In this example, $\mathcal{Y}(\psi_1) = \text{'rice grows'}$ and $\mathcal{Y}(\psi_2) = \text{'wheat grows.'}$

A string of terminals w is called *ambiguous* if w has two or more parse trees. Linguistically, each parse tree of an ambiguous string usually corresponds to a distinct interpretation.

Example 2: Consider $G_2 = (T_2, N_2, S, R_2)$, where $T_2 = \{\text{I, saw, the, man, with, telescope}\}$, $N_2 = \{S, NP, N, Det, VP, V, PP, P\}$ and $R_2 = \{S \rightarrow NP, VP, NP \rightarrow I, NP \rightarrow Det\ N, Det \rightarrow \text{the}, N \rightarrow NP, PP, N \rightarrow \text{man}, N \rightarrow \text{telescope}, VP \rightarrow V, NP, VP \rightarrow VP, PP, PP \rightarrow P, NP, V \rightarrow \text{saw}, P \rightarrow \text{with}\}$. Informally, N rewrites to nouns, Det to determiners, V to verbs, P to prepositions and PP to prepositional phrases. It is easy to check that the two trees ψ_3 and ψ_4 with the yields $\mathcal{Y}(\psi_3) = \mathcal{Y}(\psi_4) = \text{'I saw the man with the telescope'}$ are both generated by G_2 . Linguistically, these two parse trees represent two different syntactic analyses of the sentence. The first analysis corresponds to the interpretation where the seeing is by means of a telescope, while the second corresponds to the interpretation where the man has a telescope.

3. Probability and Statistics

Obviously broad coverage is desirable—natural language is rich and diverse, and not easily held to a small set of rules. But it is hard to achieve broad coverage without massive ambiguity (a sentence may have tens of thousands of parses), and this of course complicates applications like language interpretation, language translation, and speech recognition. This is the dilemma of coverage that we referred to earlier, and it sets up a compelling role for probabilistic and statistical methods.

We briefly review the main probabilistic grammars and their associated theories of inference. We begin in Sect. 3.1 with probabilistic regular grammars, also known as hidden Markov models (HMM), which are the foundation of modern speech recognition systems—see Jelinek (1997) for a survey.

In Sect. 3.2 we discuss probabilistic context-free grammars, which turn out to be essentially the same thing as branching processes. Finally, in Sect. 3.3, we take a more general approach to placing probabilities on grammars, which leads to Gibbs distributions, a role for Besag's pseudolikelihood method (Besag 1974, 1975), various computational issues, and, all in all, an active area of research in computational linguistics.

3.1 Regular Grammars

We will focus on right-linear grammars, but the treatment of left-linear grammars is more or less identical. It is convenient to work with a *normal form*: all rules are either of the form $A \rightarrow bB$ or $A \rightarrow b$, where $A, B \in N$ and $b \in T$. It is easy to show that every right-linear grammar has an equivalent normal form in the sense that the two grammars produce the same language. Essentially nothing is lost.

3.1.1 Probabilities. The grammar G can be made into a probabilistic grammar by assigning to each non terminal $A \in N$ a probability distribution p over productions of the form $A \rightarrow \alpha \in R$: for every $A \in N$

$$\sum_{\substack{\alpha \in (N \cup T)^+ \\ \text{s.t. } (A \rightarrow \alpha) \in R}} p(A \rightarrow \alpha) = 1 \quad (1)$$

Recall that Ψ_G is the set of parse trees generated by G (see Sect. 2). If G is linear, then $\psi \in \Psi_G$ is characterized by a sequence of productions, starting from S . It is, then, straightforward to use p to define a probability P on Ψ_G : just take $P(\psi)$ (for $\psi \in \Psi_G$) to be the product of the associated production probabilities.

Example 3: Consider the right-linear grammar $G_3 = (T_3, N_3, S, R_3)$, with $T_3 = \{a, b\}$, $N_3 = \{S, A\}$ and the productions (R_3) and production probabilities (p):

$S \rightarrow aS$	$p = 0.80$
$S \rightarrow bS$	$p = 0.01$
$S \rightarrow bA$	$p = 0.19$
$A \rightarrow bA$	$p = 0.90$
$A \rightarrow b$	$p = 0.10$

The language is the set of strings ending with a sequence of at least two bs . The grammar is ambiguous: in general, a sequence of terminal states does not uniquely identify a sequence of productions. The sentence $aabbbb$ has three parses (determined by the placement of the production $S \rightarrow bA$), but the most

likely parse, by far, is $S \rightarrow aS$, $S \rightarrow aS$, $S \rightarrow bA$, $A \rightarrow bA$, $A \rightarrow bA$, $A \rightarrow b$ ($P = 0.8 \cdot 0.8 \cdot 0.19 \cdot 0.9 \cdot 0.1$), which has a *posterior* probability of nearly 0.99. The corresponding parse tree is shown below.

3.1.2 Inference. The problem is to estimate (see *Estimation: Point and Interval*) the transition probabilities, $p(\cdot)$, either from parsed data (examples from Ψ_c) or just from sentences (examples from L_c). Consider first the case of parsed data ('supervised learning'), and let $\psi_1, \psi_2, \dots, \psi_n \in \Psi$ be a sequence taken iid according to P . If $f(A \rightarrow \alpha; \psi)$ is the counting function, counting the number of times transition $A \rightarrow \alpha \in R$ occurs in ψ , then the likelihood function (see *Likelihood in Statistics*) is

$$L = L(p; \psi_1, \dots, \psi_n) = \prod_{i=1}^n \prod_{A \rightarrow \alpha \in R} p(A \rightarrow \alpha)^{f(A \rightarrow \alpha; \psi_i)} \quad (2)$$

The maximum likelihood estimate is, sensibly, the relative frequency estimator:

$$\hat{p}(A \rightarrow \alpha) = \frac{\sum_{i=1}^n f(A \rightarrow \alpha; \psi_i)}{\sum_{i=1}^n \sum_{A \rightarrow \beta \in R} f(A \rightarrow \beta; \psi_i)} \quad (3)$$

The problem of estimating p from sentences ('unsupervised learning') is more interesting, and more important for applications. Recall that $\mathcal{Y}(\psi)$ is the yield of ψ , that is, the sequence of terminals in ψ . Given a sentence $w \in T^+$, let Ψ_w be the set of parses which yield w : $\Psi_w = \{\psi \in \Psi: \mathcal{Y}(\psi) = w\}$. Imagine a sequence $\psi_1, \dots, \psi_n$, iid according to P , for which only the corresponding yields, $w_i = \mathcal{Y}(\psi_i)$ $1 \leq i \leq n$, are observed. The likelihood function is

$$\begin{aligned} L &= L(p; w_1, \dots, w_n) \\ &= \prod_{i=1}^n \sum_{\psi \in \Psi_{w_i}} \prod_{A \rightarrow \alpha \in R} p(A \rightarrow \alpha)^{f(A \rightarrow \alpha; \psi_i)} \end{aligned} \quad (4)$$

As is usual with hidden data, there is an EM-type iteration for climbing the likelihood surface—see Baum (1972) and Dempster et al. (1977):

$$t+1(A \rightarrow \alpha) = \frac{\sum_{i=1}^n E_{\hat{p}_t}[f(A \rightarrow \alpha; \psi) | \psi \in \Psi_{w_i}]}{\sum_{A \rightarrow \beta \in R} \sum_{i=1}^n E_{\hat{p}_t}[f(A \rightarrow \beta; \psi) | \psi \in \Psi_{w_i}]} \quad (5)$$

Needless to say, nothing can be done with this unless we can actually evaluate, in a computationally feasible way, expressions like $E_{\hat{p}_t}[f(A \rightarrow \alpha; \psi) | \psi \in \Psi_{w_i}]$. This is one of several closely related computational problems that are part of the mechanics of working with regular grammars.

3.1.3 Computation. A sentence $w \in T^+$ is *parsed* by finding a sequence of productions $A \rightarrow bB \in R$ which yield w . Depending on the grammar, this corresponds more or less to an interpretation of w . Often, there are many parses and we say that w is ambiguous. In such cases, if there is a probability p on R then there is a probability P on Ψ , and a reasonably compelling choice of parse is the most likely parse:

$$\arg \max_{\psi \in \Psi_w} P(\psi) \quad (6)$$

This is the *maximum a posteriori* (MAP) estimate of ψ —obviously it minimizes the probability of error under the distribution P . (Of course, in those cases in which Eqn. (6) is small, P does little to make w unambiguous.)

What is the probability of w ? How are its parses computed? How is the most likely parse computed? These computational issues turn out to be more-or-less the same as the issue of computing $E_{\hat{p}}[f(A \rightarrow \alpha; \psi) | \psi \in \Psi_w]$ that came up in our discussion of inference. The basic structure and cost of the computational algorithm is the same for each of the four problems—compute the probability of w , compute the set of parses, compute the best parse, compute $E_{\hat{p}}$. In particular, there is a simple dynamic programming solution to each of these problems, and in each case the complexity is of the order $n \cdot |R|$, where n is the length of w , and $|R|$ is the number of productions in G —see Jelinek (1997), Geman and Johnson (2000). The existence of a dynamic programming principle for regular grammars is a primary reason for their central role in state-of-the-art speech recognition systems.

3.2 Context-free Grammars

Despite the successes of regular grammars in speech recognition, the problems of language understanding and translation are generally better addressed with the more structured and more powerful context-free grammars. Following our development of probab-

ilistic regular grammars in the previous section, we will address here the interrelated issues of fitting context-free grammars with probability distributions, estimating the parameters of these distributions, and computing various functionals of these distributions.

The context-free grammars $G = (T, N, S, R)$ have rules of the form $A \rightarrow \alpha, \alpha \in (N \cup T)^+$, as discussed previously in Sect. 2. There is again a normal form, known as the Chomsky normal form, which is particularly convenient when developing probabilistic versions. Specifically, one can always find a context-free grammar G' , with all productions of the form $A \rightarrow BC$ or $A \rightarrow a, A, B, C \in N, \alpha \in T$, which produces the same language as G : $L_{G'} = L_G$. Henceforth, we will assume that context-free grammars are in the Chomsky normal form.

3.2.1 Probabilities. The goal is to put a probability distribution on the set of parse trees generated by a context-free grammar in Chomsky normal form. Ideally, the distribution will have a convenient parametric form, that allows for efficient inference and computation.

Recall from Sect. 2 that context-free grammars generate labeled, ordered trees. Given sets of nonterminals N and terminals T , let Ψ be the set of finite trees with:

- (a) root node labeled S ;
- (b) leaf nodes labeled with elements of T ;
- (c) interior nodes labeled with elements of N ;
- (d) every nonterminal (interior) node having either two children labeled with nonterminals or one child labeled with a terminal.

Every $\psi \in \Psi$ defines a sentence $w \in T^+$: read the labels off of the terminal nodes of ψ from left to right. Consistent with the notation of Sect. 3.1 we write $\mathcal{Y}(\psi) = w$. Conversely, every sentence $w \in T^+$ defines a subset of Ψ , which we denote by Ψ_w , consisting of all ψ with yield w ($\mathcal{Y}(\psi) = w$). A context-free grammar G defines a subset of Ψ , Ψ_G , whose collection of yields is the language, L_G , of G . We seek a probability distribution P on Ψ which concentrates on Ψ_G .

The time-honored approach to probabilistic context-free grammars is through the production probabilities $p: R \rightarrow [0, 1]$, with

$$\sum_{\substack{\alpha \in N^2 \cup T \\ \text{s.t.}, (A \rightarrow \alpha) \in R}} p(A \rightarrow \alpha) = 1 \quad (7)$$

Following the development in Sect. 3.1, we introduce a counting function $f(A \rightarrow \alpha; \psi)$, which counts the number of instances of the rule $A \rightarrow a$ in the tree ψ , i.e., the number of nonterminal nodes A whose daughter nodes define, left-to-right, the string α . Through f , p induces a probability P on Ψ :

$$P(\psi) = \prod_{(A \rightarrow \alpha) \in R} p(A \rightarrow \alpha)^{f(A \rightarrow \alpha; \psi)} \quad (8)$$

It is clear enough that P concentrates on Ψ_G , and we shall see shortly that this parameterization, in terms of products of probabilities p , is particularly workable and convenient. The pair, G and P , is known as a probabilistic context-free grammar, or PCFG for short. (Notice the connection to branching processes—Harris (1963): Starting at S , use R , and the associated probabilities $p(\cdot)$, to expand nodes into daughter nodes until all leaf nodes are labeled with terminals—i.e., with elements of T .)

3.2.2 Inference. As with probabilistic regular grammars, the production probabilities of a context-free grammar, which amount to a parameterization of the distribution P on Ψ_G , can be estimated from examples. In one scenario, we have access to a sequence $\psi_1, \dots, \psi_n$ from Ψ_G under P . This is ‘supervised learning,’ in the sense that sentences come equipped with parses. More practical is the problem of ‘unsupervised learning,’ wherein we observe only the yields, $\mathcal{Y}(\psi_1), \dots, \mathcal{Y}(\psi_n)$.

In either case, the treatment of maximum likelihood estimation is essentially identical to the treatment for regular grammars. In particular, the likelihood for fully observed data is again Eqn. (2), and the maximum likelihood estimator is again the relative frequency estimator Eqn. (3). And, in the unsupervised case, the likelihood is again Eqn. (4) and this leads to the same EM-type iteration given in Eqn. (5).

3.2.3 Computation. There are again four basic computations: find the probability of a sentence $w \in T^+$, find a $\psi \in \Psi$ (or find *all* $\psi \in \Psi$) satisfying $\mathcal{Y}(\psi) = w$ (‘parsing’); find

$$\arg \max_{\substack{\psi \in \Psi \text{ s.t.} \\ \mathcal{Y}(\psi) = w}} P(\psi)$$

(‘maximum *a posteriori*’ or ‘optimal’ parsing); compute expectations of the form $E_{\hat{p}}[f(A \rightarrow \alpha; \psi) | \psi \in \Psi_w]$ that arise in iterative estimation schemes like (5). The four computations turn out to be more-or-less the same, as was the case for regular grammars (Sect. 3.1.3) and there is again a common dynamic-programming-like solution—see Lari and Young (1990, 1991), Geman and Johnson (2000).

3.3 Gibbs Distributions

There are many ways to generalize. The coverage of a context-free grammar may be inadequate, and we may hope, therefore, to find a workable scheme for placing probabilities on context-sensitive grammars, or perhaps even more general grammars. Or, it may be preferable to maintain the structure of a context-free grammar, especially because of its dynamic programming principle, and instead generalize the class of probability distributions away from those induced (parameterized) by production probabilities. But

nothing comes for free. Most efforts to generalize run into nearly intractable computational problems when it comes time to parse or to estimate parameters.

Many computational linguists have experimented with using Gibbs distributions, popular in statistical physics, to go beyond production-based probabilities, while nevertheless preserving the basic context-free structure. Next we take a brief look at this particular formulation, in order to illustrate the various challenges that accompany efforts to generalize the more standard probabilistic grammars.

3.3.1 Probabilities. The sample space is Ψ_G , the set of trees generated by a context-free grammar G . Gibbs measures are built from sums of more-or-less simple functions, known as ‘potentials’ in statistical physics, defined on the sample space. In linguistics, it is more natural to call these features rather than potentials. Suppose, then, that we have identified M linguistically salient features $f_1, \dots, f_M$, where $f_k: \Psi_G \rightarrow R$, through which we will characterize the fitness or appropriateness of a structure $\psi \in \Psi_G$. More specifically, we will construct a class of probabilities on Ψ_G which depend on $\psi \in \Psi_G$ only through $f_1(\psi), \dots, f_M(\psi)$. Examples of features are the number of times a particular production occurs, the number of words in the yield, various measures of subject-verb agreement, and the number of embedded or independent clauses.

Gibbs distributions have the form

$$P_\theta(\psi) = \frac{1}{Z} \exp \left\{ \sum_{i=1}^M \theta_i f_i(\psi) \right\} \quad (9)$$

where $\theta_1, \dots, \theta_M$ are parameters, to be adjusted ‘by hand’ or inferred from data, $\theta = (\theta_1, \dots, \theta_M)$, and where $Z = Z(\theta)$ (known as the ‘partition function’) normalizes so that $P_\theta(\Psi) = 1$. Evidently, we need to assume or ensure that $\sum_{\psi \in \Psi_G} \exp \{ \sum_{i=1}^M \theta_i f_i(\psi) \} < \infty$. For instance, we had better require that $\theta_1 < 0$ if $M = 1$ and $f_1(\psi) = |\mathcal{Y}(\psi)|$ (the number of words in a sentence), unless of course $|\Psi_G| < \infty$.

3.3.2 Relation to probabilistic context-free grammars. Gibbs distributions are much more general than probabilistic context-free grammars. In order to recover PCFG’s, consider the special feature set $\{f(A \rightarrow \alpha; \psi)\}_{A \rightarrow \alpha \in R}$. The Gibbs distribution Eqn. (9) takes on the form

$$P_\theta(\psi) = \frac{1}{Z} \exp \left\{ \sum_{A \rightarrow \alpha \in R} \theta_{A \rightarrow \alpha} f(A \rightarrow \alpha; \psi) \right\} \quad (10)$$

Evidently, then, we get the probabilistic context-free grammars by taking $\theta_{A \rightarrow \alpha} = \log_e p(A \rightarrow \alpha)$, where p is a system of production probabilities consistent with Eqn. (7), in which case $Z = 1$. But is Eqn. (10) more general? Are there probabilities on Ψ_G of this form

that are not PCFGs? The answer turns out to be no, as was shown by Chi (1999) and Abney et al. (1999): given a probability distribution P on Ψ_G of the form of Eqn. (10), there always exists a system of production probabilities p under which P is a PCFG.

3.3.3 Inference. The feature set $\{f_i\}_{i=1, \dots, M}$ can be accommodate arbitrary linguistic attributes and constraints, and the Gibbs model Eqn. (9), therefore, has great promise as an accurate measure of linguistic fitness. But the model depends critically on the parameters $\{\theta_i\}_{i=1, \dots, M}$, and the associated estimation problem is, unfortunately, very hard. Indeed, the problem of unsupervised learning appears to be all but intractable.

Let us suppose, then, that we observe $\psi_1, \psi_2, \dots, \psi_n \in \Psi_G$ (‘supervised learning’), iid according to $\hat{P}_\theta$. In general, the likelihood function, $\prod_{i=1}^n P_\theta(\psi_i)$, is more or less impossible to maximize. But if the primary goal is to select good parses, then perhaps the likelihood function asks for too much, or even the wrong thing. It might be more relevant to maximize the likelihood of the observed parses, *given the yields* $\mathcal{Y}(\psi_1), \dots, \mathcal{Y}(\psi_n)$:

$$\prod_{i=1}^n P_\theta(\psi_i | \mathcal{Y}(\psi_i)) \quad (11)$$

Maximization of Eqn. (11) is an instance of Besag’s remarkably effective pseudolikelihood method (Besag 1974, 1975), which is commonly used for estimating parameters of Gibbs’s distributions. The computations involved are generally much easier than what is involved in maximizing the ordinary likelihood function. Take a look at the gradient of the logarithm of Eqn. (11): the θ_j component is proportional to

$$\frac{1}{n} \sum_{i=1}^n f_j(\psi_i) - \frac{1}{n} \sum_{i=1}^n E_\theta [f_j(\psi) | \mathcal{Y}(\psi) = \mathcal{Y}(\psi_i)] \quad (12)$$

and $E_\theta [f_j(\psi) | \mathcal{Y}(\psi)]$ can be computed directly from the set of parses of the sentence $\mathcal{Y}(\psi)$. (In practice there is often massive ambiguity, and the number of parses may be too large to feasibly consider. Such cases require some form of pruning or approximation.)

Thus gradient ascent of the pseudolikelihood function is (at least approximately) computationally feasible. This is particularly useful since the Hessian of the logarithm of the pseudolikelihood function is non-positive, and therefore there are no local maxima. What is more, under mild conditions pseudolikelihood estimators (i.e., maximizers of Eqn. (11)) are consistent; (Chi 1998).

Probabilistic Thinking

1. Introduction

Some people have enjoyed playing games that involved at least a component of chance ever since civilizations—as we know them—emerged in human history.

Many of these people apparently had a fairly good intuitive idea of what we might now term the ‘probabilities’ or ‘odds’ of various outcomes associated with these games. Alternatively, at least some people (whom in hindsight we might now label ‘superstitious’) believed that the outcomes of these games could indicate something about the favorability of the world in general toward the gambler (a belief that may exist even today—at least on an implicit basis—for chronic gamblers), specifically the favorability or unfavorability of a particular god that was involved with a particular game.

In the last 600 years or so people have proposed systematic ways of evaluating probabilities—e.g., in terms of equally likely outcomes in games of chance or in terms of subjective belief. In the last 150 years or so scientific endeavor has started to make specific use of probabilistic thinking, and in the last 100 years or so probabilistic ideas have been applied to problems of everyday life. (see Gigerenzer et al. 1989). Currently, for example, jurors are often asked to determine manufacturer or company liability on the basis of differential rates of accidents or cancers; in such judgments, jurors cannot rely on deterministic reasoning that would lead to a specification of exactly which negative outcome is due to what; nor can they rely on ‘experience’ in these contexts in which they have had none. Thus, it is extraordinarily important to understand—if indeed generalizations about such thinking are possible—how it is that people think about and evaluate probabilities, and in particular the problems that they (we) have. The major thesis presented here is that both the thinking and the problems can be understood in terms of *systematic deviations* from the normative principles of probabilistic reasoning that have been devised over the past five or so centuries. These deviations are not inevitable; it is certainly possible for people to think about probabilities coherently (at least on occasion); nevertheless, *when* deviations occur, they tend to be of the systematic nature to be described here; they occur most often when people are engaged in what is termed ‘automatic’ or ‘associational’ thinking, as opposed to ‘reflective’ and ‘comparative’ thinking. (These terms will be made more precise later in this article.)

2. A Brief History (of Thought)

Beginning in early infancy, we develop intuitions about space, time, and number (at least to the extent of ‘one, two, three, many’). These intuitions are essentially correct. They remain throughout our lives basically unaltered except for small variations, and they form the foundation of far more sophisticated mathematical systems that have been developed over the past thousands of years. Moreover, their importance in our lives has been clear throughout those millennia.

In contrast, probabilistic thinking is often unintuitive, and it generally can be taught only after we are familiar with fractions, so that analogs to relative frequency are clear. Moreover, our intuitions about probabilities are often just plain wrong. For example, belief in the ‘gambler’s fallacy’ (negative recency) can even be explicitly rejected, but nevertheless implicitly influence decision making—such as when people demand a greater amount of money in preference to gambling on an outcome that is ‘due’ (e.g., a tail after five straight heads) than in preference to gambling on one that isn’t (e.g., an additional head); see Gold (1997).

The fairly recent, and somewhat ‘iffy,’ use of probabilistic judgment does not imply, however, that people did not gamble throughout the centuries. As mentioned previously, the outcomes of games of chance could provide not just monetary winners and losers but ‘signals’ from ‘the gods’ about favorability toward the gambler; this belief is well captured by the narrative of the novelist Robert Graves (1943) about Caligula’s gambling shortly before his assassination. This tyrant is both watching gladiator games, often putting to death people he has bribed to lose, and rolling a form of dice called ‘astragali’—which are four-sided dice made from pig or lamb bones.

Caligula is playing with his Uncle Claudius, who in order to avoid winning (a dangerous outcome for Claudius) hands the emperor beautiful new dice loaded to come up with a ‘Venus roll,’ which consists of four separate sides (generally with the numbers 1, 3, 4, and 6). Caligula’s subsequent success convinces him that Venus is favorable toward him that day, and he does not take the usual precautions upon leaving the games. Throughout his life, Claudius feels guilty that the loaded dice sent the wrong message to Caligula about how Venus felt about him that day—an inappropriate intervention between a god and a man. (According to Hacking 1975, the interpretation of such events as ‘signals’ from ‘on high’ is common up to the Renaissance, even after people in Europe had given up polytheism for monotheism; the reader might also note how often in the *Old Testament* people decide to ‘cast lots’ to decide what to do—apparently in the belief that God would determine the outcome.)

Of course, not everyone believed in such intervention. For example, Cicero is quoted as claiming that ‘Nothing is so unpredictable as a throw of the dice [modern translation],’ and that ‘both now and then indeed he will make it [the Venus roll] twice and even thrice in succession. Are we going to be so feeble-minded then as to aver that such a thing happened by the personal intervention of Venus rather than by pure luck?’ (see David 1962, p. 25).

Among those not so superstitious (such as Cicero, who was himself assassinated), the intuitive understanding gained through experience of which bets are good ones and which bets are bad ones led to fairly good implicit estimates of probability. Even now,

however, Wagenaar (1988) finds chronic gamblers to be more reliant on intuition and experience than on mathematical analysis.

In contrast, explicit probabilistic thinking goes beyond experience. We can, for example, indicate what are good or bad bets in gambles we have just now constructed, with which we have had no previous experience. Probabilistic thinking can also be extended to ‘personal belief’ about uncertain events, it can be used to evaluate risks, and it can serve as a guide for social policy.

Systematic, probabilistic thinking appears to have started with questions about gambling (in particular about gambles that have not yet been played multiple times). Despite the fact that people gambled a lot, however, the formal theory did not begin until the Italian Renaissance, specifically in correspondence and argumentation between Geronimo Cardano (1501–76) and his associates. The approach that has been ascribed to Cardano involved *comparative* rather than associational thinking. He proposed that the likelihood of success of a gamble could be *computed*, or at least approximated, by comparing the number of outcomes of the device favorable to the gambler divided by the total number of outcomes. In situations where the gambling device is set up to make each possible outcome equally likely, this ratio assessment of probability is used today. The ratio assessment leads to certain general principles, often termed ‘axioms,’ which in turn provide a more abstract notion of probability, and allow different interpretations of probability to be developed—just provided they lead to measures consistent with the axioms. For example, Ramsey (1931) demonstrated that when explicit probabilities are used to determine fair gambling odds, then the gambler will follow the basic principles of probability theory if and only if it is not possible to make a ‘Dutch Book’ (see de Finetti 1974–5, p. 87) such that the gambler always loses; that is, the gambler will be consistent if and only if it is impossible for a highly intelligent opponent to make a series of bets such that the opponent always wins.

After Cardano, the idea of probabilistic inference developed quite rapidly. Many French and Dutch intellectuals corresponded with each other about what constituted better or worse bets—not just in games that had been played chronically, but in games of their own invention. Interestingly, when they discussed probability, they often did so in terms of the expected value of the game, and questions were often posed as to which of the two games had a higher expected value. Then there was rapid development of probability theory—for example, Bernoulli’s Law of Large Numbers,’ (see *Statistical Methods, History of: Pre-1900* and *Statistical Methods, History of: Post-1900*) which specified the relationship between the probability of a single outcome and the probability distribution of multiple outcomes of the same type (for example, the relationship between the probability a fair coin comes

up heads and the probability that it comes up heads at least three times in 10 trials); the 'law' itself derived the limit of the proportion of heads as the number of trials becomes indefinitely large. To jump ahead to recent times, von Neumann and Morgenstern published their classic work *Theory of Games and Economic Behavior* (1944/1947), in which again the question was one of choosing between different gambles, but in terms of expected utility rather than expected value. This work was quite consistent with the earliest work, in which the question of probability was secondary to the question of choice between alternative courses of action.

3. Probability Assessments

All probabilistic analysis is based on the idea that (suitably trained and intelligent) people can at least recognize good probabilistic arguments presented by someone else, or discovered or thought of by themselves, but not necessarily generate good assessments. The very fact that there was correspondence about the gambles—and occasionally some disputes about them—indicated that people do not automatically assess probabilities in the same way, or accurately (e.g., corresponding to relative frequencies, or making good gambling choices).

The von Neumann and Morgenstern work, however, does involve some *psychological* assumptions that people can engage in 'good' probabilistic thinking. First, they must do so implicitly, so that the choice follows certain 'choice axioms' that allow the construction of an expected utility model—i.e., a model that represents choice as a maximization of implicit expected utility; that in turn requires that probabilities at the very least follow the standard axioms of probability theory. It also implies considering conditional probabilities in a rational manner, which is done only when implicit or explicit conditional probabilities are consistent with Bayes' theorem. Thus, the von Neumann and Morgenstern work required that people be 'Bayesian' in a consistency sense, although that term is sometimes used to imply that probabilities should at base be interpreted as degrees of belief. Another way in which probability assessment must be 'good' is that there should be some at least reasonable approximation between probabilities and long-term relative frequencies; in fact, under particular circumstances (of interchangeability and indefinitely repeated observations), the probabilities of someone whose belief is constrained by Bayes' theorem must approximate relative frequencies (Dawid 1982).

Are people always coherent? Consider an analogy with swimming. People do swim well, but occasionally we drown. What happens is that there is particular systematic bias in attempting to swim that makes it difficult. We want to hold our heads above water.

When, however, we raise our heads to do so, we tend to assume a vertical position in the water, which is one of the few ways of drowning (aside from freezing or exhaustion or being swept away in rough waters).

Just as people drown occasionally by trying to hold their heads above water, people systematically deviate from the rules of probabilistic thinking. Again, however, the emphasis is on 'systematic.' For example, there is now evidence that people's probabilistic judgments are 'subadditive'—in that when a general class is broken into components, the judgmentally estimated probabilities assigned to disjoint components that comprise the class sum to a larger number than the probability assigned to the class. That is particularly true in memory, where, for example, people may recall the frequency with which they were angry at a close friend or relative in the last month and the frequency with which they were angry at a total stranger, and the sum of the estimates is greater than an independent estimate of being angry period (even though it is possible to be angry at someone who is neither a close friend or relative nor a total stranger; see Mulford and Dawes 1999). The clever opponent will then bet against the occurrence of each component but on the occurrence of the basic event, thereby creating a Dutch Book.

4. The Heuristics and Biases Approach to Problems of Probabilistic Thinking

The basic conception is that we all use a series of 'heuristics' in our everyday estimation (explicit or implicit) of probabilities, and these heuristics lead to biases. These heuristics provide a type of 'bounded rationality' (Simon 1955, 1956, 1979)—in that they substitute for a very detailed or logical analysis, an analysis that may be beyond our 'computational capacity.' Just as associational thinking serves us well in many contexts, however, so do the heuristics. Occasionally, however, they lead to grossly erroneous—systematically erroneous—probabilistic thinking. The conception that heuristics have some type of 'generalized validity,' but that they often lead us astray, was well argued in a classic *Science* article by Tversky and Kahneman (1974); unfortunately, the principle has been lost on some critics, who can point out many situations in which these heuristics 'work.' Naturally, they do. If they didn't have some sort of generalized utility, they would not have survived over generations of people trying to make probabilistic judgments.

One of the most important of these heuristics is termed the 'representativeness' heuristic, which was first proposed by Tversky and Kahneman in an article concerning *Belief in the Law of Small Numbers* (1971). The idea supported in that article is that we expect very small samples to 'represent' the populations from

which they were drawn, where the ‘we’ includes even people with a fair amount of formal training in statistics. That expectation leads to judgment of probability on the basis of the degree to which an instance or a sample *matches* a population or general idea, rather than on a judgment of how it can be generated. For example, when tossing a coin, a result consisting of six heads appears to be much less likely than one of a head followed by two tails, followed by two heads and finally a tail. But of course each of the sequences is equally likely; each occurs with probability $1/64$. In fact, the sequence of a head followed by two tails followed by two heads and a tail is seen as more likely than a sequence of strict alternation of heads and tails—even though in general people believe that there is more than a chance amount of alternation when they judge what is truly ‘random’ (and in fact are most apt to pick as random the sequence that has a transition probability of $2/3$ rather than $1/2$). This incorrect expectation of alternation leads to such erroneous beliefs as that in the ‘hot hand’ in basketball when observing clusters of similar outcomes (e.g., successful shots). See, for example, Gilovich et al. (1985).

Another heuristic is termed an availability one. Briefly, we estimate frequencies on the ease with which instances ‘come to mind,’ or on our judgment of the ease with which we can recall or generate instances. It is, in fact, generally true that when there are more instances as opposed to fewer in the world, we find it easier to recall or generate more as opposed to fewer. The problem is, however, that there are determinants of ease of recall or generation that are independent of—or sometimes even in conflict with—actual relative frequency in our environment. For example, vivid instances are more readily recalled than pallid ones. (See again the result on ‘subadditivity’ in memory.) Moreover, instances that are easily imaginable (even if we haven’t actually experienced them) are more readily ‘brought to mind’ than are those difficult to imagine.

The availability heuristic creates a bias when we are unaware of the factors other than frequency that can result in ease of recall or generation, but use it as a way of estimating actual frequency. Sometimes, the bias is so strong that we even ignore instances that we *cannot* sample—a ‘structural availability’ problem. For example, clinical psychologists often claim that no child sexual abusers stop on their own without therapy. When asked to substantiate this claim, they will cite many of the child abusers with whom they have had contact, often mandated by a judge to enter therapy with them. The problem is, however, that they would not have had contact with any who had stopped on their own, and by definition they were seeing people only in a therapy setting, hence could not observe any of them stopping ‘without therapy.’ Nevertheless, the experience with such people is so salient and compelling that even while acknowledging the logical problem with the conclusion, many of these clinical

psychologists simply revert to the belief a day or a week after having publicly recognized the availability bias (see Dawes 1988, p. 102).

Following the ideas of Fischhoff and Beyth-Marom (1983) as elaborated by Dawes (1998), the standard cognitive biases and heuristics can be understood by alluding to simple forms of Bayes’ theorem. Consider, for example, the relationship between a symptom S and a disease D , and suppose a diagnostician observes this symptom S . If the probability of the disease is assessed on the basis of a pure matching or association between the symptom and the disease, independent of considerations of conditional probability, there is no normative structure to which the judgment corresponds. More often, however, the judgment will be made on the basis of the conditional probabilities—a normatively correct judgment if it is based on the conditional probability of the disease given the symptom, $P(D/S)$, but a representative judgment if it is the probability of the symptom given the disease, $P(S/D)$. Unfortunately, there is a lot of evidence that the judgment is often made on the basis of the latter relationship—when conditional probabilities are considered at all.

The relationship between these two probabilities is given by rewriting Bayes’ theorem as:

$$P(D/S) = \frac{P(S/D)P(D)}{P(S)} \quad (1)$$

It can also be written in terms of the ‘ratio rule’:

$$\frac{P(D/S)}{P(S/D)} = \frac{P(D)}{P(S)} \quad (2)$$

Because the ratio rule follows from the very definition of conditional probability, it is simply incoherent to equate the probability of the disease given the symptom with the probability of the symptom given the disease in the absence of a simultaneous belief that the probability of the disease and the probability of the symptom are identical. (Again, if someone were to make a series of bets based on ‘fair betting odds’ in such a belief, an opponent could make a Dutch Book against that person.) Classic representative thinking—e.g., ‘she gave a typical schizophrenic response, therefore she must be schizophrenic’—embraces such an identity. What is critical, of course, are the *base rates* of D and of S , yet extensive research has shown that people underutilize such base rates in their intuitive judgments—or at least fail to incorporate them to a sufficient extent into their prior beliefs, given that they are often seen as ‘not relevant.’ (Why, people often ask, should the *general* probabilities of these symptoms and diseases be relevant to a particular judgment about a particular person with a particular symptom? Such an argument is sometimes even followed by

bland assertions to the effect that ‘statistics do not apply to the individual’—a wholly erroneous conclusion, as can be attested to by the heavy cigarette smoker who develops lung cancer.)

People often do not ignore these base rates *entirely* in the judgments, particularly if the probabilistic nature of the judgment is made clear (see Gigerenzer et al. 1989). Nevertheless, the ‘underutilization’ of such base rates is ubiquitous. In the psychological literature it was first decried by Meehl and Rosen (1955), who noted that in case conferences they attended, clinical psychology and psychiatry judges tended to ignore base rates completely; later, underutilization has been established in a variety of experimental situations using a wide variety of subjects, especially by Kahneman and Tversky (1972, 1973). For example, when asked to judge whether a description is of a particular engineer or a particular lawyer, subjects make the same judgment whether the experimenter states that the description was drawn from a pool of 70 percent engineers and 30 percent lawyers, or vice versa. As Bar-Hillel (1990) points out, the 70/30 split does not appear to be ‘relevant,’ but it’s relevance would most likely be clear if the split were 99/1, and certainly if it were a 100/0. (Again, we can hypothesize that people can recognize probabilistic arguments—although it’s possible to be fooled on occasion—but often not make them spontaneously.) Thus, for example, someone who is said to be interested in sailing and carpentry and sharing model train sets with a child is judged to be much more likely to be an engineer than a lawyer, whether this person was drawn from a pool of 70 percent engineers or 70 percent lawyers. Making the sampling procedure absolutely ‘transparent’ does, however, reduce that tendency.

The use of Bayes’ theorem to understand the relationship between symptoms and disease leads naturally to its use to consider the general relationship between any hypotheses and any bit of evidence. Let e refer to some bit of evidence about whether a hypothesis h is or is not true; for example, a symptom may be regarded as a bit of evidence, and having a particular disease a hypothesis; or the hypothesis may concern who is going to win the election in the United States in the year 2020 and a particular bit of evidence may be the margin of victory or defeat of the potential candidate in a more local election. Bayes’ theorem expressed in terms of evidence and hypotheses is presented as

$$P(h/e) = \frac{P(e/h)P(h)}{P(e)} \quad (3)$$

This form of Bayes’ theorem, while true, often leads to complications when trying to evaluate the probability of the evidence. There is, however, a way to avoid having to estimate that probability. What we can do is to consider *odds* that the hypothesis is true. These odds

are the probability the hypothesis is true given the evidence divided by the probability that this hypothesis is false given the evidence—that is, by the ratio $P(h/e)/P(-h/e)$. Once we know the odds, it is trivial to compute the probability. The advantage of considering odds is that the denominator in Bayes’ theorem cancels out when we compute these odds. That is

$$\frac{P(h/e)}{P(-h/e)} = \frac{P(e/h)P(h)}{P(e/-h)P(-h)} \quad (4)$$

Now we are in a position to categorize the most common forms of representative thinking. Pseudodiagnosticity refers to making an inference about the validity of hypothesis h on the base of evidence e without considering hypothesis $-h$. Another way of stating pseudodiagnosticity is that it involves considering only the numerator of the first term on the right-hand side in Eqn. (4). People do that when they state that a bit of evidence is ‘consistent with’ or ‘typical of’ some hypothesis without concerning themselves about alternative hypotheses, or in particular the negation of the hypothesis. For example, in attempting to diagnose whether a child has been sexually abused, alleged experts in court often refer to symptoms ‘typical’ of such abuse—without concerning themselves with how typical these symptoms are of children who have *not* been abused, or the frequency with which children have been sexually abused.

Another type of representative thinking involves considering the probability of the evidence given the hypothesis or hypotheses without looking at the second terms in Eqn. (4), that is, the prior odds. The reason that these odds are important is that they yield the *extent* of the evidence and hypotheses considered. For example, being a poor speller may be evidence of dyslexia in the sense that it has a very high probability given dyslexia. However, in order to diagnose dyslexia on the basis of poor spelling, we have to know something about the base rates of poor spelling and the base rates of dyslexia in the population from which the person whom we wish to diagnose was chosen.

Dilution effects occur when evidence that does not distinguish between hypotheses in fact influences people to be less convinced of a most likely hypothesis; the problem is similar to that found in pseudodiagnosticity in that people do not realize that evidence that is not very likely given the hypothesis may be equally unlikely given the negation of that hypothesis, but may in fact believe a hypothesis less as a result of collecting evidence that is unlikely if it is true. Dilution is simply the converse of pseudodiagnosticity.

