a common orientation of lawyers and therefore, through individual causes, it deals directly with other collective actors, especially justice and the state. The more the profession is diversified, the more its political commitment is likely to take the form of the defense of a cause; and the more it is united around some specific issues, the more it is likely to become a political actor. Thus, while the value orientations of these kinds of lawyers' politics may differ, they exist in creative tension to each other, and together may come to constitute the building and maintenance of liberal politics in the modern world.

Political Machines

Though the term ‘political machine’ is sometimes used to describe any party or electoral organization noted for its efficiency and effectiveness, its principal significance, especially in American political science, is to refer to a particular kind of party organization, that draws much of its support from patronage jobs, government contracts, and other ‘spoils’ of office. This second type of machine once dominated the political landscape in most large American cities, though by the late twentieth century most such machines had declined or disappeared.

1. Two Definitions and Their Application

The term ‘political machine’ is used in two related, but distinct ways. Particularly in the 1950s and 1960s, it was often used to refer to any party or electoral organization distinguished by its effectiveness and efficiency (see, e.g., Gottfried 1968). Usually, such an organization was headed by a leader or small leadership group and imposed some measure of discipline on its members (otherwise it would not have functioned quite so effectively), but its most important quality was its ability to acquire, maintain, and use political power on a regular, predictable basis. Hence, the comparison between a human organization and a mechanical contrivance. When used in this sense, the term has a generally neutral connotation, and the study of political machines is simply one aspect of the larger subject of political party organization.

More often, however, the term political machine has been used to refer to a particular kind of party organization: one that derives its effectiveness from the extensive use of what organizational theorists call specific, material inducements. As laid out most clearly by Banfield and Wilson (1963), a specific (as opposed to general) inducement is one ‘that can be offered to one person while being withheld from others.’ Material inducements include money and any other ‘physical “thing” to which value attaches.’ Thus, a political machine attracts support to a much greater extent than other party organizations through the use of patronage jobs, government contracts, and special favors to individual voters. Because these sorts of inducements conflict with certain widely held civic norms, and because their use frequently leads to other forms of corruption, this second use of the word machine has a decidedly pejorative connotation. Indeed, those actively involved in political combat sometimes use the term as little more than an epithet. As Theodore Roosevelt once noted, one’s own organization is invariably described as a ‘club’ or a ‘party’; it is only the opposition that has a machine.

When used in this second sense, political machines have a particularly celebrated history in American politics—and American political science. Almost every large and medium-sized city in the United States was run by one or more political machines, often for extended periods of time, during the latter half of the nineteenth century and the first half of the twentieth century. Among the cities in which machines played a particularly powerful and significant role are Chicago, New York, Philadelphia, Jersey City, Kansas City, and Memphis. Moreover, since some of the most important work in the development of political science as an academic discipline dealt with city government and politics, machines also served as the principal subject matter for what are now regarded as some of the classic early works in American political science (see especially Merriam 1929 and Gosnell 1937).

It is difficult to say with much certainty how often and in what sorts of circumstances political machines have flourished, primarily because it is difficult to get reliable information about how much various organizations used patronage or graft and whether such practices were essential to their success or just an ancillary way of enriching the leadership. There is, as has just been noted, widespread agreement about the importance of machines in American urban history. Many commentators also believe that many rural counties in the South and Midwest were once run by machines, though there seems to be little beyond anecdotal evidence to support this contention. American historians and political scientists once regularly asserted that political machines were a uniquely American institution. Over the last thirty years of the twentieth century, however, it has been recognized that machine-like organizations also exist in a number of Third World or developing countries, as well as in specific locales or regions of other Western nations, such as southern Italy (see especially Scott 1969).

2. *Explaining the Rise of Political Machines*

Why did political machines play such a dominant role in American urban politics? Three principal theories have been put forward to explain the origin and survival of machines in American cities. For shorthand purposes, these theories can be described as governmental, economic, and cultural.

According to the governmental theory, machines came into existence as a solution to the unique governing problems that beset American cities. On the one hand, cities faced an extraordinary array of difficult challenges in the late nineteenth and early twentieth centuries. Their population and geographic area grew at an explosive pace. Partly as a result, and partly as a response to new technological discoveries, cities were suddenly required to provide an array of important services—water, gas, electricity, paved streets, sewer systems, mass transit—that no American city had previously had to worry about. Unfortunately, the structure of American urban government was dramatically unsuited to these tasks. Governmental power and authority in the cities was widely dispersed among the mayor, city council, and a large number of special boards, commissions, and independently elected officials. The special function of political machines, then, was that they provided an informal way of centralizing the political power that had been fragmented among the formal organs of city government (for the classic statement of this argument, see Merton 1957).

The economic explanation for machines, by contrast, argues that machines came to power because they helped serve the needs of the large number of poor and economically insecure people who lived in

American cities. When a city's population doubled in the course of just one decade, as often occurred in the late nineteenth century, the new residents necessarily consisted primarily of immigrants: sometimes from farms and rural areas within the United States, more often, especially in northeastern and midwestern cities, from foreign countries. In either case, the newcomers generally faced severe problems adjusting to their new environment and satisfying such basic human needs as food, housing, and employment. Yet, American government at this time provided little or no help at all in the way of welfare or social services. Political machines did not completely fill the gap, of course, but they were one of the few agencies that even tried, providing at least some of the urban poor with jobs, occasional gifts of food and fuel, and help when they came in conflict with the law. One early twentieth-century social worker went so far as to call the machine 'a kind of crude socialism.' In return, the lower classes, especially those of foreign background, provided a reliable fund of votes for machine candidates, and were not particularly upset if the resources the machine distributed were ultimately derived from illegal or corrupt activities.

The cultural explanation also sees foreign immigration as a key factor in the rise of urban machines, but places emphasis not on the immigrants' economic predicament, but on their political culture. Of the immigrants who came to America after 1840, few had any experience with democracy; almost none had ever cast a meaningful vote. On the contrary, most had learned to view government only as a hostile and authoritarian presence. Against that background, most immigrants naturally saw their votes less as a way of working large-scale transformations in the urban social order than as a commodity that could be exchanged for short-term personal advantages. One widely quoted formulation of this argument has been provided by historian Hofstadter (1955), who saw the clash between immigrants and natives as having been grounded in 'two thoroughly different systems of political ethics.' Where the middle-class natives 'argued that political life ought to be run ... in accordance with general principles and abstract laws,' immigrants 'interpreted political and civic relations chiefly in terms of personal obligations, and placed strong personal loyalties above allegiance to abstract codes of law or morals.'

3. *The Decline of the Urban Machine*

If political machines were once an all-but-ubiquitous feature of American urban politics, they are no longer. It is difficult to be precise about exactly when the machines lost their capacity to deliver votes on a regular and reliable basis for their favored candidates. In Chicago, for example, Mayor Richard J. Daley continued to win easy re-election all the way up until

his death in 1976, but it is questionable if the machine *per se* had much to do with his last several victories. A good case can be made that he won less because of the organization's precinct captains and patronage army than because most city voters genuinely thought he did a good job of governing the city. There is, moreover, no easy way to say who is and who is not a 'machine candidate.' Many self-proclaimed 'reformers,' once in office, would begin rewarding their supporters with jobs and contracts in ways that were largely indistinguishable from the machines they defeated.

That said, it was primarily in the years between about 1945 and 1965 that the most celebrated machines in American history suffered a series of major defeats and lost their capacity to dominate politics on a citywide basis. By the late 1960s, it was frequently asserted that of all the large cities in the United States, only Chicago still had a functioning political machine.

In general, when a machine started to weaken, the first major office it would lose control of was the mayoralty. Yet, long after many machines could no longer dominate these sorts of highly visible, media-centered campaigns, they could still reliably elect a number of their supporters to posts on the city council and to many of the less publicized offices in city and county government. In these weakened circumstances, the vestiges of machine politics linger on in a number of cities.

Why did the machines die out? Each of the three theories developed earlier to explain the growth of machines also provides a ready explanation for their decline. According to the governmental theory, machines died out because, over time, many of the worst problems afflicting urban government became more tractable. Cities stopped expanding, they gradually learned from experience how to deal with such basic demands as paving streets and providing water and electricity, and, in many cases, city charters were changed in ways that brought a greater measure of order and coordination to the formal agencies of government.

Advocates of the economic theory, by contrast, argue that machines went into eclipse because the demand for their services declined. On the one hand, a series of laws passed in the 1920s effectively shut off the flow of foreign immigration; those immigrants who were already here—and their children—gradually learned to adjust to their new environment and, especially after World War II, escaped poverty and even made it into the middle class. Equally important, with the dramatic expansion of the American welfare state in the 1930s, government now provided many of the goods and services for which the machines had once held a near-monopoly.

The cultural theory, like the economic theory, sees the passage of restrictive immigration legislation as an important, long-term threat to the machines' existence. It would also point toward agencies, such as the

public schools and the mass media, that were attempting to assimilate the immigrants' children and grandchildren and socialize them into a new set of political norms.

According to several of these theories, an important demographic trend of the 1950s and 1960s—the massive migration of American blacks from rural southern areas to northern cities—at least had the potential to revivify the machines. Like the European immigrants of the late nineteenth and early twentieth centuries, the black migrants faced enormous social and economic problems and had little previous experience with voting, and there is little doubt that their arrival in northern cities posed huge new problems for urban governance. Yet, for a variety of reasons, blacks proved to be an uncertain and unreliable constituency for the established machines. Racial antagonism and prejudice made many white ethnic groups unwilling to seek common cause with blacks—and made blacks unwilling to take their place as just one more group in the machine coalition. Equally important, the civil rights movement encouraged blacks to think of their votes as a means of effecting social change, and not just as a way of gaining particularistic benefits.

4. *Legacy and Enduring Significance*

How well did political machines govern American cities? To answer to this question, one must pose a further one: compared to what? It is, for example, easy to criticize the aid machines gave to the urban poor: such aid was clearly inadequate to the scope of the problem and was often given out in an arbitrary fashion. And it came at a price: most of the money that the bosses skimmed from the public treasury wound up in their own pockets, not as assistance to the less fortunate. Still, when compared to the contemporary alternatives—the almost complete absence of governmental aid and the paternalistic and demeaning nature of private charity—it is hard not to feel that the machines deserve a more favorable assessment.

At the very least, one can say that there is little compelling evidence to suggest that the machines governed worse than the 'reformers' they competed against—and some reason to think the opposite. All too often, reformers proved to be personally honest but largely ineffective, and to have strikingly little appreciation of the real problems and concerns of immigrants and the urban lower classes (see in particular (Holli 1969)

Good or bad, machines are simply not a very significant presence in contemporary American politics, national, state, or local. Nor is there any obvious reason to think they will be revived at any time in the foreseeable future. Yet, for several reasons, political machines are still worth studying. Most obvious is their historic importance: for at least a century, machines were one of the principal centers of political power and political conflict in almost every large city

in the United States. No one can hope to understand American urban history without coming to terms with the machine. Second, the struggle between machines and reformers left an enduring imprint on the structures of contemporary urban government. Many of the most common institutions in city government, including nonpartisan elections and the city-manager form of government, were originally developed as ways of undercutting the power of the machine. Long after the machines have declined or disappeared, these institutions remain.

W. G. Mayer

Political Money and Party Finance

Healthy democratic politics depends importantly on a free flow of information among citizens, groups, candidates for public office, and political parties. The right to speak diminishes in significance without the financial resources needed to be heard. In the legendary words of California Assembly Speaker Jesse Unruh, 'Money is the mother's milk of politics.' Yet the manner in which political money is raised and spent can undermine the legitimacy of democratic politics. Ensuring that parties and candidates have adequate resources to compete effectively in elections is problematic given the inevitable tension between the reality of economic inequality and the ideal of political equality. Efforts to prevent concentrations of wealth from undermining political equality may conflict with bedrock freedoms of speech and association. Every democracy struggles to reconcile the need for political

money with the problems it begets. None have found entirely satisfactory and long-lasting solutions. The political finance tools available to policy makers—public subsidies, limits on contributions, expenditure controls, disclosure, and regulation of campaign activity—often leave reformers with unfulfilled objectives and unanticipated consequences.

1. Institutional Context

The prominence and nature of money in politics varies across institutional settings. Party-centered electoral systems differ substantially from candidate-centered systems. In the former, most often associated with the parliamentary systems of Western Europe, political money means party finance. Most, if not all, political funds are raised and spent by political parties and the primary concerns have to do with the adequacy of funds available for routine party activities, the work of party caucuses in parliament, and election campaigns. Direct and indirect public subsidies are often provided to the parties, including cash and free broadcasting time on state-owned networks. There is substantial variation in the extent of regulation of party finance, with disclosure of large private contributions and prohibitions on paid political advertising most typical and limits on contributions the least typical. Party-centered systems have not been immune from escalating campaign costs and scandals, as the Clean Hands investigation in Italy and the more recent charges against Helmut Kohl's Christian Democrats in Germany illustrate. But the problems associated with political money in party-centered systems are relatively contained and finance practices are generally viewed as in need of monitoring and repair, not radical surgery.

In candidate-centered systems, by contrast, the focus is less on political party activity and more on campaign fundraising and spending by individual candidates. In these systems, the term of choice is campaign finance rather than party finance. The United States is, of course, the most prominent example of this class of democracies and the one most atypical in its various components. While parties once dominated the recruitment of candidates and the waging of campaigns in the US, a host of developments, including the creation of a professional civil service, the spread of the direct primary, the rise of television, the reform of party rules, and the provision of substantial staff resources to public officials, have diminished their role. Party organizations in the US have become largely appendages of incumbent officeholders—more instruments for raising money within and beyond the constraints of the law than independent political actors. Political money in the US and other candidate-centered systems is widely viewed as highly problematic and much time and energy are devoted to reporting on it and debating how best to ameliorate its harmful effects.

The demand for and supply of political money are shaped by more than the extent of party or candidate-centered elections. In the US, the sheer number of contests across the federal system, the separation of executive and legislative elections, plurality rules, constitutional protections of free speech, the high cost of reaching the large American audience, the professionalism and length of campaigns, and the permeability of the policy process all contribute to the large sums raised and spent in election campaigns. The perceived stakes of elections, the incentives and opportunities for raising and spending private resources in campaigns, and the laws and norms governing its role all condition how political money flows in democracies.

2. Problems Associated with Political Money

Rising campaign costs, scandals, and equity concerns in the early and mid-twentieth century precipitated waves of regulation of political finance and subsidization of party and campaign costs in democracies around the world (Paltiel 1981). Similar concerns kept issues of the regulation and subsidy of political finance on the public agenda in more recent years. Problems arise as parties and candidates struggle to raise adequate resources to compete effectively in times when those costs have risen sharply and when groups and individuals seek to influence election outcomes and policy decisions. At one extreme lies bribery and extortion, the illegal linkage of private resources and public authority for personal gain. Short of such explicit *quid pro quo* exchanges lie such problems as the dependence of parties and candidates on large financial contributors, conflicts of interests arising when politicians receive contributions from those who seek favorable action by a legislative or administrative body, and the impact on democratic legitimacy of the appearance of special access and influence by financial contributors. Then there are the consequences of the money chase—the unending scramble for political money—for how party and public officials allocate their time, who they see and listen to, and how both affect the deliberative processes of government.

Another set of problems are associated directly with the electoral process. Rising campaign costs and inadequate political funding depress electoral competition, discourage able people from seeking public office, give a distinct advantage to incumbent officeholders and wealthy self-financed candidates, and weaken democratic accountability by muffling the voices of individuals, groups, candidates, and parties.

A final set of problems arise from the very act of trying to cope with the others. Reforms designed to alter the flow of money in elections often produce equally problematic unanticipated consequences. Political money is fungible and legal constraints can easily divert it to less accountable passageways. Ambitious politicians naturally exploit the weaknesses and push

the boundaries of the law, threatening the effectiveness and credibility if not the complete collapse of the regulatory regime.

3. Political Finance Tools

Policy-makers have utilized a conventional toolbox in responding to the problems associated with political money, but the mix of tools and particular applications have varied widely among democracies.

3.1 Public Subsidies

In response to concerns about rising campaign costs and excessive dependence on financial contributors, public support of parties and campaigns has become nearly universal among democracies (Katz 1996). Subsidies take the form of direct cash assistance, the provision of goods and services (e.g., free broadcast time, mailings, voter brochures, and meeting space), and indirect support such as tax credits or deductions for contributions or reduced rates for political advertising. The subsidies are given to parties or candidates and directed toward party maintenance or campaign expenditures. Direct cash subsidies to parties are typically allocated in proportion to electoral strength while services and indirect subsidies are usually provided on a more equitable basis. In the United States, public matching funds are provided to candidates for their party's presidential nomination who raise the requisite number of private contributions and agree to limit their spending; full public grants are provided to the major party candidates for the general election as long as they agree to raise and spend no private funds. But unlike most other democracies, the US provides no free broadcasting time for parties or candidates and no public subsidies for candidates for Congress.

Public subsidies are not without risks. They can reinforce the dominance of established parties, increase the potential for control by the state, and weaken the connection of parties with their grassroots. Public financing conditioned on very low qualifying thresholds can also encourage fringe and patently offensive candidates and parties. Full public financing systems generate intense pressure for private resources to find alternate routes to influence elections and policy.

3.2 Contribution Limits

While public subsidies are the norm in political financing, limits on contributions are less common. Many democracies place no restrictions on the source or amount of contributions to parties or candidates. Among those that do, prohibitions on particular sources (e.g., civil servants, foreign donors, corpor-

ations, and unions) are most common. In the United States, corporations and unions have been precluded for many decades from making political contributions from their treasuries but they may form voluntary political action committees (PACs), through which they may contribute to parties and candidates. In the late twentieth century, even prohibitions on contributions from corporate and union treasuries have been rendered ineffectual through the emergence of 'soft money' donations to political parties not subject to federal regulation.

Some countries have placed statutory limits on the size of contributions from permissible sources, including France, Israel, Japan, and the United States. The contribution limits in the US are notably low, especially since they were not indexed for inflation when fixed by law in 1974. This decline in the real value of donation ceilings contributes to the fundraising demands on politicians and pressures for private donations to flow through other channels, problems associated more generally with contribution limits.

3.3 Expenditure Limits

A number of democracies place limits on spending by parties and candidates, although these limits often apply only to a brief period of time (e.g., the formal campaign in parliamentary systems), to candidates but not parties (or vice-versa), or they exempt entire categories of political activity that influence election outcomes. In Japan, candidates for the Diet face limits on campaign expenditures but these are largely irrelevant because they apply only to the 12-day formal campaign period. For well over a century, Britain limited the expenses individual candidates for Parliament could incur in their constituencies (and prohibited outside groups from spending on their behalf) but did not regulate political party expenditures at the national level, where most of the action is. However, a new law adopted in 2000 limits national campaign expenditures by political parties; it also limits the amount of spending by outside organizations and individuals for political activity during a general election.

Mandatory spending limits adopted in the US in 1974 were declared unconstitutional, while voluntary caps tied to the receipt of public funds in presidential elections remain intact. But presidential candidates, political parties, and interest groups have managed to work around these expenditure limits in the general election by fashioning political advertisements (known as 'issue advocacy' but indistinguishable from traditional electioneering) that the courts have ruled are not subject to regulation.

3.4 Public Disclosure

Transparency in the flow of political money is embraced by many democracies as a deterrent to cor-

ruption or influence peddling but the comprehensiveness and effectiveness of disclosure regimes vary widely. At one extreme are systems requiring only the filing of a single report on party expenditures well after the election; at the other are systems like the US with elaborate rules for reporting political contributions (as small as \$200) and expenditures and for making this information publicly available on a timely basis. Yet even in the US, a significant amount of electioneering falls outside the boundaries of disclosure law. While disclosure of political money is gaining in acceptance in the democratic world—Britain, for example, broke with its longstanding practice in 2000 by requiring that large donations to political parties be publicly disclosed—some Scandinavian countries continue to consider reporting requirements as an unacceptable violation of privacy.

3.5 Regulation of Campaign Activity

One way of reducing the demand for political money is to prohibit certain costly campaign activities. A surprisingly large number of countries ban paid political advertising on television, although most couple the ban with the provision of blocks of free television time to the parties. Such prohibitions are unthinkable in the United States, where free speech guarantees preclude any significant restraint on political communication. Other countries have moved to assert that a legal protection of freedom of expression limits the extent to which campaign activity can be regulated. For example, the Australian High Court declared a 1991 law that prohibited the broadcasting of political advertising during election periods unconstitutional, on grounds that it infringed the implied right to freedom of political communication.

4. Enforcement and Effectiveness

The success of any measures designed to redirect the flow of political money depends upon the ingenuity, comprehensiveness, and timeliness of the particular mix of regulatory and subsidy measures and on the mechanisms for enforcement. Short of blatant violations of criminal statutes (e.g., bribery or extortion), departures by parties and candidates from the letter and spirit of campaign finance laws often go unpunished. Politicians are reluctant to invest the requisite authority in public agencies to enforce political finance laws, a phenomenon tellingly illustrated by the structure and operation of the US Federal Election Commission. The FEC, whose six members include three from each of the two major parties, operates under very tight statutory and budgetary reins from Congress and often deadlocks on regulatory decisions. Putting in place a reasonable and workable set of regulations, appropriate criminal and civil sanctions, and administrative and judicial mechanisms has proven a daunting task in many democracies.

For all of these reasons it is not surprising that political finance reforms often fail to reduce corruption, lessen the influence of monied interests, slow the increase in campaign expenditures, or increase electoral competition. Other institutions and policies are more effective levers for combating corruption and enhancing democratic accountability. These include broad economic policies that limit the discretionary authority of public officials; institutions and practices nurturing the rule of law; an independent judiciary; adequate pay and strong ethical requirements for politicians and civil servants; transparent budget and financial control systems; and party systems supporting stable patterns of competition, accountability, and alternation of power (Kaufmann 1997, Pope 1996).

Not all political finance measures are doomed to fail, nor are they miracle cures for the ills arising from money in politics. But since neither the abolition of all private funds from politics nor the complete deregulation of political finance are feasible or sustainable, democracies will continue to struggle not to solve these problems once and for all but to contain and manage them as best as they can.

Political Parties

1. Defining Characteristics

Political parties are a form of political grouping. The term is commonly applied in different political systems to widely different bodies, ranging from the loose, decentralized, and undisciplined associations of the American Democratic and Republican parties to the tightly bonded, highly centralized, and rigidly disciplined Communist and Nazi parties of recent memory. It therefore seems appropriate to state the characteristic that appear to qualify these variegated groupings as ‘parties’:

(a) They are groups of people to whom labels—‘Republican,’ ‘Labour,’ ‘*Rassemblement pour la République*,’ ‘Baath Socialist Arab Rebirth,’ and so on—are generally applied by themselves and others.

(b) Some of the people are organized—they consciously act together to achieve common goals.

(c) The larger society recognizes as legitimate the right of one or more parties to organize and promote their causes.

(d) In some of their goal-promoting activities, parties work through the mechanisms of representative government, such as nominations and elections.

(e) A key activity of parties is thus selecting candidates for elective public office.

Most scholars agree that, taken together, these characteristics distinguish modern parties from such historic precursors as the patricians and plebeians of the Roman Republic, the Guelfs and Ghibellines of medieval Italy, the ‘hats’ and ‘caps’ of eighteenth century Sweden and the Whigs and Tories of eighteenth century England. In his classic *The Structure of Politics at the Accession of George III*, for example, Sir Lewis Namier (1929) pointed out that ‘Whig’ and ‘Tory’ were loose labels sometimes called ‘parties,’ but, since it was uncertain which label fitted many MPs, the groupings were more ‘tendencies of opinion and personal loyalty’ than fully-fledged political parties.

The last of these defining characteristics most clearly distinguishes parties from interest groups. Typical organized interest groups, such as the American Rifle Association and Handgun Control, Inc., support, finance, and sometimes organize campaigns for political candidates who take their respective positions on gun control, but they do not *nominate* candidates who will bear their labels on general election ballots. Only parties do that.

1.1 ‘Party’

There are three levels of meaning. Many scholars of American parties have embraced a suggestion made in the first edition of V. O. Key’s *Politics, Parties and Pressure Groups* (1958 [1942]). Key observed that when most Americans talk about a particular party or

parties, they have in mind one or more of three levels of meaning of the term.

(a) *Party-in-the-electorate* refers to the degrees of attachment to particular parties held by ordinary people (a concept later developed into 'party identification,' operationalized and analyzed by the authors of *The American Voter* (Campbell et al. 1960)). People who feel some attachment to, say the Democratic party do not necessarily work for the party, contribute money to it, or even vote for its candidates.

(b) *Party organization* denotes people who hold offices in the parties or contest elections as their nominees or otherwise work for them in election campaigns.

(c) *Party-in-government* means persons who are elected or appointed to public offices commonly associated with a particular party—for example, the president, members of the cabinet, subordinate administrators serving at the pleasure of the president, members of the party's congressional party caucuses and their leaders, and the like.

There are some occasions, Key said, when some people use the term 'Democratic party' or 'Republican party' to include all three levels of meaning, although they are rarely explicit—or perhaps aware—of what they are doing.

When considering what people say about the Democratic and Republican parties, Key advised, it is well to be as precise as we can about just what meaning of 'party' we have in mind. Most political scientists (though not most journalists) concerned with the major American parties have followed his advice.

2. Party Types

Each party in any democratic system is not the same in all respects as every other party. They differ mainly along the lines covered in Sects. 2.1–2.3.

2.1 Membership

Membership in a party carries with it the right to participate in the selection of the party's candidates for public office, and it may or may not also involve the assumption of some kind of obligation to the parties. Most of the parties in most democracies have memberships that are to some degree closed: the parties' rules in such places as Great Britain, Europe, and Scandinavia usually require aspirants to apply for membership, and party officials can accept or reject the applications (they usually accept them). To continue as a party members in good standing, the person must at least pay annual party dues and perhaps also take an oath of loyalty to the party's principles and candidates. Membership in US parties, however, is open: there is no formal application for membership, Democratic and Republican presidential and other candidates are selected in direct primaries, and the

right to participate in those primaries is guaranteed by law to all registered voters. In 'closed' primaries the voters are required to register their party preferences before the election, but they and they alone control their choice of parties. In 'open' primaries they do not make any public statement of their party preferences. In 'blanket' primaries they are allowed to vote in the primaries of either or both parties, although only for one candidate for each office.

2.2 Discipline

Most human organizations have some form of discipline, in which the leaders control the members by dispensing rewards and imposing punishments for the members' behavior. The leaders of every democratic party have some disciplinary powers, but some are more effective than others.

The leaders of the British Conservative and Labour parties, for example, have strong disciplinary powers. The members of their parliamentary parties know that when 'the whip is laid on'—when the leader, through the party whips, has told the members how they should vote on a particular bill—the MPs put their political careers in great jeopardy if they disobey. The prime minister, who is leader of the party in power, controls who gets ministerial offices constituting the 'government,' and the leader of the opposition controls who gets the positions in the 'shadow cabinet.' Moreover, the leader of each party controls its national organization, which has the power to deny a rebel MP reselection as the party's official candidate in each constituency and thereby effectively end the MP's political career. Perhaps the prime minister's greatest disciplinary power stems from the fact that if his or her government is defeated on a major parliamentary vote, a new election must be held, which the party—and any of its MPs—might lose. Thus an MP's vote against the whip's instructions is, in effect, a vote to risk putting the other party in power—a powerful deterrent against defections by the majority party's MPs.

US presidents are leaders of their parties (the party that does not hold the presidency has no generally acknowledged single leader), but their disciplinary powers are much weaker than those of their British counterparts. Presidents can make campaigning for one of their party's candidates contingent upon that candidate's support of presidential programs. However, most congressional candidates' electoral success depends far more on local factors than on presidential support. Indeed, it is usually an electoral asset for a congressional candidate to be seen as independent from any 'outside' party leader, including the president. Presidential discipline in American parties thus consists of little more than asking and cajoling.

Most European and Scandinavian parties give their national organizations the power to expel from the party members of the national parliamentary parties

for bolting the party line. While such expulsion is somewhat less likely than in Britain to end a parliamentarian's political career, it is still a much greater weapon than any available to the leaders of the American Democrats and Republicans.

2.3 Cohesion

Cohesion, defined as the extent to which party members holding public office act together on policy matters, is a critical party characteristic for people concerned with party responsibility. Parties in democratic countries vary considerably in cohesion. The British Conservative and Labour parties are among the most cohesive: on almost every issue before the House of Commons the members of the parliamentary majority party vote together without exception—and usually with unanimous opposition from the other parliamentary parties.

At the other extreme, some small parties in France split in parliament on almost every issue. Other democratic parties fall between these two extremes. The larger parties in Australia, Canada, and New Zealand, as well as the leading French, German, and Scandinavian parties, are almost as cohesive as their British counterparts. The American parties in Congress fall somewhere in the middle, often mustering near-perfect cohesion on such matters as the organization of the chambers, election of presiding officers, large tax cuts, increasing social welfare expenditures, and other major issues where party positions are well entrenched. Usually one or both parties split internally on other issues such as foreign aid, abortion, and free trade.

3. Party Functions

Every democratic country has political parties at the national level, and most have them at the regional and local levels as well. Moreover, all of the nations that began their existence as democracies or replaced some form of authoritarianism with democracy have also had parties from their democratic beginnings. Evidently, then, democracy and parties are in some fashion intertwined.

Why? Most scholars would say because parties perform at least two critical functions for democratic government that no other form of political organization does or can.

3.1 Organizing Elections

Popular elections of the government's top public officeholders are traditionally the main democratic device by which a sovereign people choose their

officeholders and hold them accountable. But elections, especially in democratic nations with millions of citizens, must be organized somehow. For instance, 130 million Americans fulfill the constitutional requirements for the US presidency, and theoretically the American people have the right to pick the one person they most prefer. But that right is meaningless, for no person or electorate can choose among 130 million alternatives. Some agency must aggregate the choices and reduce the 130 million to a manageable number, say, 20 or three or two. That vital function is performed in every democracy by the political parties' activity of candidate selection. Theoretically it could be performed by another agency, such as the mass media or random selection by computers. In fact, however, democratic governments have always left the task mainly to political parties.

In addition, by putting the candidates' party labels on ballots the parties provide important cues that help voters make some sense out of the 'booming, buzzing confusion' of names, offices, and issues that elections present to them—especially where there are long ballots filled with many options. Some political scientists believe that prominent party labels explain why voter turnout in partisan candidate elections is usually much higher than in nonpartisan elections or in referendums.

3.2 Organizing Government

In every modern democracy elected officials of each party in each governing body join together in some kind of party organization. In each national legislature, regional assembly, or local council there is a comprehensive organization of all the party's legislative officeholders, often called the 'party caucus' or the 'parliamentary party.' That group usually selects some of its members as a guiding committee and one of its members as the party leader.

In the two-party systems elements of the majority party's organization become the government's 'ministry,' 'cabinet,' and 'prime minister.' In multiparty democracies the leader of one of the parties negotiates with other parties' leaders to put together a multiparty coalition government with some top positions going to leaders of all the participating parties. In both kinds of democracies the parties provide the organization that not only makes possible meaningful elections but effective and accountable government as well.

Some parties and party systems may perform these functions better than others, but even the least effective makes possible the coherent government and popular accountability that democratic government must have in modern populous nations.

Political Parties, History of

The definition of a political party requires a historical perspective. The idea of a party is multifaceted and developed over time, in the light of the prevailing political, social, economic, and (especially) legal realities in which it is formed. In current language—and in the specialized terminology of the social sciences—the term ‘party’ has been in use for longer than the term ‘social class’. Etymologically, the term derives from the verb *partir*, which, in archaic French, meant ‘partake,’ or ‘share.’ The present article regards political parties as formal civil organizations that are

active in public life, in which they represent specific class, professional, or ideological interests, within the framework of the modern constitutional State, and whose goal is to run for election and, upon winning, to take power as the government.

1. Approaches and Definitions

In the past the expression ‘political party’ was also used to describe other political phenomena. Throughout the history of societies and of their political bodies, since antiquity, the expression to ‘be party to’ affairs of public life has been considered a common mode of human behavior. The translators of Aristotle use the term ‘party’ to designate opposing social groups in Athens. Specialists on ancient Rome have used the concepts of ‘Plebeian Party’ and ‘Patrician Party,’ and the famous *De viris illustribus Romae* relates to the party disputes that dilacerated the Roman Republic. The supporters of the Crown and the defenders of the rights of the nobility were also parties. Critics of the theological hegemony of the church and of the clergy were parties within the context of the political order of Christian Europe. Noble families in opposition to the Crown were parties in the making; religious and political reformers were parties. These are broad meanings of the term that are frequently to be found in the literature. Also under the broad heading of ‘parties’ can be categorized all manner of social organizations that seek political ends, even if they never stand for (or win) elections, as is the case for the mini-parties or revolutionary organizations that have no constituency among the electorate and that do not accept the validity of the electoral system, or even the dominant groups in totalitarian states. Thus, the expression ‘political parties’ is also often applied to interest groups; propagators of ideologies, doctrines, and political positions; political model makers; and mediators between citizens and government, including a vast multiplicity of bodies that participate in public life.