Finally, it is possible to describe *availability* biases as well by Eqn. (4). People believe that they are sampling evidence given the hypothesis, when in fact they are sampling this evidence given the hypothesis *combined with* the manner in which they are sampling. For example, when private practice clinical psycho-

logists claim that they are sampling characteristics of people who fall into a certain diagnostic category on the basis of their experience, what they are really sampling is people who fall in that category *and who come to them*. Similarly, when we sample our beliefs about 'what drug addicts are like,' most of us are sampling on the basis of how the media presents drug addicts—both in 'news' programs and in dramatizations (Dawes 1994b). Doctors often sample on the basis of their contact with addicts when these addicts are ill, perhaps gravely so, while police are often sampling on the basis of their experience with these same addicts during arrests and other types of confrontation. It is not surprising, then, that doctors are in favor of a 'medical' approach to drug addiction including such policies as sterile needle exchanges, while police are in favor of much more punitive policies. Both are sampling evidence *combined with* their exposure to it.

All these anomalies have been demonstrated experimentally. It is important to point out, however, that the investigation of these anomalies did not spring simply from understanding Bayes' theorem and then from creating very clever experimental situations in which subjects' inferences systematically violate it. The motive to study these anomalies of judgment arises from having observed them on a more informal basis outside the experimental setting—and trying to construct an experimental setting, which yields a greater measure of control, that will allow them to be investigated in a systematic manner. The reader is referred, for example, to the essay of Meehl (1977) or the book of Dawes (1994a) for descriptions of these biases in the clinical judgment of professional psychologists and psychiatrists who rely on their own 'experience' rather than (dry, impersonal) 'scientific' principles for diagnosis and treatment.

5. Analyzing an Important Example

This section ends with a discussion of pseudodiagnosticity, a bias that is prevalent in 'expert' proclamations encouraging 'child sex abuse hysteria' (Dawes 2001). The main problem here is that hypotheses are not compared: instead, single hypotheses are evaluated in terms of the degree to which evidence is 'consistent with' them; in addition, evidence is often *sought* in terms of its consistency with or inconsistency with 'favorite hypotheses'—rather than in terms of its ability to distinguish *between* hypotheses. This type of pseudodiagnosticity has made its way into the legal system, where experts are allowed to testify that a child's recanting of a report of sexual abuse is 'consistent with' the 'child sexual abuse accommodation syndrome' (Summit 1983). The finding is that many children who are *known* to have been sexually abused deny the abuse later (recant), therefore, the

Figure 1

Partial and total analyses of the relationship between (a) data reviewed prior to launch and (b) the full story from past flights (source: Russo and Schoemaker 1989, pp. 197–8)

probability of the evidence (the child recants) given the hypothesis (actual abuse) is not as low as might be naively assumed; therefore, recanting is 'consistent with' having been abused (i.e., can be considered part of a 'syndrome' of accommodation to abuse).

The problem with this pseudodiagnostic reasoning is that it compares the probability of the evidence given the hypothesis to the probability of the *negation of the evidence* given the hypothesis, whereas a rational comparison is of the probability of the evidence given the hypothesis to the probability of the evidence given the *negation of the hypothesis*. When considering this latter comparison, we understand immediately that the recanting would be diagnostic of actual abuse only if the probability of recanting given actual abuse were *higher* than the probability of recanting given such abuse had not occurred—a highly implausible (not to mention paradoxical) conclusion.

Such pseudodiagnostic reasoning is involved in other disasters as well, for example, the explosion of the US Space Shuttle Challenger on January 22, 1986. When considering the possibility that cold temperatures might cause the O-rings to malfunction, 'the worried engineers were asked to graph the temperatures at launch time for the flights in which problems have occurred' (Russo and Schoemaker 1989, p. 197). Thus, these engineers attempted to evaluate the hypothesis that there would be O-ring problems by asking what the temperature was given the existence of these problems. As indicated in Fig. 1(a) (Fig. 6 in

Russo and Schoemaker 1989, p. 198), there appeared to be no relationship. When, however, the temperature of launches in which there were *no* problems were considered, a very clear relationship between problems and temperature is evident (see Fig. 1(b), from Russo and Schoemaker 1989, Fig. 7, p. 198.)

Moreover, people actively seek evidence compatible or incompatible with a hypothesis rather than evidence that distinguishes between hypotheses, as has been extensively studied by Doherty and his colleagues (see for example Doherty et al. 1979). Consider, for example, subjects who are asked to play the role of medical students (and actual medical students prior to specific training, see Wolf et al. 1985) who must determine whether patients have one of two conditions. The conditions are explained, and subjects are told that a patient has two symptoms. The judges are then presented with the conditional probability of one of these symptoms given one of the diseases (e.g., that it is very likely that the patient has a high fever given the patient has meningitis). They can then choose to find out the probability of the other symptom given the same disease, the probability of the first symptom given the second disease, or the probability of the second symptom given the second disease. While virtually no subjects choose a different symptom and a different disease, the majority choose to find the probability of the *second* symptom given the first disease (the 'one that is focal' as a result of being told the first symptom). But for all these subjects know, of course, the first symptom may be more or less typical of the *alternative disease*, as may the second symptom. Finding out that the probability of these two symptoms given only one disease in no way helps to distinguish between that disease and some other. *Of course, in real medical settings doctors may have prior knowledge of these other disease/symptom relationships*, but because the diseases are not even identified in the current setting, such knowledge would be of no help.

Occasionally, pseudodiagnosticity has been confused with what has been termed a 'confirmation bias'—that is, a desire to search for evidence that is very probable given a focal hypothesis. As Fischhoff and Beyth-Marom (1983), Trope and Bassok (1982), and Skov and Sherman (1986) point out, however, such a search does not necessarily imply pseudodiagnosticity (or any other particular irrationality) because it may be possible that the evidence is *not* found—that is, that instead of finding the anticipated evidence, the diagnostician finds its negation. In fact, Skov and Sherman (1986) demonstrate that in searching for evidence—at least in their experimental context—subjects often became quite rational *when they are informed of the conditional probabilities*. The irrationality occurs in the search for which probabilities to seek, and in 'jumping' to a conclusion on the basis of only one probability (i.e., on the basis of the first term in the numerator in the odds form of Bayes' theorem).

The cognitive explanation of pseudodiagnosticity and the other heuristic-based biases covered in the section is simple. People often think by association; in fact, whole computer programs have been built to simulate human judgment on the basis of 'matching' characteristics to schemas. The point of pseudodiagnosticity is that only one 'schema' (i.e., hypothesis) is considered, whereas *coherent diagnostic judgment is always comparative*. In fact, all the biases covered here are based on associational thinking, whereas clear normative probabilistic thinking always involves comparisons.

6. Summary and Implications

When we deal with probabilistic situations in everyday life, we can often 'muddle through,' but occasionally not appreciating the comparative nature of valid probabilistic thinking can lead to judgmental disasters. Similarly, experience with games of chance can lead to some pretty good intuitive estimations of the likelihood of various payoffs, but once again there can be systematic biases, such as belief in the gambler's fallacy. Explicit probabilistic thinking has developed in our cultures only in the last 500 years or so, and in the last 150 years or so it has become increasingly important in both scientific reasoning and in our day-to-day living—and even in legal contexts (where as jurors we may be asked to judge the liability of a particular company by comparing the probability of developing cancer among those exposed to it or its product as opposed to the 'base rate' probability, or may be asked to evaluate what an expert witness states about the relationship between a symptom and a diagnosis). Here, if we rely on our intuitive grasp of probabilities, we often find that we have systematic biases, much as novice swimmers may attempt to keep their heads above water and thereby drown. These biases—which have been briefly described and catalogued in this article—involve explicitly defined deviations from the conclusions of valid probabilistic reasoning, which follow from the simplest forms of Bayes' theorem. They are not random deviations, which could be modeled as analogous to an engineering context involving a 'signal' plus 'noise.'

Of course, we are also capable of precise probabilistic thinking—just as swimmers are capable of assuming a horizontal position in the water and consequently not drowning. The point is, however, that when we deviate from the rules ('axioms') of probability theory or from coherent judgments, these deviations follow the patterns described here—as has been documented in everyday observation and studied experimentally by those advocating the 'heuristics and biases' approach to such judgment. For a greater elaboration of this approach than is found here, see the chapters in Kahneman et al.'s book *Judgment Under Uncertainty: Heuristics and Biases* (1982). These

systematic departures themselves in turn may be connected to thinking in terms of associations, whereas good probabilistic judgment always requires comparative thinking.

R. M. Dawes

Probability and Chance: Philosophical Aspects

The central philosophical issue involving probability concerns the interpretation of ordinary probability claims, such as ‘there is a 30% probability that it will rain today.’ *Epistemic* interpretations of probability understand this to be a claim about belief under uncertainty: it describes the extent to which a certain type of rational agent would (or ought to) believe that

it will rain, given the available evidence. *Objective* interpretations of probability read the claim as describing some quantifiable feature of the objective world, sometimes called ‘chance.’ The concept of chance is thought by some to be intimately connected with *indeterminism*. A variety of epistemic and objective interpretations of probability will be discussed below.

1. The Problem of the Interpretation of Probability

The problem of the interpretation of probability can be posed using a familiar example: what does a meteorologist *mean* when he or she says that there is a 30 percent probability of rain on a given day? To give an account of what a proposition means is to say what must be the case in order for the proposition to be true. If the meteorologist says that it *will* rain, this assertion is true if and only if it does rain. Whether it rains or not, however, neither outcome by itself renders the *probabilistic* claim true. So what must be the case in order for this claim to be true?

An adequate solution to this problem must provide some way of making sense of the numerical values that appear in probability claims (and must do so in such a way that those values are in accord with the basic principles of probability—see *Probability: Formal*). The claim that 30 percent of the balls in a given urn are blue has a well-understood meaning: the number of blue balls in the urn, divided by the total number of balls in the urn, is equal to 0.3. In the case of the weather report, however, no comparable formula is immediately available.

Proposed interpretations of probability tend to fall within one of two broad camps, *objective* (or *empirical*) and *epistemic* (or *subjective*) interpretations. Objective interpretations interpret probability claims as describing some feature of the world. Epistemic interpretations of probability, by contrast, interpret probability claims as claims about the extent to which the claim is or ought to be believed. Note that this standard terminology is somewhat misleading: some epistemic interpretations (such as the logical interpretation) take probabilities to be objective in the sense that they do not vary from person to person. The various interpretations of probability canvassed below are often presented as *rivals*, but it may be more appropriate to think of them as complementary. Most researchers who have grappled with interpretive issues have been of the opinion that the concept of probability has both an objective and an epistemic dimension. Accordingly, philosophers often talk of ‘objective probabilities’ and ‘epistemic probabilities.’ Objective probabilities are sometimes called ‘chances.’

Philosophers (as well as many philosophically minded statisticians) have become interested in the

problem of interpretation of probability in part because of the ubiquity of probability claims in science as well as ordinary life, and in part because of the utility of probability theory in analyzing a variety of concepts of interest to philosophers, such as causation (see *Causation: Physical, Mental, and Social*), confirmation of hypotheses by evidence (see *Atomism and Holism: Philosophical Aspects*), and rationality (see *Rational Choice Explanation: Philosophical Aspects*).

This article will focus on the philosophical, rather than the mathematical, dimensions of the problem of interpreting probability. Readers interested in this topic would also do well to read the article on *Probability: Interpretations*. Other surveys of this topic include Salmon (1967), Sklar (1993), and Howson (1995).

2. Determinism and Chance

In a famous thought experiment, the French physicist Pierre Simon de Laplace (1819) imagined a demon who could observe the exact position and momentum of every particle in the universe at a given time. Such a demon could plug this information into Newton’s equations of motion and predict the state of the universe at all future times. In this thought experiment, Laplace was articulating the concept of *determinism*. A system is *deterministic* if its state at a given time, together with the laws of evolution for that system (see *Causes and Laws: Philosophical Aspects*), uniquely determine the state of the system at later times. For Laplace, determinism meant that all *objective* probabilities would have to have values of zero or one. Laplace thus thought that probabilistic claims, such as the meteorologist’s prognostication described above, reflect human ignorance about which outcome is determined to occur.

At present, there is good reason to believe that certain physical systems described by *quantum mechanics* behave indeterministically. For example, if a vertically polarized photon strikes a polarizer that is oriented with an angle of θ , quantum theory entails that the photon has a probability of $\cos^2\theta$ of passing through. According to the orthodox interpretation of quantum theory (which is not controversial), this probability is *irreducible*: there is no further fact about the photon that determines what it will do on this occasion. If this is correct, then the probability value $\cos^2\theta$ does not merely reflect human ignorance about what the photon will do: it is an objective feature of the world. (For a thorough discussion of philosophical issues involving determinism, see Earman (1986).) One important philosophical issue is whether only such irreducible probabilities are genuine chances. If so, then it would be safe to infer that *none* of the probability claims made within the social sciences describe genuinely objective probabilities.

The word ‘chance’ is also sometimes used as a singular noun to refer to a chance that is not equal to zero or one. For example, the thesis of determinism is sometimes expressed by saying that there is no genuine chance in the world; ‘the USA soccer team has a chance of winning the next world cup’ says that the chance of their winning is greater than zero and less than one; to ‘take a chance’ is to embark on a venture that has a chance of success that is greater than zero but less than one; and so on.

3. Epistemic Probability

Laplace claimed that probability claims do not describe objective features of the world, but the state of human knowledge (and ignorance). Epistemic interpretations of probability all share this general feature.

3.1 The Classical Interpretation

If asked the probability of rolling an odd number on a six-sided die, most people would unhesitatingly respond with the answer one-half: there are six possible outcomes of the die roll, three of which are odd. This illustrates the *classical interpretation* of probability, often associated with Laplace (1819). According to this interpretation, the possible outcomes of a particular trial are divided into ‘equally possible’ cases, and the probability of outcome *F* on a particular trial is equal to the number of such cases in which *F* is true, divided by the total number of possible cases. Which cases are equally possible is determined by the *Principle of Indifference*, which states that two cases are equally possible in the absence of any reason to prefer one outcome over the other.

There are a number of difficulties with the principle of indifference. When the weather reporter claims that the probability of rain is 0.3, there seem to be at least two different types of outcome (rain and no rain) but it is hard to see what the 10 equally possible outcomes (three of which involve rain) could be. Even in much simpler cases, the principle of indifference is not precise enough to specify the equally possible cases. An urn contains both red balls and blue balls; some of the red balls are light red, and some are dark red. What is the probability that the next ball drawn is blue: are there two equally possible cases (red and blue) or three (light red, dark red, and blue)? This problem is further exacerbated when there are infinitely many possible outcomes.

3.2 Subjective Interpretations

According to the subjective interpretation of probability (whose proponents are variously called subjectivists’ personalists, or Bayesians), probability

measures the degrees of belief or *credences* of a certain type of idealized rational agent. Subjectivists regard probability theory as analogous to *formal logic*. Logic alone never tells an agent whether to believe a proposition, but it does require that an agent’s beliefs be consistent with one another. For example, the rules of logic forbid an agent to believe ‘it will rain today,’ ‘if it rains today, it will not snow today,’ and ‘it will snow today’ at the same time. According to subjectivists, probability theory is an extension of logic that allows an agent to have degrees of confidence in a proposition that range in value between zero and one. Probability theory alone will not tell the agent how much confidence to place in the proposition ‘it will rain today,’ but rather imposes a consistency-like constraint (usually called *coherence*) on the totality of the agent’s degrees of belief.

The numerical value of an agent’s degree of belief in some proposition is connected with the agent’s evaluation of bets on the truth of that proposition. For example, if an agent has a degree of belief of 0.3 for the proposition ‘it will rain today,’ that means that he or she would find a bet on rain at 3:7 odds—a bet that costs the agent three units, and buys a chance to win 10 units (for a profit of seven units) if it rains—to be fair. This connection between degrees of belief, utility, and evaluation forms the foundation of a theory of rational choice wherein an agent always acts so as to maximize expected utility (see *Rational Choice Explanation: Philosophical Aspects; Elicitation of Probabilities and Probability Distributions; Game Theory and its Relation to Bayesian Theory*).

This connection between degrees of belief and evaluation is often deployed in arguments that rational degrees of belief conform to the formal rules of probability (see *Probability: Formal*). When an agent’s degrees of belief conform to the probability calculus, then his or her overall system of evaluations will have a number of desirable features. For example, Ramsey (1926) showed that having one’s degrees of belief conform to the rules of probability is a necessary condition for having one’s overall system of *preferences* satisfy a set of plausible constraints. One such constraint is transitivity: if the agent prefers A to B and B to C, then the agent prefers A to C. A second class of results comprises the so-called *Dutch Book* theorems. (See, for example, de Finetti (1964) and Kemeny (1955).) These results show that if and only if an agent’s degrees of belief violate the rules of probability, the agent will be vulnerable to a ‘Dutch Book.’ A Dutch Book is a system of bets such that the agent finds each individual bet fair, but where the agent is guaranteed of suffering a net loss no matter what the outcome. For example, a bet on heads at 2:1 odds together with a bet of equal stakes on tails at 2:1 odds would constitute a Dutch Book, for the agent purchasing the two bets would be guaranteed of losing 2 units on one bet, and winning 1 unit on the other. (For more details, see *Probability: Interpretations*.)

The requirement that rational degrees of belief satisfy the rules of probability theory is a *synchronic* constraint on one's degrees of belief: it concerns an agent's degrees of belief at one particular time. Some subjectivists impose a further *diachronic* constraint on allowable methods for changing one's degrees of belief over time. Suppose that a rational agent's degrees of belief at some particular time are represented by the probability function P . If the agent then acquires some new piece of information I , then the agent's new degree of belief in any proposition A is equal to the *conditional probability* $P(A/I)$ (see *Probability: Formal* for the definition of conditional probability). This rule of updating degrees of belief by *conditionalizing* can also be motivated by a form of Dutch Book argument (proved by David Lewis and reported in Teller (1973)).

This rule for changing degrees of belief has been championed by so-called *Bayesians* as a theory of confirmation. According to this theory, a hypothesis H is confirmed or supported by a piece of evidence E just in case conditionalizing on E increases the probability of H . This probabilistic approach to confirmation theory has proven to be very fruitful. (See *Truth, Verification, Verisimilitude, and Evidence: Philosophical Aspects*; see also Howson and Urbach (1993).)

The various theorems invoked by subjectivists are *formal* results, and there is considerable debate over their interpretation. In particular, there is disagreement about how, or even whether, the Dutch Book theorems really show that coherence or updating by conditionalization are canons of rationality. Critics of subjectivism point out that even an incoherent agent would be capable of following the proofs of these theorems, and hence of foreseeing the dangers of Dutch Books; thus coherence and updating by conditionalization are not really necessary for avoiding financial loss (see Howson and Urbach (1993) for further discussion).

A second focus of criticism is the *subjective* nature of degrees of belief. Rational agents may differ in the degree to which they believe a proposition such as 'it will rain today'; indeed their degrees of belief may range all the way from zero to one. Moreover, the constraints of synchronic coherence plus updating by conditionalization do not rule out the possibility that one's degrees of belief are *dogmatic* in a certain respect. It is consistent with these constraints that an agent have degree of belief of 0.99 that each toss of a given coin will land heads, and after observing a thousand tails in a row, *still* believe that the *next* toss will almost certainly be heads. Subjectivists have been able to prove many interesting results about how an agent's degrees of belief *would* evolve in the face of new evidence *if* the agent's original degrees of belief (or *prior probabilities*) were nondogmatic in various ways (de Finetti's (1964) representation theorem is one important example), but there is nothing in sub-

jectivism that would *require* the agent to have such nondogmatic prior probabilities. For many, this latitude makes subjective degrees of belief ill-suited as a foundation for theories of rational choice or rational inference.

3.3 Logical Interpretations

Logical interpretations aim to avoid the problems of subjectivist interpretations by imposing further constraints on an agent's prior probabilities. Prior probabilities are determined by the logical structure of the space of outcomes, much as they are in the classical interpretation. Unlike the classical interpretation, however, probability assignments can reflect the bearing of evidence that discriminates among the possible outcomes. Thomas Bayes (1763) and Laplace (1819), who are commonly associated with the subjectivist and classical approaches (respectively), both endorsed a version of the logical approach to probability. Twentieth century proponents include Carnap (1950), Jeffreys (1961), and Jaynes (1973).

Logical interpretations of probability inherit many of the difficulties of the classical interpretation discussed above: logical considerations alone do not determine a unique prior probability distribution. Moreover, many of the most plausible candidates for logical probabilities—such as one in which a sequence of coin tosses is *independent and identically distributed* (see *Probability: Formal or Distributions, Statistical: Special and Discrete*)—turn out to be dogmatic in just the manner described in Sect. 3.2.

3.4 The Need for Objective Interpretations

Although few would doubt that our ordinary concept of probability has an epistemic dimension, it seems implausible that *all* probability claims can be interpreted epistemically. Consider the claim that a photon has a certain probability of passing through a polarizer; it would be very odd indeed if the truth of this claim (and hence of quantum mechanics) depended on the extent to which some agent(s) may believe that the photon will pass through or on the extent to which available evidence confirms this hypothesis. At best, epistemic interpretations of probability will have to be supplemented by an objective interpretation of at least some probability statements.

4. Objective Interpretations of Probability

In practice, probabilities are often inferred from frequency data. To estimate the probability that a given coin will land heads when tossed, for example, one could toss it many times and observe the relative frequency with which the coin lands heads. Such

relative frequencies are *objective* features of the world. Hence relative frequencies provide a natural resource for objective interpretations of probability claims.

4.1 Finite Relative Frequency Interpretation

Perhaps the simplest interpretation of a probability claim would be to understand it as a claim about an actual finite relative frequency. For example, if a coin were tossed exactly 10 times and then destroyed, resulting in 'heads' on six of those 10 tosses, then the probability that the coin lands heads when tossed would be 0.6. The central difficulty with this definition of probability is that it rules out unrepresentative samples by definition. For example, if a coin is fair, i.e., has a probability of 0.5 of landing heads when tossed, that should not be taken to rule out the possibility of it landing heads on six of the 10 occasions on which it is tossed. According to the finite frequency definition of probability, however, if the probability of heads is 0.5, then *by definition* the coin will land heads on exactly half of its tosses. Thus, while finite relative frequencies provide indispensable evidence for probabilistic claims, probabilities cannot be identified with finite relative frequencies.

4.2 Limiting Relative Frequency Interpretation

In order to avoid these problems with finite frequencies, some philosophers have suggested that probabilities be identified with frequencies in an *infinite* sample. If the first n tosses of a coin yields $f(n)$ heads, then the relative frequency of heads in the first n tosses is $f(n)/n$. The *limiting relative frequency* of heads in the infinite sequence of tosses is the limit as n goes to infinity of $f(n)/n$. This approach to interpreting probability was pioneered by Venn (1866); leading twentieth century proponents of this interpretation (hereafter called *frequentists*) include Richard von Mises (1957) and Hans Reichenbach (1949).

One important problem with limiting relative frequencies is that they seldom, if ever, exist: no coin is actually tossed an infinite number of times. Thus the limiting relative frequencies that determine the probability of an outcome are really *hypothetical limiting relative frequencies*: to say that the probability of heads on a toss of a certain coin is 0.5 is to say that *if* the coin were to be tossed an infinite number of times, the limiting relative frequency of heads *would be* 0.5. This is a hypothetical or *counterfactual* claim; by itself, it says nothing about what features of the *actual world* make the probabilistic claim true. The problem of interpretation of counterfactuals is itself a thorny philosophical problem (see *Counterfactual Reasoning, Quantitative: Philosophical Aspects; Counterfactual Reasoning, Qualitative: Philosophical Aspects*).

One important issue that divides frequentists is whether it is possible to ascribe a probability value to the outcome of a single trial. One tradition, following von Mises (1957), views probability as a property of a sequence of trials, or a 'collective.' Any single coin toss belongs to infinitely many different sequences: the sequence of all coin tosses, the sequence of all tosses of that particular coin, the sequence of all tosses of that coin by imparting a particular force from a particular height above the floor, and so on. The limiting relative frequency of 'heads' may be different in each of these sequences. Thus, there is no unique probability of 'heads' on a given toss, but only a probability for 'heads' in a collective of tosses. While frequentists in this tradition deny that there is one privileged sequence of coin tosses, not just any sequence of tosses is fit to bear probability values. For example, if an infinite sequence of coin tosses were to yield an alternating sequence of 'heads' and 'tails,' the relative frequency of 'heads' would be 0.5. The regularity of the pattern of outcomes would nonetheless render this sequence inappropriate for characterizing a probability value. Rather, probabilities are limiting relative frequencies in a *random* sequence of trials. There is no universally accepted mathematical characterization of randomness, although this is currently an area of active research (see Earman 1986, Chap. VIII). For a more detailed exposition of this version of the limiting relative frequency interpretation, see *Probability: Interpretations*.

One feature of this approach is that it allows chances to take on values other than zero or one even if determinism is true. It may be that on any particular toss of a coin, the linear and angular momentum imparted to the coin together with its height above the floor and so on determine the outcome of the coin toss. Nonetheless, there may be a random sequence of coin tosses where the limiting relative frequency is not equal to zero or one, for the tosses comprising the collective need not be identical with respect to such determining factors.

The relegation of probabilities to properties of collectives would seem to be a drawback of this approach to probability. When deciding whether to bet on a coin toss, or to postpone a picnic, one wants to know the probability of heads *on that particular toss*, or the probability of rain *on this particular day*. Some frequentists, following Reichenbach, believe that it is possible to assign probability values to the outcomes of individual trials. This requires that a choice be made from among all of the sequences to which the trial in question belongs. For example, a particular day belongs in an infinite number of sequences of days, and the limiting relative frequency of rain need not be the same in all of them, so which sequence determines the probability of rain on the day in question? Presumably not just the sequence of all days, for then the probability of rain would not vary from day to day. A natural thought is that what is

wanted is a sequence of days *just like this one*. No two days will be exactly alike in *all* respects, however; the best that can be hoped for is a sequence of days that are alike in all *relevant* respects. The key problem, then, is to say what makes some respects of similarity between days relevant and others irrelevant. One detailed proposal is developed in Salmon (1984, Chap. 3).

On this approach, determinism is compatible only with chances of zero or one. Suppose, for example, that on a given day, climactic conditions determine that it will rain. Then the appropriate sequence will presumably consist of days in which the same climactic conditions prevail, and hence the limiting relative frequency of rain within that sequence will be one.

4.3 Propensity Interpretation

The propensity interpretation of probability, first introduced by Karl Popper (1959), is motivated by some of the difficulties with the limiting relative frequency interpretation. According to this interpretation, a coin, in conjunction with the conditions in which it is tossed, has a certain *disposition* or *propensity* to land heads. The probability that the coin will land heads is a measure of the strength of this propensity. This propensity is a property of the particular experimental set-up, hence, it is appropriate to assign a probability to an individual trial. Moreover, this propensity provides grounds for the truth of claims about what the coin *would do* if tossed infinitely many times in identical (or relevantly similar) conditions.

While this is certainly a useful way of thinking about single case probabilities within a frequentist framework, critics wonder whether anything has really been added. A coin is about to be tossed: there is some property of this experimental set-up in virtue of which the coin *would* land heads with a certain limiting relative frequency if this experiment were repeated infinitely often; calling this property a 'propensity' of a certain strength does little to indicate just what this property is. Moreover, if propensities are *P*not simply identified with hypothetical limiting relative frequencies, it is hard to see what is supposed to ground the claim that propensities have the mathematical structure of probabilities.

4.4 Best System Interpretation

The philosopher David Lewis (1986) has proposed an interpretation according to which an objective probability claim is true when it is entailed by a probabilistic law (see *Causes and Laws: Philosophical Aspects*). On this view, objective probability is intimately connected with indeterminism. A probabilistic claim is a law if it belongs to the set of propositions that provides the best overall systematization of the world. In order to be the best systematization, a set of propositions must

obtain the optimal balance between informativeness, simplicity, and fit with data. For example, consider the claim that a photon will pass through a polarizer with a probability of $\cos^2\theta$. Although the frequency with which photons do pass through when the experiment is performed may diverge from this number, the probability value is firmly grounded in the principles of quantum mechanics, which overall provides an excellent fit with experimental data, and is a powerful and elegant theory.

Unlike the frequency interpretations, however, the truth conditions for probabilistic claims provided by the best system interpretation are not very precise. It is not clear what makes one set of propositions simpler than another, nor how simplicity is to be balanced against informativeness and goodness of fit.

4.5 Theoretical Role Interpretations

One further line of interpretation is influenced by the philosophical school of pragmatism (see *Pragmatism: Philosophical Aspects*). In this approach, objective probability claims are to be understood in terms of their role in our overall conceptual system. In particular, to understand a probability claim is to know what kinds of evidence would support or undermine that claim, and how to act accordingly if one accepts that claim as true. This approach has been developed by Mellor (1971), Skyrms (1980), and Lewis (1986).

Consider an agent whose degrees of belief conform to the rules of probability (see Sect. 3.2), and let *Ch* be a function that assigns numerical values to propositions. The agent takes *Ch* to be objective chance precisely if his or her degrees of belief are guided by beliefs about the values of *Ch*. For example, suppose that the agent believes *Ch* ('it will rain today') to be 0.3. If the agent understands *Ch* to be objective chance, then his or her degree of belief in the proposition 'it will rain today' will also be 0.3. This degree of belief, together with the agent's utility function, can then be used to decide whether or not to postpone a picnic. In this way, then, the agent's beliefs about objective chances influence his or her decisions. Moreover, since objective probability claims are now propositions about which the agent has degrees of belief, the apparatus of Bayesian confirmation theory shows how those degrees of belief will change in the face of new evidence.

This approach has a number of virtues, not least of which is that it explains why objective chances have the formal properties of probability theory: in order for beliefs about chances to guide degrees of belief in the appropriate way, objective chances must have the same formal structure as rational degrees of belief. There is, however, an important drawback to this approach. In analyzing the meaning of objective probability claims in terms of their theoretical role instead of their truth conditions, this account does not

answer what many have taken to be the central question of objective probability: what must be the case in the world in order for the (objective) probability of rain to be 0.3?

5. Conclusion

Interest in the philosophical aspects of probability dates back to the origins of the formal theory of probability in the seventeenth century. Epistemic and frequency interpretations of probability have been around for well over a century. In the second half of the twentieth century, interest in objective interpretations of single-case probabilities has dramatically increased the range of interpretive options available. Given the current lack of consensus, and the increasingly widespread use of probabilistic concepts in both philosophy and everyday life, it is safe to predict that interest in the problem of the interpretation of probability will continue into the twenty-first century.

Probability Density Estimation

Associated with each random variable, X , measured during an experiment is the cumulative distribution function (cdf), $F(x)$. The value of the cdf at $X = x$ is the probability that $X \leq x$. Features in a set of random data may be computed analytically if the cumulative distribution function is known. The probability that a random sample falls in an interval (a, b) may be computed as $F(b) - F(a)$. This formula assumes the values of X are continuous. Discrete random variables taking on only a few values are easy to handle; thus, this article focuses on continuous random variables with at least an interval scale.

The same information may be obtained from the probability density function (pdf), $f(x)$, which equals $\Pr(X = x)$ if X takes on discrete values, or the derivative of $F(x)$ if X is continuous. If either $F(x)$ or $f(x)$ is known, then any quantity of interest such as the variance may be computed analytically or numerically. Otherwise, such quantities must be estimated using a random sample $x_1, x_2, \dots, x_n$. The relative merits of estimating $F(x)$ vs. $f(x)$ are an important part of this article.

Density estimation takes two distinct forms—parametric and nonparametric—depending on prior knowledge of the parametric form of the density. If the parametric form $f(x|\vec{\theta})$ is known up to the p parameters $\vec{\theta} = (\theta_1, \dots, \theta_p)$, then the parameters may be estimated efficiently by maximum likelihood or Bayesian algorithms. When little is known of the parametric form,

nonparametric techniques are appropriate. The most commonly used estimators are the histogram and kernel methods, as discussed below.

1. Histograms and CDFs

Grouping and counting the relative frequency of data to form a histogram may be taught at the beginning of every statistics course, but the concept seems to have emerged only in 1662 when John Graunt studied the Bills of Mortality and constructed a crude life table of the age of death during those times of plague (Westergaard 1968). Today the histogram and its close relative, the stem-and-leaf plot, provide the most important tools for exploring and representing structure in a set of data. Studying the shape of a well-constructed histogram can verify an assumption of normality, or reveal departures from normality such as skewness, kurtosis, or multiple modes. The recent study of the theoretical properties of histograms has led to concrete methods for computing well-constructed figures as discussed below.

With only a random sample of data, the cdf may be estimated by the empirical cdf (ecdf), denoted by $F_n(x)$. The value of the ecdf at x is the fraction of the sample with values less than or equal to x , that is, $\{\#x_i \leq x\}$. Now the probability any one of the x_i is less than x is given by the true cdf at x . Hence, on average, the value of $F_n(x)$ is exactly $F(x)$, and $F_n(x)$ is an unbiased estimator of $F(x)$. The inequality $\{X_i \leq x\}$ is a binomial random variable, so that the variance of

Figure 1

Empirical cumulative distribution function of physicians' estimated treatment times for a patient suffering migraine headaches. The dotted line is the cdf of the normal fit

Figure 2

Frequency histogram of treatment times

$F_n(x)$ may be computed as $F(x)(1 - F(x))/n$. In fact, there is no other unbiased estimator with smaller variance.

The graph of the empirical cdf looks like a staircase function. Figure 1 displays the ecdf of the treatment times estimated by 33 physicians when presented with a hypothetical patient suffering from extreme migraine headaches (Hebl and Xu 2000). The dotted line is the cdf of the fitted normal density $N(31.3, 9.9^2)$, which appears to fit reasonably well. Figure 2 displays a histogram of the same data, which does not appear to be normal after all. Social scientists often are taught to favor the ecdf over the histogram, but in fact aside from computing probabilities, the ecdf is not well-suited for the easy understanding of data.

The probability density function, $f(x)$, carries the same information as the cdf. Since the derivative of the empirical cdf $F_n(x)$ is not well-defined, estimators that rely on grouping have been devised. A convenient interval, (a, b) , containing the data is chosen, and subdivided into m 'bins' of equal width $h = (b - a)/m$. The value h is called the bin width (and is often called the smoothing parameter). A 'well-constructed' histogram must specify appropriate values for a , b , h , and m . Given such parameters, the number of samples falling into each of the m bins is tallied. Label the m bin counts $v_1, v_2, \dots, v_m$ from left to right. If the interval (a, b) contains all the samples, then $\sum_{k=1}^m v_k = n$. A *frequency histogram* is simply a plot of the bin counts, as in Fig. 2. Although the values are all multiples of 5 min, the data may be treated as continuous. However, the bin width should only be a multiple of 5 and care should be exercised to choose a and h so that no data points fall where two bins adjoin. Here, $a = 2.5$, $b = 57.5$, and $h = 5$. The histogram suggests a departure from normality in the form of three modes. Re-examine the ecdf in Fig. 1 and try to identify the same structure.

A true probability density is a non-negative function that integrates (sums) to 1. Hence, the *density his-*

Figure 3
Density histogram of the distances of Mark McGwire's 70 home runs in the 1998 season

togram is a simple normalization of the frequency histogram in the k^{th} bin,

$$\hat{f}(x) = \frac{v_k}{nh} \quad (1)$$

The normalization is important when the data are heavily skewed and unequal bin widths are constructed. In such cases, the interval (a, b) is partitioned into m bins of width $h_1, h_2, \dots, h_m$. The bin counts $v_1, v_2, \dots, v_m$ should *not* be plotted as they are not relatively proportional to the true density histogram, which is now given by $\hat{f}(x) = v_k/(nh_k)$ in the k th bin. Figure 3 displays a density histogram of the distances of the 70 home runs hit by Mark McGwire during his record-setting 1998 American baseball season. A bin width of 20ft was chosen, and then several adjacent bins were collapsed to make the histogram look unimodal. The long right tail reflects the booming home runs for which McGwire is known.

2. Bin Width Construction

Rules for determining the number of bins were first considered by Sturges in 1926. Such rules are often designed for normal data, which occur often in practice. Sturges observed that the m th row of Pascal's triangle, which contains the combinatorial coefficients $\binom{m-1}{0}, \binom{m-1}{1}, \dots, \binom{m-1}{m-1}$, when plotted, appears as an ideal frequency histogram of normal data. (This is a consequence of the central limit theorem for large m .) The sum of these 'bin counts' is 2^{m-1} by the binomial expansion of $(1+1)^{m-1}$. Solving the equation $n = 2^{m-1}$ for the number of bins, we obtain Sturges' rule

$$m = 1 + \log_2 n \quad (2)$$

This rule is widely applied in computer software.

The modern study of histograms began in Scott (1979) and Freedman and Diaconis (1981). The optimization problem formulated was to find the bin width h to make the average value of the 'distance' $\int [\hat{f}(x) - f(x)]^2 dx$ as small as possible. The solution for the best bin width is

$$h^* = \left[\frac{6}{\int f'(x)^2 dx} \right]^{1/3} n^{-1/3} \quad (3)$$

While the integral of the derivative of the unknown density is required to use this formula, two useful applications are available. First, the *normal reference rule* gives

$$h^* = 3.5\sigma n^{-1/3} \quad (4)$$

since the value of the integral for a normal density is $(4\sqrt{\pi}\sigma^3)^{-1}$. The second application was given by Terrell and Scott (1985) who searched for the 'easiest' smooth density (which excludes the uniform density) and found that the number of bins in a density should always exceed $\sqrt[3]{2n}$ or that the bin width should always be less than

$$h^* \leq 3.73\sigma n^{-1/3} \quad (5)$$

These choices are called *oversmoothed rules*, as the optimal choices will never be more extreme for other less smooth densities. Notice that the normal reference rule is very close to the upper bound given by the oversmoothed rule. For the McGwire data, the oversmoothed rule gives $h^* \leq 42'$.

More sophisticated algorithms for estimating a good bin width for a particular data set are described in Scott (1992) and Wand (1997). For example, a cross-validation algorithm (Rudemo 1982) that attempts to minimize the error distance directly leads to the criterion

$$CV(h) = \frac{2}{(n-1)h} - \frac{n+1}{(n-1)n^2h} \sum_{k=1}^m v_k^2 \quad (6)$$

The bin counts are computed for a selection of bin widths (and bin origins), the criterion computed, and the minimizer chosen, subject to the over-smoothed bound. The criterion tends to be quite noisy and Wand (1997) describes alternative plug-in formulae that can be more stable.

All of these rules give bin widths which shrink at the rate $n^{-1/3}$ and give many more bins than Sturges' rule. In particular, most computer programs give histograms which are *oversmoothed*. The default values

should be overridden, especially for large datasets. Similarly, the error of the best histogram decreases to zero at the rate $n^{-2/3}$, which can be improved to $n^{-4/5}$ as described below. However, the histogram remains a powerful and intuitive choice for density estimation and presentation.

3. Advanced Algorithms

Density estimators with smaller errors are continuous functions themselves. The easiest such estimator is the frequency polygon, which connects the midpoints of a histogram. A separate error theory exists. For example, the oversmoothed bin width for a histogram from which the frequency polygon is drawn is given by

$$h^* \leq 2.33\sigma n^{-1/5}$$

Note that this bin width is wider than the rules for the histogram alone.

Many other estimators exist, based on splines, wavelets, Fourier series, or local likelihood, but all are closely related to the kernel estimator of Rosenblatt (1956) and Parzen (1962), which is described here. The kernel can be any probability density function, but the normal density is a common and recommended choice. Here the smoothing parameter h is the standard deviation of the normal kernel. If the normal density $N(\mu, \sigma^2)$ at a point x is denoted by $\phi(x|\mu, \sigma)$, then the kernel estimator is

$$\hat{f}_K(x) = \frac{1}{n} \sum_{i=1}^n \phi(x|x_i, h)$$

This form shows that the kernel estimator is a mixture of normal densities which are located at the data points. The oversmoothed smoothing parameter value is

$$h^* \leq 1.14\sigma n^{-1/5}$$

An example is given below.

4. Visualization

The primary uses of density estimation are to display the structure in a set of data and to compare two sets of data. The histogram is adequate for the first task, but overlaying two histograms for comparison is difficult to interpret. The continuity and improved error properties of the kernel estimators excel for this purpose.