There are three nuances of the term ‘party’ from the historical point of view: rival groups, orders, states, or dynasties; theological or ideological critics; and modern formal social organization. This third interpretation has, in part, inherited the historical characteristics of earlier forms, making it possible to make such distinctions as conservative and liberal parties; religious and lay groups; corporative interests and those of the masses; revolutionaries and reformers; left and right; center and radical; and progressive and reactionary. Such distinctions are not exclusive, are directly proportional to the degree of institutional solidity and of integration which the parties enjoy in political society, and always relate to the ideas that separate—or unite—individuals or groups. Such multiplicity is evident in the classification of parties, according to the ideological density of their manifestos, the form of internal structure, competitive or

noncompetitive organization, and of party systems (single-party, two-party, or multiparty; unipolar, bipolar, or multi-polar) concerning the political and legal frame they are put in. Unlike political science, historical research does not treat these issues in isolation, but rather, seeks to reconstruct how all such aspects relate to each other.

Political parties—in the contemporary sense of the term—became common in the nineteenth century, alongside the development of representative institutions and the suffrage, becoming gradually universal, especially in Western Europe and the USA. In the aftermath of the Congress of Vienna (1814–15) political parties had not yet been formally recognized as civil associations. Any association, assembly, or grouping united by specific goal or political interest was regarded as a party. Conversely, the pursuit of private interests and the application of abusive pressures was regarded as a constraint upon political life, as the goal of winning elections and of influencing government and public policy became the established criteria for identifying a group of citizens as a political party. In the USA, by the 1830s, parties as such were fully active. In the Western European states, it was in the final decades of the nineteenth century and the first decade of the twentieth century that this development took place. Modern political parties are full players in the public life of democratic societies. In effect, only constitutional states formed and consolidated over the past two hundred years have the institutional framework necessary to ensure regular political participation on the part of their citizens. Such a framework determines the legal principles for party actions, articulates the position of the parties in relation the system of government and the electoral system, and places them within the framework of civil law. Their social origin and ideological orientation notwithstanding, it was the placing of parties within a legal framework that created the party system—understood both as a juridical and political frame of the participation of citizens in political life.

Parties began to elicit attention from philosophers and the interest of modern historians from the time of the English revolutions of the seventeenth century, on through the revolutionary turmoil of 1848, and up until the death of Marx in 1883. They were observed by Bolingbroke and Madison, Hume, Burke, Benjamin Constant and Blüntschi, and the German social-democratic thinkers. At the turn of the twentieth century, party-political phenomena began to be the object of serious scientific methodological analysis. The earliest works in this field were published after the consolidation of parliamentary forms of democratic government, which had been in place since the mid-nineteenth century. The pioneering works of Ostrogorski (1902) and Michels (1989) examined the functioning of parties in the late nineteenth and early twentieth centuries in the UK, France, and the USA. These authors sought to put forward a general theory,

beginning with highly particular experiences and specific historical developments, such as the establishment of federative republicanism of the USA or the burgeoning power of Parliament in the Government of the UK. There are many descriptive and historical studies on political parties in specific countries and also comparative studies which seek to define possible models. Research trends generally give greater emphasis to the western model of representative democracy, in which formalized parliamentary, electoral, and political-party systems play an essential role in public life and the practices of Government (Epstein 1993; Budge and Keman 1990, Fenske 1994).

With Max Weber, who couches his remarks on parties from a sociological standpoint, modern political parties came to be understood as a product of democracy and of universal suffrage. Jean Charlot (1971), according to Lapalombara and Weiner (1966), provides a systematically historical view of parties. In order for a group to be regarded as a political party, it should fulfill four requisites. It must (a) possess a visible and stable organization, for the articulation of its local, regional, and national components; (b) ensure continuity of organization, independently of its current managers; (c) have the explicit goal of achieving and holding decision-making power, either alone or as part of a coalition with others, at all levels; and (d) have organizational efficiency, with a view to capturing the vote and harnessing popular support. It is, however, a work by Duverger (1951) that systematizes and compiles knowledge on political parties. Two of his research elements remain valid: one puts forward a theory of the origin and of the proliferation of political parties, from an institutional perspective, relating to the party phenomenon and the dynamics of institutions, whereas the other resides in a typology of parties based upon the nature of their organization. After World War II, the discredit and mistrust with which people regarded the traditional political parties of Europe—owing to their failure to avoid the emergence of fascism and totalitarian dictatorships in Italy, Germany, Spain, and Russia—hampered the reintroduction of democracy, and parties were left fragmented and disunited. The understanding came up that healthy democratic life requires political parties within a system of government that establishes clear rules for the formation of governments to exercise the will of the majority, solely on the basis of the judgment expressed through the popular vote. The political instability of the Fourth Republic in France, and of the government of Italy, for example, provided Duverger with a rich vein of material upon which to base the most ambitious essay written on the theme of political parties in the mid-twentieth century. Duverger regards the parties of the masses as the inevitable product of universal suffrage and regards many of the residual parties as being archaic, especially in postwar France. His view is supported by the movements for ideological concentration in European

public life at the onset of the Cold War and has as its inspiration the two-party systems—which he regarded as being successful—in the USA, UK, and West Germany.

Although there is still a lack broad-based comparative studies, the contributions of Robert Dahl (1966), Lipset and Rokkan (1967), and Epstein (1993), take steps in this direction. The ideological nature of parties is given an innovative treatment by Stein Rokkan, comparable with the contribution of Duverger on party organization. The analysis of party systems was advanced by Sartori (1976) and Blondel (1978), whereas electoral sociology—beginning with the pioneering work of André Siegfried on electoral statistics and geography (1913, 1927), by Richard Rose (1984), David Butler (1981), and Alain Lancelot (1988). More recently, Daalder and Mair (1983), Pierre Avril (1990), Klaus von Beyme (1985), and Daniel-Louis Seiler (1986) have sought to formulate studies from an institutional and systemic viewpoint.

2. Stages of Development (Phases) Change Over Time

The first expressions of party life began with the defense of specific interests, although in different contexts and times, such as those of the aristocracy against the power of kings and governments, or of the working class against the political, economic, and social dominance of ruling groups or elites. Such defense was not passive. It was carried out by means of consistent and prolonged actions within the representative institutions, such as the estates, consultative assemblies and parliaments. It also comprised the revolutionary movements in which the respect for rights—both effectively held and merely claimed—was demanded of the political authorities, the governing establishment or the despot.

A party emerges when a political current within society finds expression through a specific (national or regional) organization. The first steps towards the organization of a political group can be observed through the 'parties' into which England polarized in the mid-seventeenth century. Although these parties were still characterized by the discipline and discourse of religion, the political effect of the change from one system of government to another imposed by those in opposition to the power of the throne, ushered in a new form of the exercise of power within society. It goes without saying that the great revolutions of the seventeenth and eighteenth centuries—in England, France, and the USA—also gave rise to factions which the majority of historians would call 'parties.'

The typical action of parties in modern societies emerged out of the political consciousness that defined and established the notion of a universal citizenship, evolves in the new space for political protagonists (both for and against the State), the emergence of

organized political parties during the nineteenth century and investiture of political parties as being the only protagonists capable of adopting practices, expressing ideas, and taking power and exercising public office within the State. The parties of the bourgeois in the early nineteenth century protagonized opposition between the aristocracy and the monarchy; a similar process can be observed among the emergent revolutionary or proletarian parties of the end of the same century. In revolutionary France there were embryonic experiences of political-party organization: the Girondes, Montagnards, and the Jacobins. The greater part of these 'parties' consisted of small groups, without formal organizational structures. It can thus be stated that no formal parties existed prior to 1820. Three phases in the development of party systems can be identified in the nineteenth century: the earliest phase between 1820 and 1830, an intermediate phase in the 1860s, and a final phase around 1880.

In the 1820s and 1830s, the British Tories and Whigs emerged and consolidated long-held positions. At the same time, in many countries of Western Europe, and notably in France, there was a movement towards a more constitutional state, expanding suffrage and consolidating the system through application the principle of majority rule in the formation of governments. It was in this phase that the earliest political parties emerged in Latin America, as in the case of the *Partido Liberal* in Colombia (1815) and the *Colorado* and *Nacional* parties in Uruguay (1836), which arose as an immediate consequence of the wars of independence against Spain and of the ideological influence of the USA. In the intermediate phase, there was a clear expansion of political parties: the Conservative (1840) and the Liberal (1860) parties in Brazil; the Liberal Party in Belgium (1846); the Christian-Democrat and Radical-Democrat parties in Switzerland (1848); the Democratic (1848) and Republican (1856) parties in the USA; the Liberal Party in Italy (1848); the *Partido Radical* in Chile (1863); and the Conservative (1854) and Liberal (1867) parties in Canada.

In Latin America, where most countries had thrown off colonial rule in the first decades of the nineteenth century, only gradually did political parties begin to gain importance. As of 1850, the national aspirations of countries of South America came under the spreading influence of North American two-party system. The first expression of political life was the affirmation of a national identity. The main banner of the 'political parties' up until the mid 1800s was nationalism, defended as the means whereby these new states could affirm their independence in face of their former colonial masters. The 1880s witnessed the emergence of 'classical' political parties, generally in twos, and of either conservative or liberal persuasion—but always nationalist—in the former Spanish colonies. It should be noted that the emergence of political parties did not necessarily mean that they assumed a decisive role in political life. Under the Brazilian Empire (1822–89), a

two-party system existed as a means for the rural aristocracy to maintain its hold on power and, under the Republic proclaimed in 1889, this oligarchic system remained essentially unchanged.

In the mid-nineteenth century, growing social tensions and bitter social criticism led people with a political outlook to express their social and economic (and occasionally revolutionary) demands through formal political action, by means of the creation of political parties. Thus began the 'socialist' or 'social-democrat' phase, typified by formation of the Danish Social-Democratic Party (1871), the Spanish Socialist Party (1879), the German Social-Democratic Party (1863, 1869, 1875), the Swiss Socialist Party (1880), the Belgian Workers Party (1885), the Indian National Congress (1885), the Austrian Social-Democratic Party (1889), the Swedish Social-Democratic Party (1889), the Italian Socialist Party (1892), and many others.

World War I forced a pause for reflection and redefinition of the party systems in Europe. On the one hand, the victory (1917) of the Bolshevik party (1903), which upon seizing power set up a revolutionary and internationalist government in Russia, and, simultaneously, the conservative bias of the Treaty of Versailles (1919) on the other, mark the polarization of two separate and irreconcilable ideological currents. On one side, moderate, conservative democratic, and liberal parties, found themselves up against hard-line right or left-wing revolutionary opponents of a nationalist or internationalist persuasion, with scant respect for suffrage, democracy, or tolerance. The twentieth century opened with the founding of a series of communist parties (Russia 1903; Austria 1918; Greece 1918; USA 1919; UK 1920; Spain 1920; Italy 1921). These new protagonists on the political scene achieved varying degrees of importance in different places and their role was to become more prominent during the Cold War. Communist ideology and the proposals of revolutionary Marxist analyses were to assume the weight of a political mortgage at two moments: in Europe in the 1920s and 1930s, and throughout the world from 1945 to 1990. Social demands and economic crises deeply disturbed the political environment. The emergence of totalitarian and fascist dictatorships were to undermine political party structures throughout Europe until 1945. Nevertheless, these dictatorships organized political life by means of an imposed adherence to a single party. Only formally such a party was maintained as an element of legitimacy in the exercise of state power, despite the fact that authoritarian regimes could dispense this.

The success of the Western model of parliamentary democracy based upon a three-legged political system (representative and participative democracy, the electoral system, and the political-party system) is thus a recent phenomenon. During the Cold War, the ideals of representative democracy as being the end product of the modern liberal constitutionalism, with roots in

the 1790s, appeared to be a heritage limited principally to Western Europe and the USA. A few other countries, notably former members of the British Empire—such as Canada, Australia, New Zealand, and India—have practiced representative democracy since achieving their independence. In countries such as Brazil and India, where democratic pluralism exists under specific historical and cultural conditions, many political activities take place outside the formal political-party structure.

Between the world wars, growing social awareness of rights and of the need to manage an increasingly literate populace led to structural modifications among the political parties. Economic crises in Central Europe were accompanied by increasing mistrust of parliamentary institutions and the emergence of manipulative right-wing political parties. Fascism and communism radically changed the way in which political parties were regarded. Into the parties of the masses flowed all the social dissatisfaction and frustration, making them easy prey for manipulation by dictators of every stripe. In Europe, as also in other regions, the trend towards mass parties, which in principal appeared to be a sign of the triumph of democracy, in the end generally resulted in quite the opposite effect as authoritarian rulers assumed power. In many regions, however, expectations with respect to the freedom to participate in party activities was enhanced, especially after the experience of World War II.

The triumph of the Western model of liberal democracy with parliamentary representation was one of the consequences of the new international order that emerged after 1945, except in regions under the yoke of communism (Eastern Europe, China, and Cuba). Communist regimes, however, do not dispense with mass parties or even with formal parliaments, although the role of these institutions is merely figurative. After World War II, a new phase of political life began, with the restoration of the values of liberal democracy, universal suffrage, civil liberties, and parliamentary representation. The Western tradition of recording political events—at least since the Code Napoleon (1804) and the British Reform Act (1832)—has provided a framework for the organization of political life in such a manner that the formal and legal structuring of parties has advanced in parallel to the campaign for constitutional government. This has caused parties to organize and represent themselves as both defenders of an overall social vision and as pursuers of political goals. Thus, parties assume the posture of political businesses whereby they compete within a legal framework to advance the political convictions, opinions, and beliefs—and to defend the preferences and class interests—of their constituents. Diverse and intersecting interests find expression among groups, clubs, associations, and, above all, political parties. The social economic and ideological cut-lines present in the social structures were key

factors throughout the nineteenth century. Conservatives and Liberals, labor parties and revolutionaries, opposed each other in Europe and also in Latin America. In the UK, the Conservatives and the Liberals succeeded the Tories and the Whigs and were in turn superseded by the Conservative and Labour parties of the twentieth century. In the USA in the period following the Civil War, the Democrats and the Republicans definitively consolidated their hegemony over the political scene (Katz and Mair 1992).

The history of political parties clearly demonstrates that the political opportunities in the social competition for power in the State has an effect upon the parties that, for their part, have an effect upon the structure of political opportunity, i.e., parties and institutions mutually affect each other. In democracies which work regularly, disciplined voters arise, as in the European Union, for example. These voters do respond to party activities, although they are increasingly critical of the means whereby parties pursue their ends. 'Belonging' to a party tends to be more a sociological identification with a political tendency, rather than involving formal party affiliation. This suggests a salutary clarification of the boundaries between parties and their environment. The process whereby a party is identified with its leader is an interesting historical phenomenon in the political organization of societies. For example, the Braybrooke's Manuscript (1788) refers to the parties 'of the Crown,' 'faithful to Mr. Pitt,' and 'of Mr. Fox.' Another interesting and more contemporary example is of the emergence of a 'Gaullist' party in France, after 1946. The tradition of having a strong personal leader continues very much alive in Latin America, even in the late twentieth century. This tradition has influenced the social practices of parties in various ways. In Mexico, the Institutional Revolutionary Party—PRI (1911) dominated the Mexican political scene single-handedly until 2000.

With the advance of democracy and of democratic negotiating practices, conducted with a view to making government of contemporary states feasible, all parties (including the new parties that emerged out of the former communist parties of Eastern Europe, and also certain parties in Western Europe) have had to become connected. The difficulty of winning elections based solely upon their different platforms and making their will prevail has, since the 1970s, obliged parties to emphasize their capacity to draw together to form and support coalitions. Finally, all modern parties are obliged to adopt business-like organizational structures or run the risk of failing to fulfill the demands of modern life, in terms of communication, social penetration, and funding.

Evidently, the aim of assuming the mantle of government remains the principal motivation of political parties. The historical trajectory of activities undertaken by political parties is closely associated with an awareness of the structure of political oppor-

tunities within a given political system. Revolutionary organizations that reject existing institutions, social clubs, debating societies, pressure or advocacy groups with independent objectives can be regarded as entities that discreetly play significant political roles without being formally political parties. Formal political parties must, as such, compete to control a political process whose agenda they do not establish by themselves, but which cannot function without their participation. This experience is deeply ingrained in the political parties of the late twentieth century.

3. Unanswered Questions and Issues for Debate

Some important questions remain unanswered. For example, the emergence of political participation—as an alternative to traditional representation in liberal democracies—is often treated both as an essential element for modernization and as its critical consequence. To assume the mantle of government and to perpetuate the values of parliamentary democracy, strong parliamentary institutions are necessary if modern political parties are to perform their roles. This is true even in countries such as the USA—and many others in Africa and Latin-America—in which the presidency is a strong and 'personalized' institution. This applies even in cases where presidents are elected by direct vote and are endowed with special powers, as occurs in France and in Portugal.

Although much is known with respect to the details of the emergence of specific party systems, the capacity to generalize as to the reasons why different types of parties emerge in the ways and forms in which they have done so, remains incipient. There are few works that examine or seek to explain the vast variety of different contexts, and comparative studies among regions with different levels of development are rare. In the 1980s, the political development of multinational regional institutions—which initially had a solely economic focus—such as the European Economic Community, ASEAN, and (in the 1990s) MERCOSUR, has unveiled a whole new field for research into the political life of such institutions, their relations with member states, and the entire theme of supranational integration. From a historical-research perspective, only now are the first comparative studies of the political parties being carried out. This applies not only to research on existing parties in specific countries or groups of countries (as is the case in the European Union), but also with respect to an examination of the historical roots of contemporary political parties.

Not only parties, but also party systems can be analyzed from the institutional standpoint. Both the parties and the party systems of the 1970s were little different from those of the 1920s. With the exception of the ecological movement, the majority of the party groupings, i.e., similar parties, can be presented

according to their similarities. Practically all of the present parties—of the left, of the right, of the center; liberal and revolutionary parties—consolidated themselves in the 1920s, and some much earlier. Political parties are present at the heart of all activities of the state in liberal democracies. However, even under communist regimes the role of the political party is performed in a well-established manner. In the 1990s, however, it could not safely be predicted that political parties would face a future with development and prestige, similar to that they enjoyed in the recent past. At the present time, a new type of political culture is emerging. Political awareness and politics—as subject for discussion—open up a new avenue of research into general participation in political life on the threshold of the twenty-first century. Culture may help a understanding as to why certain social cleavages are successfully transposed by a stable party system, whereas others are not. Political culture and the manner in which it is created is responsible for some significant differences in the traditional organization of states, or of bodies associated to them. Political culture includes not only ideals, such as values, beliefs, attitudes, but also political practices and societal behavior.

There are certain themes in the study of political parties that still require further research from a historical point of view. Politics, with the constrained use of political power, and the politics of containment have been recurrent themes in political science since the 1970s. One of the most important contentions of political activity is the institutional framework of the state. Contemporary political research has made clear the importance of institutional factors in political life. Aside from this new institutional focus, the study of political parties has demonstrated a renewed appreciation of history, of events, of the rules and of political regimes as the active forces of political life. It is perhaps commonplace to state that 'history matters.' The 'frozen cleavages' of Lipset and Rokkan, the development models of communism, fascism and the parliamentary democracy of Moore (1968), the theories of 'critical realignment' of Burnham (1970), are good examples of historical reviews and models. The legacy of history is thus one of the limitations to which institutionalism is subject.

Socio-economic constraints are generally accepted without going into the mythical and overworked concepts that have been served up since the time of Marx. Rapid changes in international finances and economic scenarios have produced intriguing works. The exercise of social power is also constrained by cognitive means, in the use of pure reason (and more specifically, of the practical one). The knowledge society and information society will have to take into consideration non-rational features of political life, and the social and ideological factors that influence the belief systems of the masses (Meny 1989). The final two decades of the twentieth century witnessed a swift

retreat in the positivist distinction between fact and value. Specialists recognized that political agents were also ethical players (Rawls 1993), who have their own values and act in accordance with them, and that occasionally they may be persuaded (by political philosophers, perhaps) to adopt other, better values. Any attempt to divorce facts and values from the mental processes and from the underlying political dynamics, would be doomed to failure. Similarly, political science increasingly seeks to develop studies that take into account the complexity of the structures, processes, and results that it investigates. In order to do this, one must have a theoretical framework within which the history of the processes and the prevailing political philosophy must occupy a space which formally would have drawn opposition from previous generations.

Political Protest and Civil Disobedience

Political protest refers to a multitude of methods used by individuals and groups within a political system to express their dissatisfaction with the status quo. Although protest can be registered through voting, letter writing, campaign contributions, participation

in interest groups and political parties, and other traditional means, the term more commonly refers to those kinds of mass political activism that occur outside of conventional parliamentary channels, such as demonstrations and marches, sit-ins, blockades, labor stoppages, boycotts, and other methods that combine communication and persuasion, direct action, and noncooperation with political, economic, and social institutions.

Much social science research on political protest has concentrated on explaining organized, sustained forms of mass collective action such as social movements. A social movement consists of an array of organizations and individuals who share a common identity and agenda of social and political goals, and who are regarded as a collective entity by other political actors. Social movements typically pursue their goals by mixing protest actions with conventional political strategies such as lobbying, litigation, public education, and electoral mobilization. Discontented groups often resort to direct action when they are denied equal access to conventional means of participation or when such avenues are regarded to be ineffectual or inadequate for registering the intensity of their grievances. Theoretical and empirical studies of political protest have analyzed the emergence of group consciousness and solidarity, the framing of grievances, the role of social networks and community institutions in fostering cooperation, the formation of social movement organizations, the psychological make-up and motivations of individuals who engage in protest, the evolution of strategy and tactics in social movements, the influence of changing political opportunities on the course of a movement, and the efficacy of violent and nonviolent methods of protest.

Unlike protest marches, picketing, and other kinds of legal protest, civil disobedience is a particular form of political protest that is marked by the deliberate violation of the law for social purposes. Civil disobedience is not merely conscious law breaking, but rather it is law breaking with the express goal of correcting a perceived injustice. Action that would now be regarded as civil disobedience has been a regular feature of social protest throughout history even though the term itself, attributed to an 1849 essay by Henry David Thoreau, is a relatively recent creation.

The act of civil disobedience is fundamentally an act of political protest because the noncompliance is intended to convey a message of discontent to the government, media, and public. The acts of defiance are typically overt, public acts aimed at marshaling collective opposition to unjust or unconstitutional laws and policies. Civil disobedience is not restricted to protests over laws and public policies, but is also employed against the practices of private institutions such as corporations and universities, as occurred for example in the divestment campaign on American university campuses in the early 1980s, which pres-

sured universities (both private and public) to cut their financial ties to companies that conducted business in South Africa in an effort to bring an end to apartheid.

1. *Forms of Civil Disobedience*

Within this broad conceptualization, civil disobedience can emanate from different motivations and assume a number of forms. Civil disobedience can be active or passive, direct or indirect. An individual can either actively commit a prohibited act or passively refuse to conform to a prescribed action. For example, an anti-war protester may destroy his draft card or, alternatively, he may refuse to register for the draft. Both actions qualify as civil disobedience because the protester intentionally violates the law as an expression of his opposition to the war, knowing the legal consequences of his actions. Thoreau himself engaged in a form of passive civil disobedience when he chose to register his opposition to the institution of slavery by refusing to pay the Massachusetts state poll tax.

Civil disobedients often break laws that are unrelated to the law or policy they are protesting. For example, peace activists who disrupt operations at defense laboratories are not protesting laws against trespassing, but are using civil disobedience to dramatize their opposition to nuclear weapons. Supreme Court Justice Abe Fortas objected to the indirect use of civil disobedience on the grounds that it would give licence to people to break any law they wished in the service of a goal that they perceived to be more noble. But few scholars have subscribed to this restriction because, on many issues, there is no feasible direct method to engage in civil disobedience. There may, for example, be no direct method by which activists can use civil disobedience to protest the government's foreign policy or its failure to pass laws addressing issues of inequality and poverty.

A narrower definition of civil disobedience would exclude illegal actions taken by individuals who do not accept the constitutionality of the law they are violating. By this definition, an activist who breaks the law by setting fire to the American flag is *not* engaging in civil disobedience if he believes that his actions are protected by the First Amendment, but a flag burner who accepts the constitutionality of a law against flag burning *is* engaging in civil disobedience. For the purpose of defining civil disobedience, however, it may be unnecessary to make such a distinction based on the activist's frame of mind, because the crucial assumption underlying civil disobedience is that the law being broken is generally viewed to be valid by those in authority, so the actions of the civil disobedient are generally viewed to be illegal. Therefore, both flag burners are committing civil disobedience in the sense that they are breaking what is generally understood to be the law in an effort to change it, and the main

difference between them is whether they are appealing to the courts or to the executive and legislature for remedial action.

Although Thoreau assumed that 'civil' protest would be conducted in an orderly and peaceful fashion, scholars disagree over whether civil disobedience is necessarily nonviolent by definition. Some commentators insist that civil disobedience must be nonviolent or else it cannot be distinguished from rebellion, rioting, and other types of violent direct action. The two individuals who are most responsible for the association of civil disobedience with nonviolence are Mohandas Gandhi (see e.g., Gandhi 1961) and Martin Luther King, Jr. (see e.g., King 1964). Indeed, contemporary understandings of civil disobedience have been substantially shaped by the mass campaigns for equal rights organized by Gandhi in South Africa and India and by King in the United States.

Both Gandhi and King possessed the extraordinary combination of political 'savvy' and unwavering moral and spiritual commitment to the philosophy of non-violence. In his teachings, Gandhi insisted that civil disobedients must scrupulously obey laws that are unrelated to the target of the disobedience campaign and submit themselves to the punishment of the state for breaking a law they believed to be unjust. Civil disobedients do not flee or resist arrest, for in accepting penalties for their actions, they bring attention to the injustice they wish to correct and arouse the sense of injustice in others. Gandhi's concept of *satyagraha* or 'truth-force' refers to the moral conversion of one's adversary. In their quiet suffering, civil disobedients demonstrate their honor and integrity and their capacity to differentiate between just and unjust laws.

King regarded Gandhi as his mentor and shared his belief that the purpose of civil disobedience is to persuade the state and its citizens that an existing law violates a higher moral principle. Violence, therefore, must be avoided because it potentially undermines the communicative intent of civil disobedience. Adherence to nonviolence, on the other hand, indicates that one bears no malice or hatred for one's opponent. Like Gandhi, King believed that the ultimate goal of a campaign of nonviolent protest is to achieve a new moral understanding with one's opponents. Nonviolent resistance works, not by defeating and humiliating the opponent, but by winning the opponent's empathy and friendship.

2. *Justification of Civil Disobedience*

In addition to disagreements over what kinds of actions qualify as civil disobedience, there is debate over the circumstances in which civil disobedience can be justified. Civil disobedience raises issues about the nature of authority, obligation, and consent in society.

The practice originates from the idea that a person must be true to his conscience and that he is not obligated to submit to the laws or commands of the state when they violate his conception of justice. Civil disobedience therefore assumes both a right to individual freedom and the existence of a natural law that takes precedence over civil law.

Philosophical discussions of the justification for civil disobedience generally fall between legal absolutism and moral individualism. In justifying civil disobedience, it is necessary to accept that there are standards against which governments can be evaluated, and that citizens have the right to exercise such judgments. Few would argue that the law must always be obeyed; and similarly, few would contend that obeying the law is entirely a matter of individual judgment about what is morally right and wrong. One extreme supports despotic governments, while the other suggests anarchy. Whether civil disobedience undermines respect for the law is a matter for empirical inquiry. The penalties for breaking the law are usually sufficiently great that it is unlikely that people will engage in civil disobedience unless they are intensely motivated by a sense of injustice.

But do the moral criteria for civil disobedience reside only in conscience? Or are there intersubjective criteria that permit rational assessment of the morality of a law or policy? Without such objective criteria, we are in danger of every individual invoking arbitrary subjective criteria for disobeying different laws. We invite moral anarchy unless there are some agreed-upon criteria for evaluating whether a law or policy is unjust or immoral. At a minimum, the civil disobedient must be able to demonstrate that the law or policy violates principles of welfare, equality, or justice. The law or policy must be shown either to do more harm than good, to distribute benefits unequally, or to operate without the consent of certain groups. Legal methods of petition to change the law must be tried first, and the activists must grant the same rights of civil disobedience to others who believe that another law is unjust. Some would argue that the civil disobedient must also have a reasonable chance of overturning the law. According to these normative criteria, only those who believe in reciprocity and adhere to a sophisticated set of general rules of political conduct can rightfully be said to be engaged in justifiable acts of civil disobedience.

3. Effectiveness of Civil Disobedience

What are the mechanisms that make civil disobedience effective in practice? Gandhi recognized that civil disobedience could not be effectively employed for a global, distant goal such as national independence, but had to be used for specific, local issues on which the opposition had the power to compromise and make concessions. True to form, civil disobedience

campaigns led by Gandhi were most successfully applied in local disputes concerning such issues as land revenue assessments and mill workers' wages, in which small numbers of close knit, disciplined protesters were united by their interest in the issue and capable of conforming to a norm of nonviolence.

In theory, if civil disobedience is to work through persuasion, then the protesters must invoke principles or values that are shared by a large proportion of the population. In practice, however, the preferences that are converted are more likely to be those of the spectators to the conflict than those of the adversaries of the protesters. A small number of disobedients can seldom, by their actions alone, render a law inoperative, but they may be able to disrupt the social order sufficiently to draw public attention to their grievances. Although Gandhi believed that the suffering of protesters in jail would apply pressure on the government, he also recognized that the state's use of violence would serve the interests of the protesters by influencing third parties who were witnesses to the conflict. British repression of Indian dissenters confirmed to onlookers that the British ruled by force and not through the consent of the Indian population. Similarly, in the course of the civil rights movement, it was the contrast between the nonviolent protesters and the violent response of the southern police that helped to galvanize public opinion and mobilize federal government intervention in support of racial equality.

In response to a campaign of civil disobedience, the defenders of the status quo must decide whether to offer concessions to the protesters or to escalate the conflict by using force or summoning the power of the state. It is the threat of continued disruption of the normal operations of business and government that 'persuades' the targets of the protest to negotiate with the activists and to yield to their demands. During the civil rights movement, the early success of direct action campaigns in some southern cities aimed at forcing businesses to provide equal treatment to blacks made it easier for similar campaigns to succeed elsewhere because businesses foresaw the normal course of these protests and sought to cut their losses sooner rather than later. There is little evidence that the attitudes of white southerners were converted by direct action; indeed, the attitudes of many were hardened by the confrontational tactics of the movement.

Civil disobedience thus rarely works through persuasion and attitude change alone, but also depends significantly on pressure and coercion. Actions that are aimed at transforming preferences may leave attitudes unchanged, but still be effective at promoting social change because the opponents are pragmatic enough to calculate that they are better off making concessions than dealing with the disorder created by continual protests. Civil disobedience in this respect resembles a pragmatic tactic within a repertoire of potential strategies that are available to a protest

group rather than an option that is resorted to only when the conventional channels of participation have been exhausted.

Political Representation

Political representation is a process in which one individual or group (the representative) acts on behalf of other individuals or groups (the represented) in making or influencing authoritative decisions, policies, or laws for a polity. The *representative* may hold any of a variety of offices (executive, administrator, ambassador, judge, lobbyist, party leader) and may even be a collectivity (a governmental agency or political organization), but the modern concept most commonly refers to the role of a legislator. Similarly, the *represented* may be almost any individual or group, but is usually understood to be those individuals

or groups, typically called constituents, who are entitled to select the legislators. Some important work examines the relationship between legislative and other forms of representation (Stimson et al. 1995), but most has focused on one or more of three dimensions of legislative representation: relationships between the representatives and the represented; among the represented; and among the representatives.

1. Origins

Political representation in its modern form evolved over a long period from about the fourteenth to the seventeenth century as kings and nobles convened assemblies to collect revenue and conduct wars. The bodies, usually composed of members from various estates or classes, gradually assumed independent power, and came to be thought of as representative institutions. In the debates during the Civil War period in England, defenders of Parliament connected the idea of representation clearly to the idea of consent of the governed. In 1651, the members of Parliament were for the first time referred to as 'representatives' (Pitkin 1967; also see Larsen 1966, Manin 1997).

By the eighteenth century the link between representation and popular rule had become sufficiently close that Baron de Montesquieu could praise the English constitution for establishing a republic in a large state by giving the people a voice through their representatives in the legislature. Defending the new American constitution, James Madison argued that representation not only made republics possible in large territories, but also mitigated their dangers, especially the influence of factions (Wood 1972). Representative government was not yet representative democracy, because much of the adult population could serve as neither representatives nor the (actually) represented. It was John Stuart Mill who in the late nineteenth century provided the framework for the theoretical synthesis that combined the traditional virtues of representation and the emerging ideals of democracy (Thompson 1976).