In the great home run race of 1998, Sammy Sosa finished second with 66 home runs. Figure 4 displays the empirical cdfs of the distances for the two home run kings (Keating and Scott 1999). This graph clearly shows that McGwire hits longer home runs than Sosa

Figure 4

Empirical cumulative distribution functions of the distances of Mark McGwire's 70 (solid line) and Sammy Sosa's 66 (dotted line) home runs in 1998

Figure 5

Kernel density estimates of the distances of Mark McGwire's 70 (solid line) and Sammy Sosa's 66 (dotted line) home runs in the 1998 season. McGwire's data are plotted below the horizontal line and Sosa's above

at every distance. In Fig. 5, kernel estimates of the McGwire and Sosa data with $h = 10$ are overlaid. The possible structure in these data is reinforced by the similarity of the two densities. Each has two primary modes at 370 ft and 425 ft, with smaller feature around 475 ft. In addition, McGwire's density clearly shows the right tail of his longest homers. In contrast, the modes in the original histogram of Fig. 3 did not appear convincing, and were eliminated by locally adjusting the bin widths. The continuity of the kernel and other estimators makes the assessment of modes much easier.

5. Multivariate Densities

Histograms can be constructed in the bivariate case and displayed in perspective, but cannot be used to draw contour plots. Kernel methods are well-suited

for this purpose. Given a set of data $(x_1, y_1), \dots, (x_n, y_n)$, the bivariate normal kernel estimator is given by

$$\hat{f}_K(x, y) = \frac{1}{n} \sum_{i=1}^n \phi(x|x_i, h) \phi(y|y_i, h)$$

A different smoothing parameter can be used in each variable.

For three and four-dimensional data, the kernel estimator can be used to prepare advanced visualization renderings of the data. Scott (1992) provides an extension set of examples.

6. Other Materials

A number of other monographs exist that delve into various aspects of nonparametric approaches. A thorough survey of all topics by top researchers is contained in Schimek (2000). Early works popularizing these ideas include Tapia and Thompson (1978) and Silverman (1986). Wand and Jones (1994) and Simonoff (1996) focus on kernel-methods. Fan and Gijbels (1996) and Loader (1999) focus on local polynomial methods. General smoothing ideas are discussed by Härdle (1991) and Bowman and Azzalini (1997). Many other excellent references may be followed in these books.

Probability: Formal

Probability theory is a branch of mathematics that has evolved from the investigation of social, behavioral, and physical phenomena that are influenced by randomness and uncertainty. For much of its early life, probability theory dealt almost exclusively with gambling games, and, even though there were important contributions made by such distinguished mathematicians as Pierre de Fermat, Blaise Pascal, and Pierre-Simon de Laplace, the field lacked respectability and failed to attract sustained attention.

One cause of the slow development of probability theory in its early days was the lack of a widely accepted foundation. Unlike the geometry of Euclid, or even the analytical investigations of Newton and Leibnitz, the theory of probability seemed to be eternally tied to the modeling process. In this respect, probability theory had greater kinship with the theories of heat or elasticity than with the pristine worlds of geometry or algebra.

Over time, foundations for probability were proposed by a number of deep thinking individuals including von Mises, de Finetti, and Keynes, but the approach that has come to be the most widely accepted is the one that was advanced by Andrey Nikolayevich Kolmogorov (1933).

Kolmogorov's approach to the foundations of probability theory developed naturally from the theory of integration that was introduced by Henri Lebesgue and others during the first two of decades of the twentieth century. By leaning on the newly developed theory of integration, Kolmogorov demonstrated that probability theory could be simply viewed as another branch of mathematics. After Kolmogorov's work, probability theory had the same relationship to its applications that one finds for the

theory of differential equations. As a consequence, the stage was set for a long and productive mathematical development.

To be sure, there are some philosophical and behavioral issues that are not well addressed by Kolmogorov's bare-bones foundations, but over the years, Kolmogorov's approach has been found to be adequate for most purposes. The Kolmogorov axioms are remarkably succinct, yet they have all the power that is needed to capture the physical, social, and behavioral intuition that a practical theory of probability must address.

1. Kolmogorov's Axiomatic Foundations

Central to Kolmogorov's foundation for probability theory was his introduction of a triple $(\Omega, \mathcal{F}, P)$ that is now called a probability space. The triple's first element, the 'sample space' Ω , is only required to be a set, and on the intuitive level, one can think of Ω as the set of all possible outcomes of an experiment. For example, in an experiment where one rolls a traditional six-faced die, then one can take $\Omega = \{1, 2, 3, 4, 5, 6\}$.

The second element of Kolmogorov's probability space is a collection $\mathcal{F}$ of subsets of Ω that satisfy three basic consistency properties that will be described shortly. On the intuitive level, one can think of the elements of $\mathcal{F}$ as 'events' that may occur as a consequence of the experiment described by $(\Omega, \mathcal{F}, P)$. Thus, to continue with the example of rolling a die, the set $A = \{1, 3, 5\} \subset \Omega$ would correspond to the event that one rolls an odd number.

Two of the three consistency properties that Kolmogorov imposes on the $\mathcal{F}$ are quite trivial. First, $\mathcal{F}$ is required to contain Ω . Second, $\mathcal{F}$ must be closed under complementation; so, for example, if $A \in \mathcal{F}$ then $A^c \in \mathcal{F}$ where $A^c = \{\omega: \omega \in \Omega \text{ and } \omega \notin A\}$. This third condition is only a bit more elaborate; the collection $\mathcal{F}$ must be closed under countable unions. Thus, if $A_k \in \mathcal{F}$ for $k = 1, 2, \dots$, then one requires that the union $A_1 \cup A_2 \cup \dots$ of all the events in the countable set $\{A_k: 1 \leq k < \infty\}$ must again be an element of $\mathcal{F}$.

The most interesting element of Kolmogorov's triple $(\Omega, \mathcal{F}, P)$ is the 'probability measure' P . Formally, P is just a function that assigns a real number to each of the elements of $\mathcal{F}$, and, naturally enough, one thinks of $P(A)$ as the probability of the event A . Thus, one can specify a probability model for the outcome of rolling a fair die, by 'defining' P for $A \subset \Omega$ by $P(A) = \frac{1}{6}|A|$, where $|A|$ denotes the number of elements of the set A .

For sample spaces Ω that are not finite, more care is required in the specification of the probability measures P . To deal with general Ω , Kolmogorov restricted his attention to those P that satisfy three basic axioms:

Axiom 1. For all $A \in \mathcal{F}$, one has $P(A) \geq 0$.

Axiom 2. $P(\Omega) = 1$.

Axiom 3. For any countable collection $\{A_k \in \mathcal{F}: 1 \leq k < \infty\}$ with the property that $A_j \cap A_k = \emptyset$ for all $j \neq k$, one has

$$P\left(\bigcup_{i=1}^{\infty} A_i\right) = \sum_{i=1}^{\infty} P(A_i)$$

Axioms 1 and 2 just reflect the intuitive view that $P(A)$ measures the frequency with which A occurs in an imagined sequence of repetitions of the experiment $(\Omega, \mathcal{F}, P)$. For most mathematicians, axiom 3 also just reflects the most basic intuition about the way probabilities should behave. Nevertheless, axiom 3 is more subtle because it deals with an infinite collection of sets, and in some ways, such collections are outside of our direct experience. This has lead some philosophers to examine the possibility of avoiding Kolmogorov's third axiom, and over the years various attempts have been made to replace Kolmogorov's third axiom with the simpler assumption of 'finite additivity.'

2. Random Variables

In most applications of probability theory, the triple $(\Omega, \mathcal{F}, P)$ that gives life to probability as a rigorous mathematical subject is almost invisible. In practice, builders of probability models take advantage of various shortcuts that have the effect of keeping the probability triple at a respectful distance. The most important of these shortcuts is the notion of a 'random variable.'

On the intuitive level, a random variable is just a number that depends on a chance-driven experiment. More formally, a random variable X is a function from Ω to the real numbers with the property that $\{\omega: X(\omega) \leq t\} \in \mathcal{F}$ for all t . What drives this definition is that one inevitably wants to talk about the probability that X is less than t , and for such talk to make sense under Kolmogorov's framework, the set $\{\omega: X(\omega) \leq t\}$ must be an element of $\mathcal{F}$. Random variables make the modeler's job easier by providing a language that relates directly to the entities that are of interest in a probability model.

3. The Distribution Function and Related Quantities

There are several ways to specify the basic probabilistic properties of a random variable, but the most fundamental description is given by the 'distribution function' of X , which is defined by $F(t) = P(X \leq t)$. Knowledge of the distribution function tells one everything that there is to know about the probability theory of the random variable. Sometimes it even tells too much.

The knowledge one has of a random variable is often limited, and in such cases it may be useful to

focus on just part of the information that would be provided by the distribution function. One common way to specify such partial information is to use the ‘median’ or the ‘quantiles’ of the random variable X . The median is defined to be a number m for which one has $P(X < m) \leq 1/2 \leq P(X \leq m)$. Roughly speaking, the median m splits the set of outcomes of X into two halves so that the top half and the bottom half each have probability that is close to one-half.

The quantile x_p does a similar job. It splits the possible values of X into disjoint sets, so that one has $P(X < x_p) \leq p \leq P(X \leq x_p)$. When $p = 1/2$, the quantile x_p reduces to the median, and, when $p = 1/4$ or $p = 3/4$, then x_p is called the ‘lower quartile,’ or the ‘upper quartile,’ respectively.

4. Mass Functions and Densities

If a random variable X only takes values from a finite or countable set S , then X is called a ‘discrete’ random variable. In such cases, one can also give a complete description of the probabilistic properties of X by specification of the ‘probability mass function,’ which is defined by setting $f(x) = P(\{x\})$ for all $x \in S$. Here, one should note that the probability mass function f , permits one to recapture the distribution function by the relation

$$F(t) = \sum_{x \leq t, x \in S} f(x) \quad \text{for all } t$$

There are many important random variables whose values are not confined to any countable set, but for some of these random variables, there is still a description of their distribution functions that is roughly analogous that provided for discrete random variables. A random variable X is said to be ‘absolutely continuous’ provided that there exist a function f such that the distribution function of X has a representation of the form

$$F(t) = \int_0^t f(x) dx \quad \text{for all } t$$

The function f in this representation is called the ‘density’ of X , and many random variables of practical importance have densities. The most famous of these are the ‘standard normal’ (or, ‘standard Gaussian’) random variables that have the density

$$f(x) = \frac{1}{\sqrt{2\pi}} e^{-x^2/2} \quad \text{for all } -\infty < x < \infty$$

which has a key role in the Central Limit Theorem that will be discussed shortly.

Much of the theory of probability can be developed with just the notion of discrete or absolutely con-

tinuous random variables, but there are natural random variables that do not fit into either class. For this reason, the distribution function remains the fundamental tool for describing the probabilities associated with a random variable; it alone is universal.

5. Mathematical Expectation: A Fundamental Concept

If X is a discrete random variable, then its ‘mathematical expectation’ (or just expectation, for short) is defined by

$$E(X) = \sum_{x \in S} x f(x)$$

where f is the probability mass function of X . To illustrate this definition, one can take X to be the outcome of rolling a fair die, so that $f(x) = 1/6$ for all $x \in S = \{1, 2, \dots, 6\}$ and

$$E(X) = 1 \cdot \frac{1}{6} + 2 \cdot \frac{1}{6} + \dots + 6 \cdot \frac{1}{6} = \frac{7}{2}$$

In a way that is parallel—yet not perfectly so—the expectation of an absolutely continuous random variable X is defined by the integral

$$E(X) = \int_{-\infty}^{\infty} x f(x) dx$$

Here one needs to work a bit harder to illustrate the definition. Consider, for example, an experiment where one chooses a number at random out of the unit interval $[0, 1]$. From the intuitive meaning of the experiment, one has $P(A) = a$ for $A = [0, a]$, and, from this relationship, one can calculate that the density function for X is given by $f(x) = 1$ for $x \in [0, 1]$ and by $f(x) = 0$ otherwise. For the density f , one therefore finds that

$$E(X) = \int_{-\infty}^{\infty} x f(x) dx = \int_0^1 x \cdot 1 dx = \frac{1}{2}$$

From this formula, one sees that the expected value of a number chosen at random from the unit interval is equal to one-half, and for many people this assertion is perfectly reasonable. Still, one should note that the probability that X equals one-half is in fact equal to zero, so the probabilistic use of the word ‘expected value’ differs modestly from the day-to-day usage.

The probability distribution function and the expectation operation provide almost all of the language that is needed to describe the probability theory of an individual random variables. To be sure, there are

several further notions of importance, but these may all be expressed in terms of the distribution or the expectation. For example, the most basic measure of dispersion for the random variable X is its ‘variance,’ which is defined in terms of the expectation by the formula

$$\text{Var}(X) = E(X - \mu)^2 \quad \text{where } \mu = E(X)$$

Finally, the ‘standard deviation’ of X , which is defined to be the square root of $\text{Var}(X)$, provides a useful measure of scale for problems involving X .

6. Introducing Independence

The world of probability theory does not stop with the description of a single random variable. In fact, it becomes rich and useful only when one considers collections of random variables—especially collections of ‘independent’ random variables.

Two events A and B in $\mathcal{F}$ are said to be independent provided that they satisfy the identity,

$$P(A \cap B) = P(A) P(B)$$

What one hopes to capture with this definition is the notion that the occurrence of A has no influence on the occurrence of B —and vice versa. Nevertheless, the quantities that appear in the defining formula of independence are purely mathematical constructs, and any proof of independence ultimately boils down to the proof of the defining identity in a concrete model $(\Omega, \mathcal{F}, P)$.

Consider, for example, the experiment of rolling two fair dice, one red and one blue. The sample space Ω for this experiment may be taken to be the 36 pairs (j, k) with $1 \leq j \leq 6$ and $1 \leq k \leq 6$, where one thinks of j and k as the number rolled on the red and blue die, respectively. Here, for any $A \subset \Omega$ one can set $P(A) = |A|/|\Omega|$ in order to obtain a model for a pair of fair dice. Under this probability model, there are many pairs of events that one can prove to be independent. In particular, one can prove that the event of rolling an even number on the blue die is independent of rolling an odd number on the red die. More instructively, one can also prove that the event of rolling an even number on the blue die is independent of the parity of the sum of the two dice.

7. Extending Independence

The concept of independence can be extended to random variables by defining X and Y to be independent provided that the events $\{X \leq s\}$ and $\{Y \leq t\}$ are independent for all real s and t . One easy

consequence of this definition is that for any pair of monotone functions ϕ and ψ the random variables $\phi(X)$ and $\psi(Y)$ are independent whenever X and Y are independent. This mapping property reconciles nicely with the intuitive assertion: if X and Y have no influence on each other, then neither should $\phi(X)$ and $\psi(Y)$ have any influence on each other.

The importance of independence for probability theory will be underscored by the theorems of Sect. 8, but first the notion of independence must be extended to cover more than just pairs of random variables. For a finite collection of n random variables $X_1, X_2, \dots, X_n$, the condition for ‘independence’ is simply that

$$\begin{aligned} P(X_1 \leq t_1, X_2 \leq t_2, \dots, X_n \leq t_n) \\ = P(X_1 \leq t_1) P(X_2 \leq t_2) \cdots P(X_n \leq t_n) \end{aligned}$$

for all real values $t_1, t_2, \dots, t_n$. Finally, an infinite collection of random variables $\{X_s: s \in S\}$ is said to be independent provided that every finite subset of the collection is independent.

8. The Law of Large Numbers

Any mathematical theory that hopes to reflect real-world random phenomena must provide some rigorous interpretation of the intuitive ‘law of averages.’ Kolmogorov’s theory provides many such results, the most important of which is given in the following theorem.

Theorem 1 (Law of Large Numbers). Suppose that $\{X_i: 1 \leq i < \infty\}$ is a sequence of independent random variables with a common distribution function $\mathcal{F}(\cdot)$, so $P(X_i \leq t) = \mathcal{F}(t)$ for all $1 \leq i < \infty$ and all real t . If the expectation $\mu = E(X_1)$ is well-defined and finite, then the random variables

$$\frac{1}{n} \{X_1 + X_2 + \cdots + X_n\}$$

converge to their common mean μ with probability one. More precisely, if one lets

$$A = \left\{ \omega: \lim_{n \rightarrow \infty} \frac{1}{n} \{X_1(\omega) + X_2(\omega) + \cdots + X_n(\omega)\} = \mu \right\}$$

then the event A satisfies $P(A) = 1$.

9. The Central Limit Theorem

The second great theorem of probability theory is the famous Central Limit Theorem. Although it is not tied as tightly to the meaning of probability as the Law of

Large Numbers, the Central Limit Theorem is key to many of the practical applications of probability theory. In particular, it often provides a theoretical interpretation for the ‘bell curve’ that emerges in countless empirical investigations.

Theorem 2 (Central Limit Theorem). Suppose that $\{X_i; 1 \leq i < \infty\}$ is a sequence of independent random variables with a common distribution function $\mathcal{F}$. If these random variables have a finite variance $\text{Var}(X_i) = \sigma^2$, then

$$\lim_{n \rightarrow \infty} P \left(\frac{1}{\sigma\sqrt{n}} \{X_1 + X_2 + \cdots + X_n - n\mu\} \leq x \right) \\ = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-u^2/2} du$$

10. Stochastic Processes

The most fundamental results of probability theory address the behavior of sums of independent random variables, but many applications of probability theory lead to sequences of random variables $\{X_n; 1 \leq n < \infty\}$ that may not be independent. Such sequences are called ‘stochastic processes,’ and they are of many different types.

The simplest nontrivial stochastic process is the ‘Markov chain,’ which is used to model random phenomena where X_{n+1} depends on X_n , but, given X_n , the value of X_{n+1} does not depend on the rest of the past $X_{n-1}, X_{n-2}, \dots, X_1$. To construct such a process, one most often begins with an $n \times n$ matrix $T = \{p_{ij}\}$ with entries that satisfy $0 \leq p_{ij} \leq 1$ and with row sums that satisfy $p_{i1} + p_{i2} + \cdots + p_{in} = 1$. One then generates the Markov chain by making sequential selections from the set $\mathcal{S} = \{1, 2, \dots, n\}$ in accordance with the rows of the ‘transition matrix’ T . Specifically, if $X_n = i$, then X_{n+1} is obtained by choosing an element of $\mathcal{S}$ in accordance with the probabilities (p_{ij}) given by the i th row of T .

A second group of stochastic processes that is of considerable practical importance is the set of ‘martingales.’ Roughly speaking, these are stochastic processes that have the property that the expectation of X_{n+1} given the values of $X_n, X_{n-1}, \dots, X_1$ is just equal to X_n . One reason that martingales are important is that they provide a model for the fortune of an individual who gambles on a fair game. Such gambling games are relatively unimportant in themselves, but many economic and financial questions can be reframed as such games. As a consequence, the theory of martingales has become an essential tool in the pricing of stock options and other derivative securities.

The theory of stochastic processes is not confined to just those sequences $\{X_n; 1 \leq n < \infty\}$ with the discrete

index set $\{1 \leq n < \infty\}$, and, in fact, almost any set $\mathcal{S}$ can serve as the index set. When one takes $\mathcal{S}$ to be the set of non-negative real numbers, the index is often interpreted as time, and in this case one speaks of continuous time stochastic processes. The most important of these are the ‘Poisson process’ and ‘Brownian motion.’ Brownian motion is arguably the most important stochastic process.

11. Directions for Further Reading

For a generation, Feller (1968) has served as an inspiring introduction to probability theory. The text only assumes a modest background in calculus and linear algebra, yet it goes quite far. The text of Dudley (1989) is addressed to more mathematically sophisticated readers, but it contains much material that is accessible to readers at all levels. In particular, Dudley (1989) contains many informative historical notes with careful references to the original sources.

For an introduction to the theory of stochastic processes, the text by Çinlar (1975) is recommended, and for an easy introduction to Brownian motion, martingales, and their applications in finance, one can consult Steele (2000).

For background on the early development of probability theory, the books of David (1962) and Stigler (1986) are useful, and the article by Doob (1994) helps make the link to the twenty-first century. Finally, for direct contact with the master, anyone does well to read Kolmogorov (1933).

Probability: Interpretations

1. Qualitative and Quantitative Probability

1.1 Introduction

It is entirely unremarkable that the commonplace word ‘probability’ and its cognates display a wide variety of distinct meanings in ordinary language. It is used as a classificatory concept, as in ‘It is *probable* that it will snow this winter’ or ‘It is *improbable* that a fair coin will land heads 10 times in succession.’ It is used as a (qualitative) comparative relation, as in ‘It is *more probable* that someone will be killed by lightning than by a falling meteorite next year.’ And, of course, it is used as a quantitative concept throughout science, e.g., Mendel’s law, ‘The probability is 0.75 that the offspring of a cross between simple hybrids will show the dominant trait.’ What is worth noting, however, is that despite longstanding controversies over the legitimate interpretation of ‘probability,’ these diverse usages can nonetheless be linked easily to a few formal theories of mathematical probability.

The received formal theory of quantitative probability, due to Kolmogorov, is elegant. Mathematical probability is a (real-valued) function, P , with values between 0 and 1 (inclusive), defined over a field of events closed under the Boolean operations of union, intersection, and complementation. The sure event Ω is certain, $P(\Omega) = 1$, and P is additive over unions of disjoint events. The qualitative formal theory of probability uses a binary relation $\prec$ also defined on an algebra of events: $E \prec F$ means that event F is more probable than event E . The qualitative formal theory is presented through axioms that mimic the quantitative one.

The outline for this article is as follows. Sections 1.2 and 1.3 review relevant details of the received, formal (mathematical) theories of quantitative and qualitative probability, and some basic connections between them. (This section includes some technical results that the reader might bypass initially, to return to on a second reading.) Section 2 surveys several interpretations of the quantitative theory, including subjective probability (2.1), logical probability (2.2), objective probability (2.3), and an approach (2.4) here

labeled the Fisher–Kyburg theory, relating to Fisher’s enigmatic fiducial probability. Additional readings are suggested in Sect. 3.

1.2 The Formal Theory of Quantitative Probability

Begin with Kolmogorov’s (1956) mathematical theory for quantitative probability, dating from the 1930s. A measure space $\langle \Omega, \mathcal{F}, P \rangle$ is triple comprised by:

(1) a set of possibilities, Ω , whose elements, ω , are points of the space. A field $\mathcal{F} = \{E \text{ of subsets of } \Omega\}$. Elements of $\mathcal{F}$ are the events of the space. It is assumed that $\Omega \in \mathcal{F}$. Being a field, $\mathcal{F}$ is closed under finite unions, intersections, and complementation with respect to Ω . When $\mathcal{F}$ is infinite, usually it is required

(2) that $\mathcal{F}$ is a σ -field, closed under countable unions and intersections.

(3) A probability function P over $\mathcal{F}$ satisfying these axioms:

$$(3.1) \quad 0 \leq P(E) \leq 1$$

$$(3.2) \quad P(\Omega) = 1$$

$$(3.3) \quad P(E \cup F) = P(E) + P(F), \text{ whenever } E \cap F = \emptyset.$$

(finite additivity)

$$(3.4) \quad P(\cup E_i) = \sum_i P(E_i) \text{ whenever } E_i \cap E_j = \emptyset \text{ for } i \neq j. \text{ (}\sigma\text{-additivity)}$$

Moreover, when $P(F) > 0$, a conditional probability given F , $P(\cdot | F)$, is well defined over $\mathcal{F}$ by the equation

$$(4) \quad P(\cdot | F)P(F) = P(\cdot \cap F).$$

Kolmogorov’s mathematical theory provides a basis for each of the two nonquantitative uses of probability, illustrated above.

The classificatory concept of probability may be explicated as:

‘ E is *probable*’ provided that $P(E) > c > 0.5$, for some value c , determined by the context of the assertion. Then, ‘ E is *improbable*’ means that the complementary event E^c is probable.

The (qualitative) comparative concept of probability may be explicated as:

$$\text{‘}E \text{ is more probable than } F\text{’ provided that } P(E) > P(F)$$

1.3 The Formal Theory of Qualitative Probability

A mathematical theory of qualitative probability is readily obtained from the quantitative one. The binary relation $\prec$ over events is said to be a (qualitative) comparative probability relation if it satisfies the following three axioms that parallel the first three axioms of Kolmogorov’s theory.

(5.1) $\prec$ is an acyclic, transitive relation over $\mathcal{F}$. That is, if $E \prec F$ and $F \prec G$ then $E \prec G$, and it is never the case

that $E < F$. The qualitative relation that E and F are equiprobable events, denoted $E \approx F$, is defined by the condition that neither $E < F$ nor $F < E$. Then $\approx$ is transitive and reflexive, i.e., $E \approx E$ always obtains.

(5.2) $\emptyset < \Omega$ and for no event E , $E < \emptyset$.

(5.3) Provided that $E \cap (F \cup G) = \emptyset$, $F < G$ if and only if $(E \cup F) < (E \cup G)$.

Say that a quantitative probability P agrees with the comparative probability relation $<$ on the condition that, $P(E) < P(F)$ if and only if $E < F$. DeFinetti (1931) asked whether every comparative probability relation $<$ has an agreeing quantitative probability. Kraft et al. (1959) established that the answer is no, even when $\mathcal{F}$ is a finite space. However, they also showed that for finite spaces, the following (stronger) additivity condition is both necessary and sufficient for an agreeing quantitative probability to exist.

(5.4) Let $(E_1, \dots, E_m)$ and $(F_1, \dots, F_m)$ be two sequences of events from $\mathcal{F}$ such that, for each point ω in Ω , the same number of events from each sequence contain ω . If it is not the case that $F_i < E_i$ ($i = 1, \dots, m-1$), then it is not the case that $E_m < F_m$.

Aside: It is interesting to note that the very same condition, expressed for a quantitative probability, serves as a necessary and sufficient condition for extending the domain of a quantitative probability, Horn and Tarski (1948).

A different relationship between quantitative and qualitative probabilities is also worth consideration. Say that a quantitative probability P almost agrees with the comparative probability relation $<$ on the condition that $P(E) < P(F)$ only if $E < F$. That is, quantitative strict inequalities entail the corresponding qualitative (strict) inequality. However, when P almost agrees with $<$, it may be that $P(E) = P(F)$ and $E < F$. Kraft et al. (1959) provide an example of a finite space equipped with a qualitative probability relation that admits a continuum of almost agreeing quantitative probabilities but no agreeing quantitative probability. For finite spaces, the analog to (5.4) is the following necessary and sufficient condition for a qualitative probability to admit an almost agreeing quantitative probability.

(5.5) Let $(E_1, \dots, E_m)$ and $(F_1, \dots, F_m)$ be two sequences of events from $\mathcal{F}$ such that, for each point ω in Ω , fewer events from the first sequence contain ω than do events from the second sequence. If it is not the case that $F_i < E_i$ ($i = 1, \dots, m-1$), then $E_m < F_m$.

On infinite spaces, the situation is more complex and more interesting. The following illustrates how a qualitative probability may make finer discriminations than any quantitative probability, i.e., the qualitative relation $<$ is non-Archimedean.

Example: Let $\mathcal{F}$ be the set of all subsets of the positive integers $\{1, 2, \dots\} = \Omega$. Let $<$ be a qualitative probability subject to the following two constraints:

(a) Each integer, i.e., each point is as probable as any other. That is, for each pair of integers i and j , $i \approx j$.

(b) The qualitative probability relation respects proper subsets. That is, whenever $E \subset F$ (but $E \neq F$) then $E < F$.

(Aside: To establish the existence of a qualitative probability satisfying these constraints requires an appeal to the Axiom of Choice.) Condition (a) ensures that no countably additive probability agrees with $<$, since any agreeing probability must assign each point of Ω probability 0. Condition (b) insures that no finitely additive probability agrees with $<$, because, by the fact just noted, $P\{i, j\} = P\{i\} + P\{j\} = 0$. But by (b) $\{i\} < \{i, j\}$. There exists an almost agreeing (uniform) finitely additive probability for $<$, where $P\{i\} = 0$ for each integer i . Hence, this qualitative probability ordering is finer than any quantitative probability can be.

2. Interpretations of Quantitative Probability

2.1 Subjective Probability

The contemporary theory of subjective (or personal) probability has its roots in the writings by Ramsey (1926) and deFinetti (1937), from the 1920s and 1930s. Savage (1954) gives what to many is a definitive account of this line of reasoning. The subjective interpretation of the mathematical theory treats probability as a (rational) agent's assessment of uncertainty about a truth-value bearing proposition, E . (Here, equate the proposition asserting E and the event E of the mathematical theory.) The agent's uncertainty about E is expressed as her/his degree of belief in E , and under appropriate assumptions may be measured by the agent's disposition to wager on E (see *Bayesian Statistics*).

The so-called 'Dutch Book' argument offers a prudential account of why the rational agent who is willing to engage in betting (under conditions made explicit, below) will have degrees of belief that conform to the formal probability calculus. Suppose that betting is in monetary units.

Definitions:

A bet on E , at odds of $r:(1-r)$, with total stake $S > 0$ pays off to the agent with a gain of $(1-r)S$ in case E obtains, and with a loss of $-r(S)$ in case E fails to obtain.

A bet against E , at odds of $r:(1-r)$, with total stake $S > 0$ pays off to the agent with a loss of $-(1-r)S$ in case E obtains, and with a gain of $r(S)$ in case E fails to obtain.

The agent's betting odds of $r:(1-r)$ for E are fair just in case the agent is indifferent between betting on and betting against E at those odds, at least for moderate size stakes.

A (finite) set of bets constitutes a Dutch Book against the agent if the agent suffers a net loss from these bets regardless which state of affairs obtains.

The agent's fair betting odds are coherent if no Dutch Book is possible against them.

An elementary version of the 'Book' argument is captured in the following result:

The Dutch Book Theorem (deFinetti and Ramsey): Suppose that the rational agent offers fair odds for each event E in the space $\mathcal{F}$ and for moderate size stakes is willing to accept finite combinations of bets made at her/his fair odds. Then the agent is coherent, that is, immune to having a Dutch Book made if and only if her/his fair odds satisfy the axioms of mathematical (finitely additive) probability, (3.1)–(3.3).

Conditional probability, too, can be made the subject of the Dutch Book criterion by introducing called-off bets, e.g., a bet on E given F , which is annulled if F fails to occur.

Definition: A called-off bet on E given F , at odds of $r:(1-r)$, with total stake $S > 0$ pays off to the agent with a gain of $(1-r)S$ in case $E \cap F$ obtains, pays off with a loss of $-r(S)$ in case F obtains but E fails to obtain, and results in no change (0 payoff) in case F fails to obtain.

The concept of a called-off bet against E given F is likewise defined in parallel with the respective concepts for betting against an event, as is the condition of fair called-off odds. When called-off bets are included among those to be wagered on, the following improved result ensues.

Dutch Book Theorem for conditional probability:

Assume that the agent offers fair odds and fair called-off odds, and for moderate size stakes is willing to accept finite combinations of wagers at these fair odds. Then the agent is coherent if and only if the fair odds satisfy the axioms of mathematical (finitely additive) probability (3.1)–(3.3), and the definition of conditional probability, (4).

- *Remark:* The reader is alerted to the sad fact that when $P(F) = 0$, condition (4) does not establish that $P(\cdot|F)$ is a probability over $\mathcal{F}$, i.e., it may fail axioms (3.1)–(3.3). Hence, the Dutch Book argument for conditional probability does *not* establish that, given an event F of probability 0, the coherent agent's called-off fair odds given F constitute a probability.

- *Remark:* Some writers use a dynamic interpretation of the conditional probability, so that $P(\cdot|F)$ designates the agents subsequent degrees of belief upon learning that event F obtains. The Dutch Book argument for conditional probability does not underwrite this dynamic interpretation. It is part of the static constraints on a rational agent's degrees of belief at a fixed time. The called-off bets may, however, serve as a model of the agent's hypothetical reasoning at the fixed time.

Shimony (1955) introduces a more restrictive standard of coherence, which he calls strict coherence. An agent's fair odds are strictly coherent provided that there is no possibility of making a 'book' against her/him where the agent stands no chance of winning on net, but risks losing for at least one point of Ω .

Shimony establishes that an agent's fair odds are strictly coherent if and only if they are coherent and only the impossible event $\emptyset$ receives probability 0. Despite the desirability of having one's odds be strictly coherent, the resulting standard precludes continuous probability distributions, unfortunately.

Savage (1954) gives an elegant version of personal probability in which the agent's probability is reduced to her/his rational preference over acts. In the briefest outline, Savage's axioms include the assumption that the agent's preferences reveal a qualitative probability, as follows. Let b and w be prizes and assume that the agent prefers receiving the better prize b to the worse one w . For an event E , let the *wager-on- E* be the act that rewards the agent with prize b if E occurs and with w if E fails. Thus, these wagers are generalization of the bets used in deFinetti's Dutch Book argument. Savage postulates that the agent strictly prefers the *wager-on- F* to the *wager-on- E* if and only if the qualitative probability relation $E \prec F$ obtains. Savage introduces additional postulates to insure that exactly one (finitely additive) quantitative probability agrees with this qualitative probability. That quantitative probability is offered as the agent's personal probability over events (see *Decision Theory: Bayesian*).

2.2 Logical (or Classical) Probability

Dating to Laplace's (1951) eighteenth-century work, at least, is the view that quantitative probability is determined once the space $\langle \Omega, \mathcal{F} \rangle$ is fixed. In its simplest version, LaPlace's *Principle of Insufficient Reason* states that the points of Ω determine equiprobable states. However, this principle leads quickly to a variety of inconsistencies, which are worth noting.

For one, LaPlace's principle makes the probability of an event depend upon which partition of states is used to describe it. A die's landing with the 1-spot up is made equiprobable with its not landing that way when Ω is just the binary partition; in which case, by LaPlace's principle, the probability is $\frac{1}{2}$ for each outcome. However, if the state space is partitioned into six points depending upon how many spots land facing upwards, LaPlace's principle yields a probability of $1/6$ for the outcome with 1-spot showing uppermost. We may continue to refine the state space, to include the information that the sum of the visible side faces on the die (as seen from a given perspective) is either less than, or is equal to, or is greater than the face showing uppermost. Then there are 14 distinct possibilities, but only one of these has a 1-spot uppermost. Then, by LaPlace's principle, the probability of a 1-spot uppermost is $1/14$.

When the state space is continuous, the problem of applying LaPlace's principle grows more serious as a transformation to an equivalent random variable may lead to a different probability. For example, if Ω is the set of real numbers in the unit interval $[0,1]$ and $\mathcal{F}$ is

the space of Borel measurable subsets of the identity variable $X(\omega) = \omega$, then Laplace's principle yields a uniform distribution over X . However, if we transform the space so that $\Omega' = [0, 1]$ with $\omega' = \omega^3$ and define the equivalent random variable $Y(\omega') = \omega'$, then Laplace's principle yields a uniform distribution when applied to the equivalent random variable Y . But a uniform probability distribution over X is evidently inconsistent with a uniform probability distribution over Y .

In an early-twentieth-century variant of Laplace's idea, Keynes (1921) strove to revitalize the principle by applying it to a formalized language in the fashion of Russell and Whitehead's *Principia Mathematica*. Moreover, Keynes's theory has the added subtlety that takes qualitative probability as primitive, and that relation is only partially defined: Not all propositions can be compared even by a qualitative probability relation in Keynes's system. Following Keynes, Carnap (1950) developed quantitative probability for a logical calculus. At first, Carnap sought to determine a single, well-defined quantitative probability for the monadic predicate calculus. But soon enough his approach, Carnap and Jeffrey (1971), became one best described as subjectivist, favoring symmetry conditions for atomic propositions similar to deFinetti's concept of exchangeability. Papers by Scott and Krauss (1966) and Gaifman and Snir (1982) continue this tradition.

A more productive alternative than appeal to a formalized language to revive Laplace's principle is the use of mathematical symmetries as a basis for fixing the necessary equiprobable states. Most notable is Jeffrey's (1961) theory of *Invariance*, dating from the 1930s. Jeffrey's sophisticated Bayesian treatment appeals to transformational invariants of parametric statistical models of the observed data to determine a 'prior' probability for the parameter. For example, a uniform 'prior' probability is the invariant distribution for a location parameter, e.g., for the mean μ of data from a normal $N[\mu, 1]$ distribution. Fraser (1966) uses mathematical groups to determine the necessary invariances for fixing a probability, e.g., Haar measure. Each of these theories provides a *local*, not a *global*, interpretation of probability. That is, these theories provide necessary conditions for probability defined with respect to a specific inference problem. When multiple inference problems are considered at once, e.g., when the same theoretical quantity is a location parameter for one data set and a scale parameter for a second data set, difficulties ensue. These theories then generate what must be seen as either inconsistent or non-unique solutions. Furthermore, the invariant probabilities are not always countably additive. So called 'improper' priors, e.g., a uniform distribution over a real-valued parameter, correspond to a purely finitely additive probability by assigning equal probability to each unit interval for the parameter, which intervals constitute the elements of a countable partition. Dawid et al. (1973) provide an important litany

of 'paradoxes' for these theories, involving both transformations of parameters and multiple, simultaneous inferences.

Yet another approach for reviving Laplace's principle is found in the original work of E. T. Jaynes (1983), who uses entropy as a guide to uncertainty. His principle of *Maximum Entropy* dictates that, subject to a set of constraints (i.e., expectations for bounded random variables), a rational agent should fix probability over the space by choosing that probability that simultaneously satisfies the constraints while maximizing entropy. (For discrete spaces this requires choosing the probability $P = \{p_i; i = 1, \dots\}$ to maximize $-\sum_i \log(p_i) p_i$ subject to the constraints.) For example, when Ω is finite and the constraint set is vacuous, the uniform distribution over Ω maximizes entropy. Unfortunately, the Maximum Entropy principle inherits the problems of Laplace's principle, as it is sensitive both to repartitioning the space Ω and, in the continuous case, equivalent transformations.

2.3 Objective Probability

2.3.1 Limiting and finite frequency interpretations. Since Venn's (1876) writings in the nineteenth century, at least, it has been popular to attempt to link probability with limiting frequency in infinite sequences of repeated trials, thereby underwriting an objective interpretation. Von Mises' (1931, 1939) work in the early twentieth century offered a mathematical program for this approach. For von Mises, probability applies to a collective, which is a suitably random sequence of repeated trials. For example, a (hypothetically infinite) sequence of repeated flips with a particular coin that can land either only heads-up or tails-up forms a collective and supports the fact that the objective probability of heads up is $\frac{1}{2}$ provided that:

(a) the limiting frequency in the sequence of the outcome heads up is $\frac{1}{2}$.

(b) the sequence of outcomes is random, i.e., this limiting frequency for heads up is invariant over selections of infinite subsequences.

Several important mathematical problems attend this approach. As is well known, the set of events that have a limiting frequency in a given sequence may fail to form a field (let alone a σ -field). Moreover, when Ω is infinite, even when limiting frequencies do exist they may fail to be σ -additive. However, the formal aspect of von Mises' program that has been given most scrutiny is the theory of randomness.

Evidently, for a sequence to pass muster as random in von Mises's sense, not all infinite subsequences are relevant. That is, assuming the limiting frequencies of the binary events {heads up, tails up} exist and are not either 0 or 1, trivially, there will be, e.g., the infinite subsequence consisting of outcomes with only heads

up, whose limiting frequency for that event is 1, not $\frac{1}{2}$. To sidestep this reduction of the randomness concept, von Mises proposed that only certain families of subsequences are relevant to objective randomness. These subsequences are determined by combinations of place selection rules, e.g., choose every k^{th} trial, and tests for after-effects, e.g., consider the subsequence of outcomes preceded by two-consecutive 'heads up' outcomes. One intuition von Mises offered for these restrictions is that the random sequence should be shown to be immune to sure profits from any feasible gambling system that might be used against it. Wald (1937) showed that a formally consistent theory was possible if the tests for randomness were limited to a countable infinity of rules. Church (1940) suggested using the denumerable class of recursive functions, in an attempt to make the concept of a random sequence language invariant. However, Ville (1939) showed that collectives based on denumerably many selection rules fail to validate some of the basic 'strong law' theorems of Kolmogorov's theory, e.g., the law of the iterated logarithm fails. Also, by appeal to martingale theory, Ville showed that such collectives fail von Mises's intuitive criterion for randomness: they do not preclude successful gambling systems.