2. Legislators and Constituents

At least three aspects of the role of the representative should be distinguished. The first concerns the *mode* of representation—how constituents are represented. It expresses a continuum in which the limits are specified by the traditional contrast between trustee and delegate. The second aspect is the *locus* of representation—which citizens are represented. Among the possibilities are the nation as a whole, a political party, the state or district, and various groups and organizations. The district is more complex than is often assumed. For example, many legislators are bound to

local elites and national interest groups whose interests may diverge from those of other groups in the district, and some legislators see themselves as representatives of under-represented groups, such as blacks and women. The third aspect refers to variation in the *content* of representation—the types of issues with which a representative deals. A legislator may act, for example, as a delegate of the district majority on welfare issues, as a delegate of the national majority on civil rights, but as a trustee of both on foreign policy.

Given this complexity, it is not surprising that the most plausible normative theories refuse to privilege any one of these roles; what each representative should do depends on the nature of the particular issues, what other representatives are doing, and the biases in the political system. Similarly, when political scientists use the simpler conceptions of role, they rarely find any general correspondence between a representative's conception of role and actual behavior. The most robust accounts of legislators' conceptions posit decision trees with multiple branches and a complex set of factors (Kingdon 1981, p. 244).

On any account of the role of the representative, there is the further question of how representatives can be held accountable. The methods vary, depending on the political system, and on assumptions about what political accountability means. The form of accountability that has received the most attention is the electoral connection between representatives and constituents. Much of the empirical literature on the linkages between the policy preferences of constituents and legislators has been influenced by the classic model presented by Miller and Stokes (1963), which highlights four major variables: legislators' personal attitudes, roll call votes, constituency opinion, and legislators' perceptions of constituency attitudes. The vast literature on this linkage shows that the conditions under which each has an effect are quite variable. It is now recognized that roll call votes fail to capture much important legislative activity, and do not always reflect the actual views of legislators. A still unresolved puzzle is why individual representatives (even in safe seats) exert so much effort to please their constituents and collectively act in ways that track mass public opinion even while the evidence indicates that constituents and the mass public are not well informed about what their representatives believe and do (see Uslander 1986).

A related trend is the growing importance of constituent service (a practice in which representatives help constituents and groups in dealing with their particular problems with government, such as immigration and state and federal grants). The electoral effect of constituency service remains a subject of some controversy among political scientists, but there is agreement that the practice is now more prevalent (Cain et al. 1987). Another effect that has provoked important work is pecuniary. Since at least the eighteenth century students of legislatures have stud-

ied and often criticized the influence of money and wealth on the behavior of representatives. Political scientists have not generally found strong correlations between contributions and roll call votes on broad policy areas even in the US system. But they have found that money may buy access—marginal time, energy, and legislative support.

3. *Constituents*

All legislative representation is group representation. Even in societies governed by individualist norms such as 'one person-one vote,' the definition of the constituency implicitly identifies a group or groups that are to be represented.

Party-based representation is associated with a modified form of proportional representation in which the share of votes that each party receives determines how many of the candidates from its lists win seats in the legislature. The system usually produces multiple parties, and thus gives voters a wide range of ways to express the interests they wish to have represented. However, it gives voters less choice about which particular candidate should serve as their representative, and in this respect differs significantly from the purer form of proportional representation, the system of the single-transferable vote, in which every successful candidate has a unanimous constituency.

Geographical representation usually relies on single-member plurality systems, and tends to produce only two or three parties. The parties represent broader interests than do the parties in modified proportional systems, but if party discipline is weak, as in the USA, the geographical basis encourages the representation of particular regional and other interests. No single type representational system has been shown to be superior in all or most circumstances, and the choice generally involves a trade-off: the wider the range of interests represented in the legislature, the less the likelihood that any particular interest will be fully represented in legislation actually adopted. The most useful scholarship on these and related questions has been comparative (Klingemann et al. 1994, Converse and Pierce 1986).

In systems such as the USA, where many of the districts that define constituencies do not follow any natural geographical boundaries, the issues of how the districts are drawn and whether they produce fair representation have stimulated important normative and empirical research. Political scientists have examined the partisan and incumbency biases in various redistricting schemes. Some of the most interesting theoretical work in this area combines empirical and normative approaches. One study has developed more analytically robust concepts of 'fair representation' in electoral systems (Beitz 1989), and another has revived the theory of descriptive representation for 'marginalized groups' (Williams 1998).

4. Legislators

Much of the research on this element of representation has dealt with the tension between individual and collective behavior in the legislature. In the USA a phenomenon that has received considerable attention is what is sometimes called legislative individualism, the tendency of legislators to act in ways that promote their own re-election without regard to the effect on collective product of the legislature. Such individualism has been shown to produce a pattern of 'particularized benefits' (dams in certain regions, tariffs for local industries, and military bases in the district) and the neglect of more general public benefits (such as education, health, and the environment). The explanations for these outcomes vary, but they are generally structural, locating the problem in the incentives of the system, rather than in the character of legislators. They generally assume that, given the structure of the political system, individually rational behavior by legislators produces collectively suboptimal outcomes in the legislature.

If all legislators are pure individualists seeking only particularized benefits for their own constituents, how (under conditions of majority rule and weak parties) can the legislature adopt any legislation at all, even the pork barrel kind? This puzzle has been extensively studied by formal theorists, who propose various solutions for achieving policy equilibria in legislative institutions. One of the most plausible relies on a committee system to set an agenda and limit the scope of conflict. But shared interests and cross-cutting cleavages would still be necessary in any actual system. These are more likely to exist or to arise in legislatures that encourage or at least permit representatives to change their positions through interaction with their colleagues. This is one of the advantages of deliberative theories of legislative representation, which allow for changes in the preferences of both representatives and the represented over time (Gutmann and Thompson 1996, Chap. 4).

D. F. Thompson

Political Science: Overview

Political Science is an academic discipline that has been entrenched in university curriculums for about a hundred years. It takes as its subject matter government and politics very broadly defined, meaning the study (in whatever setting) of outcomes deemed important by participants or observers. This means that there is politics, and therefore in principle political science, concerned with, *inter alia*, organized crime, organized sports, organized religion (Reese), business firms (Bauer et al. 1963), family life, and markets (Dahl and Lindblom 1953). Most commonly political scientists study social patterns and practices associated with the apparatus of the state, identified by Max Weber as an institutional complex located within a specific territory that monopolizes the legitimate use of force.

One formula describing the scope of the field is contained in the full title of one of Harold Lasswell's path-breaking books: *Politics: Who Gets What When How*. This definition, by focusing on what people 'get,' leaves uncertain the demarcation between political science and economics, and may lead to the impermissible inference that answers to the question 'who benefits' are by definition the same as answers to the question 'who governs.' Perhaps a more useful des-

cription of the scope of the discipline is David Easton's formulation of politics as 'the authoritative allocation of values' in society, entailing the study of authority and its bases, allocation and its modes, and the shaping and sharing of values. Political scientists adopt many different approaches to the study of politics, and so it may be helpful to contrast political science, which is a discipline whose practitioners are united by very little other than a focus on a population of dependent variables or effects of human intention or organization or action with, e.g., sociology or psychology, which are unified around a preferred set of independent variables or causes of varied social and personal outcomes. This is not to say that political scientists do not write about causes as well as effects; rather, when they do so, they borrow freely from other disciplines. There are no psychological or sociological mechanisms that are the monopoly of political science. What is distinctive to political science is what it is about: politics. Political science draws on and elaborates ideas from other disciplines in seeking to account for, or explain, or understand political life. This helps us understand why no clear-cut mainstream tradition exists in political science, rather a number of different traditions of inquiry, organized in part around the differing scale and character of different topics within the field, of which I shall mention several.

Political scientists draw on several branches of psychology in attempting to understand attitude formation and the preferences of citizens and individual voters, as well as the choices of leaders. The development of sophisticated survey instruments for the purpose of understanding individual attitudes and opinions has taken place almost wholly outside political science, but political scientists have been quite successful in adapting these tools to the tasks of understanding how individuals think about political outcomes, make voting choices, and form views of their political world (Converse 1987, Zaller 1992). Social psychology and the social psychological branch of cognitive science have also framed and explored principles of human behavior (some of which are called 'heuristics') that shape political scientists' explanations of political outcomes (Tversky and Kahneman 1974, Abelson et al. 1968, Simon 1957). Finally, the multifaceted Freudian and neo-Freudian traditions of inquiry have had an impact on the study of the behavior both of masses and elites (Greenstein 1969, George and George 1956).

A second focus of research for political science has been the study of social organizations, groups, and classes, in which mainstream sociology has provided intellectual inspiration. In some cases, despite the restricted domain of political scientists' interests, political scientists have entered into protracted and serious dialogue with sociological students of such topics as organizational design and reform, community power, and social capital (Wilensky 1967, Polsby 1963, Putnam et al. 1993).

On a still broader scale, political scientists study institutions as large and consequential as nation-states and their constituent elements: executives, legislatures, courts, parties, elections, interest groups, drawing on a great many specialized studies by historians, legal scholars, and journalists as well as other social scientists (Greenstein and Polsby 1975).

Relations among nation-states is a fourth domain in which political scientists work, exploring questions like the extent to which inter-state cooperation on small or less contentious matters such as the regulation of financial markets or trade increases the probability of harmony on larger matters touching national security interests and forestalls hostility (Haas 1968, Deutsch et al. 1957).

In the study of international affairs (as is also the case in other domains) we may note a significant influence on the agendas of political scientists, namely the preoccupations of politicians who are themselves the objects of study. Just as diplomats historically have sought to find a balance of power among nation-states, students of international affairs have concerned themselves with issues of international political stability, the formation of security communities, and the causes of war (Waltz 1959, Van Evera 1999). This illustrates the fact that the intellectual agendas of political scientists are made in part from political events and not only from problems posed by the ongoing literature of political science.

A fifth focus for political scientists has been the history of ideas about social and political organization, sometimes studied through the elucidation of great books in the heritage primarily of Western Civilization, sometimes through the examination of prescriptions about social organization and the textual or empirical study of prerequisites of their fulfilment (Skinner 1978, Berlin 1969, Wolin 1960, Dahl 1956). Thus a political scientist may be a historian of ideas, or a philosopher, or draw inspiration from those disciplines.

As a professional discipline organized into the curriculums of the world's universities, Political Science is, like the other social studies, only about a century old. Systematic political study, to be sure, is as old as the Greek philosophers of the fourth century BC, notably Plato and Aristotle. The oldest University chair in the subject is at the University of Uppsala which in 1622 established the Johan Skytte chair of Eloquence and Government, helpfully mentioning one of the classic disciplines (rhetoric; moral philosophy and law are two others) from which late nineteenth century political science emerged as a separate subject offered on a regular basis in the newly professionalizing universities of Europe and, especially, North America.

The editors of a new British journal of politics and international relations estimate that today about 85 percent of all the political science being studied worldwide is located in the USA. Where the discipline

flourishes elsewhere it is more likely to be limited to studies in public law or philosophy and to lack the autonomous ability to sponsor the discovery and pursuit of its own program of study as has been possible for political scientists in the US, at least since the formation of the American Political Science Association in 1903. The Association now has about 15000 members, the largest aggregation of political scientists in the world. It sponsors an annual meeting and two journals, one (*American Political Science Review*) scholarly and one (*Political Science*) professional (Somit and Tanenhaus 1964).

Like other social sciences, the pursuit of disinterested inquiry into political life requires a political atmosphere that tolerates disinterested inquiry. Without this atmosphere political science is suffocated. It can be no accident that contemporary political science is primarily to be found in those nations most advanced in their incorporation of the values of the Enlightenment, which underwrite academic freedoms.

Political science as knowledge can be distinguished from political lore or political news primarily by reference to the social organization that produces, conserves, and criticizes it. Political news is the property of a nation's political class and it is spread by journalists or chains of gossip. Political lore consists of precepts codifying and sustaining the practices of political practitioners. Political science may incorporate content from either of these bodies of knowledge but the social organization that certifies knowledge as political science at any given time and sponsors criticism and new exploration in the field is the congeries of academic departments variously called political science, political studies, politics, or government in colleges and universities worldwide. These departments promote inquiry and conserve knowledge by educating undergraduates, training graduate students, producing texts, announcing discoveries, criticizing work, and maintaining a community of mutually attentive scholars (or, more accurately, a set of sub-communities) who participate in a loosely articulated status system, recognize common intellectual ancestors, promote fads, award prizes, and otherwise establish and enforce social boundaries.

In the USA alone, some 125 departments grant the Ph.D. in political science, and roughly five times that number of colleges offer undergraduate majors in the topic. Substantial numbers of universities in Canada, Europe, India, Japan, and Australia do likewise, but graduate studies in political science in other places, where they exist, are more likely to be subsumed under law, history, or philosophy as, for example is the case at Cambridge University in the UK.

The incorporation of the term 'science' in the disciplinary label political science has from time to time provoked controversy on the ground that no inquiry into the behavior of sentient beings can possibly approximate the predictive capacities of

physics or chemistry. This charge is made against all the human sciences but because of the discipline's eighteenth century—largely pre-scientific—name it is sometimes assumed that in the case of political science ambitious claims for prediction or control of human behavior are being advanced. There are several standard answers: (a) That the term 'science' in historical context makes reference not to some social analogue to atomic physics but simply to 'knowledge'; (b) that the application of political knowledge was thought to be desirable in the creation of new constitutions, notably the US Constitution of 1787; (c) that political knowledge takes many forms requiring only the recognition of patterns of social behavior. This facilitates the codification for example, of comparative information about analogous activities (voting, budget-making, social/political protest) in different political systems; (d) that the goals of prediction and control as a means of understanding social behavior are best understood as applying not to historical events but rather to variables abstracted from events which may lend themselves to historical interpretation; (e) and that social patterns and other manifestations of human behavior can be more competently observed and explained by reference to standards and canons of inquiry (especially recourse to evidence and codification of findings into propositions of some generality) associated with more scientifically advanced disciplines.

Political scientists themselves vary in the extent to which they pay explicit attention to rules and methods of scientific inquiry. As the twentieth century advanced, more and more did so, creating among other things, sub-fields devoted to methodology—mainly adapting to political materials the methods of survey research and econometrics—and to specialties sometimes called rational choice or formal or positive theory—adaptation of the economist's propensity to describe simplified versions of human activity by means of mathematical models. (Solow 1997).

Earlier, with growing influence from the 1950's onward, a so-called 'behavioral revolution' took place in which political scientists in many sub-fields of the discipline sought to introduce into their work the rigorous intellectual habits of the other social sciences with their concern for evidence and for structuring their inquiries so as to alert investigators to unexpected or generally applicable outcomes—e.g. by referring to null hypotheses, or by adhering to falsificationist standards of proof. This has facilitated storage and retrieval of information and led to the cumulation of findings in several branches of the discipline. While these practices have spread in the last half-century, they have not wholly supplanted more traditional modes of inquiry such as the close reading of classic texts or the clarification—or at least discussion—of key concepts, such as 'democracy' or 'power' or 'coalition' or 'party.' (Lasswell and Kaplan 1950, Sartori 1984).

Political Sociology

Political sociology is a border field between political science and sociology, and the term encompasses the overlap between these two neighboring disciplines. It denotes the analysis of the inter-relationship between the social and the political, social structures and political institutions, between the society and the state. There is no stable consensus of what counts as political sociology in contrast to sociology and political science proper. There have been great variations over time in the popularity of political sociology and in the tendencies to emphasize it as a genuine field of its own. Nevertheless a common element is that political sociology is related to the distinction between the social and the political.

1. Historical Roots of Political Sociology

The historical development of political sociology can be roughly outlined by emphasizing three periods of special importance.

(a) The birth of political sociology can be dated to the mid-nineteenth century, when the founding fathers of social science began to conceive of the social and political, the society and the state as separate entities, and to analyze their relationships (Runciman 1963, pp. 22–42, Pizzorno 1971, pp. 7–18). This type of inquiry had its intellectual roots in the writings of earlier philosophers about the state and the social life, however, as a broad and joint interest of an academic community, political sociology emerged in the schol-

arship of the nineteenth-century fathers of social science.

(b) The post-World War II studies of the conditions for and the citizen activities in political democracies with a special focus on parliamentary elections conceived them as expressions of the political competition between different social groups. The joint focus on the prerequisites of democracy and voting patterns proliferated during the 1950s and 1960s, receiving institutionalized expression in the work and activities of the Committee of Political Sociology, founded in 1959 with Seymour Martin Lipset as chairman and Stein Rokkan as secretary and functioning under the auspices of both the ISA (International Sociological Association) and the IPSA (International Political Science Association) (Rokkan 1970, pp. 1–20).

(c) The late twentieth-century studies of nation and state building placed a special emphasis on great political transformations and breakdowns of regimes. This type of inquiry received a strong impetus from the renaissance of Marxist thinking in the 1960s and 1970s, but it was not restricted to social scientists with a leftist orientation (Linz and Stepan 1978, Skocpol 1979).

1.1 The Establishment of a Distinction between Society and State

In a great number of their texts, most of the path-breaking social science theoreticians of the second half of the nineteenth century and the early twentieth century analyzed the relationships between the social and the political. One of the first thinkers to delineate an empirical political sociology was Karl Marx in his systematic insistence on seeing politics as an expression of conflicts between different social classes. His theorizing had a factual historical background in the emergence of the bourgeoisie and the industrial working class as distinct and dominant social groups (Pizzorno 1971, pp. 7–9).

Max Weber on his part wrote many of his works as rejoinders to Marx, but even apart from his counterclaims against Marx, there is in Weber's writings continuous analyses of the social institutions and the types of authority existing in modern society (Runciman 1963, pp. 53–7).

Among the great founders of sociology Émile Durkheim is not normally thought of as a scholar of politics, but his preoccupation with order, social integration, and social solidarity had considerable implications for the analysis of the relationship between society and politics.

Vilfredo Pareto was a pioneer both in econometrics and in the sociological study of elites. His ability to relate the circulation of elites to large-scale social and political changes makes him one of the founding scholars of political sociology.

Karl Marx, Max Weber, Émile Durkheim, and Vilfredo Pareto were not primarily political sociologists, but instead more generally the great founding fathers of social science theory building. There are, however, some nineteenth-century scholars who can be labeled as specialists in political sociology. They are not unknown as scholars in history and in the study of politics, but their fame rests basically on the fact that they were important creators of the tradition of political sociology with its focus on the relationship between society and politics. Among them Lorenz von Stein, Alexis de Tocqueville, Mosei Ostrogorski, and Robert Michels deserve special mention.

Lorenz von Stein (1815–90) was a forerunner of Marxism in the sense that he explicitly emphasized how material and social conditions mould political development. His *Geschichte der sozialen Bewegung in Frankreich* (1850) contains not only a history of the French Revolution but also analyses of the importance of the property distributions and educational opportunities for political activities, and of the phenomena of class struggles and sudden outbursts of social change. It has been emphasized how some of Karl Marx's ideas were influenced by the writings of von Stein.

Alexis de Tocqueville (1805–1859) descended from an ancient and distinguished noble French family. His visit to the United States in 1831–2, which was of decisive importance for his scholarship, resulted in a study of American democracy published in two volumes *De la démocratie en Amérique* (1835, 1840). Although the work made him well known, his great scholarly fame was established only after the Second World War and to a considerable degree by the then growing political sociology. Especially the English translations of his works, *Democracy in America* (1945) and his study of the French revolution, *The Old Regime and the Revolution* (1955; originally published in French in 1856), became standard works for political sociologists. His great contribution was that he specified the conditions for pluralism and democratic systems. He argued that social cleavages and competition between social groups and strata are necessary conditions for consensus in industrially developed societies. He emphasized voluntary associations and active, partially autonomous local communities as crucial in creating and sustaining a plural democracy. In the texts of political sociology, de Tocqueville has often been contrasted to Marx. While Karl Marx envisaged conflicts and social cleavages as one-sidedly destructive, de Tocqueville emphasized their importance for obtaining consensus in well-functioning democracies (Lipset 1960, pp. 4–9).

Although Mosei Ostrogorski (1854–1919) was born in Tsarist Russia and died in the Soviet Union, during important parts of his life he worked in Paris and London. Early in his career he published studies of the suffrage demands of the women's movement, but his main work was a critique of party democracy in

Democracy and the Organization of Political Parties (1902). Although it was an empirical study of the political party organizations in Britain and the United States, its main theme was that the mechanical and massive organization of political life into bureaucratized political parties, aimed at manipulating individuals and masses, was harmful for real democracy.

As was Ostrogorski, Robert Michels (1876–1936) was a critic of the emerging party bureaucracies in modern states. Through his education and activities Michels had background liaisons with Germany, France, and Italy. Politically he started as a socialist with a syndicalist orientation but developed later profascist opinions. He took Italian citizenship in 1913, and although he was active as a professor and scholar in many countries he regarded Italy as his home country. His major work *Zur Soziologie des Parteiwesens in der modernen Demokratie* (1911) is considered a classic in political sociology. It treats many of its central themes, including the theory of elites, political movements on the left, processes of bureaucratization, and the gap between democratic theory and practice. His central thesis, known under the name of *the iron law of oligarchy*, is that organization necessarily leads to oligarchy, or as Michels summarized it, ‘it is organization which gives birth to the dominion of the elected over the electors, of the mandataries over the mandators, of the delegates over the delegators. Who says organization, says oligarchy.’ Despite Michel’s pessimism and one-sidedness, his work and the iron law of oligarchy has inspired a great number of studies of political and other civic organizations.

1.2 The Institutionalization of Political Sociology after World War II

The period between World War I and II, and especially the 1930s, were poor as regards studies in political sociology. The European political scene was turbulent, little support was given for studies in the social sciences, and in the 1930s the Nazi, Fascist, and Communist regimes ended most social science research in a number of countries. During the period between the world wars there were nevertheless some pathbreaking studies of voting and electoral behavior. Already before World War I André Siegfried had introduced the analysis of geographical variations in electoral behavior by studying voting patterns in French constituencies. A summary of his results was published in *Tableau des partis politiques en France* (1930). His central conclusion was that electoral behavior was steered by stable, deep-seated, regional traditions. After Siegfried the concept of *political traditions* became central in descriptions of voting patterns. Another innovator was the German-American Rudolf Heberle, who had started his career with an analysis of the tendencies to radicalization of the Swedish labor movement. His leading

work *From Democracy to Nazism* (1945) about the appeal of Nazism to the rural population in the German province of Schleswig Holstein was published when he already had settled as professor in Baton Rouge, Louisiana, USA.

Large-scale studies of voting behavior, however, were not undertaken until after World War II, and this subject became a leading problem area of political sociology during the first postwar decades. It had a background in the postwar situation, as great hopes were attached to the possibility of building a better world with the aid of social science and research. Studies of the prerequisites of democracy became important, and parliamentary elections were seen as the major mechanism for establishing and securing democratic rule. Studies of the social background of political behavior represented an almost empty space between political science and sociology. Political scientists had been mainly preoccupied with constitutional problems and methods of steering the states, whereas sociologists had focused their interest on studies of social structure and behavior in social groups. Political sociology moved into a vacuum, and it became soon both an important field of research and an activity of interest to the general public. Although the study of electoral behavior later became mainly a field within political science, the first pathbreaking studies were made by sociologists. Theoretically fruitful conceptions and hypotheses, such as the tendency of cross-pressures to lead to political passivity, were developed at the Bureau of Applied Social Research at Columbia University under the inspiration and leadership of Paul Lazarsfeld (Lazarsfeld et al. 1944).

It was, however, through the founding of the Committee of Political Sociology at the International Sociological Association’s Fourth World Congress in Stresa in September 1959 that political sociology became an established and institutionalized field of research. It led to a new kind of cooperation between political scientists and sociologists, and the committee also became a research committee of the International Political Science Association. The Committee’s first chairman, Seymour Martin Lipset, had already published several innovative books in political sociology, and its first secretary, Stein Rokkan, had started to develop means for comparative, cross-national research. The year 1959 represented in many senses an important mark in the development of political sociology. In 1959 Lipset obtained the copyright for his *Political Man. The Social Bases of Politics* (1960), which became the leading text of the period of birth of an institutionalized political sociology.

The references and data sources in Lipset’s book reflect the fact that at the end of the 1950s political sociology had become a small industry with young researchers all over the industrially developed world digging up data about the social bases of politics. The work of the Committee led to new developments. This is evident by a comparison of Lipset’s *Political Man*

and the first comprehensive book produced by co-operation within the Committee, namely Lipset's and Rokkan's *Party Systems and Voter Alignments: Cross-National Perspectives* (1967). It contains a lengthy and theoretical introduction by Lipset and Rokkan, and chapters about individual countries, including the United States, Canada, Great Britain, Australia, New Zealand, France, Italy, Spain, West Germany, Finland, Norway, Japan, Brazil, and some West African states. Both the theoretical introduction, with its application of Talcott Parson's A-G-I-L scheme, and most of the country chapters, reflect attempts to combine a structural and institutional approach and to study both the social bases of politics and the effects of politics on social structures. One of the members of the Committee, Giovanni Sartori, described the change in orientation in a paper entitled *From the Sociology of Politics to Political Sociology* (1969). Political sociology had ceased to be a subfield of sociology and had become a genuine border field of its own.

Studies of voting patterns were by no means the only ones conducted and presented at the conferences of the Committee and by its members. The first part of Lipset's book on the *Political Man* consists of an analysis of the prerequisites of the democratic order. At the turn of 1950s and 1960s several studies analyzed the conditions of democracy. In addition to the formal criteria of democracy such as popular representation and individual freedoms, political sociologists were keen to stress some factual social conditions as prerequisites of a democratic order. Of particular importance were *effectiveness*, the government's capacity to implement policy, *efficacy*, peoples' subjective feelings of being important for the politicians, and *legitimacy*, beliefs that the existing political institutions are appropriate and lawful. Some of the studies were particularly focused on breakdowns of democracy and the rise and appeal of Fascism and Communism, such as Raymond Aron's *L'Opium des intellectuels* (1955) and William Kornhauser's *The Politics of Mass Society* (1959). Democracy was studied from many angles, such as in the study done by Lipset and his associates on the conditions for democracy in labor unions, Robert Dahl's studies of democracy on the local community level, and Ralf Dahrendorf's analyses of the conditions of conflict regulation in industrial society.

Even if studies of and data about voting and electoral behavior formed a central point of departure for the political sociologists in the 1950s and 1960s, their aim was more general than to give information about how people behave during elections. The basic interest was in studying conditions for democracy, breakdowns of regimes, nation and state building, and master processes of societal and political change. From the 1970s onward the electoral studies became methodologically more sophisticated at the same time as they increasingly became a preoccupation of spec-

ialists of political issues and mass media effects within the field of political science. Initially such studies had a center at the University of Michigan under the leadership of Angus Campbell.

1.3 The Re-entry of the State and its Transformations

The disappearance of electoral studies from the central agenda of political sociology was not an isolated phenomenon. From the beginning of the 1970s many of the original topics of political sociology lost much of their popularity. One of the reasons was that the student rebellions and leftist radicalism in the 1960s and 1970s had severely criticized the agenda of the prevailing political sociology. Another reason was that some fields of research had become routine and were incorporated into either sociology or political science.

Despite a decline of the distinctiveness of political sociology, some research themes have remained central and typical for political sociology. The problem sphere of political sociology comprises increasingly master patterns of societal change, i.e. simultaneous changes and pressures to change in the political order, the social system, and the socioeconomic composition of societies. Such studies had been initiated by members of the Committee of Political Sociology already during its preoccupation with voting studies. Thus, there were studies of the formation and fall of empires by S.N. Eisenstadt (1963), studies of the historical formation of European centers and peripheries by Stein Rokkan (Rokkan and Urwin 1983), and studies of the breakdown of democratic regimes by Juan Linz (Linz and Stepan 1978). Also many scholars who never had been associated with political sociology as such wrote influential texts. An outstanding representative in this category is Barrington Moore's often-quoted major work *The Social Origins of Dictatorship and Democracy* (1966).

In the 1980s and 1990s interest in master patterns of change, and in state and nation building proliferated. The state was reintroduced as a truly central concern. Major representatives of the new orientation were especially Theda Skocpol (1979), who penetratingly emphasized the state as the originator of social outcomes, and Charles Tilly (1975), who rather than seeking one particular important unit, has stressed how national developments were formed by a complicated web of warfare, fiscal policy, bureaucratization, and state-making. Göran Therborn's (1995) studies of modern developments in the European states have also emphasized the multidimensional nature of national development and warned against beliefs in irreversible tendencies. The increased interest in state and nation building also went beyond a focus on national states by studies of worldwide tendencies of development, as seen in the work of Immanuel

Wallerstein (1974) about the origins of the European world economy in the sixteenth century.

The developments from the 1970s onward made it increasingly difficult to define the borders of political sociology. There was for instance a recrudescence of studies of ethnicity, ethnic groups, and the role of ethnic identities in the formation of nations. The studies of ethnicity are sometimes counted as part of political sociology, sometimes as a field of its own. Yet, the borderline problem is fairly clear. It is a question of where the main emphasis is. When the aim is to describe the role of ethnicity and ethnic identities in the formation of nations and political development on the macro level, as in Stein Rokkan's (Rokkan and Urwin 1983) studies of the formation of European centers and peripheries, they are of great relevance for political sociology.

It is much more difficult to evaluate the character and place of Marxist-oriented and radically critical studies which multiplied from the second half of the 1960s onward. Earlier this type of scholarship had been mainly carried out by specific individuals. In studies of the power elite, C. Wright Mills definitely treated the relationship between the social and political, but he was not generally counted among the political sociologists (Kimmerling 1996). In the 1960s there was a rise—indeed a renaissance—of whole schools of critical sociologists such as the Frankfurt School of dialectical sociology and the dependence theorists who emphasized the hopeless fate of the underdeveloped countries in a world dominated by international capitalism. It is an open question whether these and kindred groups should be included in political sociology. Usually they were not counted as such. It is again a question of how one conceives of their main emphasis. If the main intent is to present social critique, the studies are usually not counted as political sociology, however, if the studies present hypotheses and concepts useful in most studies of societal and political development, they are regarded as political sociology. In the 1980s the radical thrust in the social sciences came to an end. The studies in political sociology began to combine elements from studies of very different political shades. It is characteristic of most of the studies of nation and state building mentioned above that they had assimilated elements from both Marxist and liberal thinking and scholarship.

2. The Consciousness-creating Functions of Political Sociology

Whatever solution is reached as regards the labeling of radical social critiques, it is obvious that political sociology is always directed towards expanding and creating awareness of macro changes and fundamental problems of societies. Nevertheless, it is seen as important that political sociology should not basically

serve political aims. There are strong claims that political sociology should be empirically oriented, aim at theory building, employ a comparative approach, and systematically consider historical factors. The combination of the two claims, the consciousness-expanding function on one hand, and the quest for systematic comparative, historically based, and theoretically oriented studies on the other, has been astutely analyzed by Birgitta Nedelmann (1997) in a critique of the failure of German postwar political sociology to account for the period of National Socialism in German history.

Even if a successful delineation of political sociology never emerges, some main problem areas can be listed with the help of the two claims and objectives listed above. Political sociology studies (a) master patterns of simultaneous social, cultural, and political change in society, (b) dominant sociopolitical and emerging new cleavages, (c) the formation of states and nations as well as breakdowns of social and political orders, (d) prerequisites of and threats to democratic regimes, (e) problematic features of modern states such as bureaucratization, centralization, tendencies to corporatism, and (f) the political consequences of globalization such as the formation of continent-based political units and institutions.

Political Thought, History of

Reflection about political phenomena in a wide sense of the term is as old as human community itself. It focuses on a triad of related problems that might be broadly delimited as follows. First, there is the problem of constituting a community bound together by a normative order, secondly that of establishing the legitimacy and the terms of enforcement of such an order, and, thirdly, that of finding criteria for a proper and just allocation of resources as well as of entitlements. Jointly these three sets of problems entail that political theory and the history of political theory, as distinct from, say, a theory of scientific validation or a theory of argumentation, will be characterized by an inherent duality. Thus it will not only, as these other types of theory, be an account of rules of contestation and signification. It will also have to involve an account of which such rules are and which are not

upheld by a normativity that is, in the last instance, enforceable by violent means. Put in everyday language, political theory will in its core be a theory both about meaning and communication and a theory about power, enforcement, and, ultimately, violence. It is easy to see that different political theorists have come to emphasize different strands in this duality, but the duality itself is irreducible and constitutive of political thought.