Reichenbach (1938, 1949) proposed a rival frequency theory that avoided von Mises's randomness conditions, even permitting its application to finite sequences. In doing so, however, the resulting theory depends ever more heavily on epistemic considerations for its warranted application. For example, a (sequence) that alternates successively between heads up on odd numbered flips and tails up on even numbered flips has a limiting frequency of $\frac{1}{2}$ for each outcome. But, given that fact about the order of outcomes, we would be hard pressed to find a good use for this 'objective' probability when making inferences about such a process.

A more interesting finite-frequency interpretation is based on Kolmogorov's (1963, 1968, 1984) idea for interpreting randomness as informational complexity in finite sequences. A proper account of this approach is beyond the scope of this entry. For first-rate discussions see Fine (1973) and van Lambalgen (1987).

2.3.2 Chance and propensity interpretation. The philosophers Braithwaite (1953), Hacking (1965) and Levi (1980) propose and defend an objective interpretation of probability based on the idea that an objective chance is a theoretical, quantitative disposition for a process or kind of trial to respond when activated. That is, consider a process or kind of trial described as flipping this coin by hand. The chance of its landing heads up on such a process is taken to be an unobserved, quantitative disposition for the coin to respond when flipped. The propensity interpretation is thin, on purpose, in that chances satisfy the mathematical theory of probability by stipulation!

What is particularly novel in these approaches about making chance a theoretical concept is that probability is *not* reduced to observed frequencies, contrary to the frequency interpretation. Rather, the meaning of the theoretical term *chance* is given by rules for testing chance claims (Braithwaite) or by rules linking chance with subjective probability (Hacking and Levi). In the latter case, central to the meaning of chance is a so-called *Direct Inference* principle. Put simply, that principle asserts: the personal probability P for a specific outcome O of the kind of the trial occurring is p , given the information that the chance is p for outcome O on that kind of trial. To wit: $P(\text{coin lands heads up on a toss} \mid \text{chance is } p \text{ that the coin lands heads up on a toss}) = p$.

This treatment of chance as a theoretical term, with its meaning supplied by rules for application of the concept, accords with the Pragmatic turn in philosophy as proposed by Peirce (1932) in the nineteenth century, though Peirce himself favored a frequency interpretation.

2.4 The Fisher–Kyburg Interpretation

Fisher (1956) and Kyburg (1961) introduce an original semantics for probability, focused on the single-case assertion, e.g. (*) The probability is $\frac{1}{2}$ that the next flip of this coin lands heads up.

For this theory, probability is fundamentally epistemological, grounded on both knowledge and ignorance of class-frequencies. The statistician who asserts (*) is required to have:

(a) *knowledge* of frequencies of outcomes of heads in the population of flips with this coin, a population that includes the next flip.

(b) *ignorance* of the statistics of outcomes in a smaller statistical population of coin flips that includes the next flip.

In this sense, their theory takes instances of direct inference (based on frequency information about populations) as the definition of probability.

For both Fisher and Kyburg, this interpretation of probability underwrites an important statistical analysis, e.g., Fisher's fiducial probability. For example, let the random variable X take values from a population with known frequencies approximated by a normal distribution, $N(\mu, 1)$, but with parameter μ unknown. Then the pivotal quantity $V = (\mu - X)$ has a known distribution in this population. Its values are distributed according to a normal $N(0, 1)$ distribution. Suppose $X = 7$ is observed on a particular trial. The Fisher–Kyburg theory then asserts that on this same trial, given $X = 7$, the statistician's probability distribution for V is $N(0, 1)$. This claim rests on the assertion of ignorance on the part of the statistician: the statistician knows of no smaller population that includes this trial with statistics for V different from those of the $N(0, 1)$ population. The upshot is a

fiducial $N(7, 1)$ probability distribution for μ , given $X = 7$. When a random variable X has a continuous, parametric distribution $F(X, \theta)$, then F itself may be treated as the pivotal quantity, having a known uniform $U[0, 1]$ distribution. Fiducial inference about F , given the observation that $X = x$, yields probability for the unknown parameter satisfying Fisher's enigmatic formula: $P(\theta|X) = -\partial F / \partial \theta|_{X=x}$. Kyburg's theory has the added generality over Fisher's in that he uses interval-valued frequency information, leading to a theory with lower and upper probability for single-case assertions. Despite the considerable novelty of this approach, it is challenged severely by nuisance parameters. That is, this interpretation of probability provides only a limited account of marginal probability, as its theory of conditional probability is not well defined, at least not as required by Bayes's theorem.

3. Additional Readings

Nagel's (1936, 1939) essays on quantitative probability are excellent reviews, still, of philosophical issues relating to rival interpretations. In particular, one important issue not addressed here is whether objective probability requires a commitment to indeterminism in science. Nagel makes clear why there is no conflict between objective probability and deterministic laws in science. A more elementary presentation of rival interpretations of quantitative probability is found in Kyburg's (1970) textbook.

Fine's (1973) book gives a good overview of complexity theories and randomness, relating in particular to Kolmogorov's theory from the 1960s.

Fishburn's (1968) article offers a wealth of insights on both philosophical and formal questions relating qualitative and quantitative concepts of probability. The bibliography there is particularly noteworthy. Also valuable is the discussion of comparative probability given in Walley and Fine (1979).

T. Seidenfeld

with the question of whether this ethos fitted the spirit of entrepreneurial capitalism. Yet in the 1920 preface to his collected papers on world religions, Weber's interest was rationalization processes, including the rise of capitalism. These changes had gone furthest in the West, and Weber wondered why.

If these two stories about sociology's questions carry a moral, the lesson is not that persons nowadays regarded as sociology's founders did not know what they were up to. The message amounts to a methodological command on meritorious problems. Durkheim grasped that seemingly small questions become pertinent when taken as subproblems of larger ones, and Weber understood that it is wise to divide mammoth problems into more modest ones, and those in their turn into even more tractable questions. Durkheim and Weber entered sociology's hall of fame because they pointed towards a bunch of smaller questions falling under one and the same heading. The subtitle of *Le suicide* runs *Étude de sociologie*, lifting a phenomenon from psychology into that science which studies society—and the extreme case of leaving it.

Problem Selection in the Social Sciences: Methodology

Social methodology textbooks state techniques of proper empirical analysis. For instance, they tell how partial coefficients of association are to be computed, adding that these coefficients provide a more severe test of multifactor explanations than bivariate associations. Books on theory building in sociology set standards for determining whether certain hypotheses are better than others. Logically unfalsifiable ones are out, future propositions should provide more information than current ones. Any science starts with problems. Are there precepts for selecting problems too? Yes, and this entry draws upon principles intimated by sociologists (Lenski 1966, p. 20, Blau and Duncan 1967, pp. 9–10, 194–9, 402), proposed by philosophers of science (Bunge 1967, pp. 165–221), and applied by sociologists to sociology (Merton 1959, Ultee 1980). These standards are elucidated by cases from sociology's past and present.

1. Overarching Problems and Subproblems

Durkheim 'was not interested in suicide at all,' so says Collins' 1994 textbook on sociological traditions. But then, why did Durkheim dub his 1897 study *Le suicide*? Weber in 1910 grumbled that his critics understood him to explain the rise of capitalism fully from the ethos of protestantism, and retorted that he only dealt

2. Problem Structures and Their Dynamics

For Durkheim, a society's suicide rate tells about its cohesion: the higher the rate, the less cohesive a society. Weber observed that a society's inhabitants do not always use their economic freedoms, for instance those of enterprise and labor, and supplemented the problem of how these rights became included in a society's code of law, with the problem of the strength of a person's motivation to use these liberties. Both questions were part of the question of why entrepreneurial capitalism arose in the West. In its turn, the question of the rise of capitalism, including bankers' as well as entrepreneurial capitalism, was a subquestion of the even larger question of the speed of rationalization processes in the West during the last couple of centuries.

In Durkheim's *oeuvre*, the question of a society's degree of cohesion also comprises long-term trends in the prevalence of economic exchanges when comparing ancient Israel, the Roman Empire, and medieval Burgundy, and the degree to which assemblies of hunters and gatherers are religious in nature. Weber's question of rationalization led to less grand ones on the rise of science and the bureaucratization of states. Any methodology of problem selection should contain the rule that questions should not be judged on their own, but according to their place in a structure of overarching problems and subproblems. However small a problem seems, it has more appeal if it is part of an overarching problem. And however towering a question appears, it grows less scary if it is broken down into subquestions.

Figure 1
The Durkheimian problem structure and its dynamics

2.1 The Durkheimian Problem Structure

Figure 1 depicts the Durkheimian problem structure. The novelty of *Le suicide* was not simply that Durkheim turned the question of suicide into a subquestion of the larger one of societal cohesion. Hobbes (1651) took order and its opposite violence as the master problem of those studying the body politic. For him, civil wars and wars between sovereigns were part of the problem of order and violence. Next to it, Durkheim placed the problem of the presence and absence of ties between a society's members. The counterpart of the question 'why do people not always live in peace?' is not only 'why do they sometimes use violence?' It also is 'why do they sometimes live relatively isolated from each other?' For Durkheim, suicide was the supreme example of severing the ties between persons and the society in which they live.

Apart from *Le suicide*'s question, Fig. 1 encompasses the questions guiding Durkheim's two other main studies. *De la division du travail social* from 1893 focuses on the frequency of economic transactions between a society's members at various points in history. It narrows this question down to that of the degree to which cooperative law (civil law regulating economic contracts by restitution) is more widespread than criminal law (penal law involving repressive sanctions). *Les formes élémentaires de la vie religieuse* from 1912 notes that Australian aborigines disperse when hunting and gathering their food, and asks to what extent their leisurely meetings celebrate a totem and turn them into members of one society. Durkheim's questions involve a shift from questions on economic ties, by way of questions on co-living, to questions on religious ties, yet they always pertain to societal cohesion.

Given the Durkheimian problem structure, later scholars can raise questions on types of attachment to which Durkheim paid limited or no attention. Examples are questions on changes in the rates of marriage, birth and divorce in industrial societies. A

wedding creates a sexual and domestic bond between two members of the opposite sex, divorce dissolves it, and a higher birth rate amounts to more parent-child relations in a society. Goode (1963, 1993) focuses on the making and undoing of sexual and domestic ties. These monographs amount to a new branch of the Durkheimian problem structure.

2.2 The Weberian Problem Structure

The Weberian problem structure and its dynamics are given in Fig. 2. The overarching problem is that of rationalization, and Merton (1938) pursued the subproblem of the rise of science in the West, and Blau (1974) that of bureaucratization. The art historian Gombrich (1960) studied questions on the skills of painters to furnish a faithful representation.

The relation between problems as depicted in Figs. 1 and 2, are logical in nature. An overarching problem, usually by way of uncontroversial auxiliary assumptions, implies subproblems. It is another, and less important, matter whether a person raising a subproblem of the overarching problem of an earlier scholar, studied under that master or read a book by him or her. Merton and Blau took the lead from Weber, Gombrich was not influenced by him. Weber invokes Heinrich Wölfflin once when discussing the question of representational skills, Gombrich quotes Wölfflin frequently.

As stated, the step from an overarching question to a subquestion involves largely undisputed assumptions. Few would argue that capitalism is less efficient than slavery. Yet this proposition was belied by Fogel and Engerman's (1974) test for the American South shortly before slavery was abolished. A scholar working on a question can make progress by replacing these auxiliary assumptions by better approximations. Weber did not do so, but Durkheim did. In countries prescribing suicide under certain circumstances, suicide is not an instance of low cohesion, but of

Figure 2
The Weberian problem structure and its dynamics

strong solidarity. In that case, Durkheim spoke of altruistic suicide.

Behind Weber's distinction between bankers' and entrepreneurial capitalism lurks evidence speaking against the hypothesis that the rise of capitalism is always accompanied by the growth of banking. Protestant businessmen did not take out loans. Their religion put a premium on frugality, and contributed to reinvestment of profits in their enterprise. The background of Weber's distinction between laws granting people economic freedoms, and the use of these freedoms by a society's members, forms the observation that people sometimes do not use their rights, as well as the hypothesis that they exercise these rights only if they are motivated to do so. Classical economics assumed that every person had this drive, Weber held that protestantism strengthened it. A wise rule is to state the background of a question as fully as seems necessary for bringing out a problem structure.

2.3 The Weberian Problem Structure Radically Revised

The division of an overarching problem into sub-problem may drastically alter. Studies by Smith (1776), Elias (1939), Samuelson (1954), Van den Doel (1979), and De Swaan (1988) imply the revision of the

Weberian problem in Fig. 3. Weber never made clear what state bureaucracies were doing. States possess the legitimate monopoly on the means of power, Elias added that states wield the legitimate monopoly on taxation. Were all taxes spent on armies, police and prisons? This obviously is not the case. Here the hypothesis is useful that markets make for the optimal production of individual goods (Smith), but not for the optimal production of collective goods (Samuelson). The production of collective goods approaches optimality in a state with universal suffrage and a bureaucracy which executes its laws (van den Doel).

De Swaan listed collective bads and laws contributing to their elimination and to the production of collective goods. Firstly, poverty is a collective bad. Poor people are more likely to trespass the law, and crimes form a general threat to life and property. Following De Swaan, this danger is alleviated by state insurance against disability and unemployment. Contagious diseases amount to a second collective bad. If local authorities provide each household with piped water and an outlet on the sewers, public health improves. Thirdly, compulsory schooling lowers the percentage of children who cannot read and write, and makes for a more optimal functioning of markets and bureaucracies. Weber's conception of the state is saved by the assumption that armies, police and prisons

Figure 3
The Weberian problem structure radically revised

avert collective bads. Armies lessen a threat to a state's independence, police patrols contribute to safety on the streets, prisons deter.

2.4 Problem Structures and Theories

As the saying goes, a question well put is a question half answered. If it is clear that some problem is part of a larger problem, and if a solution for the overarching problem is at hand, a possible solution to the smaller problem is available too. But then, if an answer to a particular smaller question of a larger one turns out to be false, the opportunities to disestablish a solution to another subproblem of the larger one increase. Additionally, the notion that problem structures exist and have a dynamic, makes the project of sociology have more continuity than suggested by Boudon (1979) and Gove (1995). They accepted that sociology's questions to outsiders show a bewildering variety, and bypassed the possibility that one and the same larger question may harbor a host of seemingly disparate questions.

3. Contradictions and Issues

One way of formulating a problem in a more useful way is to ascertain its place in a problem structure. Are there much injunctions for problem choice? Sociologists debating sociology have argued about the primacy of theory vs. the supremacy of research. In contrast, Popper (1962) asserted that every science, including sociology, most fruitfully starts with contradictions between general hypotheses and specific research findings.

Contradictions—or, to use Kuhn's 1962 terms, puzzles and anomalies—contribute to sociology's growth. For Merton's (1973) sociology of science, the

prevalence of priority disputes in a field was surprising in several respects. Its explanation was not the egotism of the scientists having made discoveries, since their part in the disputes was small. Nor was it to be accounted for by the increasing competition between scientists, since the frequency and intensity of priority disputes in the West decreased over time. A rule of method runs: single out contradictions.

Incompatibilities between hypotheses also invite new research and theorizing. They sometimes are called issues, but that term also refers to false alternatives. An example is the question of whether intelligence is determined by social or by genetic factors. Intermediate positions are possible, the list of social factors may be incomplete, and the location of intelligence on genes may be unknown. Popular science states issues in a metaphorical way: are we born with a brain hardwired with rules for language, or is the brain a big sponge, capable of creating rules for language by mopping up what we hear?

The phrasing of a contradiction problem sometimes contains seeds for its solution. For instance, Huizinga (1941) asked how it was possible that painting and other forms of culture flourished in the Netherlands during the seventeenth century, so shortly after this society became independent from Spain. His answer was that Dutch culture blossomed because the Netherlands was a new state. In states which have recently become independent, the upper social strata have risen from the lower and the more open a country's elite, the more its culture will flower. Trevor-Roper (1976) wondered how it was possible that an emperor as preoccupied with expanding his territory as Charles V (1500–58), furthered the art of painting so much. In the end Trevor-Roper surmised that Charles V commissioned paintings to the extent that, and precisely because, they legitimated his political power.

Apart from the rule for theory building to mobilize the information in a contradiction problem, there is the precept to turn the problem around. Rather than asking why the number of unruly passengers on airlines is increasing, it might be worthwhile to ponder why this number did not increase much more strongly until now. A more academic example is as follows. Marxism noted that a lot of workers refrain from joining unions and strikes, and raised the question of how workers come to have a false consciousness. Olson (1965) held that unions and strikes produce collective rather than private goods, applied the *prisoners' dilemma* from game theory in mathematics predicted that rational workers would not strike, and raised the question of why people participate in social movements. However, it should be clear that any theory with some substance to it should explain that some people join labor unions and certain others do not.

4. *Strings of Questions*

The terms problem and question sometimes are used interchangeably, referring to queries of any specificity. However, everyday usage of expressions like object of investigation, task, question and problem, suggest that some inquiries are more focused than others. What does the articulation of problems involve?

4.1 *Problem Articulation*

If it is maintained that sociology is about societies (and not about individuals), it sometimes is said that the object of research has been stipulated. Yet no single feature of this unit has been singled out for explanation. If this property is taken to be, say, the 'functioning' of a society, the object of inquiry turns into what has been called a task. Yet the circumscription of this aspect remains limited, since the term does not focus any particular way of functioning. If a distinction is made between optimal and suboptimal functioning, the study involves a question, with the term question being taken in a narrow sense. Of course, other types of functioning may be distinguished too. Questions in their turn do not allude to possible causes. If research on some sample of societies determines the extent to which less stability in a society's environment goes together with a less optimal functioning of this society, the matter at hand is articulated so fully that the problem now is whether some logically falsifiable hypothesis is true. Putting a question mark behind a falsifiable proposition amounts to posing a problem in some narrow sense of that word.

The example of a string of increasingly articulated queries just presented neglects any difficulty in ob-

taining measurements for the degree of stability in a society's environment, and the extent to which the functioning of a society approaches optimality. It has been held that questions should refer to directly observable phenomena only, and therefore in the human sciences to outward behavior and not to mental states. This rule is a leftover from a wrongheaded empiricist philosophy of science. All terms to some extent are theoretical, and any proposition whatsoever, whether about acts or thoughts of persons, or processes and situations within of societies, never can be definitely proved.

4.2 *From Descriptive to Explanatory Questions*

There are strings of questions of another kind. A researcher's early questions often are descriptive: how many of the people living in 1972 Britain and born to working-class parents had moved up to the higher classes? A follow-up question might be whether this probability to climb equals the chance to descend from the upper to the lower classes. A yet later question presupposes the answers to both earlier questions, and seeks to ascertain whether upward and downward mobility were as prevalent in 1949 as in 1972. By raising additional descriptive questions, narratives become richer.

At some point researchers leave descriptive questions behind them, to raise explanatory questions. The explanatory question following up on the previous string of descriptive questions ran: why during the 1970s was upward mobility less widespread in Britain than in Sweden, and more widespread than in France? The obvious answer to that question was that left-wing governments make for more upward mobility (Heath 1981, Goldthorpe 1987).

4.3 *From Superficial to Deeper Explanatory Questions*

Some explanations 'scratch the surface only,' others delve deeper. Why would particular ideologies make for more upward mobility? Just as individuals, governments cannot always attain their goals. By which means then do social democrats attain the goal of more upward mobility? Does Sweden have more upward mobility than Britain, because social democrats make children branch out at a later age to schools which demand more or less of pupils? Or is this the case because social democrats pursue a policy of full employment? And then, if the second question fares better in empirical research, why would there be more upwardly mobile persons in a society without unemployed persons?

There is no obvious point at which the hunt for deeper explanations should stop. Some theoreticians

in effect defend that 'the buck stops here.' No one nowadays seriously defends propositions about societies being logically independent from propositions about individuals. However, whether rock-bottom explanations of the features of societies should always refer to the motives and aversions of a society's members, as well as the opportunities they have and the barriers they face, is controversial. In the discussion on 'methodological individualism' (O'Neill 1973) the borderline between methodological rules and substantive requirements was violated. Perhaps it is wise to state this debate no longer in terms of theories explaining societal phenomena, but to settle it by recognizing that shorthand statements of sociology's questions refer to societal features only, and that these questions, if they are stated fully, always refer to the persons making up a society's population, that is, to *individuals* and *societies* (Ultee 1997).

4.4 From Meagre to Thick Descriptive Questions

Some descriptive questions—and their ensuing explanatory questions can be meagre, whereas others aim for lavishness. Thus, it often has been ascertained that no society ever has been or ever will be completely egalitarian. As Lenski (1966, p. 20) maintained, in the debate between the conservative and the radical tradition in sociology, it is possible to make headway by transforming problems stated in a categorical way into problems phrased in variable terms. It may indeed be the case that full equality never has been observed in any society, but is the lowest degree of inequality observed until now the lowest that is possible? And do long-standing differences between highly industrialized countries in their ruling ideology explain differences in their degree of income inequality? Questions about equality that demand 'yes' or 'no', are less precise than questions about degree of inequality.

Following Lenski, progress also can be made by breaking down the compound concepts contained in problems into their constituent elements. Thus the question of whether power—in the singular—determines privilege—in the singular—will not do. Rather, the question is to what extent differences in the consumption of a certain good in a particular society depend on the control of various resources. When answering this question, Lenski distinguished the skills of hunters and gatherers, the size of gardens in horticultural societies and of fields in agrarian societies, the possession of metal weapons, the private ownership of machines, the technical skills of the people designing machines, the range of legitimate command accruing to a political position, and the right to vote in elections. Lenski also suggested that the change from agriculture to industry was accompanied by the shift, from the right to vote in infrequent political elections for only the propertied classes, to universal suffrage in periodic elections. By breaking

down compound problems into their constituents, thick descriptions and detailed explanations are obtained.

4.5 Erroneous and Well-stated Questions

If explanatory questions are logically prior to descriptive questions, explanatory questions may be wrong. Answers to questions can turn out false, questions themselves may be mistaken. The question of why in the 1970s social mobility was more widespread in France than in Sweden is erroneous, since in that decade mobility occurred more often in Sweden. The Olson question, of exactly which selective incentive makes persons protest against the hunting of seals, assumes that some selective incentive is always at work, which may not be the case. This example suggests that if a rock-bottom explanation slips into a question, that problem turns into a leading question.

Methodological rules which stipulate conditions banishing erroneous questions, and guaranteeing well-stated ones, seem doomed. It is wise to review the presupposed description, but checking has to stop somewhere. In this respect it is interesting that the answer to an explanatory question always implies that the original question may not have been fully right. When Durkheim asked why protestantism goes together with more suicide than catholicism, he devised the hypothesis that more tightly knit religions show a lower suicide rate. To derive what he wished to explain, Durkheim assumed that catholics are more integrated than protestants. He knew that this assumption was off the mark for England, since the Anglican Church was a state church. Yet in this way he could account for England as the deviant case to the regularity he wished to explain. Malewski (1964) showed with examples from social psychology that every explanation of a regularity predicts conditions under which exceptions occur to the regularity being explained.

Duncan held that the question of factors influencing the chances that the members of a society move up or down poses the issue poorly. The prime factor is the father's occupation. However, the proposition that the lower the occupational prestige of a person's father, the higher this person's chances of upward mobility, forms a truism. After all, the hypothesis thrives on bottom- and ceiling-effects. To test more interesting hypotheses, according to Duncan, questions on change in a person's life should not be stated in terms of some difference score, but as questions on the strength of the relation between a person's earlier and later score, and on the factors influencing that relation.

4.6 Undertheorized Questions

Schütz (1933) raised the question of why individuals understand one another, and did so with a certain

urgency by phrasing his question as 'how it is possible that people understand each other?' This query sounds like a contradiction, but although casual observation suggests that some people in some places and at some times indeed do understand one another, no particular hypothesis has been derived from a specific theory that holds that it is impossible for human beings to understand each other. Thus the theory rendering the question compelling is lacking. The Parsonian problem of how order is possible (Parsons 1937) is undertheorized in a similar way. Any derivation of the hypothesis that society is violent, from the principle that persons follow their interests, involves additional assumptions. These can be wrong, which makes the question of how order is possible less pressing than it sounds. Indeed, a full statement of the question 'how is order possible?' implies the conditions under which order occurs, and those under which it does not.

Recent research addresses the question of whether the association observed in a cross-sectional sample of a society's inhabitants between their year of birth and a particular characteristic, is to be accounted for as an age, cohort, or period effect. As methodologists point out, this question is undertheorized too. The available hypotheses do not predict some age effect, some cohort effect and some period effect. Those hypotheses are so vague that their conjunction is almost, if not fully, logically unfalsifiable. The hypotheses at hand have more substance: if people marry, grow up in lean times, and live through a war, then their values will be less post-materialist (Inglehart 1977). Those variables can be independently ascertained, making statistical models identifiable.

5. Conclusion

Ziman (1987) argued that the question of how scientists choose their problems is erroneous, since most researchers do not have a choice. Their problems are pre-given by the organization which employs them. This observation does not do away with the question of problem choice, but makes the question of the formal rules for problem choice by the higher authorities of these organizations more pressing. The methods outlined above should not only be taken as principles for researchers who have a choice, but also as precepts for institutes run on a budget, and for foundations which award subsidies.

In everyday life researchers consider some problems difficult, others significant, and yet others exciting. These notions are difficult to put into formal rules. However, a more difficult problem might be taken as an explanatory question to which several solutions have been proposed, none of which worked or led to closer approximations. Thus, difficult problems are specific kinds of Popperian contradictions. Also, a structure consisting of overarching problems and subquestions, goes some way towards formalizing the

intuition that a problem is significant. Perhaps a problem area is called exciting, if, after many a failed attempt, the solution of an overarching problem seems near, because progress is being made on subproblems.

Problem Solving and Reasoning: Case-based

Case-based reasoning (CBR) is a paradigm of *artificial intelligence* and *cognitive science* that models the reasoning process as primarily memory based. Case-based reasoners solve new problems by retrieving stored 'cases' describing similar prior *problem-solving* episodes and adapting their solutions to fit new needs.

As case-based reasoners process each problem, they learn by storing records of their problem solving as new cases to guide future reasoning. CBR research studies the CBR process both as a model of human cognition and as an approach to building intelligent systems. Principles from CBR research serve as a foundation for applied computer systems for tasks such as supporting human decision making, aiding human learning, and facilitating access to electronic information repositories.

1. Case-based Reasoning as Cognitive Model

Initial research on CBR was motivated by observations of how humans remember, reason, and learn from experiences. People who encounter surprising events are often reminded of similar past events and use these reminders to help them understand and respond to the new situations (Schank 1982). For example, a doctor whose patient has an unusual reaction to a medicine might be reminded of a previous patient who had similar reaction. Remembering the treatment used for the prior patient suggests a candidate treatment for the new patient; remembering the outcome of the previous treatment helps to predict the new outcome and warns of potential pitfalls to avoid.

Psychological studies provide evidence supporting human use of CBR for a wide range of problem-solving tasks such as learning programming, performing mathematical problem solving, explaining anomalous events, and decision-making (see Leake 1998) for examples of this work). Another use of CBR is for classification or *interpretation*. For example, in *legal reasoning* in the American legal system, prior cases are the basis for legal judgments: lawyers build arguments about how to interpret rules of law by comparing and contrasting precedent cases to the current situation (see Ashley and Rissland (1988) and *Legal Reasoning Models*).

Research on CBR as a cognitive model studies the knowledge and processes that underlie human CBR, addressing topics such as *memory organization*, *similarity assessment*, and *analogical mapping* (Kolodner 1993, Leake 1998). Computational models developed in this work illuminate functional constraints on reasoning processes and provide testable hypotheses about human reasoning for psychological investigation.

2. Steps in Case-based Problem-Solving

Computer CBR systems have been developed for numerous tasks including planning (Hammond 1989, Veloso 1994), design (Pu and Maher 1997), and explanation (Schank et al. 1994). Regardless of the specific reasoning task, any CBR system retrieves relevant prior cases, adapts their lessons to fit the new situation, evaluates and applies the result, and retains

the results of processing as new cases to guide future reasoning. Thus, computer models of CBR must account for four main processing steps: *retrieval*, *adaptation*, *evaluation/application*, and *storage*.

2.1 Retrieval

In order to facilitate retrieval of relevant cases, stored cases are organized by *indices* characterizing circumstances in which the cases are likely to be relevant. For example, in a medical CBR system to suggest treatments for illnesses, treatment cases could be indexed by the diseases they treat and the characteristics of patients (e.g., age) that tend to determine whether a given treatment is appropriate. Given a new problem to solve, a case-based reasoner first performs *situation assessment* to analyze the input problem and describe it in terms of the indices used to organize cases. Retrieval algorithms use the description to retrieve the cases in memory expected to be most relevant. For example, nearest-neighbor retrieval algorithms select the most similar prior cases according to a metric that weights features by their relative importances. Alternatively, case libraries may be organized into discrimination networks to enable retrievals based on only a small number of feature comparisons. After candidate cases have been retrieved, a finer-grained similarity assessment process is often used to identify the best candidates and to determine differences requiring adaptation

2.2 Adaptation

The case adaptation step revises the lessons of the retrieved case (or revises and combines the lessons of multiple retrieved cases) to generate an appropriate new solution. For example, a doctor might have to adopt a prior treatment by reducing the dosage if the prior patient was an adult and the current patient is a child, or might combine elements of prior treatments to address multiple complaints. Computer CBR systems often use rule-based reasoning to determine how to transform prior solutions. In interpretive CBR, the case-based reasoner does not modify the retrieved case, but instead develops justifications for why the prior interpretation applies (or does not apply) to the new situation.

2.3 Evaluation/Application

Tentative results of case adaptation are evaluated to assess the appropriateness of the new solution and to determine whether additional changes are needed, possibly resulting in a cycle of repeated adaptation and evaluation. Once a solution is judged acceptable, it is applied to the real problem. If the solution fails, it may be repaired, reevaluated, and reapplied.

2.4 Storage

Each processing episode of a CBR system, whether resulting in success or failure, is stored to guide future reasoning. Cases containing successful solutions suggest solutions for similar future problems, while cases storing failures provide warnings of problems to avoid and information on how to avoid them. The storage step packages information about the problem, solution and its results in a new case. It also assigns indices for the case and places it in the case library (also called the 'case base') for future use.

3. Research Issues

3.1 Retrieval and Similarity Assessment

Effective case retrieval depends on appropriate retrieval algorithms, well-organized case bases, and indices that are useful for the current task. In case-based problem solving, cases are indexed by information about the problems they solve. For example, a case-based planning system may index plan cases by the goals they achieve and constraints they satisfy. Indices should be predictive of the relevance of cases and should involve features of problems that are likely to be known to the reasoner; both abstract and concrete features may be useful. A crucial research issue in CBR is developing appropriate *indexing vocabularies* for particular reasoning tasks. In order to retrieve useful cases for novel situations, methods are also needed for reformulating or transforming indices to widen search when no directly relevant cases are available. There is also considerable interest in replacing traditional measures of similarity with similarity criteria that directly reflect pragmatic needs by predicting which prior cases will be easiest to adapt to fit the new situation (e.g., Smyth and Keane 1998). Research on retrieval algorithms investigates methods for achieving rapid retrievals from large case bases (e.g., by exploiting parallel algorithms).

3.2 Case Adaptation

Developing case adaptation rules is often difficult because of knowledge acquisition problems: the needed knowledge may not be available or may be difficult to codify. Consequently, improving case adaptation methods is a fundamental challenge for CBR. Research areas include applying machine-learning techniques to automatically generate case adaptation rules; applying CBR to a CBR system's internal processing, to adapt cases based on prior adaptation experiences rather than rules; using a *derivational analogy* process to account for new circumstances by replaying a prior solution-generation process, rather than revising a prior solution (Veloso 1994); and applying artificial intelligence methods

such as constraint-based reasoning to guide the adaptation process. It is important to note that sufficiently powerful case adaptation can enable cases to be used in very novel ways; research on flexible retrieval and adaptation processes has given rise to CBR models of creative problem solving.

3.3 Case-base Maintenance

As CBR systems receive long-term use, keeping the case base accurate becomes an important problem. Likewise, as cases are accumulated, it may be necessary to reorganize or update the case base in order to improve its coverage of important problems and to avoid slow retrievals. This has led to considerable interest in methods for improving case quality and retrieval efficiency by strategic deletion, revision, and addition of cases to a case base. Because cases are increasingly generated by multiple distributed sources (e.g., different offices of an organization), additional issues concern how to update and access distributed case information.

3.4 Integration with Other Methods

CBR systems may be integrated with other systems and approaches—both artificial intelligence systems and other systems—to leverage off the strengths of each. For example, case-based and rule-based reasoning may be integrated with each other, with cases used to guide interpretation of rules or to suggest targets for rule-based reasoning. CBR may also be used for speed-up learning, with initial rule-based problem solving building up a case library that can then be used instead of rules, bypassing costly reasoning from scratch, or to avoid errors by storing exceptions to rules. Conversely, rule-based reasoning may be useful to augment the case library and extend the range of problems that a CBR system can solve.

4. CBR Technology

Applications of CBR include both autonomous and interactive systems. As observed by Kolodner (1993), human users are often adept at evaluating the relevance of prior cases and applying their lessons, but may lack the experience needed to acquire a sufficient set of cases. On the other hand, case adaptation and evaluation are difficult for CBR systems, but practical methods exist for accessing large case libraries. These complementary strengths have led to increasing focus on case-based ‘retrieve and propose’ systems that support human reasoners by providing them with relevant prior cases to aid their decision making (cf. *Decision Support Systems*). For example, case-based ‘help desk’ systems are used widely to aid telephone

support personnel who diagnose customer problems, and commercial CBR ‘shells’, are available to facilitate the development of such applications (Watson 1997). As novel problems and solutions are added to the case base during use, the system builds a sharable *corporate memory*, of cases, aiding corporate *knowledge management*.

CBR is also increasingly applied to *electronic commerce*. For example, case-based support systems are used during on-line purchases of computers, to help buyers configure their systems by presenting similar past configurations as a starting point for them to modify. This helps users find a good match to their needs, even if they do not know all the important features of the product they are ordering.

In addition, the CBR cognitive model and CBR principles are guiding the design of educational systems by, for example, suggesting when useful learning is most likely to occur and how to retrieve examples to support that learning. Likewise, CBR is being applied to accessing hypermedia and on-line repositories of information—providing indexing vocabularies and example-based query interfaces—and is being used to focus information retrieval, in order to extract task-relevant information from large-scale information sources. Another active research area, textual CBR, develops methods for facilitating knowledge acquisition by automatically capturing and indexing cases in textual form. Leake (1996) and Lenz et al. (1998) present projects illustrating these applications areas.

5. Relationship to Other Artificial Intelligence Methods

Much artificial intelligence research focuses on methods for generating new solutions from scratch by chaining together general rules (for example, see *Expert Systems in Medicine*). CBR is an interesting alternative for a number of reasons, including: (a) simplifying knowledge acquisition (experts often find it difficult to provide rules for their actions but can easily provide examples, and CBR systems can be fielded with small case libraries and learn additional cases during use); (b) providing natural explanations of decisions (by accounting for decisions in terms of actual previous examples, rather than in terms of rules that users may not understand or trust); (c) increasing problem-solving efficiency by reusing the results of prior reasoning; and (d) facilitating system development in domains that are hard to codify in terms of general rules (e.g., because the rules would have too many exceptions). In CBR, traditional rule acquisition issues are replaced by issues of capturing and representing reasoning episodes, selecting similarity and indexing criteria, and capturing case adaptation knowledge.

The learning done by CBR systems strikes a middle ground between knowledge-poor and knowledge-rich

learning approaches. Unlike knowledge-poor inductive learning methods, CBR exploits domain knowledge (e.g., many CBR systems use explanations to guide indexing and adaptation). Unlike knowledge-rich methods, such as explanation-based generalization, CBR can still be in the absence of a rule-based domain theory.

In its emphasis on building up knowledge by learning, CBR research is in the same spirit as research on neural networks (see *Connectionist Approaches*). However, CBR contrasts in storing and reasoning from examples rather than storing only learned generalizations. Also, CBR performs 'lazy learning.' Rather than immediately generalizing training instances and discarding the examples, as in, for example, explanation-based and neural network learning, CBR stores cases with minimal processing and processes them further only if and when adaptation is needed to solve new problems. In addition, unlike neural networks, case-based reasoning systems can change behavior immediately in response to new examples: a single correct example of dealing with a situation, and no further training, is all that is needed for the system to process that situation correctly in the future.

6. Conclusion

A case-based problem solver solves new problems by retrieving stored problem cases and adapting their lessons to fit new circumstances; it learns by storing new episodes for future use. This process can provide robust reasoning and learning even in domains that are hard to codify in rule-based form. CBR research has provided computational cognitive models of human information processing, artificial intelligence techniques, and information technology for a wide range of task domains.

The CBR cognitive model is discussed in Kolodner (1993) and Leake (1998). A volume edited by Leake (1996) surveys the field with chapters on issues and applications in tasks such as decision aiding, knowledge navigation, design, diagnosis, and education; Kolodner (1993) provides an in-depth examination of key issues; and a volume edited by Riesbeck and Schank (1989) includes chapters on important early CBR research projects and 'micro-versions', of the computer programs those projects developed. The process of developing CBR applications is described by Watson (1997). A volume edited by Lenz et al. (1998) presents chapters on CBR technology for tasks including supporting electronic commerce and textual CBR.

Problem Solving and Reasoning, Psychology of

This article discusses two important aspects of human thinking: how people solve problems and how they use systematic thought to reach conclusions from premises. The two processes are intermingled closely in most everyday human thinking.

Woodworth (1938) wrote:

Two chapters (of 30!) will not be too many for the large topic of thinking.

Woodworth here understates somewhat the importance he assigned to 'higher mental processes,' for another chapter examines reading, and nine others, memory, and learning. In the second half of the twentieth century, the small role of high-level cognition in experimental psychology has been enlarged greatly by treating thinking as symbolic information processing, formulating theories of thinking as non-numerical computer programs, and introducing new observational methods and instruments to capture

increased temporal detail in thought processes (Newell and Simon 1972).

Woodworth (1938) divided his final two chapters ‘according to the historical sources of two streams of experimentation ... One stream arose in the study of animal behavior and went on to human problem solving; the other started with human thinking of the more verbal sort.’ Two branches of the first stream investigated (a) search as the basic problem solving process (trial-and-error, then selective, search; e.g., Morgan 1894, Thorndike 1898), and (b) insight (e.g., Köhler 1917). Little attention was given to expert problem solving.

The second stream of research, on verbal thinking, included concept attainment (e.g., Hull 1920), logical deduction (‘reasoning’), creativity (mostly anecdotal reports on inventors, scientists, and artists), and verbal problem solving, the latter initiated by Selz (1913, 1922) and further developed by Duncker (1935) and De Groot (1946). All of these lines of work were important harbingers of the new information processing psychology, but the connections among them only became apparent later. This article describes today’s knowledge of thought processes within the information processing framework down to, but not including, the neural implementation.

1. Problem Solving

Modern theories of problem solving have gone through three stages. Most early research viewed problem solving as a search process. In the 1960s, attention began to turn to expert problem solving and its dependence on recognition that evoked knowledge from memory. A decade later, it had become evident that solving complex problems usually also required interacting search in several distinct problem spaces.

1.1 Problem Solving as Search

Problem solving is often described as search: moving in a problem space from an initial situation toward a goal situation that satisfies all the conditions for a solution. Problem difficulty was initially thought to vary with the size of the problem space. A space with b choices at each point in the search, and paths s steps in length, would contain b^s different paths.