1. Political Thought in Historical Context

Thought about such matters is found in clearly articulated form from the middle of the first millennium BCE onwards in all the major civilizations of Afro-Eurasia. Thus it is manifested in written texts in the sixth century by Confucius and two centuries later by Mencius, in China and the writings during the same period in India, as well as in the prophetic age of Jewish religion and during the era of classical philosophy in Greece. The emergence of imperial-like political orders across Afro-Eurasia in the last centuries of the first millennium BCE also gave rise to a range of texts about the nature of political order. This is equally valid for texts about the Roman and Byzantine empires in the Mediterranean region to texts highlighting features of rulership in Parthian and later also in Sassanian Persia, in Maurya India, and in the Han Empire of China.

The recording of political thought in the form of the writing of histories of such thought is however a much more recent phenomenon. At its focus it is the relationship of community-wide rules to forms of enforcement and an effort to arrive at an understanding of the historical context in which particular types of such relationships occur. The emergence of clearly articulated forms of historical thought is largely coterminous with the emergence of history and social science as forms of scholarly activity performed within reformed or newly created universities and higher education institutions from the early nineteenth century onwards. In order to understand the key features and characteristics of the writing of histories of political thought it is first of all necessary to bring out key conditions of political thought in the region in which such an early disciplinary condition first occurred, namely in Europe.

2. Political Thought and Early Modernities

In a broad sense political thought in early modern Europe was a way to understand the nature of ruling in human communities and to grasp the conditions of normative argumentation and enforcement in such communities. The need for new understandings of these types of phenomena was itself directly related to the gradual decline and eventual demise of the two

most prominent institutional forms of medieval Europe. Those were, first, the cultural world of Western Christendom, epitomized first by the all-embracing Christian Church and second by its secular counterpart, namely the pervasive, but elusive, political order of the Holy Roman Empire. By the twelfth and thirteenth centuries, however, city republican rule, particularly in the northern half of Italy, had emerged as a new form of political order. Originally it was often modeled on trading communities and was created out of a sense of the necessity of mutual support and protection in areas exposed to incursions and with little or no protection provided by the nominal Imperial rulers.

Similarly, incipient national monarchies were starting to assert their authority vis-à-vis both pope and emperor. In this secular process the French king played a pioneering role. In particular, he had earlier than most other kings and rulers demonstrated his ability to strengthen his own position and financial basis, e.g., by confiscating lands and goods of the order of the Templars. This example was to be followed by kings across Europe in their confiscating the lands and riches of monasteries and religious orders in centuries to come.

In this sense, the Reformation and the Counter-reformation meant that in Protestant and Catholic countries alike, national monarchies, normally of a composite nature (cf. Elliott 1992), were created or reformed. This occurred on the basis of the previous dominant ideals of church, empire, and city republics, but in a form that synthesized parts that had previously been separated. Furthermore, the new national and composite monarchies almost invariably involved efforts on the part of rulers to appropriate lands and resources that had previously been controlled by the church or religious orders. Thereby they were also able to secure a fiscal basis for the new forms of political ruling, if often at a horrendous price of protracted religious civil wars and cleansings.

Under these conditions the pre-eminent political questions became that of grasping the nature and legitimacy of a normatively binding communal order and to outline the range of legitimate means for upholding and enforcing that order. Many of the early modern classical political thinkers, from Machiavelli to Jean Bodin, provide answers to these very questions. They have, however, significantly less to say about the two other sets of questions discerned above and that were to become prominent in later political thought. These were the questions of the very constitution of a community of human beings and of the principles underlying decisions about the allocations of resources or the granting or withholding of entitlements.

All this was to change with the final breakdown of the old political and cultural order in Europe in the middle of the seventeenth century. In China, even in the embattled transition from the Ming to the Ching dynasty at roughly the same time, the general linguistic

and political order was preserved. In Japan a long period of internal warfare and turmoil came to an end with the establishment of one of the most effective forms of absolutist rule, namely the Tokugawa shogunate. Across the Islamic world, the three parallel empires of the Ottomans, the Safavi, and the Mughals, constituted stable political entities. In Europe, however, a new system of states took form and was promulgated in the Westphalian peace treaty of 1648, based on an explicit recognition of religious diversity and monarchical pre-eminence. It was also based on the tacit recognition that an all-encompassing imperial polity was no longer even possible as a viable political ideal and that religious diversity was not to be overcome.

3. Political Thought as the Constitution of a Political Community

In this unfamiliar context, there was an urgency about finding ways of granting legitimacy and meaning to the new order that emerged in the wake of the Westphalian peace treaty and the provisional end of a century and a half of bloody civil wars in Europe. Thereby a sea change occurred in political thought, namely a deep-seated shift from a concern with the enforcement of normative political order to a concern with the nature and very emergence of political community in the first place.

The concern with the constitution of political community becomes the central one in political thought from Hobbes and Pufendorf to Locke all the way to Rousseau. Within this wide range of answers there is, however, a recurring and predominant concept, namely an inquiry into the conditions for the establishment of a social contract. The existence of such a social contract was normally seen also to entail an answer to the question of which types of enforcement of the normative order constitutive of the political community are legitimate. More specifically only those types of enforcement are sanctioned that, implicitly or explicitly, follow from the terms of the social contract itself.

Political theory from Hobbes onwards is centrally preoccupied with the nature of and the consequences of a transition from an imaginary state of nature to the contractually constituted political community. Ultimately all such forms of theorizing seem to depend on a limited set of assumptions about human beings and the nature of their joining together in societies. One such set of assumptions refer to the assignment of some kind of human rights, i.e., rights that accrue to human beings irrespective of their origins and other accidental traits and characteristics. Furthermore, there is a set of assumptions that refer to the thought-experiment of society being created through a process, normally described in terms of a contract, whereby

human beings agree about their association in political form.

Questions about enforcement, separate from an answer to the question of the constitution of a political order, based upon legitimately agreed upon contractual arrangements, were of subordinate and derivative importance relative to this overriding concern. The same is true of questions pertaining to the allocation of resources and the assignment of entitlements to the members and subjects of a political community. Thus such matters have to be dealt with and negotiated in accordance with the terms of those agreed upon in the original contractual arrangements.

Thus European political theory in this classical form emerged in a particular historical context both in European and world history. It also involved forms of theorizing that portrayed an imaginary contractual past as the point of constitution of polities. However, it was not in itself characterized by an effort to reflect on the history of political theory as a key component of developing such a theory. This form of reflexive consciousness was to become a key characteristic of yet another major transformation in intellectual and political history.

4. The Formation of Modernity and the Transition from Political Philosophy to Social Science and History

The late eighteenth and early nineteenth centuries are often described in terms of the coterminous occurrence of major transformations of both technological and economic practices and of political order. Often these transformations are captured with terms such as the industrial revolution and the political transformations inherent in the French and American revolutions. However, in this period there also occurs a major restructuring of ideas about nature and society and, more broadly, in the forms of knowledge and beliefs about the world. This intellectual transformation had deep repercussions for the emergence of new forms of political thought and reflection about the historical context of such forms of thought and for the decline of other forms of political thought.

In this period broad genres of thought about the world gradually gave way to more differentiated forms of knowledge. Slowly natural philosophy and political philosophy came to be replaced by a variety of different natural and social sciences. At the core of this transformation were epistemic shifts where ideas about biological and historical processes, about language and interpretation, about human beings and their capacities and bonds were created or reformulated. Some scholars have even spoken of this period as a second scientific revolution, where modern disciplines emerge in rudimentary form and where there is a shift in the institutional locations of scholarly and scientific activities toward new research laboratories

and universities. In this process, society itself may even, to quote one scholar (Manent 1994, pp. 80–3), be said to have been discovered in its modern form, as distinct from the political order of the prerevolutionary period, whether it had the form of an absolutist monarchy or a constitutional one. Contrary to older forms of contractual reasoning, which postulated social contract as the hypothetical medium that had created political order, the new forms of social thought were distinctly historical and could also draw on anthropological experiences of human beings and societies in different parts of the world (Fox et al. 1995).

Broadly speaking, four distinct forms of thinking about human beings, societies, and political order emerged. These new forms of reasoning and the transition from generalized moral and political philosophy to social sciences had deep repercussions for political thought.

First, there was, with roots in the political economy and moral philosophy of the Scottish Enlightenment, a view of human beings as rational and deliberative individuals and of society as a compositional collective. This also made possible a new way of thinking about political community and its legitimacy. More precisely, it provided the possibility for thinking about political order as formed through the consent of individual human beings. However it was not, as in older contractual thinking, a consent that would have ushered in a distant and hypothetical social contract but rather a consent that could be assessed and rationally evaluated in terms of its reasonableness in its present and historical context.

Second, there emerged, often enough out of the experiences of the relative inability of the French Revolution to create stable institutions, a conception of human agency as formed and constrained by structural and systemic properties and of society as an organic totality. Such a conception would in a conservative version lead to theories of the necessity to restore an organic political order. In a radical version it could, however, also usher in demands for the overthrow of unnatural and illegitimate order. In a more broadly defined liberal or republican tradition, it might and would be compatible with ideas of the type that thinkers, often inspired by Durkheim, would propound toward the end of the nineteenth century in their combat against the ideological enemies of the republic. Thus it could support the idea that modern society was not an atomistic and distorted form of human community but could relate to an organic solidarity compatible with the life of free citizens in a free republic.

Third, and often in relation to historical and linguistic thought among representative of German philosophical idealism, a conceptualization of human beings took form in terms of the linguistic-interpretative nature of human agency and of society as an historically emergent totality. In this sense, political

community did not have to derive its legitimacy from dynastic tradition but from the historically grown experience of a community. Such communities in turn were constituted by human beings sharing a language and a history and where the community of shared life forms was seen as deeper, more genuine, and more real than the artificial boundaries of a minor princely state. It is easy to see that demands for national self-determination and for both popular rule and a nation-state easily flow from a conception along these lines.

Finally, in parallel to the dramatic development of forms of statistical analysis, there emerged a statistical-inductive way of representing the interactions of human beings and of society as a kind of systematized aggregate. Such views did not immediately entail a specific form of legitimate political community, but it would mean that any such community would have at its disposal infinitely more detailed knowledge of the polity and its members than even the most absolutist monarchy (cf. Brian 1994).

Thus the great intellectual transition entailed a deep shift in the history of political thought which affected both conceptions of the nature of a political community and the nature of legitimate and illegitimate enforcement. By virtue of this it also had profound implications for conceptions of the proper distribution of entitlements. Thus it was simply no longer possible, as observed most clearly perhaps by Tocqueville (1964, [1850]), to deny demands for popular participation with reference to tradition or dynastic legitimacy. The thought of a right to the political entitlements belonging to all members of a society, that had been manifested in the proclamations of the revolutionary upheavals, could never again, despite all efforts of the Vienna Congress and the Holy Alliance, be unthought. They were to pervade the political struggles first of European and American societies throughout the nineteenth and the early twentieth centuries and eventually in the world at large.

5. Triumph and Crisis of Liberal Political Thought

The end of World War I marked a sea change in world history. It spelt the end of European global pre-eminence. It also meant that the transition in Western Europe, normally from forms of constitutional monarchical rule, to parliamentary democratic rule was dramatically increased. In the Eastern half of Europe all of the four imperial political entities, the Russian, the Habsburg, the Wilhelminian, and the Ottoman, crumbled under the impact of external military defeat and internal revolutionary upheavals. However, the very triumph of liberal principles of representative democracy was coterminous with the emergence of new forms of political thought that transcended the traditions of the prewar world.

Leninist political thought, which before and during the war had been a radical version of classical Marxism, gradually came to take on the features of an official ideology of the new Soviet state. Precisely in its historical imaginary, Leninism differed from both revisionist and orthodox thought in a Marxist tradition, as epitomized by Bernstein and Kautsky respectively, of the Social Democratic mainstream of the Second International in the late nineteenth and early twentieth centuries. Thus Leninism cast its own claims to legitimacy and its right to use forms of violent enforcement, previously unthought of in late nineteenth century socialist thought, in terms of an historical account and of a projected visionary transition to a stateless society of communism.

Experiences of the mass violence of the war itself, as well as of the violent national and social struggles of the immediate postwar period, formed the environment out of which fascism emerged as a violent rejection of both Marxism and of the whole mainstream tradition of liberal political thought. Even if fascism had roots in prewar forms of radical conservative thought, it marked a form of transcendence of such traditions and indeed of the legacy of modernity itself. Thus even if fascism in power, and its radicalized form of National Socialism, embraced technological modernization, it represented a rejection of basic premises of political thought of modernity in the form it had taken since the late eighteenth century. In particular this is true of the basic presupposition of political thought of modernity of a principled equal right to participation in governance. It is also true of fascism's rejection of another basic presupposition of modernity, namely the legitimacy of a public sphere with free access for all and a principled freedom of every member of a polity to speak not only about but also to the rulers.

In a sense fascist political thought was a form of political thought that invoked history, or rather historical mythology. However, it was not in itself characterized by historical reflection. In Germany, the challenge of fascism to the political order of the Weimar republic was manifested in a range of debates, one of the most important of which concerned the nature of legal order and of the state itself. It was in this debate that the contesting positions of the radical and pro-Nazi decisionism of Carl Schmitt was confronted by the legal positivism of Hans Kelsen and the complex and sophisticated thought of Hermann Heller.

The outlines of a radical rethinking of the history of Western philosophical and political thought can be discerned in the elective affinity between fascism and some forms of philosophical thought, in particular that of Heidegger of the late 1920s and early 1930s. However, such a program was never elaborated or extended, nor was the decisive response and resistance to it on the part of a thinker such as Ernst Cassirer. Instead the military defeat of fascism in World War II

was seen to entail the definitive demise of features of political thought characteristic of fascism.

In the French context, the response to the challenges of fascism was to be found in several quarters. These would range, in political terms, from Marxism to radical Catholic political thought, and in scholarly terms, from sociology in the tradition of Durkheim to the profound renewal of historical studies of the Annales School. In the period after World War II, the French intellectual scene may have been the most important one in Europe in terms of a renewal of political thought. Thus it would comprise the nexus of contributions made by scholars elaborating a Marxian philosophical existentialist position, most importantly of course Sartre, but also thinkers such as Claude Lefort, who, starting out from such a position came to question the core of Leninist political thought. It would also comprise some of the most articulated liberal political thought as epitomized by Raymond Aron.

In the interwar years, the new challenges to liberal political thought had already given rise to a profound renewal of political thought in historical context. These were the years when new standard histories of political thought were being written. The most prominent example in the Anglo-Saxon world might have been a book that was to become a classic for generations, namely George Sabine's (1937) majestic volume *A History of Political Theory*. Refugees from continental Europe made key contributions to this debate. A classical example is the analysis of the meaning of democracy in historical context that was articulated by Joseph Schumpeter (1943) in *Capitalism, Socialism, and Democracy*. Most importantly, perhaps, Karl Popper transcended the bounds of philosophy of science and wrote one of the most quoted works in political thought during the twentieth century in his two-volume opus on *The Open Society and Its Enemies* (Popper 1966, [1945]). This was, of course, a work that was pre-eminently characterized by the links between historical analysis and political philosophy of immediate and contemporary relevance.

In parallel, leading representatives of Scandinavian political and legal science made some pathbreaking contributions both to an understanding of fascism and of the nature of democracy. In this respect the names of Herbert Tingsten and Alf Ross stand out, particularly with Tingsten's pioneering studies of fascism and his and Ross's contributions to a political theory of democracy.

One prominent characteristic of antiliberal political thought of the first half of the twentieth century was its emphasis on the right of the polity to resort to enforcement and violence against the enemies of the polity without being bound by any other constraints than those of pure convenience. Thus the constitutive boundary between members and enemies of the political community, between those chosen to fulfill the destiny of that community and those deemed to

stand in the way and worthy of being removed from community, and ultimately from life, became the most crucial one. The political community itself was seen as constituted in terms of a historical account, whether of the struggle of a class for its liberation against oppression or of a people for its legitimate sphere of life and domination. Resistance to such types of political thought of a historicist nature formed the core of the argument of Popper's political philosophy. It also formed the focus for a range of contributions criticizing totalitarian political thought. Among the main contributors to this critique were thinkers as different as Jacob L. Talmon, Hannah Arendt, and Claude Lefort.