Choosing a chess move was very difficult, for from a typical current position 10^{20} or more branching paths might lead to stronger or weaker positions, and ultimately to won, lost, or drawn games. As a human being could search only an insignificant fraction of these paths, skill depended on discovering just those that might lead to favorable outcomes. DeGroot (1946), showed that stronger players did not search much more extensively than weaker players, and that even grandmasters rarely looked at more than 100 positions before making a move.

These findings led to a theory of problem solving postulating: (a) an ‘understanding’ process that generates a problem space from the problem description, (b) a selective (heuristic) search process that uses rules of thumb to follow the most promising paths, and (c) a position evaluation function to assess the relative merits of the positions reached. The process can be repeated, re-evaluating the situation after each step. Several chess programs that deliberately limit themselves to searches of the magnitudes that humans can make demonstrate that chess of credible quality can be played in this way, confirming and extending experimental findings about human players (Simon and Schaeffer 1992).

The same scheme applies to problems generally, not just to chess. Methods for generating paths include: generate-and-test (i.e., trial-and-error), hill-climbing (moving toward higher values of an evaluation function), and means-ends analysis. At each step in means-ends analysis: (a) one or more differences are discovered between the current situation and the goal conditions; (b) using past knowledge and experience, an operator is applied that usually eliminates or reduces differences of the kind discovered; (c) the process is repeated until all differences have been removed and the goal attained.

Suppose the goal is to solve an equation for x : $7x + 10 = 4x + 22$. The operators add or subtract the same expression from both sides of the equation or multiply or divide both by the same expression. The differences between the given expression and the solution ($x = N$) are the presence of a stand-alone number on the left side of the equation, an expression in x on the right, or a coefficient other than 1 for x on the left. In the equation above, means-ends analysis would discover an unwanted number, 10, on the left, then an expression in x , $4x$, on the right, and would subtract both from the equation, leaving $3x = 12$. Now it would notice x ’s coefficient, 3, and would divide, obtaining $x = 4$.

1.2 Knowledge for Solving Problems

Some problems are hard even though their problem spaces are small. For example, the Chinese ring puzzle, which requires freeing a metal bar from a series of rings, has an unbranching problem space, so that the solution can be reached simply by never reversing direction. Nevertheless, this problem, with seven rings, is seldom solved in less than half an hour. It has been found that people apply ‘reasonable’ heuristics, e.g., never reconnect a ring that has once been removed. But adherence to this plausible means-ends principle guarantees that the problem will not be solved. Gradually, recognition that rings sometimes have to be reconnected uncovers the solution strategy.

Comparing the problem-solving by experts and novices soon demonstrated that domain-specific knowledge (of which this is a simple example) lay at

the basis of expert skills, connecting problem solving with memory. A large discrimination net in the expert's memory permits sensory recognition of common stimulus patterns in the domain. Thus, a chess grand-master can recognize perhaps 300,000 configurations of pieces that occur repeatedly in games (e.g., 'fork,' 'open file,' 'weak bishop,' etc.). Associated in memory with each such pattern is knowledge of actions that should be explored whenever the pattern is present. Most 'leaps' in thought called intuitive, insightful, or creative are produced by this knowledge-based pattern recognition (Richman et al. 1996).

The expert, then, recognizes familiar patterns, evoking knowledge that guides search to strong moves in a limited time, searching only a little more than the novice, but along productive instead of unproductive paths.

1.3 Multiple Problem Spaces

As empirical studies advanced, it became apparent that problem solving search employs many different spaces, including a space of potential problem spaces. Searching for solutions may also be preceded by searching for effective generators of actions. Problems of scientific discovery require search in spaces of potentially useful instruments, experimental designs, and hypotheses. The Soar program developed by Newell, with Laird and Rosenbloom (Newell 1990), searches in multiple spaces of these kinds.

2. Reasoning

Reasoning encompasses thinking that is orderly or 'logical': for example, the processes of formal logic and of concept attainment (see *Problem Solving: Deduction, Induction, and Analogical Reasoning; Problem Solving and Reasoning: Case-based*). Hence, most problem solving processes can also be called 'reasoning.' In logic, reasoning begins with premises (a situation), and uses rules of inference (actions) to derive conclusions (attain a goal). It may be inductive or deductive.

2.1 Forms of Reasoning

In inductive logic, the premises usually are empirical assertions and the rules of inference produce generalizations of these using terms like 'all,' 'most,' 'probable.' For example, from observation of many white swans, and none of other colors, one may reason inductively to: 'All swans are white,' 'Probably all swans are white,' 'The probability that any swan is white is 99 in 100,' or 'Most swans are white.' At one time or another, all of these sorts of induction have been proposed.

In deductive logic, the initial premises are taken as axioms and the rules of inference are tautologies (e.g., If all A are B and c is an A, then c is a B), so that, in any possible world in which the premises hold, the conclusions must hold.

Reasoning may be used to discover either a concept, an inductive conclusion, or a deductive conclusion; it may also be used to verify such a concept or conclusion, once reached. Discovery is a wholly different process from verification.

Verifying a proof is a deductive process: simply examining each step to assure that it was obtained from previous steps by an application of the rules of inference. It requires no real search. However, discovering a proof is an inductive problem solving process, which involves searching for a path from the premises to the conclusion, using the rules of inference. (The task of the first computer that simulated problem solving, the *Logic Theorist*, was to find, inductively, proofs for theorems in symbolic logic (Newell and Simon 1956)).

In concept attainment, the task is to find, by examining instances, a rule that distinguishes instances from noninstances of the concept: swans from non-swans. This is an inductive task, where the search proceeds in two spaces: a space of possible instances and noninstances and a space of rules (e.g., feature descriptions that can distinguish instances from noninstances). Search in the space of rules generates possible concepts; search in the space of instances generates objects for testing the rules.

2.2 Everyday Reasoning

Much remains to be learned about how human beings reason in their everyday affairs. One attractive hypothesis, only partially substantiated by the evidence, is that they use the same processes that they use for structured problems. Each situation a person encounters evokes from memory a constantly changing array of knowledge, beliefs, and goals, with varying degrees of mutual consistency and inconsistency. Current goals and the problem spaces they evoke trigger search that leads to actions and thence again to changes in the situations and the materials evoked from memory.

The difficulty of understanding such a system largely derives from the size and complexity of memory, with its idiosyncrasies of what it does or doesn't recognize at any moment and does or doesn't know, believe, like, or dislike about the things recognized. The closest approaches to theories of such systems have been simulations (unified theories) of sizable subsets of the cognitive processes (see Richman et al. 1996).

2.3 Reasoning Mechanisms

Sometimes it has been proposed that specific kinds of reasoning employ specialized machinery in the brain,

just as sensory and motor processes have their specialized organs. Chomsky (1976), for example, has claimed that there is a special language facility (not merely language ‘regions,’ but biological structures specialized to processing language). Rips (1994) has made claims for an inherited machinery for logical reasoning. Comparable claims have been made for ‘pictorial’ reasoning, using mental imagery.

The alternative hypothesis does not deny the evidences for brain localization and specialized functions but claims that all these faculties rest upon the same basic associative neural processes and organizations.

The latter alternative has been explored by constructing simulations that are capable of performing these functions without specialized mechanisms. Thus, without any specialization for logic, syllogistic reasoning will be carried out by all systems that employ if-then rules (production systems), because whenever all the conditions (‘ifs’) of a rule are satisfied in memory, the actions (‘then’) will be executed—a generalization of the classical stimulus-response mechanism. Production systems, conjoined with associative memories, provide a completely general architecture for symbolic processing, ‘logical’ or not (Eisenstadt and Simon 1997). They can reason about mental diagrams and can combine verbal with visual reasoning.

Concept attainment, as well as various kinds of verbal learning and expert memory performance, can be achieved by a discrimination net which grows, by exposure to stimuli and feedback of results, a network of tests of stimulus features that classify the stimuli. Linked to the discrimination net, and indexed by it, a large associative (semantic) memory holds information about each of its concepts, permitting the kind of problem solving by recognition that was discussed in Sect. 1.2 (Richman et al. 1996).

The evidence available at the turn of the twenty-first century allows no clear choice between specialized mechanisms for special domains of reasoning vs. regional localizations of functions that all employ production systems capable of reasoning and learning (i.e., acquiring new productions) and discrimination nets for recognition, and share an associative semantic memory of knowledge and beliefs, indexed by the net. Whichever turns out to be the actual architecture, there will remain the important task of finding the neural mechanisms that implement it.

Problem Solving: Deduction, Induction, and Analogical Reasoning

1. The Closing of Gaps in Human Problem Solving

Deduction, induction, and analogical reasoning, the three basic forms of logical thought, were derived from natural or everyday situations, where they were originally embedded in commonplace forms of interaction and communication. The differences are explained in the respective paragraphs.

Depending on the context, the German word ‘*schließen*’ (‘conclusion’) may mean to ‘close,’ ‘conclude,’ ‘reason,’ or ‘infer.’ Generally speaking, the term implies the bridging or closing of a gap, be this a *literal* gap between two entities or, in the metaphorical sense, a *logical* gap between a problem and its solution. The closing of such metaphorical gaps by means of reasoning or inference usually entails a series of cognitive ‘steps.’

Problems can be defined in terms of three characteristic stages: (a) an initial state (e.g., the arrangement of the figures on a chess board, an algebra or geometry exercise, or a balance of trade), (b) an end state (e.g., putting the opponent’s king in checkmate, solving the maths exercise, or finding ways of improving the balance of trade), and (c) a well-defined series of cognitive ‘steps’ by which the initial state is transformed to the end state: the solution to the problem (or one of a number of solutions).

They are still to be found in their original, undifferentiated form as IF-THEN relations: in barter, trade, the manufacture of implements, and the planning of collective action, for example. Once raised to the metalevel of pure thought, these forms of reasoning became a subject of philosophical inquiry in the fields of mathematical logic, linguistics, and psychology. Over the course of history they even became independent areas of scientific systematics. It was only at a very late stage, in the time of the great Greek philosophers, that the three types were differentiated, defined, and each traced back to its logical structure. This represented the first step on the path to European or Western thought and the scientific advances that were entailed. And the first to tread this path were the great trio of Ancient Greek thought—Socrates, Plato, and Aristotle.

2. Three Great Greek Philosophers and the Foundations of Logic

In the early Socratic *Dialogues*—preserved in Plato’s writings—the processes of reasoning are dominated by IF-THEN relations. These and other dialogues demonstrate the inevitability of human thought. When we are told that all men are mortal and that Socrates is a man, our cognitive processes preclude us from harboring any doubts that Socrates is mortal. We will return to this aspect. First, it should be noted that this kind of logic is not rooted in words. It was one of Plato’s fundamental theories that the objects perceived by the senses are but imperfect copies of Ideas, the mental representations now known as concepts. Socrates had already used inductive arguments to formulate definitions of concepts by gradually identifying their characteristic properties or features. Regardless of the countless possible variations in the shape perceived as a triangle, for example, the sum of the angles must always be equal to two right angles,

and half the product of baseline and height must always be equal to the area. This is Plato’s concept—or Idea—of triangularity.

By applying the principle of dieresis—the breaking down of a concept into ever more narrowly defined subconcepts—Plato developed a general taxonomy of concepts and a system of concept-subconcept relations. This laid the foundation for the Aristotelian system of classification: first the broad general category (*genus proximum*), then the more specific (*differentia specifica*)—for example, a tree is a plant with branches and leaves or needles.

In his treatise *On Interpretation*, Aristotle stripped away the semantic content of propositions, revealing the comparable structures behind the words. ‘First we must define the terms “noun” and “verb,” then the terms “denial” and “affirmation,” then “proposition” and “sentence.”’ Spoken words are the symbols of mental experience and written words are the symbols of spoken words.’ It was another 2000 years before Wittgenstein again addressed this issue in such clear terms. Aristotle’s approach enabled him to formulate the figures of classical logic, the syllogisms. His theory of syllogistic reasoning drew on Plato’s hierarchical ordering of concepts, and a syllogism was defined as ‘discourse in which, certain things being stated, something other than what is stated follows of necessity from their being so.’ A well-known example is the syllogism: A is true of all Bs. C is an A. Therefore, B is true of C. ‘All humans are mortal. Socrates is a human. Therefore, Socrates is mortal.’ Negation operates on similar lines: ‘No self-luminous bodies are planets. All fixed stars are self-luminous. Therefore, no fixed stars are planets.’ These syllogisms were central to philosophical and logical inquiry throughout the Middle Ages and on into modern times.

Although examples with natural terms were mainly used to analyse and dispute the universality of the logical structures, it was not until 1679–90 that a new level of knowledge was attained in the field of logic. Scholars began to ask which inferences can be made when the premises of an argument are derived from prior experience, and do not allow universally valid conclusions to be drawn. This question was first formulated in clear terms by Gottfried Wilhelm Leibniz. Leibniz envisaged a universal formalized language, a ‘*Mathesis universalis*,’ for the general analysis and description of human knowledge, a kind of algebraic representation of logical reasoning in human thought. The system was to encompass even those cases in which the given circumstances and available data did not allow definitive conclusions to be drawn. Leibniz suggested calculating the degree of probability that a logical conclusion would be reliable. Bolzano (1970) followed this line of thought, postulating that the prediction of a conclusion is governed by the conditions of occurrence in a sequence of events. This approaches the twentieth century definition of probability as the likelihood of an event. These are

examples from an era in which the ground was prepared for a new method for acquiring the precise definition of inductive reasoning.

3. Drawing Conclusions from Insufficient Information: Induction

Inductive reasoning occurs when a conclusion does not follow necessarily from the available information. As such, the truth of the conclusion cannot be guaranteed. Rather, a particular outcome is inferred from data about an observed sample B' , $\{B'\} \subset \{B\}$, where $\{B\}$ means the entire population. That is, on the basis of observations about the sample B' , a prediction is made about the entire population B . For example: Smoking increases the risk of cancer. Mr X smokes. How probable is it that Mr X will develop cancer? As this example illustrates, inferential statistics (t-tests, analyses of variance, and other derived forms) are based on this kind of inductive reasoning.

The problems associated with the use of induction in scientific reasoning have been addressed from both philosophical and the mathematical perspective. From the philosophical point of view, the question arises as to what this process—the drawing of universal conclusions about a given phenomenon on the basis of the probability in a sample—actually entails. Logicians, as we now discuss, have responded in a variety of ways (v. Mises, Reichenbach, Keynes, Jeffrey, and Carnap).

Carnap's influential approach to this issue represents a form of compromise. Carnap calculates probability on the basis of accumulated experiential data, where confirmations of one hypothesis as opposed to another are entered into the equation as weights, basically resulting in a kind of weighted mean.

4. Psychological Assumptions from Bayes' Theorem

In psychological research (artificial or experimental) many attempts have been made to analyse beliefs about probability on the basis of examples. For example, marbles are randomly selected from a jar containing an unknown number of red and black marbles, and study participants asked to predict the next color to be drawn. Participants' predictions are sometimes based on *a priori* probabilities, i.e., unconditional, fixed relative frequencies. In central Europe, for example, the probability that it will rain in July is very high; the probability that it will snow is very low. These predictions would have to be modified for the month of April, and may even have to be reversed for January. Everyday human decision-making is rarely determined by such absolute probabilities however. This can be illustrated by the example of a horse-racing enthusiast's gambling be-

havior. Let us assume that the gambler is familiar with the horses taking part in the race and decides to bet that the favorite, horse E, will win. He goes to the tote and sees that horse E is injured and will not be taking part in the race. Our gambler immediately modifies his predictions, selecting the second favorite from the list of starters and placing a bet on this horse instead. This is not necessarily the horse he had previously predicted would come second, however. He might even decide not to bet on second place. Either way, his decisions are still based on estimates of probability, but as a result of the change in circumstances there are now fewer possible choices available. This points to the conditioned probabilities. The *hypothesis set H* for the decision H (horse E) has been reduced by the conditional probability $p(E|H)$. This can be seen in relation to the probability of the alternative hypothesis.

In calculating the so-called *a posteriori* probability, a comparison is drawn between these two quantities. $p(E|H)$ is weighted with the *a priori* probability:

$$p(E|H) \times p(H)$$

This is then placed in relation to the set of all possible positive or negative outcomes according to probability, resulting in the theorem named after Thomas Bayes:

$$p(H|E) = p(E|H)P(H)/P(E)$$

Many experiments in the field of psychology (see Gluck and Bower 1988) have been conducted to test whether the *a posteriori* probability is indeed as effective in human decision-making behavior as this calculation suggests. While some findings confirm the effectiveness of these components, some significant deviations from the theorem have also been registered. These deviations have provided important psychological insights, however. Edwards and Schmidt (1966), for example, conducted in-depth investigations into the ways people adapt their estimates and decision-making behaviour to the changed circumstances when the given information is modified—H-D Schmidt on the basis of high-risk hits of balls, Edwards using gaming chips and estimates of chance. Both found high levels of interindividual variation in the adaptability of study participants. While some people are flexible with respect to their predictions, many others—the so-called 'conservative estimators'—try to retain their initial predictions for as long as possible.

The findings reported by Kahnemann and Tversky (1973) are also very interesting in this context. They found that study participants largely ignore *a priori* probabilities in their predictions of specified variables, preferring to orientate themselves to conditional probabilities. This result is not counterintuitive, as the

conditional probabilities are the most salient. The so-called Monte Carlo effect is another example of the insensitivity to *a priori* probabilities. Suppose that marbles are drawn with replacement from an urn containing an equal number of red and black marbles. The probability of randomly drawing a marble of either colour is 50 percent. If a red marble has been drawn on a number of consecutive occasions, however, study participants regularly predict that it is more likely that a black marble will be selected next. They overlook the fact that each draw is an independent event, and that the *a priori* probability is independent of the previous draws, i.e., remains constant at 50 percent.

In a fictitious diagnosis experiment, Gluck and Bower (1988) found a high level of correspondence between the estimates made by study participants and the odds calculated using Bayes' formula. On the basis of a medical chart, study participants were asked to judge which of two diseases their (hypothetical) patients were suffering from. The *a priori* probability of one of the diseases was three times higher than that of the other. The conditional probabilities were then varied by the listing of symptoms relevant to the diagnosis. Gluck and Bower found a high degree of correspondence with the Bayes' calculations. When asked to estimate the frequency with which a symptom is associated with one of the two diseases (the rarer one), however, the study participants were unable to make reliable predictions. Hence, the 'diagnosticians' came to a Bayesian conclusion without using Bayesian methods. Gluck and Bower refer to this as implicit knowledge.

5. Implicit Knowledge in Reasoning

The question remains of how such a data compilation functions on the cognitive level. It can be assumed that such processes involve the compression of accessible information and that they are of a non-algebraic character. They constitute abstractions about data sets, leading to a kind of blurred conceptual knowledge. Examination of the effects of quantifiers in logical arguments has provided insights into these processes. The *modus ponens* is quite categorical: If P, then A holds. In other words, P implies ($\rightarrow$) A. Given P then A, hence $P \rightarrow A$. If it rains (P), then the lawn will be wet (A). It has rained, therefore the lawn is wet; $P \rightarrow A$. Is the reverse (not P) also true? That is: $\neg P \rightarrow \neg A$? Not necessarily; the lawn may well have been watered with a sprinkler or a hosepipe. It has been shown that, in more abstract contexts, even adults have difficulties in understanding this so-called *modus tollens* (Wason and Johnson-Laird 1972). But does the *modus ponens* also hold for conclusions beginning with the quantifier 'some'? For instance does it follow from 'some As are Bs, and some Bs are Cs,' that, 'some As are Cs'? Not necessarily. For instance, substituting 'women' for As, 'doctors' for Bs

and 'men' for Cs, we would arrive at the conclusion that some women are men. Alternatively, assuming that some Bs are As and some Cs are Bs, does it follow that some As are Cs? Again, this is not entirely true, as is immediately apparent when terms from natural language are entered into the equation (cf. Anderson). Wason and Johnson-Laird (1972) have investigated the acceptance of such logical arguments in detail. Cosmides and Tooby (cf. Horgan 1995) have attempted to provide an explanation, postulating that such halo effects on techniques acquired over the course of evolution help to reap the maximum benefits. For example, they suggest that the need to detect deception on the part of one's interactants is an essential incentive for the development of human intelligence. The well-known prisoner's dilemma is another such phenomenon. At issue here is whether players trust in the other player having a positive attitude to sharing, or whether they attempt to appropriate the entire winnings at the risk of losing everything. There is no doubt that the maximum-benefit motive plays a role in numerous decision-making processes. In general, however, the evolutionary influences on logically motivated decision-making behavior are located at a deeper level—in strategies which remain stable over the course of evolution and account for both individual and group interests. And not only in the sense of reaping the maximum social benefits. The so-called Monte Carlo effect (see earlier discussion) is but one example. Since time immemorial, humans have experienced that even prolonged natural processes such as weathering, drought, rain, floods, epidemics, disease, etc. eventually come to an end. And it generally holds that the longer these processes have been operating, the more imminent (i.e., the more probable) their conclusion. Such an approach appears to be the heritage of experiences gathered over the thousands of years of hominid history. The fact that humans prefer to extrapolate to the future—as implied by the *modus ponens* with its deterministic IF-THEN relations—is a favorable predisposition, increasing the chances of survival. It is very simple: It is more important to react to potential future events than to past occurrences. As there is only limited storage space in a modular nervous system, some bodies of knowledge become overgeneralized, perhaps as a result of being classified in line with the *modus ponens*. A similar pattern emerges for the weaker inductions of the *modus tollens*: In order to behave appropriately in one's environment, it is less important to know what can be inferred about the antecedent conditions from the absence of an event than vice versa.

6. Reasoning and Analogies

While deductive reasoning, in logic, refers to the *necessary* outcomes of a set of conditions, inductive reasoning is concerned with determining the likelihood of an outcome. Only *possible* conclusions can be

Figure 1
The basic structure of analogical reasoning. A–A': the source area with relation (s) R, between them. B–B': the target area with similar relations R_1 . S_1 and S_2 : mappings between source and target area

drawn, since not all of the conditions influencing or determining the outcome of a given situation are known. Analogical reasoning has a different character; it is basically a more precise form of conjecture. It is based on the mapping of structures or relations valid in one domain of knowledge onto another—less familiar or unknown—domain. The structures to be mapped are selected on the grounds of the similarity between the novel problem and the familiar one. The novel area is defined as the target domain of analogy construction, the familiar area as the source domain. With respect to the truth values of the conclusion, analogical reasoning spans all variants—from the absolute certainty of the *modus ponens* to a *posteriori* probabilities according to Bayes' Theorem, some of which are very weak. Suppose, for example, a second pair of terms is sought for a pair of numbers such as 3:6. Pairs such as 8:16 and 64:128 among many other combinations meet the requirements of the analogy.

As shown in Fig. 1, analogy construction can also be applied to geometric figures. It may be, but does not have to be the same factor of horizontal stretch which is mapped to produce a rectangle from a square or an oval from a circle. The boundaries within which

geometric analogies are accepted are fuzzy, but when these boundaries are overstepped, the analogies are rejected. The same holds for meaningful words in natural languages. Let us imagine that analogous pairs with the same relational correspondence are to be generated for the following pairs of words: (a) collie: dog, (b) walk: run, (c) oak: birch. A good number of satisfactory analogies can be found, for example: (a) rose: flower, (b) speak: shout, (c) carp: trout. In each pair, the first term has all the relevant properties of the second (animal, voice, plant), as well as some of its own. The first pair is characterized by a sub-super-concept relation, the second by the intensity of the characteristic feature (the semantic relation of the comparative). The third pair shares a super-concept with common properties, but each term has specific properties of its own (the semantic relation of coordination). Pairs of terms such as dress and bullet or flea and fog do not allow analogies to be drawn on the basis of common properties, as these are non-existent. Clearly, similarity between the terms is an integral element in the construction of analogies. This similarity is not necessarily rooted in common properties, however. For us pairs of terms such as (a) ship and ocean, (b) hunter and deer, and (c) surgeon and scalpel, for example, do not share common properties. Nevertheless, the relational connections between the concepts are comparable with those found in other pairs of terms. In example (a) the shared relational connection is the location (as in flower and garden), in (b) it is the object of the action (as in butcher and cow), and in (c) the instrument (as in farmer and scythe). More complex relations can also be involved, as in 'learn: know' paired with 'fight: win.' Here, the common semantic relation is the objective or purpose. Such relational connections are the basis for analogy construction: 'The shark is the wolf of the ocean,' for example, or 'May is the Mozart of the calendar' (Erich Kästner). Many such examples are to be found in the Bible, particularly in the parables of the New Testament.

7. The Origins and Original Function of Analogies

Analogies are evidently not isolated examples of mental games, but a constant cognitive law. But what is the point of these transfers between bodies of knowledge? Is it just a case of juggling with combinations of words that match in some way? Or do analogies reflect a deeper (perhaps even social) need of *Homo sapiens*? Viewed from this evolutionary perspective, the question arises of where, exactly, the origins of analogical thought are to be found.

Analogical thought is primarily to be found in language use. Indeed, the key word 'language' puts us on the right track, for the evolutionary origins of

analogy are rooted in the need to communicate, and similes and metaphors are its direct evolutionary source. The cognitive function of analogy is to facilitate discourse; when an interlocutor does not understand a particular term or statement, the speaker attempts to clarify its meaning. This he or she does by referring to common knowledge that is as similar as possible to the term or statement in question. Similes and metaphors are essential ingredients of this procedure. The comparative phrase 'is like' is often added as an explicit reference to the existing similarity (Rumelhart 1979). For example, it is quite possible to imagine the following explanation being given in the course of prehistoric dialog:

Question: 'What's a quagmire?'

Answer: 'It's like a trap in the mud.'

The second term functions as a source of new knowledge. Indeed, the very purpose of this dialog is to impart (or acquire) new knowledge. This is also the case when adults explain things to children: 'The heart is like a motor driving the body,' 'pathologists are like butchers,' or 'rules are like corsets,' for example. Complete analogies can be viewed as extensions of such metaphors—for example, 'Rock in the opera—that's like heavy metal in cathedral,' an executioner in the Salvation Army is like a monk in the artillery,' or 'a June meadow in the mountains is like a bride in her wedding dress.' The list is never-ending. Such examples are no longer explanations or supplements to existing knowledge, but this is the source from which they originated. And, as illustrated by Eichendorff reference, they display originality and creativity of thought: 'It was as if the Sky had silently kissed the Earth, so that she, in the glimmer of blossoms, now had to dream of him.' A somewhat more mundane example can be drawn from one of General Moltke's cadet examinations. When Moltke asked a cadet, 'How wide is the Thames in Paris?', the boy replied, 'Just as wide as the Seine in London, your Excellency.' By inverting the terms, the cadet demonstrated that he was well aware of the existing relations. Analogies can thus also be a source of smiles and approval.

8. Cognitive Procedures in Analogy Construction

Without a doubt, the recognition of structural similarities between the source and target domains plays a pivotal role in the acceptance of proposed analogies, as well as in their completion (e.g., supplying a fourth term when three are given), and creation (suggesting a new and possibly unique second pair of terms). Similarity is a necessary precondition in all three cases.

Different approaches to the definition of conceptual similarity have emerged in the literature definition in terms of (a) shared conceptual properties, as proposed primarily by Tversky *et al.* and (b) structural similarity, as suggested by Gentner and Stevens (1983). A compromise between these two approaches has been

formulated by Bachmann (1989) after Jaccard and Tanimoto.

Tversky defines the similarity between two objects in terms of the relationship between the features common to both structures and the features distinct to each, be they perceptual structures or sets of conceptual properties. As in Tversky's experiment, both components were then aggregated and compared to the estimated values. This resulted in a significant improvement on the correspondence between feature overlap and estimated similarity. The degree of improvement varied from concept, but correspondence calculated on the basis of common features alone was significantly lower.

The weighting on each of the semantic relations in similarity judgments is another matter of interest, and can be inferred from the sequence in which the individual relations are selected and entered into the analogous structure. Participants usually chose the actor and recipient first (e.g., hunt: hunter → game), followed by the instrument (e.g., rifle), the location (e.g., forest) and, often at a comparatively late stage, the objective (e.g., to bag a deer). This sequence of concept selection points to the existence of saliency weightings in the components of the individual concepts. Moreover, these results confirm that a moderate degree of similarity is essential not only for felicitous metaphors, but for creative analogies. Our experiments have shown that particularly characteristic features or relations can have preferential status in both the recognition and construction of analogies (Klix and Bachmann 1992). The originality of an analogy is dependent on factors such as the age and intelligence of its constructor, and analogy completion tasks are often employed in intelligence tests such as the Raven 'progressive matrices,' Sternberg (1977) has linked the factor structure of human intelligence to the solution of analogy tests. Moreover, Gentner and Sternberg have constructed algorithms which realize analogy detection. All of these are based on the comparison of features or semantic relations (Greeno and Riley 1984).

9. Models of Analogy Detection

Following the initial, very simple approaches to the processes of analogy detection, the dominant paradigm is now based on a model devised by Rips *et al.* (1973) which has been modified and extended by Bachmann (1998). According to this model, the following three aspects must be checked before an analogy can be accepted:

(a) Do the terms to be compared share a common feature which is much more salient than others? In train: railway and bus: truck; for example, the means of transport is so prominent that the analogy is immediately accepted.

(b) If this is not the case, the global impression is assessed. This entails a kind of compression of the available information, as discussed above in connection with Gluck and Bower's experiments.

(c) If this global comparison does not result in a decision, the concepts are closely scanned for common features and relations (deliberate checking). If no acceptable similarities are found, the analogy is rejected.

Unfortunately, the question of how much processing time is required for each of these components is as yet unanswered.

10. The Role of Analogy Construction in Scientific Innovation

The relationship between analogical reasoning and intelligence has been investigated in countless experiments and tests, with children and young adults of various ages, using plant, animal, object, and abstract analogies. However, there has been far less investigation of the ways in which analogy construction has impacted on the history of science, and the momentous mental achievements and creative insights which have resulted from this (see *Scientific Reasoning and Discovery, Cognitive Psychology of*).

Many significant examples can be found to illustrate how analogical reasoning has helped to break new ground in the history of science. The origins of analogy-based scientific innovation can be traced back to the early stages of Greek thought, with Archimedes one of its most eminent representatives. The Egyptian shadoof—a long-armed water-raising device used to draw water from wells—was invented long before Archimedes' time, and it was known that levers could be used to amplify physical force. It was left to Archimedes, however, to discover the relationship between the two arms, and thus to establish the principle of the lever. Hence mechanics—an essential precursor of physics—was founded on the basis of a number-pair analogy between the respective distances from the fulcrum and force relations according to the principle of levers. This development was founded on a paradigm of analogical thought, i.e., load arm: effort arm = length A: length B. Using the same method, i.e., in analogy to the principle of the lever, Archimedes was also able to calculate the surface area of any segment of a parabola (Serres 1994).

Eratosthenes is thought to be the first person to have calculated the earth's circumference. People had known how to determine the circumference of a circle using 360° since Babylonian times (influenced by the Sumerian sexagesimal system). Eratosthenes applied this knowledge in the following analogy: The distance between Syene (now Aswan) and Alexandria was approximately 800 km (in today's system of measurement). Once a year, the sun was at its zenith directly over a well in Syene and hence there are no shadows at

that location at that time. At the same time in Alexandria, it cast a shadow from which it could be calculated that the sun was 7° from the zenith. This represents a difference of about $1/50$ of a complete circle, hence the distance between Alexandria and Syene is about $1/50$ of the earth's circumference. By multiplying the distance (800 km) by 50, Eratosthenes calculated the earth's circumference to be approximately 40,000 km.

In his famed *Dialogue on the Two Chief World Systems* (the Ptolemaic system and the Copernican system), Galileo contradicted the Aristotelians of the time. The Aristotelians advocated the Ptolemaic hypothesis, and presented the following argument against the Copernican model: Assuming that Copernicus is right in saying that the earth rotates around its own axis, the circumference of the earth is such that this must happen at high speed—40,000 km in 24 hours (or 920 m in some 2 seconds' free fall). As a test of the Copernican system, one can climb a high tower, drop a stone from the top, and note the position at which it hits the ground. Since the earth is turning while the stone is falling, the stone should be noticeably removed from the foot of the tower when it makes contact with the earth. This is not the case, however. The stone falls perpendicular to the tower and hits the ground at its foot. According to the Aristotelians, this disproved the Copernican system. Using the character of Salviati in the *Dialogue* as his mouthpiece, Galileo refuted this argument with the following analogy: Imagine a sailing boat traveling at high speed. If a stone is dropped from the top of the mast, it will hit the deck at the foot of the mast, since it retains the speed of the boat until it hits the ground. Galileo thus invalidated the anti-Copernican argument by means of an analogy.

The most impressive known example of analogical reasoning in scientific discovery is provided by the equations describing electromagnetism derived by James Clerk Maxwell in 1864. Maxwell's contemporary, Michael Faraday, had demonstrated the existence of electric and magnetic fields, showing that iron filings sprinkled on a thin piece of paper held above a magnet are attracted to its 'lines or force' or its poles. Maxwell investigated the properties of the lines of force described by Faraday and discovered similarities between the behavior of these lines of force and the flow of a liquid in a pipe. The equations for the latter were already known. Maxwell transferred this knowledge to magnetic fields and electric currents, and was thus able to define the behavior of magnetic lines of force at and between poles. Writing on this means of discovery, Maxwell postulated that in order to form an idea of physical laws for which no theory is available, it is necessary to familiarize oneself with the existence of physical analogies. The discovery of the interaction between electric currents and magnetic fields laid the foundations of the theory and practice of electromagnetism, and hence of the dynamo tech-

nology at the close of the nineteenth century. Moreover, it was the precursor of radio and television wave transmission, since one of Maxwell's analogous equations had suggested that radio waves must also exist. Twenty years after Maxwell presented his basic equations, Heinrich Hertz indeed succeeded in producing radio waves under laboratory conditions—another demonstration of how creative thought in the form of analogical reasoning can impact dramatically on the history of science and the fate of humankind.

Problem Solving (Everyday), Psychology of

This article reviews developments in the psychology of everyday problem solving. The adjective 'everyday' is interpreted by contrast with the puzzles and academic tasks that have been the main focus of psychological problem solving research. This leads to an emphasis on the relation between planning and action, and between the mental representation of the problem and the physical situation in which problem solving takes place. The role of artifacts in support of everyday problem solving is discussed, and the idea that problem solving can be understood as an adaptation to environmental constraints is reviewed.

1. Background

The psychology of human problem solving was transformed by the work of Newell and Simon (1972) and all subsequent theorizing has used their work as a platform. Newell and Simon (1972) developed a very general abstract conception of problem solving as search through a problem space. A problem is defined by a goal state, a start state, and a set of operators, and the problem solver must achieve the goal state by applying a sequence of operators so as to transform the start state into the goal state. The set of states that are generatively defined by the start state and the operators is called the 'problem space,' and problem solving can be viewed as a search of this problem space for the goal state.

Newell and Simon's early empirical work within this framework concentrated on discovering the heuristics that people use to direct search through the problem space. This led them and their followers initially to

concentrate on well-defined puzzles, with a pre-determined set of operators and a completely specified problem space. This program of research was very effective, leading at least one prominent reviewer (VanLehn 1989) to claim that the psychology of human problem solving had been 'solved' (leaving as a residual mystery the question of what is learned from problem-solving experience).

But however valuable puzzles like the Tower of Hanoi or letter-arithmetic might be for the study of human problem solving, they are clearly not 'everyday' problems. There is no doubt that the problem space theory and search heuristics such as means-ends analysis and hill-climbing are vital to a full understanding of everyday human problem solving. But equally, the salient and manifold differences between many everyday problems and well-defined, self-contained puzzles raise important issues for the problem solver and for the psychologist.

Consider the following examples of everyday problems (from Anderson 1990, p. 193, given by his students as answers to the question 'name a problem that you tried to solve in the last 24 hours').

- Finding a route from a hotel to a restaurant
- Debugging someone else's code
- Getting subjects to sign up for my experiment
- Getting two Diet Cokes from a Coke machine
- Getting my car registered

Perhaps the most obvious special property of puzzles like Tower of Hanoi compared to these problems is that all the knowledge needed for a solution is provided in the problem statement. (This is not quite true of letter-arithmetic, of course, but even then the additional knowledge required, that is, arithmetic, is well-defined and strictly demarcated.) In particular the set of applicable operators is constrained and pre-determined.

An extensive literature has extended the study of human problem solving to 'knowledge-intensive' domains, in which the application of the solver's experience (in particular by choosing operators from long-term memory) is the critical issue. The most extensively studied domains have been academic domains like mathematics, physics, and computer programming (as well as chess, which is self-contained in principle, but reliant on long-term memory in practice), and the most extensively used methodology has been a comparison of expert and novice problem solving. The classic established finding of this research is that experts are better problem solvers than novices not because they are better able to use search heuristics, but rather because their knowledge of the domain allows them to identify and classify problems in terms of the methods that will be useful to solve them, thereby obviating the need for extensive search of the problem space. Experts tend to work forwards from problem statements to solutions, whereas novices tend to work backwards from the goal, searching memory for applicable knowledge (Larkin et al. 1980).

Most everyday problems are even less well-defined than academic problems in terms of the applicable operators. If you want to register your car and you don't know how, the problem is discovering the applicable operators, not merely ordering them. Furthermore, in contrast to puzzles and to academic problems, most everyday problem solving involves interacting with (so as to change) the everyday physical and social environment.

2. The Problem of Everyday Problems

Perhaps the single most important issue that the study of everyday problem solving prioritizes is the nature of the interplay between mental activity and physical activity, or between the mental problem space and the physical setting in which problem solving takes place. Within the traditional domains of problem solving research noted above, this has seldom been treated as a serious issue (although it should be noted that Newell and Simon recognized its importance, and have contributed some important analyses of the relation between external and internal representations, e.g., Simon 1975). Search of a problem space is primarily a mental activity: the current state is mentally represented, operators are considered, and imagined next-states are evaluated. Perhaps hierarchies and sequences of operators are mentally considered ('planning' or 'look-ahead'). Eventually an operator or sequence of operators is chosen, and then enacted. Many computational models of human problem solving gloss any distinction between mental and physical application of an operator. And early AI planning systems, building on Newell and Simon's analyses of search, computed entire sequences of operators from start state to goal state before acting on the world. People are seldom so patient. Instead they iteratively interleave planning and action. Since the early 1980s a body of literature has shown that in many everyday problem-solving situations the specifics of the physical situation and the problem solver's management of the relation between planning, perception, and action are crucial determinants of problem-solving success.

Consider one observation from some very influential empirical studies by the cognitive anthropologist Jean Lave and her colleagues (1984). A supermarket shopper picked up one slab of cheese from a shelf of similar cheeses to be surprised by its price. She guessed that it had been wrongly labeled but wanted to check. She might have used mental division to compute its price per unit weight and then performed the same computation on one of the other slabs (as usual the cheeses varied somewhat in weight and therefore price). Instead she searched the shelf for a cheese of very similar weight and directly compared the prices of the two cheeses.

A similar observation of in-situ problem solving was made by Scribner (1984). She observed dairy workers completing orders for partially full crates of

milk bottles. For example, a packer might receive an order of 1-6, meaning one crate-six bottles. Instead of completing this order by taking a full crate (16 bottles) and removing six bottles, the packer might find a crate has eight bottles in it and add two. This 'nonliteral' strategy involves mental effort, using arithmetic to recode the original order, but saves physical effort. (Scribner found that nonliteral strategies were common among skilled packers, and could almost always be accounted for by the saving of physical effort.)

Both the packer and the shopper are evidently managing a tradeoff between physical and perceptual activities (such as searching a display for relevant items) and mental activities (arithmetic operations). To fully understand their problem-solving behavior it is necessary to understand the opportunities for this tradeoff that are provided by the situation, and the cognitive mechanisms by which the tradeoff is managed.

3. Cognitive Artifacts

The first issue becomes particularly salient when coupled with the observation that much everyday problem solving is supported by 'cognitive artifacts' or tools of thought, ranging from pencil-and-paper through conventional representations like diagrams and graphs to computational systems. How can we understand the role of such artifacts in problem solving?

One theoretical approach is to simply redraw the boundaries of the cognitive agent away from the human problem solver to include the artifacts being used (Hutchins 1995). This approach has led to some insightful descriptions of how various human-machine systems perform their specific tasks (e.g., how a cockpit remembers its speeds). In the work of Zhang and Norman (1994) it has been developed into a general framework for the understanding of distributed cognitive tasks, in which the relation between external and internal representations is the primary focus. Zhang and Norman (1994) argue that when aspects of the representation of a problem can be offloaded into the physical environment, problem solving becomes easier.

A second approach focuses on how the artifact changes the cognitive task of its user. For example, Larkin and Simon (1987) have analyzed how diagrams facilitate certain problem-solving strategies by allowing simple perceptual judgments (such as whether two lines intersect) to replace more demanding mental computations.

Diagrams might be referred to as 'read only' cognitive artifacts. Artifacts that are 'read-write' can have more complex mediating effects on cognition. Consider the use of a simple appointment diary (Payne

1993). Recording an appointment in a diary changes the task of remembering that appointment in several ways. First, the fact that the appointment has been named and written will affect the internal memory trace for the appointment. And of course, the diary can act as an external memory, allowing its user to retrieve the appointment by reading. Furthermore, in conventional paper diaries the act of writing a new appointment leads to the inevitable rehearsal of already noted appointments.

A third approach to understanding cognitive artifacts is to focus on the properties of the artifact itself as an information system, and to ask how readily it allows certain information-processing operations. This approach has been pioneered in the field of human-computer interaction by Green (1989) under the banner 'cognitive dimensions of notations.' Green's enterprise is to define a limited number of widely applicable dimensions on which cognitive artifacts can be compared in terms of the extent to which they support flexible patterns of use. (Green has been particularly concerned with artifacts that are used in design tasks, such as spreadsheets, programming languages, document processors, and musical notations, and with supporting opportunistic design, in which initial drafts are iteratively revised.) One cognitive dimension is 'role expressiveness,' the extent to which a notation exposes meaningful structure. As a simple example, the use of meaningful variable names in a program will tend to increase role expressiveness. Another dimension is 'viscosity,' the extent to which a notation is resistant to local change. Consider a text with section numbers. Insert a section and all subsequent numbers must be changed.

All these approaches are set to continue in various guises. Understanding the cognitive effects of artifacts is one of the most important open problems for the theory of human problem solving.

4. Rational Approaches to Problem Solving

Let us now turn to the second crucial issue raised above, that is, how the tradeoff between mental and physical activity is managed. Scribner (1984) in her analysis of milk crate packing, suggested that packers might be explicitly trading mental and physical costs and benefits. More recently this basic idea has been developed, particularly in the work of John Anderson (1990) on what he has called the rational analysis of cognition. The general idea is to analyze cognition as an optimal adaptation to the probabilistic structure of the environment. Such an analysis asks *why* cognitive behavior is the way it is, and may help structure the subsequent investigation of *how* cognition approximates the optimal solution.

This approach has already thrown some light on the critical characteristics of everyday problem solving.

First, consider the interplay between planning and acting. From a rational perspective, a problem solver should plan before acting to the extent that the estimated benefits of planning outweigh the costs. The benefits of planning will relate to a reduction in the number of actions required and the individual costs of those actions. We might suppose that Scribner's dairy workers would have been less inclined to transform their orders arithmetically if moving bottles around had been somehow much easier. This idea has been tested in a series of experiments by O'Hara and Payne (1998) who showed that clumsy user interfaces to puzzles (i.e., interfaces that made each move more costly in terms of keystrokes or time) produced fewer-move solutions to puzzles than did more efficient interfaces.

The use of cognitive artifacts has also been illuminated by an adaptive analysis. A simple case is the electronic calculator. There are many problems that can be computed either mentally or by calculator. An experiment by Siegler and Lemaire (1997) showed that people are able to make this choice adaptively according to an accurate model of their own capabilities: that is, they reliably choose to do a task mentally when that is indeed the quickest way to do it, and to use the calculator instead when that has real benefits.

Finally, Pirolli and Card (1999) have shown that aspects of people's use of complex computer-based information retrieval systems can be well modeled by equations based on optimal foraging theory. In other words, people behave as if they could compute and use accurate estimates of their current and previous rates of information gain (cf. an animal's intake of energy from a food supply) and of the costs of searching different information resources (cf. an animal's journey to a new food supply).

5. Conclusions

Some theorists have argued that the situational contingencies of everyday problem solving render the abstract cognitive theory of Newell and Simon useless. However, an alternative view is that instead these complexities simply emphasize certain theoretical questions over others, and the required reworking is best considered as an elaboration of aspects of Newell and Simon's framework. This second approach has the advantage of allowing incremental development in our understanding of the psychology of human problem solving.

Problem Solving (Joint), Psychology of

'Joint problem solving' refers to the situation where two or more people work together to solve a shared problem, where agreement on a single solution may or may not be required. The proverb says 'two heads are better than one,' but why so, or when so, is not explicitly understood yet. Despite this folk knowledge, studies have shown that joint solving does not always result in better performance than that of the most capable solos. Rather, careful studies of the processes have revealed that there are clear cognitive process gains in the joint endeavor. In joint situations, the

participants tended to deepen their conceptual understandings of the topic problem (Miyake 1986), or the subjects generated a greater number of experimental hypotheses and had better chances to duplicate a scientific discovery (Okada and Simon 1997). The reasons for such gains are still under investigation, but research findings suggest that the joint situation allows the participants to naturally externalize their solving processes, and this externalization provides chances for flexible revisions of their trials, leading them to more conceptual understandings and newer ideas.

1. Gains of Joint Processes

Joint problem solving has been extensively studied in social psychology, mainly with an interest in whether people in groups, thus in 'social' situations, would perform better than solos. Hastie (1986) gives an extensive review, where joint cases are compared against solos on tasks like number estimation, vocabulary tests, and arithmetic brainteasers. Hastie summarizes the field and concludes, 'these studies tended to find that group performance exceeded the performance of the average individual, [but] for most of these problems groups did not match the performance of their best members' (p. 150). He also suggests that 'the critical characteristic of performance on the tasks is solution demonstrability, with higher levels of group performance associated with tasks where correct solutions are easily demonstrated and communicated to group members, and relatively low levels of performance associated with difficult-to-demonstrate solutions' (p. 150). His interest was mostly in categorizing group performances on tasks and group membership, not on cognitive aspects of the solving processes.

Miyake (1986) tried to clarify the cognitive gains associated with paired performance. She asked three pairs of subjects to understand how a sewing machine made its stitches and analyzed their verbal protocols. The sewing machine problem has interesting characteristics of having different levels of answers. One answer to the question would just mention that the machine uses two intertwined pieces of thread to fasten the cloth. On hearing this, one can further ask about the exact physical configuration of the seam, which turns out to be a loop-in-loop. Discovering this could open up a new puzzle because it is physically impossible to form a loop-in-loop with two threads without free ends. (At a middle point in sewing, for both upper and lower threads, one end of them is in the spindle or in the bobbin, while the other end is tightly sewn to the cloth.) In fact, while the upper thread comes down into the machine, its loop goes entirely around the bobbin. This is a perfect answer until one starts wondering how, then, the bobbin itself is attached to the machine.

This hierarchical nature of the possible answers to the sewing machine problem made it possible to analyze the protocols in terms of when they reached the intermediate understandings and how and when they noticed the insufficiency of their solutions and started to ask the 'one level deeper' questions. Miyake found that each of her subjects descended this hierarchy according to his or her individualistic formulation of the question. This often resulted in situations where members of the pair worked at different levels at the same time: while one person may worry about the physical configuration of the seam, the other could try to find how the loop-in-loop configuration is possible with two threads without free ends. Because of this disagreement, the subjects were almost always in conflict, which contributed to push each individual to refine his or her own models so that 'the other member would understand my points.' In summary, Miyake argues that the process gain of joint problem solving does not necessarily lie in the performance, but rather in raising the necessity and motivation for deepening and refining each individual's understandings.

In the 1990s, the amount of research on joint problem solving increased, showing more positive results for both pairs and groups. Conditions for successful collaborations were identified where earlier studies focused on degrees of mutual participation, while the more recent studies identified explicit types of talk that contributed to the success (e.g., Teasley's 'transactive' talks, Teasley 1997). A similar style of research has been extended to cover topics of learning and development (e.g., Rogoff 1990). Hatano and Inagaki (1991), for example, analyzed a science classroom where the children selected among the alternative hypotheses provided by the teacher and debated among them. By analyzing the discussion they identified what they named 'the partisan motivation,' shared by the naturally grouped members with the same alternative, that acted as an enhancer for the self-motivated articulation of their explanations.

2. Joint Problem Solving in the Real World

Okada and Simon (1997) took a slightly different course of identifying causes for pairs' success in an experimental scientific 'discovery.' Using a computer-simulated task of making a discovery in molecular genetics, paired subjects were found to be superior to single subjects. This success was associated with higher levels of explanatory activities of the pairs, and further, such explanatory activities were facilitated when paired subjects made explicit requests of each other for explanations and testable hypotheses.

This change occurred with the search into more ecologically valid research in the domain of problem solving. Daily problems often get solved in groups,

and there are pragmatic needs and interests in finding out how groups should be organized to be productive. This led cognitive problem solving research to take an 'in vivo' form (Dunber 1995), where workers and scientists in realistic situations were carefully studied. Dunber observed four laboratories carrying out immunization research and followed their daily scientific activities for a year, with various methods from attending the research meetings and taking notes, reading their lab diaries, to extensive interviews. His findings are diverse, and factors he found positive include frequent exchange of ideas, nonauthoritative membership, positive attitudes toward even negative intermediate results, use of local analogies, etc. In an interview-based study of a real R & D team in a detergent company, Ueda and Niwa (1996) found that having an outsider's view at the right time was crucial for the team to change the course, which led them to produce a new successful product. All such reported factors tend to confirm the folk expectation of what should contribute to high group performance. Yet how we can coordinate these factors to make them all work simply remains to be discovered. Furthermore, the overall conclusion we could draw from these sets of research is that the quality of group performances depends heavily on the organization and activity control of the groups.

3. Joint Problem Solving from a Cognitive Anthropology Perspective

In contrast, cognitive anthropologists have maintained more positive perspectives. Hutchins (1990) observed a team navigating a large ship and found that there was overlapping knowledge shared among the team members that strongly coordinated the teamwork. In the reported case of a 'fix,' or a joint activity of finding the exact location of a ship, at least three roles are involved. The bearing-taker measures the angles between the ship's direction and selected landmarks using a gyroscope, and calls out the number through a tube to the charting house. Then this number is repeated by the bearing timer-recorder who writes down the number into the log book. The number then gets converted to the angle on the device that allows the plotter to make lines on the chart so that they can pinpoint the location of the ship onto the map. Staff start working in this team as the bearing-taker, who after some experience is promoted to the timer-recorder job, who would later move into the plotter position. Thus the plotter knows everything the other two know, and the timer-recorder knows all of what the bearing-taker knows. It is also possible for the lower-rank staffs to closely observe what the staff one rank higher is engaged in. While a cross-sectional, one-shot observation might make this teamwork appear to be highly coordinated across divisions of work, in reality what coordinates this team is the shared

knowledge of a longitudinal, historical nature. Laboratory-oriented, puzzle-based experimental studies of joint problem solving have been quite weak on this aspect.

Hutchins' report maintains one more important observation on how the teamwork is divided and carried out. In the above example of taking a fix, there are three subtasks, each of them producing some intermediate results. Careful inspection reveals that each of them takes quite a different, and redundant form of representation of the intermediate results of a single process. The first outcome of the bearer is by voice, which is then written down in number symbols, which is then again converted into lines on the chart. These different forms, at different times of representation, provide different and redundant forms for people involved to check the process from different perspectives. In this sense this is a real-world documentation of what Hastie called 'demonstrability,' which, in realistic situations, does not just provides the information concerning the correctness of the solution but opens up the possibility for other interpretations and possibly flexible redesigning of the process itself.

4. Toward Further Research into the Mechanisms of Joint Gain

Paired subjects could, in fact, take advantage of externally shared objects in the course of simpler experimental tasks. Shirouzu et al. (1999) asked subjects to indicate two-thirds of three-quarters of the area of a square, folding paper measuring 15 cm × 15 cm. They report that in various conditions people strongly opted (over 90 percent on average) to use external resources to do this arithmetic, either by folding the paper or by marking the edges with their fingers and partitioning, etc. Because this reliance on external resources is quite strong, most of the single subjects did not change the solution method (from folding to calculating, for example) even when they were consecutively asked the second question, i.e., to indicate the area of three-quarters of two-thirds of the same sized paper. The subjects did not change it even after seeing the 'externalized' result to be exactly one-half of the paper. They compared this to pair performances and reported that the pairs are a lot more flexible in choosing different solutions to the second question (70 percent of the pairs changed the solution methods while less than 20 percent of the single subjects did so). By analyzing the solving processes and the protocols of such subjects they found that the flexible pairs were in fact gradually responding to the constantly changing externalized forms of the paper while they worked together, rather than each randomly contributing newer ideas at their turns.

As a future course of joint problem-solving research, new learning studies focus on collaborations. As indicated above, joint situations tend to provide the

participants with verbal expressions and tangible externalized objects that each member can manipulate to concretely suggest newer, or at least different, ideas. In rapidly changing societies, the goal of learning is not only digesting what is taught. Learners are required to acquire skills to learn, to become self-regulated learners. In order to fulfill this goal, it is necessary to give learners more chances to be reflective than currently enforced, to scrutinize upon and revise what they themselves do and how others do similar tasks. Studies on joint problem-solving situations are expected to provide rich resources to help develop effective learning situations (e.g., Bransford et al. 2000).

Procedure: Legal Aspects

1. The Subject Matter of Procedure

Procedure addresses the work of adjudicatory processes that are based in courts. While the subject may appear dry (if not boring), the rules of any procedural system are interesting because they must respond to difficult political and social questions.

Traditionally the world of procedure has been divided into three categories—civil, criminal, and administrative. For example, civil cases are those in which no criminal penalties (often but not exclusively incarceration) are sought. Administrative law proceedings are those in which (typically) the government is a party and the case is processed in administrative agencies devoted to a particular subject matter rather than in generalist courts. Courts in turn are defined as institutions that handle civil and criminal cases. However, these lines are blurring. For example, while civil disputes often involve private citizens, in a substantial proportion of civil cases the government is a party, as either plaintiff or defendant. Concerns about overcrowded court dockets have prompted some commentators to recommend that mandates to agencies be enlarged—turning more agencies in essence into specialized courts.

What is shared among civil, criminal, and administrative proceedings is that someone (an individual, a group, or a representative of the government) claims that another has violated a legal norm. In all three categories a third party, empowered by the state, is called upon to determine the validity of the claim—whether a legal right exists ('liability') and what form of response ('remedy') is appropriate. In all three categories, the parties have some degree of autonomy to fashion the contours of the dispute and yet are also limited by conventions and rules. In all three categories, questions exist about the power of decision-makers, the constraints imposed upon them, the kinds of sanctions or remedies that might be imposed, and the ability to seek reconsideration of the decisions rendered. And, in all three categories, the procedures are assessed as to whether they are fair and efficient.

What makes for fair and impartial judgments? Should everyone have a 'right' to an authoritative adjudication, or may courts insist that litigants settle or resolve cases by other means? If trials are permitted, should they be decided by judges (professional adjudicators) or by lay juries? If judges are central, how is their impartiality and independence assured? Does the gender, race, or ethnicity of a decision-maker matter to the perceived or actual fairness of the outcome? Should state subsidies, including free lawyers, be provided for those too poor to litigate to facilitate access to justice?

Of course, some of the questions for proceduralists are more technical, such as: What injuries are grounds for a lawsuit? How does one actually start a case? In

which court? Whom should one sue? Yet responses to even these questions depend on judgments about the role of government, the degree to which individuals should be permitted autonomy as rights seekers, and the harm that litigation itself can inflict on unwilling participants. Therefore, rules of procedure embody, express, and help create values and attitudes about what constitutes fair decision making by, or through, the powers of the state. Procedure is laced with questions of legal policy and political philosophy.

In some countries, those questions are also framed in constitutional terms. For example, the US Constitution deploys the phrase ‘due process of law’ in its Fifth and Fourteenth Amendments, guaranteeing protection against deprivations of life, liberty, or property. Also detailed are rights of jury trials for criminal defendants and for civil damage litigation, as well as rights of counsel for criminal defendants. Other countries expressly address these and yet other rights, such as providing criminal defendants with a right of translation into their own language.

The set of problems facing proceduralists is rich, not only because rules of procedure inevitably implicate basic social and political values. Procedure is also compelling because those rules intersect with all the major problems of contemporary life. Under the umbrella of ‘cases’ can come the full range of social problems—disputes over personal assets, and familial relationships; claims of physical injuries from products like asbestos or tobacco; disagreements about commercial contracts made or breached; regulatory arguments about possible hazards to the environment or the illegal pricing of products; assertions of violations of state or federal statutes providing for civil rights, consumer information, or personal security. In short, Procedure must address the theories, aspirations, and values that animate procedural systems; the kinds of disputes that may prompt litigation; the means by which lawsuits are started and stopped, as well as what happens in between and who can participate; consideration of the identity and characteristics of the participants (parties, lawyers, witnesses, judges and juries); the powers of decision makers; what the structure of courts is, has been, and how it might be changed; and what role courts in turn play in a particular governmental structure or as trans-national institutions.

2. Lawsuits: From Injuries to Litigation

When thinking about Procedure, it is important to remember that not all moments of discord result in the filing of lawsuits, let alone in the kinds of proceedings described in newspapers or the trials that are televised. In fact, individuals and groups disagree a lot without ‘naming’ the problem a conflict. In contrast to popular

assertions, for example, that the US is awash with litigation, scholars of dispute resolution instruct otherwise. When injured, individuals have a variety of responses (from ‘lumping it’ and never seeking redress to ‘claiming’ injury and then ‘blaming’ others); a numerically small percentage of such occurrences results in the actual filing of civil, criminal, or administrative proceedings. How often people file suit, in turn, is related to what forms of redress regulatory and social welfare regimes provide, and to conceptions of what role courts should take in a given polity. The role litigation plays in countries therefore differs.

Moreover, litigation should not be equated with adjudication through trial. In some countries, of cases that are filed, very few conclude by trials. Take the federal courts of the US as an example. Of 100 civil cases filed in the year 2000, about a third will be resolved by judicial rulings in advance of trial; most of the remaining two-thirds will be concluded through settlement. Trials will begin in only three or four cases.

The rate of trial in the US declined during the last decades of the twentieth century, as courts built into their processes a ‘pretrial phase’ that becomes the focus of lawyering and that offers a means of dispute resolution without trial. Many countries have given litigants rights of access to information in advance of trial; ‘discovery’ and ‘disclosure’ are terms of art in the US to refer to such pretrial exchanges. Further, negotiation, mediation, and arbitration (sometimes called ‘alternative dispute resolution’ or ‘ADR’) are concurrent options—or requirements—throughout the course of disputes.

Some procedural systems are styled ‘inquisitorial,’ by which is meant that judges determine a good deal of the shape of the inquiry. Others, described as more ‘adversarial’ and associated with common law countries, authorize parties (or more accurately their lawyers) to determine the scope of a controversy, to develop the information about the events at issue, and to frame legal theories. During the twentieth century, many common law countries revamped their procedural systems—as did civil law regimes—such that the two forms of adjudication are moving closer to each other.

In the US, federal rule makers undertook major reorganization of the procedural system in the 1930s. They spoke about aspirations for a simple, accessible justice system and they crafted a ‘trans-substantive’ set of procedures, by which it is meant that the same rules were to be used, regardless of the kind of case. By the 1970s, some litigants, judges, and lawyers became concerned that the system created decades earlier had generated its own problems. They complained about lawyers exploiting pretrial opportunities for personal gain and to inflict misery on opponents. Critics charged abusive discovery, incivility, and adversarial excess. Some reformers urged lessening reliance on lawyers by reeducating clients to look for resolutions

of disputes without, or with less lawyering. Others proposed rules aimed at constraining lawyers.

Many common law countries turned to judges to take more responsibility for the shape of lawsuits. Judges and other court personnel began to take an active role in scheduling and monitoring the pretrial phases of cases—to move cases along, to urge settlement, to attempt to supervise attorney behavior. Judges came to act as ‘managers,’ working with lawyers to set time frames in which parties may be added or dropped from cases, to resolve disagreements about the relevance of information sought from opponents, and to urge that disputes be ended by mandatory settlement conferences, court-annexed arbitration, and mediation. Procedures once termed ‘extrajudicial’ have been built into rules, and are now regular features of civil and criminal processes.

The term of art—in the US, England, Wales, Canada, and Australia—for such work is ‘case management’ but the content of such work varies by country. In the US, a good deal of the focus is on managing lawyers. In this respect, rules of procedure are connected to rules of professional conduct. Rules of lawyering ethics and rules of procedural systems increasingly overlap as both are aimed at structuring the behavior of attorneys.

Late twentieth-century reforms seek to lower the costs of process and to shorten the time to decision. Some reformers believe that these changes will help lower-income individuals gain access to courts. Critics view the rules as less friendly to small claimants because of limitations on discretion and flexibility. These debates point to a more general feature of procedural rule making. Procedural reforms of any era need to be understood as not ‘only’ about procedure; they are related to the creation of professionalized judiciaries, to country-specific social movements, and to institutionalization of courts as corporate actors within governments. Moreover, rule making is often driven by ‘repeat player’ litigants who have the economic wherewithal and the political interest and insight to seek to shape procedural regimes.

3. *The Many Configurations of Lawsuits*

Given the diversity of problems, not surprisingly the configurations of lawsuits vary. Some cases involve two disputants seeking attention from a single judge, readily envisioned as a pyramidal triangle, with the judge at the top and the two disputants on either side. Other litigations are multi-party conflicts, for which a Calder mobile offers a better visual image; the many parties realign depending on what issue is to be determined in what forum.

Many questions have emerged, including: Should one-on-one cases be paradigmatic of adjudicatory processes? How should aggregate litigations affect

one’s understanding of the purposes and forms of adjudication? The costs of lawyers to individuals make pursuit of remedies expensive; evolving norms of judicial process discourage labor-intensive attention for ‘small’ claims. Further, the paradigmatic car crash, sometimes assumed to involve individual disputants, is often a dispute controlled by two insurance companies rather than by individual litigants. Many commentators urge that such conflicts be turned over to ‘no-fault’ administrative systems that would provide compensation according to schedules and that other ‘small cases’ be resolved through lower cost and lower visibility processes located in administrative agencies.

At the opposite end of the spectrum are large-scale cases, some involving tort law arising from accidents (like airplane crashes) and others related to allegedly defective or injurious products (such as diet drugs, nicotine, and asbestos). Some large-scale cases involve contracts and consumer claims, from shareholders of companies to purchasers of goods; and yet others relate to group-based rights claiming (about issues involving environmental harms to air, food, or water or the fair treatment of women). Such litigation also raises questions of whether administrative models are more appropriate modes of disposition than adjudicatory ones.

Given widespread allegations of injury and hundreds or thousands of lawsuits involving similar or the same parties, courts have devised means, both formal and informal, to process cases *en masse*. Procedural systems respond through mechanisms such as ‘consolidation,’ ‘class actions,’ ‘interpleader,’ ‘bankruptcy,’ ‘multi-district litigation’—all procedures designed to assist in reaching resolutions across categories of claimants.

4. *A Variety of Venues*

Not only do lawsuits vary in size and scale, they also go to an array of places for resolution, both public and private. Once a decision is made to file a lawsuit, a choice often exists about where to file a lawsuit. Some courts have ‘general jurisdiction’—they can handle all kinds of cases. Other courts have ‘limited jurisdiction,’ tied to a particular subject matter or amount in dispute.

In some instances, the jurisdictional grants overlap, and courts may have ‘concurrent jurisdiction.’ When more than one venue is available, common law systems give the power to the parties to decide the court in which to proceed. Upon occasion, defendants argue that plaintiffs have made the wrong selection—either because a particular tribunal lacks authority over the subject matter of the litigation (‘subject matter jurisdiction’) or because the tribunal has no power to compel a particular defendant to appear and defend or

is an inappropriate place to rule on the merits ('personal jurisdiction' or '*forum non conveniens*').

More institutions than courts are available for dispute resolution. Many government agencies are also quasi-courts. In the US for example, the Social Security Administration, the Equal Employment Opportunities Commission, and the Immigration and Naturalization Service process thousands of disputes annually, far in excess of the number decided by the federal court system. Further, court systems in courthouses or in administrative agencies often do not exhaust the set of options. Again using the US as an example, Indian tribes have court systems as well. Given the overlap among courts and the demographic mobility of the citizenry, inter-jurisdictional cooperation among state, federal, and tribal systems has begun to develop.

An increasingly global economy makes international decision-making tribunals ever more important to litigants within the US. One project, based at the American Law Institute, is to develop transnational rules of procedure to which countries or litigants might subscribe voluntarily. Another approach is to create universal jurisdiction for certain kinds of offenses; the International Criminal Court, a product of the Treaty of Rome, exemplifies that effort.

Governments are not the only source of courts. Associations may decide to establish their own 'private' courts and may compel those who contract with them or those employed by them to rely on such tribunals in lieu of proceeding in state-based courts. Further, governmental agencies and courts may also urge litigants to devise means of resolution of disputes without adjudication and may contract for services with 'private' institutions. During the second half of the twentieth century, a number of private providers of dispute resolution have come to the fore. As the market of private providers of dispute resolution services has expanded, some worry that publicly based and financed systems may lose support as those with the resources go elsewhere.

5. Tiers of Decision Making

If cases are decided within formal court or administrative systems (by judges, juries, or hearing officers), losing parties may have a 'right' to appeal to a higher court, which has (often limited) authority to review decisions made below. In many jurisdictions, there are three or four tiers of decision-makers, some working at the trial level, which has 'original' jurisdiction, and others in an appellate system. Some appellate systems are obliged to review lower court rulings when presented with an appeal, whereas others enjoy discretion to decide whether to review cases and if so, which ones. At each stage, parties typically have the option to settle or withdraw.

The concept of 'preclusion' bears on these tiers of decision making. The idea is that at some point, procedural systems prohibit further consideration of a problem—because participants have (knowingly or inadvertently) 'waived' their rights by failing to raise certain claims in a specified time or because participants have made and lost claims along the way. '*Res judicata*,' '*estoppel*,' 'double jeopardy,' and 'statutes of limitations' are some of the legal terms that capture these principles of closure and finality. Yet most procedural systems also have safety hatches—means by which to reopen and reconsider issues because of new information, changing circumstances, or the passage of time. Child custody decisions are typically subject to reopening, and in criminal cases, the availability of '*habeas corpus*' marks a narrow window of reconsideration. Herein lies an exemplary tension of procedural rules, attempting to capture both the impulse toward closure and the recognition of limited knowledge and the imperfections of judgment.

6. The Demography of the Court House

During the twentieth century, the demographics of the participants of the legal system changed. Women gained juridical rights to bring lawsuits, as did peoples of many colors. Further peoples of all colors and both genders gained rights of access to the professions of lawyering and judging. These individuals prompted professional interest in the demographics of the court house to understand more about the racial, ethnic, and gender composition of judges, jurors, lawyers, court personnel, witnesses, and litigants, and to learn whether the processes of decision making are affected by the demographics.

Judiciaries and/or bar associations in countries around the world convened special task forces on the effects of gender, race, and ethnicity in the courts and in the legal profession. These joint bench and bar efforts fall within a long tradition of concern about the administration of justice; judges and lawyers have engaged in studies ranging from the problems of prison litigation and the death penalty to how to handle large numbers of asbestos filings. Proceduralists thus have new knowledge and perspectives from which to consider the processes of justice.

The work on race, ethnicity, and gender in the courts has generated data about the composition of the judiciaries and the bar, as well as about the experiences of male and female lawyers of all colors, and more limited information on litigants. Most of the reports conclude that court systems—like the culture in which they exist—reflect stereotypic assumptions about race, ethnicity, and gender. Women judges and women lawyers are often in dramatic minorities as contrasted with the number of women litigants and, in systems with juries, of women jurors. Women and men

who are lawyers and judges, and peoples of differing colors report different perceptions of the relevance of gender, race, and ethnicity to processes of adjudication. Studies in the US have found that women attorneys believe that gender affects both process and outcome, and describe its effects on their professional lives and the legal system. In contrast, male judges and lawyers are less likely to report gender as relevant to the administration of justice or the legal profession. Studies of minority judges and lawyers have parallel data: people of color report the relevance of color while non-minorities describe its unimportance to the justice system. As a consequence of these projects, topics once considered gender- and race-neutral—from the specifics of jury instructions and courtroom conduct to larger questions about the role of the judge, the nature of lawyering, and the allocation of work among the courts—are being revisited to consider how to make good on the promises of fairness.

7. The Role of Resources

Because providing legal process costs money, takes time, and requires energy, the role of resources is critical to the study of procedure. Rules that treat all individuals as similarly situated belie the reality that some of us are richer than others, some of us have more access to help than do others, and some of us are more likely to be harmed than are others. Procedure must therefore consider how rules affect the costs of lawyering and the impact of rules that shift costs from one side to the other or that provide for government subsidies for lawyers, investigation, expert witnesses, filing fees and other costs associated with litigation. Economic analysis of many areas of law has become commonplace. In this arena, such inquiries consider the incentive structures created by procedural rules, the means by which adversaries can inflict costs on opponents, the mechanisms by which bargaining can occur, how rules about sanctions for failure to settle affect differently those who are 'risk prone' and those who are 'risk averse,' and the impact of attorney fee-shifting rules. Constitutional and political theorists, analyzing the meaning of the 'equal protection' and 'due process' guarantees, consider whether the government has an obligation to make courts readily accessible; if so, for what categories of claims, and how, given economic disparity, to craft rules to implement such principles.

8. The Constant Questions

Despite all the variation in the resources of litigants, the kinds of cases, the people and problems involved, the courts systems, and the procedures themselves, the underlying problems that procedural systems have to solve are the same: Who can seek redress? For what

kinds of injuries? Requesting what remedies? Based on what kind of information? Presented to what decision-maker? With any review or possibility of reconsideration? Obviously these questions do not admit to easy, unvarying answers; ideas about procedure are deeply rooted in the social-political fabric, and the issues central to procedure are value-laden. The questions to be addressed include: Why have process at all? Why care about how a decision is made? If process is required, how much should be provided? Are opportunities to be heard adequate? How formal should a procedure be? How expensive should it be? Who should pay? How free should the parties be to initiate lawsuits? Who gets to litigate and who is foreclosed? And what about the decision-makers—what kinds of information should be required prior to decision? What remedies should courts be able to order? How much power should judges have, and when should that power be constrained? When may decisions be reconsidered, and when should they be considered 'final'? Over and over again, procedure returns to these basic, and central, issues.

Procrustes Analysis

Procrustes analysis is concerned with matching two, or more, configurations of points. Imagine two maps of a region, each giving the positions of the same towns. The two maps are oriented differently, are of different sizes, differ in their accuracies, and use different map projections. At a first glance it may be difficult to see much resemblance between the two maps. Procrustes analysis addresses such problems, usually taking one of the configurations as a target and fitting the other to it, optimally, by using appropriate transformations. The 'maps' may be derived in many ways and may be in several dimensions but, for the concept of matching to be meaningful, it is important that the configurations refer to two representations of the same things: the same towns, the same cases (in multidimensional scaling), the same variables (in factor analysis), the same products (in marketing), the same landmarks (describing biological organisms).

The name comes from Greek mythology where Procrustes was an innkeeper who had a bed (sometimes two). Travelers were stretched or limbs chopped to make them fit the bed; with two, adjustment was ensured. The pejorative implications are no worse in

Procrustes analysis than in other forms of data-analysis where, misguidedly, data may be fitted into the straightjacket of an unrealistic model.

1. Factor Analysis

The origins of Procrustes analysis (see Hurley and Catell 1962) are in factor analysis, where loadings $\mathbf{X}_1$ of k factors $\mathbf{f}$ occur in the form $\mathbf{X}_1\mathbf{f}$ and so may be replaced by $(\mathbf{X}_1\mathbf{T})(\mathbf{T}^{-1}\mathbf{f})$ showing that they are determined only up to the arbitrary $k \times k$ matrix $\mathbf{T}$. By choosing a suitable $\mathbf{T}$, we may match $\mathbf{X}_1$ 'the traveler' to a previously determined, or hypothetical set of, loadings given in a matrix $\mathbf{X}_2$ 'the bed'; $\mathbf{T}$ represents the 'chopping/stretching transformation. Usually the degree of match is judged by least squares, minimizing $\|\mathbf{X}_1\mathbf{T} - \mathbf{X}_2\|$ the sum of the squared distances between like points of the target and transformed configurations. Without further constraint, this is the multivariate multiplenegression problem with well-known solution

$$\mathbf{T} = (\mathbf{X}_1'\mathbf{X}_1)^{-1}\mathbf{X}_1'\mathbf{X}_2.$$

Two of the most important constraints on $\mathbf{T}$ are:

- (1) $\mathbf{T}$ must be orthogonal (denoted here by $\mathbf{T} = \mathbf{Q}$); and
- (2) $\mathbf{T}$ must be a direction cosine matrix (denoted here by $\mathbf{T} = \mathbf{C}$)

Both choices relate to the interpretation that $\mathbf{f}$ is expressed relative to an orthogonal system of co-ordinate axes and the columns of $\mathbf{T}$ give direction cosines of new axes relative to the original orthogonal axes. When $\mathbf{T} = \mathbf{Q}$, a new set of orthogonal axes is being sought that give a better match to $\mathbf{X}_2$; when $\mathbf{T} = \mathbf{C}$ we imagine $\mathbf{X}_2$ as being referred to oblique axes. The orthogonal Procrustes least-squares solution is $\mathbf{Q} = \mathbf{V}\mathbf{U}'$ where $\mathbf{U}\mathbf{\Sigma}\mathbf{V}'$ is the singular value decomposition of $\mathbf{X}_2'\mathbf{X}_1$. With $\mathbf{C}$, minimization is intrinsically more difficult and is less well defined than in the orthogonal case. This is because there are at least two ways of expressing the position of a point relative to oblique axes and also because there are good arguments for replacing ordinary leastsquares by a weighted form which measures distance in the metric appropriate to the chosen system of oblique axes, giving four variants in which $\mathbf{T}$ is either $\mathbf{C}$, $\mathbf{C}'$, $\mathbf{C}^{-1}$ or $(\mathbf{C}')^{-1}$. The simplest case, $\mathbf{T} = \mathbf{C}$, was first discussed by Mosier (1939) but not finally solved until Browne (1967) gave a practical numerical method for solving the normal equations. Special algorithms have been proposed by Browne and Kristof (1969) and Gruvaeus (1970) for the case $\mathbf{T} = \mathbf{C}^{-1}$. However, all problems may be tackled uniformly by proceeding as if the directions of all but one of the axes are known and then estimating the optimal direction of the remaining axis; cycling through all the

axes iteratively until a stable solution is found for all the directions.

Rather than handling the indeterminacy of factor loadings as above, the modern tendency is to use an internal criterion of simple structure such as Varimax (Kaiser, 1958) that has no reference to an external target $\mathbf{X}_2$. Alternatively, $\mathbf{X}_2$ may be coded in binary form where $x_{ij} = 1$ indicates a desired high loading of the i th variable on the j th factor and $x_{ij} = 0$ indicates a low loading. This latter form remains a type of Procrustes problem but least squares is no longer appropriate and is replaced by choosing $\mathbf{T}$ to maximize the ratio of the sum of squares of the squared high loadings to the sum of squares of the squared low loadings (see Lawley and Maxwell 1971).

2. Variants and Later Developments

The problems outlined above are referred to as two-sets Procrustes problems because two configuration matrices $\mathbf{X}_1$ and $\mathbf{X}_2$ are involved. There are many variants:

- (1) alternative constraints on $\mathbf{T}$ such as $\mathbf{T}$ is a rectangular column, orthonormal, or is a permutation matrix;
- (2) two transformations: minimize $\|\mathbf{X}_1\mathbf{T}_1 - \mathbf{X}_2\mathbf{T}_2\|$;
- (3) isotropic scaling: minimize $\|\rho\mathbf{X}_1\mathbf{T} - \mathbf{X}_2\|$;
- (4) anisotropic scaling: minimize $\|\mathbf{X}_1\mathbf{S}_R\mathbf{T} - \mathbf{X}_2\|$, or $\|\mathbf{X}_1\mathbf{T}\mathbf{S}_R - \mathbf{X}_2\|$, or $\|\mathbf{S}_L\mathbf{X}_1\mathbf{T} - \mathbf{X}_2\|$, or $\|\mathbf{S}_L\mathbf{X}_1\mathbf{S}_R\mathbf{T} - \mathbf{X}_2\|$, or $\|\mathbf{S}_L\mathbf{X}_1\mathbf{T}\mathbf{S}_R - \mathbf{X}_2\|$, or $\|\mathbf{S}_L\mathbf{X}_1\mathbf{S}_{R1}\mathbf{T}\mathbf{S}_{R2} - \mathbf{X}_2\|$ for unknown diagonal $\mathbf{S}_R$ and $\mathbf{S}_L$;
- (5) replace least squares by e.g., L1-norm, inner-product trace ($\mathbf{X}_2\mathbf{X}_1\mathbf{T}$), robust estimation method;
- (6) two-sided Procrustes problems $\|\mathbf{R}\mathbf{X}_1\mathbf{T} - \mathbf{X}_2\|$ where $\mathbf{R}$ and $\mathbf{T}$ are to be estimated, usually under specified constraints;
- (7) weighted forms—minimize trace $\mathbf{N}(\mathbf{X}_1\mathbf{T}_1 - \mathbf{X}_2)'\mathbf{W}(\mathbf{X}_1\mathbf{T}_1 - \mathbf{X}_2\mathbf{T}_2)$ where $\mathbf{N}$ and $\mathbf{W}$ are given matrices, one of which may be ignored;
- (8) handling missing values.

Brief comments on the above list must suffice. It should be clear that $\mathbf{X}_1$ and $\mathbf{X}_2$ no longer represent factor loadings. Isotropic scaling allows for differences in size; the more esoteric versions of anisotropic scaling verge on the more pejorative interpretation of the Procrustes legend: real violence being done to the data. The product of two orthogonal transformation matrices is equivalent to one and the inner product and least-squares criteria then give the same result. Weights $\mathbf{N}$ are useful to cover replication or missing rows of $\mathbf{X}_1$ and need not be diagonal, though they usually are. Note that weights are given matrices whereas anisotropic scaling is expressed in terms of unknown diagonal matrices requiring estimation. However, sometimes, $\mathbf{W}$ may be a function of the unknown $\mathbf{T}$, as with oblique Procrustes analysis in a metric where $\mathbf{W}$ is $\mathbf{C}'\mathbf{C}$ or its inverse.

Changes in orientation are given by an orthogonal matrix $\mathbf{Q}$, which includes rotations and reflections, leaving intact the essential distance and angular properties of the configuration. A $p \times q$ orthonormal matrix $\mathbf{T} = \mathbf{P}$ with q columns represents a projection from p to q dimensions. Projections may be interesting:

- (1) because $\mathbf{X}_2$ has fewer dimensions than $\mathbf{X}_1$;
- (2) a match may be required in some specified number of dimensions, say, $q = 2$.

When $q < p$ we may still match in p dimensions by rotating in the higher dimensional space; e.g., we may rotate three points lying on a line to fit three points lying in a plane. All we have to do is to augment $\mathbf{X}_2$ by $p - q$ zero columns. That $\|\mathbf{X}_1\mathbf{P} - \mathbf{X}_2\|$ can be less than $\|\mathbf{X}_1\mathbf{Q} - \mathbf{X}_2\|$ (where $\mathbf{X}_2$ is augmented by zero columns) has been seen as a justification for preferring projections to rotations but this is not comparing like with like. I believe that projection Procrustes analysis is rarely justified.