6. *Renewal and Critique in Political Thought*

The history of political thought in the first part of the latter half of the twentieth century is characterized by three parallel developments. First, political thought in this period cannot but reflect the deep tensions in a world with two superpowers in a state of cold war. At the same time large parts of the Third World were emerging out of the experiences of a colonial past and seeking a place in this new world of fundamental tensions. One manifestation of this historical context, was the absolute absence of publications in the tradition of liberal political thought in the countries under Soviet dominance, but also the relative absence of Marxist political thought at many universities in the English-speaking world. Another indirect consequence was a persistent interest in exploring the empirical basis of liberal democracy. In this sense, the contributions by scholars such as Robert Dahl and some of his colleagues at Yale university, not least Charles Lindblom, stand out as exemplary. Second, a classical mainstream tradition of historically orientated political philosophy made significant advances. Isaiah Berlin and Judith Shklar are pre-eminent representatives of this type of scholarship, and the works of Charles Taylor and Norberto Bobbio should also be included here. Third, however, philosophical and theoretical contributions were made that were to reshape the history of late twentieth century political thought. I shall highlight some of these contributions and their consequences in terms of two of the major conceptualizations of human agency and of society that were discerned in the section above about the rise of the social sciences at the turn of the eighteenth century.

In a rationalistic-deliberative tradition, a landmark was established by the publication of Kenneth Arrow's (1951) *Social Choice and Individual Values*. A few years later, economic theorizing would enter political science at large with Anthony Downs's (1957) book *An Economic Theory of Democracy*, to be followed in the early 1960s by a range of books applying game theory and social choice theory to political phenomena.

(Incidentally, as testified by Gabriel Almond (1990, p.117) the institutional role of the Center for Advanced Study in the Behavioral Sciences at Stanford was a crucial one for some of the interactions involving Arrow, Dahl, and others. These interactions were of immediate importance to the very publication of Downs's book but also more generally to the breakthrough of rationalistic forms of analysis).

A few decades later, what had once appeared as an interesting but rather marginal concern of some specialized political theorists had evolved into a broad tradition of rational choice analysis with pervasive influence on both the theory and practice of political thought, particularly in North America. Society as a compositional collective was described not just as an analytically convenient metaphor but as a representation of societal order and with consequential claims concerning the nature of legitimate political action. One thrust of theorizing in this tradition was to demonstrate the limitations, or even the impossibility, of delimiting an unambiguous common good, whether arrived at with the help of a social welfare function or of a majority decision. It is in this context that John Rawls's (1971) *A Theory of Justice* appeared as a pathbreaking book. Drawing on an individualistic and contractual form of reasoning, succinctly criticised by several scholars, most notably perhaps Michael Sandel, Rawls was able to reintroduce discussions of justice and just distributions and allocations into the core of political philosophy. Even after decades of discussions and critique, both Arrow's and Rawls's contribution retain their stature. However, both of them signal a rupture with historical and contextual reasoning rather than the opposite.

In the broad tradition of linguistic-interpretative conceptions of human action and of society as a form of emergent totality in historical context, important new developments also occurred. Thus contributions by continental European phenomenological and hermeneutic philosophers in the 1950s and 1960s came to merge with influences from Anglo-Saxon linguistic philosophy in the tradition of Wittgenstein and Austin. Three forms of such thought, in particular, emerged and have exerted a deep influence on the ways of studying the history of political thought.

In 1959, Reinhart Koselleck (1987), drawing on a tradition of hermeneutic and historical scholarship, published a book on critique and crisis. This book had the deep transformation of intellectual and political order at the turn of the eighteenth century as its focus but also contained the core of a research program on the history of key concepts of society and political order in a long-term perspective. This program was realized through the publication during the following decades of a set of nine massive volumes tracing the history of a limited number of such concepts, primarily in continental Europe.

Roughly at the same time, Jürgen Habermas elaborated another research program, drawing on the joint

traditions of critical Marxist thought, hermeneutics, and speech act theory. In 1962 Habermas published a volume that had an analogous empirical focus as that of Koselleck (Habermas 1989). Thus it was a reinterpretation of the emergence of a new type of public sphere in the late eighteenth century. Habermas's subsequent long-term program has consistently linked these different traditions and may in one sense be seen as a form of historical positioning but also a radical generalization of the philosophical insights of linguistic philosophy and speech act theory.

This later tradition also inspired Quentin Skinner's (1978) two volume major opus *The Foundations of Modern Political Thought* (a work, incidentally, written largely at the Institute for Advanced Study at Princeton). Skinner came to be the major representative of a new school, often identified with his—and John Pocock's old—university, namely Cambridge. It involved the setting of new and significantly more rigorous standards for the writing of the history of political thought, particularly in its demand that the linguistic and intellectual context of the actual writing of major works be carefully brought to the fore of analysis. After decades of discussions, there can be little doubt that intellectual history has made advances in this period, inspired by the works of Skinner and several of his colleagues, that still by no means have been fully explored. At the same time, it is also clear that these works still leave room for a more extensive inquiry into the relationship between long-term institutional and intellectual change.

Finally, links between political thought and political agency are prominent in studies of mechanisms of inclusion and exclusion and on the granting and withholding of entitlements for human beings. Gender studies has clearly entailed a renaissance of the writing of the history of political thought with pioneering contributions by Carole Pateman and Seyla Benhabib, just to mention two of the most distinguished scholars on the late twentieth century.

Historically orientated scholarship has in recent years seemed to open up the possibility for situating political thought in a much more encompassing context than has hitherto been customary. Not least, scholars writing in countries outside of the North Atlantic and West European context seem now to be about to help bring about a more truly global effort to rethink the history of political thought. That would also, almost inevitably, contribute to a transcendence of some of the most severe limitations of contemporary political thought, in particular the following ones:

The relative inability of political thought in the rationalistic tradition to transcend a theory of agency that is manifestly impoverished vis-à-vis available historical research but also vis-à-vis demands that social and political thought itself cannot but make concerning a theory of agency (cf. Joas 1996, 2000).

The relative inability of the so-called communitarian critics of this tradition to supply a sustained historical account of their

preferred community and to escape a tendency of entering into circular justifications of those very societies which they themselves happened to be located or identified with.

The relative inability of research in the traditions of conceptual history and linguistic contextualism to contribute to an understanding of the institutional formation of political order in a long-term and also extra-European perspective.

In order to be able to advance beyond these limitations, it seems that political thought must become significantly more prepared to engage in studies of long-term processes of intellectual and institutional transformations. This will in all likelihood entail efforts to invigorate historical social science of a type that was characteristic of the classics of social science, not least Weber (cf. Schluchter 1996). It would then also stimulate culturally and contextually sensitive social science of a type that has been advocated most ambitiously and consistently by scholars across a range of the social and historical sciences and with S. N. Eisenstadt (1995) as one of its most prominent representatives. The history of political thought in the last three decades of the twentieth century involved impressive advances. At the turn of the millennium, however, the need for historically and comparatively orientated research programs able to transcend the limitations of contemporary political thought also stand out as possibly more urgent than at any time since the emergence of social science itself in the end of the eighteenth century.

Political Trials

The term 'political trial' is popularly associated with 'show trials' like the Moscow Purge trials that were conducted by Stalin during the 1930s. Such trials represent an extreme example of political repression and are viewed as sham legal proceedings designed by the authorities to dramatize specific political campaigns and/or to eliminate prominent individuals. In this context the political trial is taken to be a 'show' in which politicians and not jurists are those who pull the strings and determine the results of the trial in advance. This pejorative use of the term also helps designate regimes that resort to such techniques as the antithesis

of liberal democracies. Yet, as Otto Kirchheimer observed, the most effective usage of political trials occurs precisely within liberal democracies, in societies committed to the rule of law. What can explain this gap between popular perceptions and the actual practice of political trials? Can we distinguish a political trial from a 'show trial'? Should we continue to view political trials as opposed to the very essence of liberal democracies, or should we accept them as part and parcel of this system, deserving a sustained theoretical elaboration?

In his seminal book *Political Justice* Kirchheimer defines political trials as instances in which 'court action is called upon to exert influence on the distribution of political power' (Kirchheimer 1961). This broad definition includes the use of the court by the ruling elites or by outgroups and dissenters to achieve political goals by judicial means. Many writers regard the central factor in such trials as the political motive behind them. The connecting thread between the trial of Socrates for corrupting the youth of Athens (399 BC), the trial of Jesus for blasphemy and sedition (AD 30), the trial of Joan of Arc (1431) for heresy and witchcraft, the trial of Thomas More (1534) for remaining silent when asked about Henry VIII's supremacy in religion, the trial of Galileo (1633) for heretically suggesting that the earth moved around the sun, and many other trials is that, in each case, men in power believed that the defendant was a threat to them (Becker 1971, Belknap 1981). For this reason the prototype of a political trial has been the criminal trial of a political adversary for political reasons. This broad definition encompasses trials in which the defendant has directly attacked the established order by acts such as treason or sedition, but also trials involving common crimes in which only the personality or the motive of the offender indicates their political nature. Other writers try to refine this definition by expanding its scope to legal proceedings other than criminal trials such as impeachment, congressional hearings, and truth commissions. It has also been suggested that the definition be extended to include trials involving larger group conflicts such as ethnic, race, or labor struggles. Some move the emphasis from the political motive of the authorities to the political identity of the defendant. Yet others conclude that the important factor is not the motive but the competition of stories over the identity of the polity that distinguishes such trials. Notwithstanding their differences, all writers on the subject agree that political trials are inevitable not only in authoritarian regimes but also in constitutional democracies, although this is generally denied. Critical of such denials, they set out to replace them with an honest recognition of the existence and function of political trials in both types of regimes.

Why should the term political trial cause such anxiety and widespread denial? Since law tends to stabilize the status quo it is not surprising that there

are always people who feel justified in ignoring the law in order to bring about drastic and necessary changes. This is especially true for powerless groups that are prevented from participating effectively in important institutional decisions affecting their lives (Hakman 1972, Fletcher 1995). When the authorities put on trial those who challenge the basic value distribution in society, especially those who are willing to disregard existing laws to this end, the result is a political trial. Despite this regular occurrence of political trials within democratic societies the term is widely resisted because of its connotation with notions of 'show trials' in which either the charge is a 'frame-up' to conceal the political motivation of the prosecution, or the hearing itself fails to meet minimum standards of judicial impartiality and independence. For this reason, writers attempt to distinguish among different types of political trials. One classification distinguishes among the politically motivated trial, politically determined trial, and trials with substantial political consequences (Friedman 1970). Another differentiates between political 'trials' (abridgment of due process guarantees) the 'political' trial (camouflaged as a criminal trial) and the political trial (politically motivated) (Becker 1971). These efforts at classification have proved frustrating because of the immense historical variations and the widespread existence of political trials in very different regimes. Writers have identified a variety of characteristics of political trials but none has proved to be a sufficient and necessary condition. This literature has largely been descriptive but has failed to assess the compatibility of political trials with liberal values and thus to overcome the negative connotations the term arouses. In order to address this question it is necessary to expose the hidden engine of political trials—their legitimizing function—and its relation to democracy.

The legal system offers a tempting opportunity for those in power to damage enemies, tarnish their image, and isolate them from potential allies by casting them as criminals. This temptation becomes especially strong in democracies that constrain the ruling elite from resorting to more direct devices of repression. What distinguishes political trials from other political devices is their legitimizing function, i.e., their ability to turn a political adversary into a criminal defendant and thereby reinforce the legitimacy of those in power. However, this function can be served only if the public perceives the trial as providing the defendant with a 'fighting chance.' In constitutional democracies this 'fighting chance' is generally assured by the relative autonomy of the judges and the constraining effects of the rule of law (Kirchheimer 1961). Moreover, these guarantees introduce an element of uncertainty into the trial, and encourage political defendants to use it to expose the illegitimacy of the policy or value system advanced by the authorities. Indeed, from Socrates's trial (399 BC) to the Chicago Conspiracy trial (1969), there have always been defendants who have exploited

the limited forum that the political trial provided them to articulate their oppositional views. Some have adopted a defiant stance, proclaiming their right to commit the crime (Solomon Tellirian—as a protest against the Armenian massacre by the Turks in 1921; Dr Jack Kevorkian—advocating euthanasia in 1999), or refusing to respect the traditional decorum of the courtroom altogether (Bobby Seale–Black Panthers in 1969; Klaus Barbie–Nazism and Vichy France in 1987); others have played by the rules in order to win an acquittal that would confirm their claim that they were being prosecuted for their political beliefs (Dr Spock–Vietnam War in 1968). Insight into this legitimizing function and the element of uncertainty that it introduces into political trials in democratic regimes exposes the tension between politics and justice inherent in them. This has made political trials a fascinating area for research since the 1960s.

1. Political Trials in the Transition to Democracy

Political trials are most salient in times of transition between regimes, especially when a new democratic regime confronts crimes of the old regime. Indeed, the first attempts to seriously consider the compatibility of political trials with liberal–democratic values appear in the literature on the transition to democracy. Unlike a military revolution that sustains its authority by brute force, democratic regimes are committed to the rule of law and are inclined to address the evils of the previous regime with the help of legal devices. However, the new regime's commitment to the rule of law also makes it aware of the dangers of using *ex post facto* laws and indulging in 'victor's justice.' At such times, the various expectations from the law—to punish the guilty, to ascertain the truth about the old regime, and to enhance reconciliation in society—seem to overwhelm the legal system and to push it in opposite directions. Moreover, the forward-looking direction of the architects of democracy who are concerned with the efficacy of the transition often conflicts with the backward-looking direction of legal proceedings and their narrow focus on individual guilt (Osiel 1997, Nino 1991, Teitel 1997). For these reasons trials of transition bring to the foreground the clash between politics and justice. Two main approaches to the problem have evolved since World War II: Exemplary Criminal Trials and Truth Commissions, both of which can be considered political trials of sorts and have received extensive theoretical elaboration.

Following the end of World War II the Allies established an international military tribunal in Nuremberg (1945) to judge the leaders of the Nazi regime. This was the first time in history that the leaders of a defeated country had faced criminal prosecution for war crimes, crimes against the peace, and crimes against humanity by an international tribunal. The charge that was applied in the trial—conspiring to

wage an aggressive war—allowed the prosecution to tell a general historical narrative. Could the obvious political end of using the court to teach a history lesson (through *ex post facto* laws, and victors' judges) be reconciled with the demands of liberalism? Confronted with this dilemma, Judith Shklar made the first serious effort to reconcile the legacy of liberalism with political trials occurring in the transition to democracy (Shklar 1964). A legalistic understanding of liberalism, she argued, could justify the Nuremberg trials only at the high cost of denying their political nature altogether. In her view, procedural safeguards to defendants could only guarantee that the trial would not deteriorate into a show trial, but this in itself could not justify deviating from basic liberal demands such as an independent judiciary, established court, nonretroactive laws etc. Paradoxically, Shklar came to the conclusion that the political dictate of founding a democracy justified the divergence from strict legalism in the Nuremberg trials. In other words, it was only an honest recognition of the political aspects of the trials, their educational and symbolic contribution to the building of democracy in postwar Germany, that could justify them. Later writers accepted Shklar's consequentialist approach to transitional justice but limited its applicability to trials that guarantee the due-process rights of the defendants (Osiel 1997).

A very different attempt to address the crimes of the Nazi regime was made in the Eichmann trial (1961). This time it was not the international community but an Israeli court that undertook to judge one of the central figures in the administrative massacre of the Jews. The political nature of the trial was evident, among other things, from its reliance on the particularistic law of 'crimes against the Jewish people.' Likewise the heavy reliance on victims' testimonies about their suffering (and through them the telling of the Jewish Holocaust) conflicted with the liberal demand that the trial concentrate on proving the deeds of the accused. Hannah Arendt and other writers criticized the Israeli prosecution for politicizing the trial in this way (Arendt 1963, Segev 1993, Lahav 1992). Others see the decision as stemming from the general dilemma of political trials of how to strike a balance between the need to establish the truth about an oppressive regime, the need to give voice to the victims, and the need to ascertain the guilt of the defendants (Bilsky 2001).

This dilemma is compounded when the former authoritarian regime retains enclaves of power and opposes any attempt to bring to justice the officials of the former regime. In South America, Argentina remains the only nation that has indicted and prosecuted military officers in public trials for their role in acts of repression carried out under the former regime. The political nature of these trials was evident in the decision to prosecute only the masterminds and the worst offenders, and in the greater priority given to the value of learning about the evils of the authoritarian

past than to prosecuting every individual who was involved. Again, the justification for such selective prosecution is given in consequentialist terms—to what extent the trial serves to strengthen the emerging democracy (Nino 1991). A central dilemma that emerges in transitional trials of this kind is the breakdown of common discourse which undermines the legitimacy of the trial for some segments of society. Thus, the Argentinian court's decision to limit the evidence to proving the deeds of the accused, without allowing them to be situated within the wider historical narrative about an alleged war of self-defense against attacks on the regime by guerrilla forces, was deemed political and undermined the legitimacy of the trial in the eyes of the military (Osiel 1997).