Nowadays, applications of Procrustes analysis are more often than not more to do with matching configurations other than factor loadings (Commandeur 1990). For example, $\mathbf{X}_1$ and $\mathbf{X}_2$ may be the two sets of points given by different multidimensional scalings (MDS) of the same data, or they may refer to MDS solutions based on different proximity/distance matrices measured between the same p objects, perhaps based on different variables. Fruitful applications have been found in the food sciences, where $\mathbf{X}_1$ and $\mathbf{X}_2$ are derived from scores given by two judges on traits of several products (e.g., Dijksterhuis and Gower 1991/2). Applications in the biological sciences include the analysis of shape where the configurations refer to the directly measured coordinates of landmark features on organisms (see e.g., Bookstein 1991, Dryden and Mardia 1999). In shape analysis the matching of one configuration to another is often termed registration.

3. Generalizations

Given k configurations $\mathbf{X}_1, \mathbf{X}_2, \mathbf{X}_3, \dots, \mathbf{X}_k$ we may match them in pairs by doing the corresponding two-sets Procrustes analyses, minimizing $s_{ij} = \|\mathbf{X}_i\mathbf{T}_1 - \mathbf{X}_j\mathbf{T}_2\|$ for all pairs (i, j) . Each s_{ij} may then be assigned to a matrix $\mathbf{S}$ and analyzed by some form of MDS (see Gower 1971 for an example from physical anthropology).

Alternatively, we may minimize $\sum_{i < j}^k \|\mathbf{X}_i\mathbf{T}_i\mathbf{X}_j\mathbf{T}_j\|$, which for the least-squares criterion, rejecting the solution $\mathbf{T}_i = 0$, is equivalent to minimizing $\sum_{i=1}^k \|\mathbf{X}_i\mathbf{T}_i\mathbf{G}\|$ where $\mathbf{G} = \frac{1}{k} \sum_{i=1}^k \mathbf{X}_i\mathbf{T}_i$, often termed the group-average. Thus, generalized Procrustes analysis is a three-mode method of analysis. For some information on algorithms, see ten Berge (1977). To help interpretation, each dimension of the analysis may be summarized in an analysis of variance, partitioning

the total into terms for the group average and for departures from the group average. Some dimensions may be identified with noise and some with signal, further subdivided into displayed and undisplayed parts (Dijksterhuis and Gower 1991/2).

The concept of a group average plays an important part in several psychometric methods (see e.g., Individual Differences Scaling) as a useful summary of k data sets. Perhaps, for this reason, it has been suggested that maximizing the group average of Procrustes analysis should be a main objective of Procrustes analysis. For orthogonal $\mathbf{T}$, both approaches are equivalent, but for projections, maximizing the group average is not the same as minimizing the criteria given above. The situation gets very convoluted, especially when the variants listed in Sect. 2 are admitted. This is because when focusing on the group average, the transformations, isotropic, and anisotropic scaling may be regarded as being attached to $\mathbf{G}$ rather than to the $\mathbf{X}_i$, giving two versions of every variant.

The leading eigenvector of the matrix with (i, j) th element trace $(\mathbf{T}_i \mathbf{X}_i \mathbf{X}_j \mathbf{T}_j)$ estimate isotropic scaling factors and also when $\mathbf{T}_i = \mathbf{I}$, this matrix is the basis of the STATIS method. This and similar links between Procrustes analysis and other methods that involve a group average, are likely to be an area for research in the immediate future. Research relating to biological landmark data and shape analysis is currently active and will continue (see Kendall et al. 1999). Other research will focus on algorithms, the effects of estimation criteria and the difficult area of inference.

Production Systems in Cognitive Psychology

A *production system* consists of a collection of if-then rules that together form an information-processing model of some cognitive task, or range of tasks. Production systems have some special properties that make them highly suited to modeling cognition. From their origins as models of problem solving, production systems have grown to become a major formalism for modeling cognitive skill and aspects of learning. Since the 1990s, they have become increasingly identified with the topic of integrated cognitive architectures.

1. What is a Production System?

A production system is a model of cognitive processing, consisting of a collection of rules (called *production rules*, or just *productions*). Each rule has two parts: a *condition* part and an *action* part. The meaning of the rule is that when the condition holds true, then the action is taken. The basic idea is best illustrated with a nonpsychological example. Consider the following simple production system, with just two rules, describing the behavior of a thermostat in controlling a heating system:

Rule 1: if temperature $< 20^\circ\text{C} \Rightarrow$ turn on heating.

Rule 2: if temperature $> 20^\circ\text{C} \Rightarrow$ turn off heating.

When the room temperature is below 20°C , the condition part of Rule 1 is true, so the thermostat takes the action specified by the rule and turns on the heating. (The rule is said to *fire*.) When the temperature is above 20°C , Rule 2 similarly fires and turns

off the heating. Taken together, the two rules specify a process which describes the behavior of the thermostat.

A production system serving as a cognitive model usually has many more than two rules, perhaps as many as thousands. The production system operates in a cyclic fashion. First, a rule whose conditions are satisfied is identified. Then, that rule is fired, i.e., its action or actions are carried out. Usually, the actions will change the current situation in some way, so that now a different rule has its conditions satisfied, and the cycle repeats. This process is referred to as the *recognize-act cycle*, because the condition parts of the rules can be regarded as forming an active network which monitors the current situation and recognizes when each individual rule is applicable, triggering the act of firing the rule.

1.1 Production System Architecture

A particular production system operates within a definite structure of memories and processes known as its *architecture*. (For clarification of the term 'architecture' used in that sense). The architecture of a production system includes at least two memories: the *production memory*, and the *data memory*.

The production memory holds the rules. It is taken to be a long-term memory, in that its contents persist over time. Indeed, usually it is assumed that a production rule, once acquired, is never lost from memory.

The data memory holds the dynamic information about the task being worked on. (In the research literature, this memory is often described as the 'working memory,' but that terminology is avoided here because of the possible confusion with the psychological notion of working memory, with which it has a close but not straightforward relationship, see *Working Memory, Psychology of*.) The data memory is taken to be a short-term memory whose contents disappear with time, indeed possibly during the processing of a task. It holds the information which is tested by the condition part of production rules. In other words, the conditions of production rules consist of tests or patterns which are matched against the contents of the data memory.

1.2 Conflict Resolution

In a production system with more than a small number of rules, it is almost inevitable that sometimes more than one production rule has its conditions satisfied. Such an occurrence is known as *conflict*. Some production system architectures simply fire, in parallel, all the rules whose conditions are satisfied. Most

architectures, however, insist that a single rule be chosen to fire.

The procedure for selecting a single rule to fire from those that have their conditions satisfied, is known as *conflict resolution*. Different production system architectures use different principles for conflict resolution, which take account of factors such as the recency of the data being matched against, the activation levels of the data, the complexity of the rule conditions, the order in which rules were acquired, and so on.

2. Origins in Problem Solving

Production systems were introduced into psychology by Newell and Simon (1972) in their study of human problem solving. There is a natural connection between production systems and the way that Newell and Simon analyse their data.

Newell and Simon (1972) recorded participants thinking aloud as they solved puzzles in logic, chess, or cryptarithmic (where digits have to be substituted systematically for letters to make a correct arithmetic problem). Such recordings are known as *verbal protocols* (see *Protocol Analysis in Psychology*). Newell and Simon use the protocols to reconstruct the problem-solving steps taken by the participant. They then look for regularities in the participant's behavior. If, for example, whenever the participant assigns a digit to a letter, he or she then scans for another place where the letter is used, it is natural to express that regularity in the form of a production-like rule: 'if digit newly assigned to letter, then scan for occurrence of letter.' With some further attention to detail, a collection of such rules can be treated as a production system, and it then becomes an empirical question as to how well the production system models the participant's problem solving.

3. Properties of Production Systems

A production system specifies a computational process, and is therefore a kind of programming language. However, production systems differ from ordinary computer programming languages in a number of ways.

(a) *Parallel and serial processing*. Production systems exhibit aspects of both parallel and serial processing, corresponding to the two phases of the recognize-act cycle. The recognize phase, i.e., the testing of conditions, occurs in parallel, across possibly hundreds of thousands of rules. In the act phase, a single rule is chosen for firing, so the actions are carried out one at a time.

(b) *Independence of the rules*. Each rule in a production system is potentially independent of all the other rules. Each rule can be written to be self-

contained, expressing an item of knowledge which the problem solver is postulated to know.

(c) *Interruptible and flexible control.* A production system is not forced to follow a fixed control structure, such as a rigid hierarchy of routines and subroutines. Because the processing at each step is determined by what the rule conditions 'recognize' in the data memory, the control can be very flexible. For the same reason, it is interruptible. If relevant information appears in the data memory, the production system can abandon its current line of processing and follow a new one.

These and other properties make production systems well suited to the modeling of cognitive performance and cognitive skill.

4. Models of Cognitive Skill

Production systems have been written to model many different cognitive skills. Although only a few researchers have actually written production system models, their influence, as with other forms of computer modeling, has been far beyond their number. Production systems have now become a medium of choice for theorizing about cognitive skill, especially for skills requiring a large body of knowledge. This section summarizes just a small sample of the published work.

4.1 Written Subtraction

A model of errors in children's written, multicolumn subtraction illustrates how some of the properties of production systems support their application as cognitive models. Young and O'Shea (1981) present a simple production system, of around a dozen rules, for performing subtraction correctly. They proceed to show how small perturbations of the model reproduce many of the errors commonly found in 10- to 12-year-old children's performance.

Several of the most common errors arise by simply omitting one or more rules from the production system. For example, if the rule is omitted that initiates borrowing when the lower digit is larger than the upper, then the model never borrows but instead just subtracts the smaller from the larger digit in each column—a mistake common among children. The implication is that some children have failed to acquire the appropriate rule. Other errors arise by adding erroneous rules, or erroneous versions of rules, to the production system. For example, children who usually subtract correctly but simply copy the lower digit when subtracting from zero can be modeled by adding the corresponding zero-pattern rule to the production system. Although inappropriate for subtraction, that rule is appropriate for addition, suggesting that some children have not acquired sufficiently distinctive conditions for the rule.

The ability to add and remove rules in this fashion and still leave a model which runs and faithfully

reflects children's behavior, depends critically upon several of the properties of production systems mentioned above. Young and O'Shea (1981) discuss the crucial role of the independence of the rules, of the flexible control structure, and of the particular conflict-resolution principles used in the model.

4.2 Reading

Reading is another practically important cognitive skill which has been modeled with production systems. Just and Carpenter (1987) present an ambitious model of the reading and comprehension of single sentences and connected text. Their production system provides an integrated model of the cognitive processes involved in reading, from word encoding and lexical access, through syntax and semantics, to textual understanding. Many aspects of the model are based upon data from participants' eye movements (see *Eye Movements in Reading*).

4.3 Knowledge-intensive Cognitive Skill

Production systems are well suited to building models that encode and deploy large amounts of knowledge. For this reason, they are frequently used in the construction of *expert systems*, a branch of applied artificial intelligence that developed in the 1970s at around the same time as production systems were making their appearance in psychology (see *Expert Systems in Cognitive Science*). On the same grounds, production systems are much used in psychological models of expert skill, such as medical diagnosis, chess playing (see *Chess Expertise, Cognitive Psychology of*), and many other domains of knowledge.

5. Learning and Development

The ability to add rules to a production system, mentioned in Sect. 4.1 in the context of subtraction, raises the possibility of modeling certain aspects of learning and cognitive development by 'growing' a production system, one rule at a time, to correspond to the gradual acquisition of a cognitive skill. Some of the earliest applications of production systems were in the field of learning and development (see Klahr et al. 1987). It continues to be an active area of research. Simon and Halford (1995), for example, report on several computational models of the mechanisms of developmental transition, among which production systems figure prominently.

6. The Emergence of Cognitive Architectures

Since the 1990s, production systems have become increasingly identified with the newly emerging topic of integrated cognitive architectures, of which the

main exemplars are SOAR (Newell 1990) and ACT (Anderson and Lebiere 1998) *Cognitive Theory: SOAR; Cognitive Theory: ACT*).

The primary advantage of locating a production system within a broader, more encompassing theory is that the architectural details of the production system are determined in a principled way, and fixed. In consequence, the architecture of the production system becomes theory-laden, no longer serving just as a convenient and expressive notation but also carrying part of the burden of explanation. This removes extraneous degrees of freedom from the modeler, thereby leading to stronger explanations and theories.

Professionalization of Social and Behavioral Scientists: United States

This article focuses on social and behavioral scientists as professionals in the United States. It addresses the nature of these professions, the process of professionalization, the role of credentials, patterns in degree production, and the contours of the labor force in social and behavioral science (hereinafter called

social/related science) fields. In this context, professionalization refers to the processes through which individuals become socialized as professionals. Certification refers to the authorization or authentication of credentials. And, labor force refers to that portion of the population (in this case of these professions) that is economically active; that is, either employed or, if unemployed, available to work.

1. The Social and Behavioral Sciences as Professions

The social and behavioral sciences constitute more than a single profession. Disciplines like economics, political science, psychology, and sociology have their own specialized training, expertise, reward structures, associations, networks, and norms. As scientific fields dedicated to the study of human social phenomena, they share features in common. Yet, because of their arenas of knowledge, occupational cultures, collegial interactions, labor markets, and how they are perceived by others, they comprise different professional groups. Moreover, these professions are not the same as the academic profession—although many persons with advanced degrees in the social/related sciences (especially with doctoral degrees) are employed in colleges and universities and, as such, are also academic professionals.

2. The Process of Professionalization

Professionalization involves the development of skills, identities, norms, and values associated with becoming part of a professional group. Through this process, recruits to the social and behavioral sciences acquire both substantive and methodological knowledge and develop understandings of their roles that permit them to function as professionals in these fields. Also, by training newcomers, these professions seek to ensure that the work of their sciences will continue congruent with certain principles and practices.

Research on professionalization dates back to the 1950s. Early research focused on the medical (e.g., Becker et al. 1961, Merton et al. 1957) and legal (e.g., Lortie 1959, Warkov and Zelan 1965) professions. Scholars also began examining graduate education in relation to academic or scientific careers (e.g., Pease 1967, Wright 1964). As these and recent studies (see, e.g., Keith and Moore 1995) indicate, although professionalization continues during the early years of employment, graduate departments are the primary socialization sites. In departments, students learn what is expected and rewarded and, conversely, what constitutes unacceptable practices (e.g., Anderson et al. 1994).

Across scientific disciplines, graduate education aims to develop in students a level of scholarly

proficiency through formal (e.g., courses, qualifying exams, dissertations) and informal (e.g., attendance at scholarly meetings) training. A curriculum that initiates students progressively into more independent work and autonomous thinking helps develop professionals who can both master knowledge and produce original work (Sullivan 1991). Also important is a curriculum that examines the range of roles integral to being a professional scientist (e.g., teaching, engaging in peer review of others' work). Similarly, a curriculum needs to address what it means to be a professional in terms of oral and written communication, ethical conduct, and other career skills. Finally, quality mentoring is key (e.g., Keith and Moore 1995, Anderson et al. 1994). It makes a difference for students' productivity, belief in the norms of appropriate conduct, professional activity, self-confidence, and satisfaction with graduate school.

Through the professionalization process, graduate students also develop shared norms of science that transcend any one discipline. Merton (1973) saw these to be 'universalism'—research should be judged based on scientific merit; 'communalism'—findings should be made public; 'disinterestedness'—research should be done to advance knowledge; and 'organized skepticism'—the scientific community should suspend judgment until the evidence is in. While scholars debate the influence of these norms and the presence of countervailing norms (Zuckerman 1988, Ritzer and Walczak 1986, pp. 225–35), few would dispute that there is a culture of science and that socialization in graduate school aims to engender support for and adherence to its norms.

Professionalization is important as well to the development of expertise, patterns of activity, and values that are discipline-specific. Scientific disciplines differ as to their intellectual tasks, their methods of inquiry, and how their work is done and rewarded (e.g., Biglan 1973, Lodahl and Gordon 1972). For example, chemistry in comparison to sociology has a longstanding tradition of intensive collaboration on more tightly defined problems. Thus, chemistry students are more closely supervised, work in research teams, and are involved in joint publication; sociology students have more intermittent contact with advisors, work more independently, and may or may not engage in collaboration (see Anderson et al. 1994, Babchuk et al. 1999). Sociology students, however, work and publish more collaboratively than do anthropology students, who are in a field more influenced by single-investigator, ethnographic research (Babchuk et al. 1999).

Not unexpectedly, departments vary within and across fields of science in how they structure training programs and the quality of what they do. While successful recruits exit with the same formal credential (a doctoral degree), their actual experiences differentially prepare them to work productively and navigate successful careers. Above and beyond any effects of

department prestige on graduates' careers, the nature of graduate training has far reaching implications for professional development.

3. Credentials and Certification in the Social/Related Sciences

Credentialing generally refers to a system or process that establishes the status, legitimacy, or expertise of persons. With respect to individuals, credentials may be issued in the form of: (a) degrees, diplomas, or other certificates by educational organizations; (b) licenses regulated by states; or (c) certificates by professional associations. Institutions too are credentialed by governmental agencies (e.g., incorporation charters) or private accreditation processes (e.g., regional accreditation associations), which create standards for operation and attest to the quality of what is being offered (Freidson 1986, Chap. 4).

For academic and scientific professions, university-level training is key. In these professions, completion of a program of training culminating in the award of a degree is the most basic credential that attests to expertise. Credentials such as degrees formally bestow on individuals the right to practice a profession or use a professional title (Freidson 1986). The legitimacy of the degree, as Freidson pointed out, relies on the fact that educational institutions themselves are credentialed (i.e., accredited) by the state or, formally or informally, by professional associations.

In the social and behavioral sciences, the advanced degree awarded to an individual constitutes the basic professional credential. The masters degree provides a measure of stature for an individual as a professional in these sciences. While there is a growing market of interest for MA-level social/related scientists (especially outside of the academic workplace), the doctoral degree is still considered to be the full credential.

Psychology is the only social/related science discipline with a well-established process for certifying individuals beyond the advanced degree or for accrediting programs. To engage in clinical practice, psychologists need to be licensed by the states in which they intend to practice. Licensure in psychology requires demonstrating proficiency in designated areas and passing a standard examination created by the Association of State and Provincial Psychology Boards, an alliance of agencies across North America responsible for licensure and certification of psychologists. In terms of accreditation, the American Psychological Association (APA) has a widely used, voluntary process for accrediting doctoral programs in the specialty areas of clinical, counseling, or school psychology programs (or combinations thereof). Some applied or practice associations in other social/related science disciplines are initiating such efforts (e.g., in 1995, the Society for Applied Sociology joined with

the Sociological Practice Association), but none has substantially taken hold.

Despite intermittent calls within some social/related sciences, there has been no strong impulse to further attest to individuals' expertise through additional credentials or certification programs. The American Sociological Association (ASA), for example, established but quickly abandoned a certification program for social psychologists in the early 1960s due to concerns about their certification by APA. In 1986 and 1990, respectively, Ph.D. and MA certification programs were launched by the ASA but generated little interest. In 1992, the ASA's MA Certification Program Committee expressed doubts about continuing the Program, noting that certification of sociologists is handled through receipt of an MA or Ph.D. In 1998, the ASA Council terminated the Association's program.

In the end, the conferral of advanced degrees through the university seems to provide a sufficient credential across fields of science. For each social/related science discipline, only a small proportion of academic departments has the authority to prepare the next generations for careers in their profession. In 1997, approximately 240 of the 4,009 institutions of higher education awarded doctorates. Except for psychology, there are only 110–50 Ph.D.-conferring programs and 90–170 MA-only programs in the social sciences (psychology, with its clinical specialty, has approximately 435 doctoral- and 260 MA-only programs). Thus, while scientific professions generally do not control the market through elaborate mechanisms of certification and accreditation, the size and structure of their educational systems affect the supply of trained professionals.

4. Degree Production

4.1 BA Degrees

Undergraduate majors in social/related science fields constitute the potential pipeline of those who might be attracted to and eligible for becoming social and behavioral scientists. They are also an important 'client' group that creates demand for trained social/related scientists as faculty members in the academic workplace. And, finally, even with only a bachelor's degree, they are a sector of the future workforce that may ultimately be employed in jobs classified as social/related science occupations (ostensibly among those that do not require more advanced expertise or skills).

Compared to mathematical, physical, and biological sciences, undergraduates declare majors in the social/related sciences later in their academic careers. This is primarily attributable to the scarce attention given to the social/related sciences as fields of science

in the elementary and secondary school curricula. Therefore, many undergraduates have their first exposure to these fields as part of fulfilling their general education requirements.

Despite later exposure to these fields, the social and behavioral sciences confer a substantial number of BA degrees. In 1967, even excluding psychology, there were twice as many BA degrees in the social sciences (72,398) as in the next highest field of science and engineering (36,197 engineering BAs). By 1997, the biological/related sciences had more than doubled, but there continued to be more BA degrees conferred in the social sciences than in other fields (see S&ED 2000, Table 5).

The number of BA degrees also varies within the social/related sciences. A comparison of four disciplines—economics, political science, psychology, and sociology—makes the point. As shown in Table 1, in 1967 these fields attracted similar numbers of majors, but by 1997 there was much more dispersion. Most obvious is the substantial increase, almost four-fold, in the number of BA degrees in psychology between 1967 and 1997. Also, there are fluctuations in levels of interest in different disciplines at different points in time. Over the current period—1990 to 1997 (not shown in table), sociology and psychology had the largest proportional increase in BAs (55 and 38 percent, respectively) while political science and economics conferred a declining number of degrees (about –10 and –30 percent, respectively). These data are based on S&ED 2000, Tables 50, 52–4.

4.2 MA and Ph.D. Degrees

As with BA production, both MA and Ph.D. production has generally increased across fields of science since the late 1960s (see S&ED 2000, Tables 12, 19). For most social and behavioral sciences, substantial growth was evident between 1967 and 1972, followed by a dip in the 1980s, and continued growth in the 1990s. At the MA level, the social/related sciences continued to put more MA-trained persons into the labor force than did other science and engineering fields (although there are also a substantial number of MA engineers). At the Ph.D. level, despite growth, there were also differences over time among fields. In the most recent 5-year period, doctoral degree production in the social sciences, biological sciences, and engineering continued to increase, but physical sciences and mathematical/computer sciences declined or remained level.

Within the social/related sciences, there were also variations in Ph.D. production by discipline (see Table 1). Between 1967 and 1997, the number of doctoral degrees awarded in psychology was substantially higher than in other disciplines in absolute numbers and in growth. In 1997, psychology conferred about 3,600 doctoral degrees, about six times more than

Table 1
Degrees awarded in Social/Related Sciences, select years 1967–1997

	Year						
	1967	1972	1977	1982	1987	1992	1997
<i>Bachelor's Degrees</i>							
Economics	13,829	16,408	16,674	21,880	24,402	24,976	17,701
Political Science	19,332	30,677	30,972	31,630	33,876	47,214	37,807

Sociology	17,751	35,630	25,008	16,333	12,359	19,644	24,750
<i>Master's Degrees</i>							
Economics	2,147	2,636	2,662	2,506	2,321	2,564	2,804
Political Science	3,326	5,573	10,162	10,210	9,933	10,767	13,368
Psychology	2,898	5,293	8,320	7,849	8,165	9,852	13,633
Sociology	1,193	1,987	1,851	1,183	970	1,379	1,752
<i>Doctoral Degrees</i>							
Economics	691	1,056	983	940	960	1,051	1,161
Political Science	501	911	879	709	647	804	970
Psychology	1,295	2,279	2,990	3,159	3,173	3,263	3,566
Sociology	331	639	725	568	449	512	598

Source: Data are from the Department of Education/National Center for Education Statistics, Integrated Postsecondary Education Data System Completions Survey (IPEDS), and National Science Foundation/Division of Science Resources Studies (NSF/SRS) Survey of Earned Doctorates (SED). Data are tabulated by NSF/SRS, and published in *Science and Engineering Degrees: 1966–97*. (NSF00–310, NSF/SRS), Tables 50, 52–4 (S&ED 2000)

sociology and three times more than economics (although about 35 percent of these were clinical doctorates). Because of a decline in clinical doctorates in recent years, psychology has grown only modestly over the 1990s (about 10 percent) in comparison to political science and sociology that have both increased their Ph.D. degree production by about 30 percent (based on S&ED 2000, Tables 50, 52–4).

4.3 Women and Minorities and the Ph.D. Degree

4.3.1 Gender. Since the 1960s, there has been a dramatic increase in women receiving Ph.D. degrees across all fields of science and engineering (see S&ED 2000, Tables 19, 23, 26, 35, 49–51). In 1997, 8,921 women received their Ph.D. degrees in contrast to 1,096 women in 1967. These numbers represent a substantial difference in the shares of Ph.Ds. awarded to women (32.8 percent in 1997 and 8.4 percent in 1967). Fields, however, vary considerably in the proportion of Ph.Ds. awarded to women, with the social/related sciences and the biological sciences conferring a much higher proportion than the physical sciences and engineering.

There are notable differences within the social and behavioral sciences as well (see S&ED 2000, Tables 50, 52–4). For example, in sociology and psychology, women received approximately 20 percent of the Ph.Ds. in 1967, and 55 and 66 percent, respectively, in 1997. In comparison, in economics and political

science, even with increasing proportions of women awarded Ph.Ds., in 1997 women still received no more than about 30 percent of these degrees.

4.3.2 Race/Ethnicity. The data on earned doctorates for racial and ethnic minorities were first reported in the 1970s. By 1977, across all fields of science and engineering, the number of persons of color receiving Ph.Ds. (about 750) was quite small (see SED 1997, Table 8). In 1977, proportions of minorities receiving Ph.Ds. ranged from 5 to 7 percent in the life sciences, physical sciences, social/related sciences, and engineering. While the proportions of persons of color receiving Ph.Ds. increased over time, by 1997, they were still quite low—ranging from 12 to 18 percent across fields of science.

Important differences are evident among fields of science in the percentage of doctorates awarded to racial/ethnic minority groups (see SED 1997, Table 8). In 1997, in the physical sciences, Asian-Americans received the highest proportion of Ph.Ds. at over 7 percent and blacks the lowest proportion at under 2 percent. The social sciences included much higher proportions of black and Hispanic Ph.Ds. Overall, across the social/related sciences, somewhat more than 5 percent of the Ph.Ds. were awarded to blacks, slightly less than 5 percent to Hispanics, and slightly less than 4 percent to Asian-Americans.

There are also differences within the social/related sciences (see S&ED 1991, Table 3, SED 1997, Table A-

Table 2

Percentage of scientists with degree training in field of occupation by employment in field of occupation, 1997

Degree	Computer/Math Scientists		Life/Related Scientists		Physical/Related Scientists		Social/Related Scientists		Engineering	
	%	N	%	N	%	N	%	N	%	N
BA	41.5	(722)	10.4	(885)	23.3	(382)	2.6	(2,316)	53.9	(1,380)
MA	51.8	(245)	29.0	(157)	40.3	(115)	21.6	(485)	58.8	(431)
Ph.D.	77.5	(37)	59.9	(163)	60.5	(122)	67.6	(161)	66.6	(98)

Source: National Science Foundation, Scientists and Engineering Statistical Data System (SESTAT 1997): Table A-3

*Number is rounded in thousands of scientists employed at highest degree attained (e.g., 2,316 is 2,315,500 social/related scientists employed with highest degree attained at BA level)

2). For example, in 1997, economics and sociology awarded 28 and 25 percent, respectively, of their Ph.Ds. to racial and ethnic minorities, but varied as to which minorities received Ph.Ds. In economics, 16 percent of the Ph.Ds. were awarded to Asian-Americans and 6 percent to African-Americans; in sociology, almost 10 percent were awarded to African-Americans and 6 percent to Asian-Americans. The overall small number of Ph.Ds. awarded to racial/ethnic minorities signals the need for more intentional outreach to *all* persons of color at earlier stages in education. Despite increases in awarding Ph.Ds., the proportion conferred to racial/ethnic minorities is still below their proportion in the US population.

5. The Social and Behavioral Science Labor Force

As noted in the introduction, the labor force includes those persons who are economically active—either employed, or, if unemployed, available for work. In 1998, according to the Current Population Survey (CPS) conducted by the US Census Bureau, approximately 137 million persons were active in the civilian workforce of the US, including 6 million unemployed persons. Social and behavioral science professionals constitute only a miniscule segment of this overall labor force (approximately one-half of 1 percent) if such professionals are defined as persons having an advanced degrees (an MA or Ph.D.) in a social/related science.

5.1 Employment Status of Social and Behavioral Scientists

The overall employment status of those with advanced degree training in the social and behavioral sciences is quite favorable. According to the National Science Foundation's Scientists and Engineering Statistical Data System (SESTAT), there are some 656,100 social/related science professionals in the labor force (494,100 and 162,000 at the MA and Ph.D. levels, respectively). Employment rates for these individuals

are strong. In 1997, only 0.9 percent of all Ph.Ds. and 1.8 percent of all MAs in the social/related sciences were unemployed (see SESTAT 1997, Table B-2).

Of the 160,500 employed Ph.Ds. with social and behavioral science training, the vast majority (87 percent) was employed full-time (see SESTAT 1997, Tables B-2 and B-5). Also, approximately 117,000 of these Ph.Ds. were employed in science and engineering occupations. This proportion (73 percent) is consistent with other fields of science (see SESTAT 1997, Table A-3). Also, as might be expected, most of these Ph.Ds. (108,000) were working directly in social/related science occupations.

5.2 Social and Behavioral Science Occupations and Professional Training

In terms of standard approaches, the labor force in the social/related sciences can be conceptualized as: (a) those persons *trained* in the social and behavioral sciences, or (b) those persons *working* in social and behavioral science *occupations*. In contrast to a focus on degree training *per se*, classification into occupational categories includes persons trained in other fields who are working in these areas but excludes persons with relevant training who are working in other occupational areas. For example, social/related science occupations would include persons with Ph.Ds. in business who are teaching sociology in a university but would exclude persons with Ph.Ds. in sociology managing a business (see National Science Foundation 1999).

SESTAT classifies persons into occupations in terms of both work and education. Based on the SESTAT surveys, in 1997, approximately 350,000 persons with a BA degree or higher were classified as being in a social/related science occupation. This occupational category includes jobs that vary widely as to the nature of the work and required expertise. As might be expected, most persons classified as working in this occupation received their highest degree in a social/related science (approximately 80 percent across all degree levels). Furthermore, having an advanced degree beyond the BA also matters: the vast majority of persons working in a job classified as a social/

related science occupation have an advanced degree (see SESTAT 1997, Table A-3).

The value of an advanced degree can further be seen by looking at the relationship between BA, MA, or Ph.D. training in a field and working in an occupation classified as being in that same field (i.e., 'in-field' occupation). As shown in Table 2, for all fields of science, persons at successively higher degree levels are more likely to be working in occupations classified as 'in-field.' In the social and behavioral sciences, 2.6 percent of those persons with BAs was working in a social/related science occupation compared to 21.6 percent and 67.6 percent, respectively, of those with MA and Ph.D. degrees. By the Ph.D. level, there is also far less variability across fields of science in the proportion of persons working in 'in-field' occupations.

5.3 Sectors of Employment

Examination of Ph.D.-level professionals in the social and behavioral sciences shows the centrality of the academic workplace in relation to other work sectors. Across scientific fields, more Ph.Ds. were employed by 4-year colleges and universities than by any other employment sector (in 1997, 43.4 percent for all degree fields and 47.4 percent for the social/related sciences). The next highest work sector for all Ph.D. fields was business at 30.5 percent overall, although not as high a proportion of social science/related scientists was employed by the private sector as in other fields (see SESTAT 1997, Table C-2).

While specific disciplines within the social and behavioral sciences followed this overall pattern, there are important differences. As shown in Table 3, in 1997, a substantially greater proportion of sociologists (72 percent) than psychologists (34 percent) were employed by 4-year colleges and universities. In contrast, greater proportions of psychologists and economists were employed in the business sector. Also, for psychology, a larger proportion of Ph.Ds. is self-employed (17 percent), ostensibly due to the sizable number of psychologists who are in clinical practice.

5.4 Women and Minorities in the Social/Related Science Labor Force

5.4.1 Gender. Based on the 1997 SESTAT surveys, of the 160,500 employed Ph.Ds. with social/related science training, 62 percent were male and 38 percent were female (see SESTAT 1997, Table C-2). As could be anticipated from changes in the gender composition of Ph.D. degrees conferred over the years, substantially more employed female Ph.Ds. received their degrees in recent years. Of those who received their degrees 20–4 years ago, approximately 70 percent were male. In contrast, of those who received

Ph.Ds. within the last 5 years, approximately 45 percent were male (see SESTAT 1997, Table C-10). This pattern holds across social/related science disciplines—from psychology that substantially increased in the production of female Ph.Ds. to economics that continued to produce more male Ph.Ds. (see SESTAT 1997, Table C-9).

Males and females with Ph.Ds. in the social/related sciences vary only modestly in terms of sectors of employment. Gender differences within disciplines are more striking than any overall trends. For example, a higher proportion of male than female economists was employed by 4-year colleges and universities (56 versus 49 percent) while a higher proportion of female than male economists was in the government sector (20 versus 12 percent) (see SESTAT 1997, Table C-2).

5.4.2 Race/Ethnicity. Of the 160,500 Ph.Ds. in the social and behavioral sciences employed in the workforce in 1997, the vast majority across social/related science disciplines was white (88 percent). The data on Ph.Ds. of color in the workforce are consistent with what is known about the production of minority Ph.Ds. since the mid-1970s (see SESTAT 1997, Table C-9). Of those who received their Ph.D. degrees 20–4 years ago, 92 percent were white and 2.9, 2.5, and 1.7 percent were black, Asian-American, and Hispanic, respectively. In comparison, of those receiving degrees within the past 5 years, 82 percent were white and 4.4, 9.5, and 3.7 percent were black, Asian-American, and Hispanic, respectively (see SESTAT 1997, Table C-11).

The 1997 data on employment sector reveal an important difference between minority and white Ph.Ds. in the social/related sciences (see SESTAT 1997, Table C-4). Higher proportions of Ph.Ds. of color were employed in 4-year colleges and universities than were their white counterparts (57, 56, and 54 percent, respectively, for blacks, Asian-American, and Hispanic Ph.Ds. compared to 46 percent for white Ph.Ds.). That higher proportions of minority Ph.Ds. are employed in higher education compared to white Ph.Ds. likely reflects strong efforts by the academic sector to diversify its workforce in the context of a very low number of Ph.Ds. of color being trained.

5.5 Current Patterns for New Ph.Ds.

Analysts examining the current employment picture for social/related scientists are variously optimistic, with some being quite favorable (Spalter-Roth et al. 2000) and others being more cautious (Siegfried and Stock 1999). A recent survey of graduates awarded their Ph.D. degrees between July 1996 and August 1997 provides important data. The survey focused on 14 scientific fields, including economics, political science, psychology, and sociology.

Table 3

Employed Social/Related Scientists in selected fields where highest degree attained is Ph.D. by employment sector, 1997

Employment Sector	Social/Related Scientists			
	Economists Percent	Political Scientists Percent	Psychologists Percent	Sociologists Percent
Universities and 4-year colleges	57.1	67.4	34.3	71.7
Other educational	0.6	3.1	5.6	3.9
Private not-for-profit	5.0	5.0	10.1	7.6
Private for-profit	16.7	9.5	21.9	6.2
Self-employed	2.2	3.6	16.9	3.4
Government	13.9	11.3	11.2	7.1
Total	**95.5	100.0	100.0	100.0
Total number*	20,080	15,820	79,320	13,230

Source: National Science Foundation, Survey of Doctoral Recipients (SDR 1997). Data are published in *Characteristics of Doctoral Scientists and Engineers in the United States 1997*, NSF00-308, NSF/SRS, Table 17

*Number is estimated number of persons employed at highest degree attained. Numbers may not add up to 100 percent due to rounding

** Total is not 100 percent because 4.5 percent of economists were classified in 'Other' employment sector (not shown on this table). Also, 0.1 percent of psychologists were so classified

As shown in Table 4, unemployment is generally quite low for newly exiting graduates. With the exception of chemistry and political science at 4.6 and 7 percent, respectively, other disciplines were all below 4 percent. Furthermore, Ph.Ds. in the social/related sciences fared very well. While compared to other scientists, a somewhat higher proportion of social and behavioral scientists were employed part-time (in particular political science and psychology), a lower proportion were in temporary positions. Most striking is the relatively high proportion of social/related science Ph.Ds. employed in the academy, with sociology being the highest at 83 percent. Also, these data suggest a favorable academic market for social/related scientists. Newly minted Ph.Ds. in economics, political science, psychology, and sociology were finding employment in the academy in proportions comparable to, if not higher than, their overall presence in this sector (compare Table 3).

6. Continuing Issues for the Social and Behavioral Science Professions

For at least the next 10 years, the academic market appears to be positive. Despite the complexities of making predictions (see, e.g., Breneman 1988, Smelser and Content 1980, Schuster 1992), Bowen and Sosa (1989) anticipated these trends. In particular, the picture for social/related scientists is consistent with their projections of an undersupply of Ph.Ds. due to such factors as high undergraduate enrollments, stable to diminished graduate enrollments, anticipated fac-

ulty retirements, and increases in nonacademic employment. Bown and Sosa projected more demand than supply through 2007 and believed this pattern would continue, though at a slower rate.

It is important to keep in mind that the academic marketplace is broad and undergoing a restructuring. In reality, it consists of multiple and overlapping markets (e.g., research universities, liberal arts colleges) that have different 'buyers' and 'sellers' (see Smelser and Content 1980, Schuster 1992) and that vary in prestige and mobility. Furthermore, these markets themselves are not fixed. The community college, for example, is currently the fastest growing sector of academic employment. Finally, potential changes in the structure of these markets (e.g., increases in student-faculty ratios, more use of part-time or contractual teaching appointments, increased use of distance learning) could affect Ph.D. shortages.

The market for social/related scientists outside of the academy also merits more attention. For certain disciplines, like economics and psychology, the proportions working in nonacademic settings are sizable. Furthermore, the data indicate that social/related scientists are increasingly located in these settings. A National Academy of Sciences report (1969) observed a slow but evident trend to greater nonacademic employment. Between 1968 and 1997, there was a 12 to 20 percent decrease in the proportion of sociologists, political scientists, economists, and psychologists employed in educational institutions. Consistent with commentators (e.g., Rosenfeld and Jones 1988, Schuster 1992) noting a 'pull' not a 'push' to these work sectors, the steady increases in nonacademic employment seem to occur irrespective of the tightness of academic markets.

Table 4

Employment status of recent Ph.D. graduates

Field of Study	Percent			
	Unemployed	Employed Part-time	Employed in temporary positions	Employed in academe
Biochemistry and Molecular Biology	4.0	2	79	73
Chemistry	4.6	2	58	57
Chemical Engineering	3.2	0.5	26	25

Data on sociology were updated by the American Sociological Association based on a more complete response

As the social and behavioral sciences move into their second century as professions, the overall environment for these fields is currently strong. The challenges before them, however, are also many. They are at a juncture where their ambitions could enlarge and these professions could grow to address some of the most challenging issues of human behavior and society. How they organize themselves and their work and how they prepare their next generations for contributing knowledge and expertise will, more than any other factors, shape what these professions are and become (see *Infrastructure: Social/Behavioral Research (United States)*).

Professionalization/Professions in History

In modern historical scholarship, the professions include the occupations of doctors, lawyers, professors, and engineers, among others. Professions are characterized by special functions and structures, motives, representations, forms of knowledge, and sociocultural styles. Professionalization refers to processes affecting the social and symbolic construction of occupation and status. The history of the professions investigates the ways in which functional groups and status groups are regulated and institutionalized. It shows how meanings, functions, and structures de-

velop in social and temporal context and how professions, in the restricted sense of the term, differ from the status groups and occupations of entrepreneurs, merchants and clerks, skilled manual workers (crafts, *métiers*) and the so-called semi-profession. Professionalization involves the formation of an occupation, on one hand, and interrelated developments regarding the social division of labor, structures of authority, and sociocultural inequality, on the other. Historical research on professionalization concentrates on such issues as the distribution of scarce resources at a particular point in time, the social definition of behavioral prerogatives, and the regulation of central values and functions. It is concerned with the motives, interests, and strategies of actors who either promote or hinder processes of professionalization.

Recent historical research on professionalization has tended to oscillate between individualizing historical perspectives and systematic social science perspectives. The former emphasize the peculiarities of particular professions or the special features of the professions in a particular historical context. The latter concentrate on general features and tendencies. Historical and comparative research shows that, while the professions are often concerned with the same or similar functions, problems, and tasks, these may be interpreted in different ways and institutionalized in different contexts. Similarly, depending on the characteristics of a particular profession and on the particular historical circumstances, the paths, cycles, and types of professionalization and deprofessionalization may vary. By taking these points into consideration, scholars have relativized both teleological understandings of professionalization and static conceptions of the professions.

1. Definitions of Profession and Professionalization

Abstract and temporally undifferentiated concepts of the professions have only a heuristic value in historical research. Therefore, one usually begins with a historical explication of the concept and then asks how professionalization is articulated in a specific context with regard to the relevant dimensions in particular domains. The individual dimensions and processes are more or less closely linked in concrete historical cases. The result is that the professions and professionalism find expression in a graded series of variations. The professions are characterized ideally by the following series of interrelated dimensions. Capabilities and skills are justified scientifically or systematically. Professional knowledge is described in such terms as 'exclusive,' 'more profound,' 'inaccessible to lay persons,' and 'not easily understandable.' It is acquired in special institutions such as universities, professional schools, and internships with professionals. It forms the basis of the superiority of the professional over lay

persons and clients. Also included in this body of knowledge are rules and attitudes which govern its application in a way which promotes trust between the professions and their social environment. These include formal procedures, ritual, titles, a professional habitus of studiousness, collegiality, and altruism, and a general orientation toward the common good. The professions claim for themselves a specific style of earning a living that is characterized by the principle of remuneration 'befitting ones rank' and through specific forms of contract and recompense. The professions demand for themselves higher prestige. They develop specific organizations for collective integration, self-administration, self-control, and for the representation of their interests, such as the 'chartered professions' in England, the disciplinary councils and chambers on the European continent, and, more generally, professional associations of various kinds. The professions strive for 'autonomy.' Viewed historically, this means, first, exiting from relations of patronage with traditional secular and clerical elites and, second, the reduction of external control and dependence on the state, on the rich and powerful, on clients or beneficiaries, and on employers.

Professionalization is a social project, which articulates itself in discourses on science, performance, honor, public welfare, and society and, in the ideology of professionalism. It is intended to secure for professionals a high or mid-range status in the system of social and cultural inequality. The historical literature distinguishes between professionalization that is externally controlled and professionalization that is controlled by the occupational groups themselves. Similarly, it distinguishes between heteronomous and autonomous professions. In the classical research on the 'free professions,' especially in the Anglo-Saxon literature, professionalization is understood largely from the perspective of members of the occupational groups themselves. In recent research, however, the analytical concept of professionalization is used increasingly for professionals who are occupied in state and private administrations and enterprises as well (Burrage and Torstendahl 1990, Perkin 1989, Siegrist 1988). Previously, and especially on the European continent, scholarly interest in professions such as these was often guided by concepts such as 'higher education,' 'meritocracy,' 'bureaucracy,' and 'civil servants.'

The historical connection between occupational role and social status is articulated concretely in concepts such as the 'gentlemanly professions,' the 'learned professions,' or, more simply, the 'professions' in England and the United States; '*professions libérales*,' '*bourgeoisie à talents*,' '*capacités*' in France; '*gelehrte Stände*,' '*höhere Berufe*,' '*bürgerliche Berufe*,' '*mittelständische Berufe*,' '*Akademiker*,' and '*Bildungsbürgertum*' in the German-speaking lands of Europe; '*professioni maggiori*,' '*professioni nobili*,' and '*borghesia umanistica*' in Italy; 'intellectuals' in Western

Europe and '*intelligentsia*' in Eastern Europe (Siegrist 1988, 1996; Freidson 1986; Conze and Kocka 1985; Malatesta 1995; Charle 1996; McClelland et al. 1995). In the twentieth century, professionals express claims to membership in the middle classes through discourses on the 'loss of middle-classness' and the 'threat of proletarianization.' Under National Socialism and Fascism, the meaning of the 'free professions' was hollowed out, as professionals were redefined as militant 'thinking workers,' who took part in the 'struggle of the Volk and the master race.' In the communist world, the concept of the socialist intelligentsia implied the transcendence of class relations, the end of occupational privileges, and the subordination of professionals to the state and the party. Modern western concepts such as 'technocrat' and 'expert' define the role and position of professionals independently of social or economic class.

2. Conceptions and History of Professionalization and Professions

The history of the professions begins in the Middle Ages and in the early modern era with the autonomous corporate colleges of the higher professions (lawyers, physicians, university professors) and the lower professions such as surgeons and notaries (Prest 1986, Betri and Pastore 1997). The various professions have specific orders of knowledge. They enjoy privileges with regard to education, the control of access to the professions, the practice of the professions, and ethical monitoring. The specific way of earning a livelihood distinguishes the higher professions from commercial occupations and handicrafts. The institutional pattern and the mentalities of the old European corporate occupational culture varied according to the degree of the abstraction of knowledge and the social proximity to the nobility, the patriciate, and the urban bourgeoisie. As a rule, the right to practice a profession was limited to a specific territory.

The traditional culture of the professions came under pressure and began to dissolve in the eighteenth and early nineteenth centuries. In the authoritarian and bureaucratic societies of Europe, the reformed professions were ruled under the control of the state. In radical-liberal, democratic, and egalitarian societies such as France in the revolutionary era, the United States, and Switzerland in the mid-nineteenth century, the professions were largely deregulated or were established as free trades (Ramsey 1984; Siegrist 1988, 1996). The general orientation of the different professions varied between (a) loyalty to and dependence on the state, (b) a progressive-liberal worldview, and (c) the desire to defend or revitalize traditional professional cultures and corporate mentalities. Different professions displayed many similarities with regard to the level of education, the orientation toward science and scholarship, and the social position of their

members. Nevertheless the various occupational groups often competed with one another for cultural hegemony, social prestige, and political power.

2.1 Institutionalization of Professional Training

The specific way in which education and training are institutionalized plays a central role in processes of professionalization. The states of the European continent led the way in the creation of theoretically and scientifically based training programs and in the transfer of such programs to (reformed) universities and elite institutions of higher learning such as the French *Grandes Écoles*. On the other hand, it is also true that (complementary) training through practice survived and even retained a central importance (trainees in state agencies, mandatory internships with practitioners, or, for example, when the first professional years serve, in effect, as a sort of apprenticeship). In Anglo-Saxon countries, the transition from 'training on the job' or 'shop culture' to 'school culture' has intensified since the late nineteenth century (Lundgreen 1990). A comparison of the length of time required for professional training in different countries reveals significant differences, even for the same occupation. Some of these differences may be attributed to variations in the contents of training programs, while others depend on factors such as tradition, restrictive state policies affecting the labor market, or the exclusive strategies of the professions themselves.

2.2 The Institutionalization of Professions

Beginning in the eighteenth century, it is important to distinguish between the legal institutionalization of the professions by the state, on one hand, and the formalization and regulation that is intended and implemented by the occupational groups themselves, on the other. With regard to the latter, one must also distinguish among (a) the continual development of a premodern profession, which, in principle, was never dissolved (such as the English 'bar'); (b) the restructuring of professions, which had been temporarily deinstitutionalized (as was the case with physicians and lawyers in the United States); and (c) the formation of new professions by members of functional and occupational groups that first arose in the nineteenth century (especially engineers but also a number of other 'new' professions). All of these involve long processes, which typically culminate in accreditation through the state or the legislation.

In much of Europe, the state or the government or legislation took the initiative to regulate and institutionalize the professions (Siegrist 1996; Ramsey 1984; McClelland et al. 1995). The state, as the guarantor of the legal order, the promoter of culture, and as an

intervening force in society, needed professional services and provided the professions with knowledge, rights, and duties. In this way, the state distinguished the professions symbolically from the occupations and functional roles of business, commerce, and agriculture, which had been deregulated through the abolition of guilds and the liberalization of the trades. Henceforth, the professions included only those vocations that were occupied with central goods and values or with securing property, honor, health, public order, morality, and science. In this new configuration of the professions, the old European conceptions of profession, guild and vocation were combined with the ideas of progress, order, and freedom.

In contrast to liberal and democratic societies, monarchical, bureaucratic, and statist societies tend to define professionals as civil servants and to establish a specific hierarchy of the professions: at the pinnacle of this hierarchy are professionals in the civil service, who are followed by state-appointed professionals, then by highly qualified members of the 'free professions' and finally by those professionals whose training and practice are not prescribed exactly. In liberal societies, the hierarchy is less pronounced, and the free professions stand at the pinnacle (Siegrist 1996). Since the late nineteenth century, professionals have been increasingly employed in private enterprises such as industrial firms, banks, insurance companies, and research laboratories. The occupational and status groups of professionals who are employees develop their self-understanding with reference to the social types of the civil servant, the free professional, and the entrepreneur.

The professional and social types of the nineteenth century may be characterized as follows:

(a) Professionals who are 'civil servants' are to a great extent bound in the service of the king or the state. If necessary, the individual lawyer, physician, engineer, or professor must disregard professional criteria and follow the directives of his superior. Due, however, to the increasing recognition of professional competence and of the indefinite tenure of higher civil servants, specific ideas and forms of professional autonomy also come into play in the judiciary, in the administration, and in higher education. Professions such as the engineers who were educated in the elite technical colleges in France and then entered into the civil service developed a special *esprit de corps* (Schweitzer 1999);

(b) Members of 'state-appointed professions' are holders of public office. Professionals such as these enjoy a kind of protected market, but they are also monitored closely. Political appointment strengthens the authority of the expert in society but limits his autonomy, impedes the formation of a self-defined collective consciousness of the profession, and makes the organization of professional associations more difficult. Examples include the Prussian, Bavarian, and Austrian lawyers well into the late nineteenth

century, the French and Italian court lawyers (*avoués, procuratori*), the Prussian county physicians, and the community physicians of Italy. In the late nineteenth century, some of these state-appointed professions were able to emancipate themselves from state protection, which had come to be viewed as patronizing. Linking discourses on political freedom and the free market with discourses on professional autonomy, they expressed the desire to become 'truly free professions.' Since clients increasingly made similar demands, many states changed the corresponding laws and regulations in the last third of the nineteenth century;

(c) The 'free professions' are characterized by more elaborate forms of training and examination and distinguished titles. Credentials are derived mostly from the state, but the free professional must be able to adapt to one or more segments of the market for professional services. Minimal standards for both professional and ethical behavior are often regulated by law, at least in principle. In practice, such regulations are enforced either by professional courts of honor (disciplinary bodies with the authority of public law or executive boards of associations with informal authority) or by ordinary courts and clients;

(d) In those areas where professional functions are exercised in the form of free trade, the constraints of the market and the increasing authority of science and scholarship encourage informal processes of professionalization. Professionals are themselves motivated to improve their own qualifications. An elite defines professional qualifications, founds an association, and attempts to marginalize or discredit so-called semi-professional practitioners.

2.3 Cognitive and Emotional Orientations and Strategies

In the eighteenth and nineteenth centuries, the contents, forms, and meanings of professional knowledge changed. As was the case with other societal elites, professionals formulated new scientific discourses and new models for professional conduct. The physician achieved greater recognition as a scientifically and practically trained healer and health expert (Huerkamp 1985; Léonard 1981), while the lawyer came to be viewed as a legal expert and 'priest of justice,' who was responsible for the realization of the rule of law and for securing the rights, the property, and the honor of the citizens (Siegrist 1996). The engineer was the chief proponent of scientific and technical progress, and was long considered to be an expert for administration, supervision, and organization (Schweitzer 1999). The university professor and the teacher in the gymnasium or *lycée* were the experts for education, aesthetics, and morality. Finally, the Protestant minister was the educated theologian, whose legitimacy was no longer derived from faith and piety alone.

The degree of the systematization of knowledge increased over the course of the nineteenth century, but the superiority of the professions and the efficiency of professional conduct remained controversial for an extended period of time. This is evident in the debates over the competence of university-trained 'physicians,' practical 'surgeons,' 'herbalists,' 'quacks,' nuns, midwives, and orderlies, and, more generally, over 'professional knowledge' and the knowledge of 'lay' persons. The professions had enduring difficulties in their efforts to prove their greater efficiency and to legitimize their autonomy with reference to science. Therefore, they attempted to support their claims to professional autonomy with supplementary appeals to values and attitudes that they shared with most of their bourgeois clients and employers. The leading concepts in these efforts were independence, responsibility, impartiality, altruism, public service, acting 'in good faith,' and 'delicacy' in the sense of tact and discretion. These values and attitudes were often codified in laws, professional regulations, codes of ethics, and professional manuals. In many cases, such moral standards applied to the whole person of the professional, i.e., not only to his occupational activities but also to his behavior as a private person and citizen as well.

Compulsion and persuasion served to bridge the gap between professional culture and lay culture. Studies that conceive of professionalization as an element in the historical development of disciplinary processes and the growth of class domination emphasize the compulsive character of the social action of professionals. With the spread of medical, legal, technical, moralizing, and educational practices, professional culture as a combination of knowledge and power penetrated all aspects of modern life and thought (Goldstein 1984, 1987). The professions are said to have used their knowledge in order to secure for themselves social and economic advantages. On the other hand, empirical social and cultural historical studies, in which concrete interactions between experts and lay persons are investigated, often conclude that experts were hardly able to realize their cultural projects in a pure form. For quite some time, lay persons avoided contact with professionals by seeking advice with regard to health from pastors or priests and by seeking legal council from union secretaries.

The historical record shows that the professions that were close to the state or involved with legally regulated cases and procedures were, as a rule, more successful in compelling recognition of their competence. In contrast, clients who made a short visit to the doctor's office, to a lawyer, or to a priest were not exposed to experts to the same degree. On the whole, the free professions had to rely more heavily on persuasion. This explains why symbolic performances, clothing, decoration of work spaces, rituals, and rhetoric are such an essential part of professional culture.

2.4 Professions, Markets, and Economic Situation

The rise of the professions in the nineteenth and twentieth centuries was due largely to the increased and increasingly differentiated demand of private and public customers for goods and services. To a degree, professionals were able to stimulate this demand as well. They fulfilled a continually growing need for the explanation of the world, the formulation and attribution of meanings, for edification, and for entertainment. Through their influence, questions of law and property and of health and death were viewed less fatalistically. Many new opportunities arose for them in the construction trade, commerce, industry, banking and insurance, research, higher education, and also in agriculture. The professions profited from a general increase in prosperity and in the cultural needs of the middle classes. In the twentieth century, there was a rising demand for medical, social, and cultural services on the part of lower social strata, which had previously been neglected. Due to developments in the fields of education and insurance in the welfare state, and because of a general rise in income levels, these strata developed into a new mass market. The changing profile of the clients led to a revision of the traditional attitudes and practices of the professions.

The economic situation of the professions has at no time and in no place been homogeneous. The spectrum ranges from the modest conditions of the lower middle class (*petite bourgeoisie*) to those of the upper middle class (*haute bourgeoisie*). Income and wealth vary according to stages in career development. They depend upon individual abilities and performance, on regulations governing fees and honoraria, on conditions in the various markets, and on general economic cycles. In the nineteenth and early twentieth centuries, it was not uncommon for income to be augmented by supplementary, non-professional activities, by doweries and inheritance, by earnings from real estate, or by stocks and bonds. This was typical of the bourgeois and petit bourgeois milieus to which the professionals belonged through birth, marriage, or social relations. In the twentieth century, the income of professionals was still significantly higher than that of workers or than the national average. Due to increasing competition, to increasing recruitment from families of humbler background, and to economic and political crises, professionals have often become convinced that their heyday is behind them and that they are threatened with decline (Jarausch 1990). Under these circumstances, there is often an intensification of conflict within the professions between protectionists and those favoring a more aggressive market orientation.

Beginning in the late nineteenth century, as the model of the free professions continued to spread, all of the professions became increasingly dependent upon the market. In reaction to this, there were many

debates among professionals over the 'overcrowding' of the market and the closure of the various professions. There was a general trend toward lengthening training programs and making them more difficult, in order to stem the influx of young aspirants. The pattern of discrimination against female candidates was widespread. In principle, women had been admitted to higher education since c. 1900, but they were effectively hindered in practicing the classical professions for quite some time (Jacobi 1994). In Central and Eastern Europe, members of religious and ethnic 'minorities,' who had been emancipated in the nineteenth century, still experienced discrimination when they attempted to gain admission to the professions. Due to their supposed 'overrepresentation' in universities and academic occupations, Jews were often made responsible for the worsening of the working conditions and the standard of living among professionals (Jarausch 1990; McClelland et al. 1995). It was not until the second half of the twentieth century that discrimination on the basis of religion, ethnicity, and gender gradually came to be forbidden.

3. Particularism Versus Universalism

Depending on varying perspectives among both contemporaries and historians, the modern history of the professions may be understood in terms of the nationalization of culture and society or in terms of the universalization of knowledge and of the culture of professionalism. In the process of nation-building, members of the professions became elites, which supported the development of national society, politics, science, and culture. The national system provided them with opportunities and assigned rights and duties to them. As functional and cultural elites of the nation, they had a common interest in maintaining the interconnection of power, status, knowledge, and earnings. In both the public arena and in more exclusive spheres, they represented themselves through professional and bourgeois discourses and symbols; these included historical accounts, myths, and *lieux de mémoire* as well as cultural artifacts such as busts, statues, and portraits of famous professionals in public buildings. Professionals have tended to view their own structures, practices, and status as being nationally specific, even in those cases, where, in objective terms, there is a dominant international pattern or style, which is subject only to slight variations and nuances.

Comparative historical research and the history of institutional and cultural transfer has relativized national interpretations and led to significant revisions of national views of history. Such approaches have shown how states and national professions imitate and vary foreign symbol systems and institutions, when they are convinced that this will lead to an improvement in their performance and in their status in international competition (Ramsey 1984; Lundgreen

1990; Siegrist 1996; McClelland et al. 1995). In some cases, occupational patterns that were originally imposed by European empires were maintained after the end of imperial domination. French models for advocates and for engineers were imposed on other lands during the Napoleonic era; but subsequently they were adopted voluntarily, because they were found to be compelling. The Habsburg monarchy influenced the structure of the professions in Southeastern Europe. Prussian prototypes exerted a strong influence in the development of civil service and the professions in northern Central Europe. During the colonial period, the model of the English and French professions diffused worldwide, and they have retained their attractiveness in the postcolonial era as well. The Soviet model of the socialist intelligentsia spread after 1945 to the lands of the Eastern Bloc. In Europe, American patterns have competed with national ones at least since the 1980s.

Since the late nineteenth century, the European or universal character of knowledge and professional culture has often been celebrated at international congresses, but national patterns survived into the twentieth century. In Europe, these have only begun to weaken in recent decades, in the wake of liberalization, the integration of the European market, and globalization. This is a clear indication of the fundamental difference between the professions and other occupations, which were liberalized at an earlier date and more thoroughly.

4. *Historiography and Emphases in Current Research*

Traditional historiography tended to be focused on a single profession. It served primarily to affirm a tradition and to establish an identity, to further the understanding of one's own profession and even to celebrate it, to delimit the profession vis-à-vis other occupations and semi-professions, and to justify the status quo and lend support to demands made in the public arena (Burrage 1990; Siegrist 1996). The oldest genres in the historiography of the professions include works which defend traditions, privileges, and customs in the face of threatening political, social, and legal developments or, alternatively, polemical works by outsiders and civil servants who want to reform the professions. Since the nineteenth century, there has been a proliferation of biographies and memoirs of exemplary professionals, of *festschriften* on the occasion of anniversaries, celebrations, and congresses, of memoranda and surveys with historical aspects, and of learned historical treatises in encyclopedias on general developments and various special aspects of the professions. More ambitious historical monographs on particular professions first appeared in the late nineteenth century. The authors were typically either academic or leading members of the profession

in question with an interest in history. Until recently, academic historiography has only showed a moderate interest in the history of the professions. Prior to the 1960s, both amateur and academic historians were more interested in individual professions than in typical aspects of the various professions and rarely took the approaches and theses of the sociology of the professions into account.

Precursors of the systematic historical comparison (and sociology) of the professions include works which, beginning around 1800, compared local and regional occupational ordinances and occupational conditions with foreign equivalents. This sort of comparison and historical reflection was conducted in connection with the preparation of national laws pertaining to professions. Around 1900, representatives of the new discipline of sociology began to take abstract and systematic approaches to individual professions, to groups of professions, and to specific aspects of processes of professionalization. In the efforts of sociologists to discover the 'essence' of the professions or to develop a 'general theory' of the professions, historical aspects and cultural peculiarities were neglected. In the 1960s, research based on the sociology of class and social conflict and pioneer contributions to international comparison reintroduced a historical perspective to the study of the professions (see the historical overviews on the sociology of professions by Freidson 1986 and Burrage 1990). These works inspired the new historical research on the professions, in which the development of the professions is historicized and recontextualized, without, however, sacrificing the goals of systematizing, conceiving of historical types, and contributing to the formulation of a general theory. Today, the history of the professions is an established and dynamic field of social history, cultural history, the history of the sciences, and the history of education. Historical approaches to gender have shown why professionalization has, until very recently, remained a male phenomenon and how professionalization and gender have entered into specific kinds of symbiotic relationships.

Professions in Organizations

The study of professions in organizations is about the intersection of two areas of enquiry that have quite distinct histories, namely, the study of professions and the study of organizations, but that converge over the

course of those histories. There have been times when they have been related strongly and other times when they have gone their distinct ways. In fact, the study of professions in organizations has gone through three, overlapping, phases since the mid-twentieth century. The first phase, started in the 1950s and particularly strong in the 1960s, and still apparent today, was that of a critical examination of the role of professionals in bureaucratic organizations. The second phase, begun in the 1970s and again, continuing until today, critically examined the orthodox view of professionals and gave a more power-based, labor market analysis of their position and how it affected organizational labor markets. The third phase, which has its origins in the 1960s and 1970s, and blossomed in the 1980s and 1990s, emphasized the dynamic nature of professionals in organizations and acknowledged the variety of organizational locations. This article outlines these phases, dealing with the central concepts and findings, examining the questions that each one raises, and pointing the way to the next phase of research in this rich field.

1. Professionals and Bureaucracy—1950s Onwards

The origins of the initial discussion of the relationship between professionals and organizations lies in the sociology of the professions and the discussions of defining characteristics of a profession. There are a number of contributions, but one that is often seen as central is that of Greenwood (1957) who suggested that professions have: a basis in systematic theory; prolonged training and certification; recognized authority; community sanction and legitimation; professional culture and codes of ethics. In essence, he came up with a set of traits or components that, when present in their entirety, defined the complete profession. This trait approach was echoed in a variety of ways by Wilensky (1964) and Hickson and Thomas (1969). There were two thrusts to these discussions. The first was to establish the characteristics that make up a profession. The second was to determine empirically which occupations were 'truly' professional and which were 'partly' professional and which 'aspired' to the status of a profession.

Out of these discussions came a relatively agreed upon set of characteristics of a profession that had structural and value aspects. The structural aspects were such things as a full-time occupation, a training and certification system, a professional association, and an ethical code. But, more importantly for the study of professionals and organizations, was the extension of Greenwood's notion of a professional culture into a set of values which encompassed peer reference, vocation, public service, self-regulation, and autonomy. When this work in the sociology of the professions connected with the sociology of organi-

zations it was in terms of the relationship between the values held by professionals and those promulgated by the modern, bureaucratic organization. This relationship was seen primarily as antagonistic (cf. Hall 1968).

Through the 1950s and 1960s the great influence on the sociological study of organizations was Weber (1949). Weber's principal contribution to this field was his characterization of organizations in terms of the authority relations within them (systems of imperative coordination) and the ways in which such systems had evolved historically. Each ideal type of authority, charismatic, traditional, and rational-legal, had its associated organizational form. Weber saw the rational-legal authority system with its organizational form of bureaucracy as the dominant institution of modern society. The authority system is rational because means are designed expressly to achieve certain goals and it is legal because authority is exercised through an office with its associated rules and procedures. For Weber the bureaucratic organization was technically the most efficient form of organization possible.

In terms of Weber's evolutionary history of social systems, bureaucracies represent the final stage in depersonalization. Offices (jobs) are held by experts who are arranged in a hierarchy. Rules and procedures provide predictability and consistency. Information is recorded and stored. Personal and business affairs are separated. There is 'the methodical attainment of a definitely given and practical end by means of an increasingly precise calculation of means.' Starting in the economic sphere, bureaucracy is such a potent method of organizing that it becomes characteristic of all areas of society such as education, government, politics, religion, and so on. Much of organizational analysis of the 1950s, 1960s and 1970s was essentially concerned with establishing, extending, and critiquing Weber's notion of bureaucracy (e.g., Pugh et al. 1969).

As Abbott (1988) in his influential work has pointed out, this 1950s and 1960s view of professions had an underlying assumption of professionalization as a natural process; that is, a regular sequence by which an occupation moved to 'full' professionalism (Wilensky 1964). Essentially, this view, together with 'the search for bureaucracy' produced a unitary view of both professional occupations and organizations. Professionals, it was suggested, were socialized into occupations where the key values were autonomy, peer control, and vocation. For example, Hall (1968) operationalized professional values as the professional organization as a reference, a belief in service to the public, a belief in self-regulation, a sense of calling to the field, and feelings of autonomy. Bureaucracy was operationalized as hierarchy of authority, division of labor, rules, procedures, impersonality, and technical competence. However, his conclusion was 'an assumption of inherent conflict between the professional or the professional group and the employing organization appears to be unwarranted.'

Of course, both sides of this coin, the professional and the organization, could be, and were opened up to scrutiny. On the organizational side of the coin, Scott (1965) had put forward the notion of Autonomous and Heteronomous Professional Organizations. Pugh et al. (1969) distinguished between Full Bureaucracies, Workflow Bureaucracies, and Personnel Bureaucracies as well as Implicitly Structured organizations. The point of these taxonomies and typologies was to open up the possibility of there being organizational forms in which the values espoused by individual professionals would be embraced and protected, thus potentially transforming the nature of the debate beyond an inherent conflict.

On the other side of the coin, the changing nature of professions was being stressed together with their organizational locations. Two issues are important. First, there was a trend of increasing professionalism within bureaucratic organizations. Occupations were arising that claimed professional status, such as social workers, nurses, and managers. These were bureaucratically produced and located occupations. Second, Hastings and Hinings (1970) suggested, from their work on chartered accountants, that there were established professions that carried out tasks that were centrally located in bureaucratic organizations and that, as a result, there was little or no conflict between professional and bureaucratic values in these situations.

This 'opening up' of both organization and profession led to new developments in understanding professionals in organizations. However, this theme of potential conflict between certain forms of organization and professionalism continues today. For example Raelin (1991) has examined the management of professionals in organizational contexts, writing about 'the clash of cultures' when generic managers are responsible for professionals. In the UK, and Europe more generally, there has been a concern with 'The New Public Management' and its organizational impact on professionals employed in healthcare, government at all levels, and education. The concern or thrust is still that there are incompatibilities between professional ways of working and values and certain kinds of organizational principles and practices. It continues to be a fruitful area of study.

2. Professionals in the Labor Market—1970s Onward

The second phase, begun in the 1970s and again, continuing until today, critically examined the orthodox view of professionals and gave a more power-based, labor market analysis of their position and how it affected organizational labor markets. The basis for this was laid down in critiques of the 'professionals in organizations' approach in the previous decades. The previous research questions had been anchored firmly

in issues about the structure and values of professionalism with notions of an underlying process of professionalization arising from the nature of work in modern economies.

The problems that were raised continued the opening up of professional occupations away from a homogeneous view of them. The uneven nature of professionals was stressed; that is, they could not and should not be considered as a unitary set of occupations. Similarly, the rise of the bureaucratic, organizationally based professions both in the context of the state and the private sector was recognized more fully. Abbott (1988) calls this the 'monopoly school' which attributes developments in professionalization 'to a desire for dominance or authority' (p. 15). The occupational/professional project is to control the conditions of work (the labor process and the labor market) and to increase and maintain occupational status and power (Johnson 1972, Larson 1977, Friedson 1986).

The issues raised by this approach 'dislocate' the relationship between professionals and organizations both because it makes our understanding of professional occupations more complex, and also because it shifts the locus of debate away from values and structure to power and control. Indeed, the connection of this critique of the functions of professions is not as strongly related to the theme of professionals in organizations as the theories being critiqued. The emphasis becomes recentered on the nature of a profession and the professional project. In particular, the claim to professional status by an occupational group, for example, social workers, is seen as a way to control entry to the occupation and the demand for membership, and to establish an authoritative position within the labor market.

In a sense, the connection to organizations is primarily through an analysis of the rise of new professions and a continuation of the theme of 'the professionalization of everyone' (Wilensky 1964). Because a key question to be answered is why new occupations make the claim to be professional, that is, the professional project, the examination is, in part, one of organizationally based occupations. Thus, the issue of professionals in organizations is not one of 'traditional,' autonomous professionals coming to terms with the rise of the bureaucratic organization, but the establishment of functionally and bureaucratically derived new occupations as professional. The issue for the new professional in this organizational setting is to acquire authority and control the conditions of their occupation's existence.

Thus, the professional/organizational relationship is not one of adaptation between two different sets of structure and values, but of an occupational group that is functionally defined and organizationally embedded acquiring the legitimacy and dominance that comes from professional status. The professional/organizational relationship is one of power plays,

control of the labor process and fights over legitimacy that are played out both in the organizational setting and the institutional/regulatory setting within a particular society. This approach continues to be part of the discussion of professions in organizations and is to be particularly found in discussions of the healthcare sector (Friedson 1986, Larson 1977) and of the new public management. One of the issues that is raised by this stream of theorizing is that of the 'semiprofessions.' This was an attempt to distinguish between fully professionalized occupations and other occupations that aspired to professional status. These latter occupations tend to be primarily those that are organizationally produced and located and where the individual occupation members do not work as independent practitioners. Johnson (1972) sees this distinction (and the use of other descriptors such as 'quasi,' 'marginal,' or 'limited' professions) as an illustration of power relations between occupational groups. For him, professions retain positions of authority vis-à-vis the semiprofessions, whose claim to professional status is contested. As he puts it, 'the pervasiveness of the ideology (of professionalism) is not indicative of the extent of professionalism' (p. 59).

The theoretical and research issue of competition between groups for professional status continues to be an important topic. Several writers have observed the phenomenon of stratification within the professions. Abbott (1988) observes that interprofessional competition is a fundamental fact of professional life with jurisdictional disputes between occupational groups over claims to particular expertise and knowledge bases. And with more and more occupational groups that lay claim to such expertise and knowledge being strongly based in organizations, then the dynamic between professionals and organizations changes, on both sides.

3. Professionals in Professional Organizations—the 1980s Onwards

The third phase, which has its origins in the 1960s and 1970s, and blossomed in the 1980s and 1990s, emphasized the dynamic nature of professionals in organizations and acknowledged the variety of both professional and organizational locations. The issues of the variety in professional settings had been increasingly raised and, at the level of the professional system, Abbott (1988) has pointed out that there is continuous competition and jurisdictional disputes between professional groups as they dispute claims to expertise. Similarly, on the organizational side, the typologies and taxonomies of organizations both differentiated between types of bureaucracy and introduced new organizational forms.

This discussion has emerged in two different forms. The first is setting the discussion within the changes occurring in national and international economies. As

thinking about 'the new economy' and 'globalization' has developed (Aharoni and Nachum 2000), so two issues have been emphasized which bring together much of the previous theorizing about professions. On the one hand there is the rise of new occupations which claim professional status. For example, in the software development industry there are computer engineers, software engineers, and systems analysts who are highly educated but operate in paraprofessional environments across boundaries of time and space. Financial services have grown rapidly, as has the whole sector of business services, and along with these have come investment analysts, financial planners, and mergers and acquisitions specialists whose professional status is unclear although one sees the same processes as were written about in the 1960s and 1970s, namely those of educational qualifications, professional associations, examinations, and designations and the ideological claim to professional status.

On the other hand there is the rise of the 'knowledge-based organization' (Alvesson 1995) together with the development of concepts such as the flexible organization and the learning organization. The suggestion is that organizations of the new economy are increasingly different from the various kinds of bureaucracy of the old economy. One of the reasons for this is that they are more service-based and that those services require highly educated employees who, in value terms, are much more like the 'old' professions, being committed to autonomy, vocation, and collegiality. These new organizational forms are seen as much more friendly and hospitable to professionals. Also, it is suggested that these forms are spreading into old economy organizations as they respond to the rigors of global competition.

The second form of the discussion is a renewed interest in the professional service firm, for two different reasons, each connected to new organizations and new occupations. Peters (1992) and Alvesson (1995) have suggested that the professional service firm is an example of the flexible, knowledge-based organization; that there is a wealth of experience in these organizations from which the newly developing knowledge-based firms can learn. But, at the same time, with the explosion of knowledge-based services, and, in particular, the tremendous expansion of business services in OECD economies, there is much more competition over professional jurisdictions. If one takes the example of the 'Big 5' accounting firms (formerly the Big 8 and the Big 10), there has been a continuous expansion of services within these firms and more and more integration across services and across nations (Greenwood et al. 1998).

The same processes are at work within other professional jurisdictions and professional service firms. In law, for example, there are strong internationalization pressures. Also, there is much discussion over the multidisciplinary practice, allowing non-lawyers to have a controlling interest in law firms.

In 2000, the Law Society of New South Wales (calling itself 'the most progressive legal jurisdiction in the world') voted to allow multidisciplinary practices in law firms and also to allow them to incorporate.

Part of the process of defining these issues and also a result of them being articulated has been a rise in interest in the professional service firm (PSF). There were classic studies by Smigel (1964) and Montagna (1968) that examined the ways in which professionals operated in the professional service firm. But because of the concerns of theorists with issues of the rise of the bureaucratic organizational form and the response of professionals to that, and the concern with the monopoly critique, there was little or no interest in studying the professional service firm *per se*, even though it was the implicit, professionally hospitable setting contrasted with the bureaucratic form. It is this which has become the focus of much interest and research in the past two decades and in its own way it reflects issues of professionalization and bureaucratization, although the latter has been recast as managerialism and located in the context of knowledge-based organizations and globalization.

The theoretical and empirical location of studies of professional organization has been, primarily, in either the professional association and system or nonprofessional organizations. Very little study had been done of professionals in professional organizations, organizations that can be described as PSF. One important dimension in understanding professions in organizations is the extent to which they are primarily located in professionally dominated organizations or in other kinds of organizations, the so-called bureaucratic professions. For example, practicing lawyers are employed primarily in law firms that are organized as professional partnerships; only a small proportion are employed outside legal practices; for example, as corporate counsel or as lawyers within the public defender justice system. Accountants tend to be split about 50/50 between private practice and employment in private and public sector organizations. However, almost all accountants are trained in private practice. Engineers are employed overwhelmingly in private and public sector organizations with only a small proportion of the profession being employed in engineering consulting firms. And engineers receive their postuniversity professional certification training in a wide variety of settings.

There are three points to be taken from this. First, professionals work in a variety of organizational settings, something that has been ignored in much previous work. Second, there are some professionals who primarily work in bureaucratic settings and experience little or no conflict. Hastings and Hinings (1970) showed that chartered accountants working in industrial settings experienced little role conflict and they argued that part of the activity of accountants is to bureaucratize others. Similarly, the debate over the semiprofessionals such as social workers, teachers,

and nurses centered around the fact that they were located entirely in bureaucratic organizations and did not have independent, autonomous practices. But, third, the arena of professional work that had been ignored in particular was that of the professional service firm in spite of the fact that implicit in many analyses of professionals, their location in independent professional organizational settings was considered to be very important as the archetypal setting for an autonomous professional practitioner.

Much of the work of the 1980s and 1990s has been concerned with understanding the nature of the professionally based, private practice organization (Nelson 1988, Brock et al. 1999). As this work developed it also embraced the theme of bureaucratization although in a different guise, as managerialism.

This initial work was concerned with elaborating the nature of the traditional professional service firm, which Greenwood et al. (1990) typified as the P² form. The P² stands for the two key elements of professionalism and partnership. The PSF is an organization whose core workers are professionals. Traditionally they are from one dominant profession such as accounting or law. And the governance system of the organization is a partnership where the senior members of the professional group jointly and severally take responsibility for the direction of the firm.

There are a number of organizational consequences to these twin defining features. In human resource terms, one is the 'up or out' system or tournament. Young professionals either make it to partner or leave the firm. Organizationally, they are relatively loose structures, representative and collective decision-making with management being something that is done after dealing with clients. Issues of management and methods of organizing are not issues that are seen as important to discuss in the P² firm. The emphasis is on the individual professional and their ability to do good professional work. There are clearly strong echoes in this of the kinds of discussions that have arisen in the 1980s and 1990s about the knowledge-based firm with its employment of highly qualified individuals who are applying new, and sometimes esoteric knowledge, and, it is suggested, require freedom and flexibility to achieve results. In the P² organization, interesting work and the freedom and flexibility to do it are prized.

However, the nature of the professional firm has been changing due to changes in the institutional and market contexts of professional work. Because of the development of the new economy and the rise of services generally and business services in particular, there have been increasing pressures on the established professions such as law, accounting, and medicine. For more than a decade now, Western economies have been in a period of deregulation with the ideology of the market being dominant. Thus, jurisdictional boundaries have blurred and the level of

inter-professional competition has increased. The rapid rise in the numbers of management consultants, financial services advisors, software development engineers, information technology consultants, media and marketing occupations, etc. has changed the dynamics of professional organizations. Similarly, there have been substantial changes in markets. On the one hand the demand for these professional business services has increased markedly, making it one of the most rapidly growing sectors in many economies. But the demands for these services are from increasingly sophisticated clients, operating on a global scale.

It has been suggested that a major consequence of these pressures and changes is that the professional, P² organizational form is in decline (Brock et al. 1999), and that it is being replaced by forms that place a greater emphasis on managerialism (Cooper et al. 1996). Cooper et al. (1996) named this new organizational form in professional firms the Managed Professional Business (MPB). In such an organization professionalism becomes centered on developing lines of business, hierarchies develop, strategic planning is introduced, targets are more binding, and decision-making rests in the hands of management teams rather than the partnership at large. So, the argument goes, the terms and conditions of work in the MPB move towards those of the regular corporation. However, this can only go so far because of the knowledge-based work of professionals (Rose and Hinings 1999).

What this suggests is convergence for professionals in organizations, but of a new kind. It is not convergence around either professionalism or managerialism (bureaucratization), *per se*, but around a combination of these which is organized around the increasing role of knowledge in 'postindustrial,' service-based organizations. As yet, we have not sufficiently tracked these kinds of developments to write authoritatively about them.

4. Conclusion

So what can we conclude about research in this rich field and the status of our current understanding? There are a number of things. A very important one is the continuing theme of the potential conflict between professionalism and bureaucratization and/or managerialism. That is, the notion of a professional encompasses values and cultural statements that are inimical to the forms and cultures of hierarchically organized, profit-driven corporations. However, this continuing theme has been modified in two important ways, both of which require much more study.

The first is the opening up of the idea of the professional. There is still a tendency to work with ideas of 'true,' 'full,' or 'traditional' professions that are seen as archetypal or at least worked with as ideal types. But, much of the original work on the professional-bureaucratic relationship, and, in particu-

lar, the ideas of the monopoly school, suggested that there are a range of professions exhibiting varying degrees of compatibility with bureaucratic working. More research is needed which starts from the *diversity* between professionals, rather than the assumption of homogeneity. There are still incompatibilities between some professional ways of working and their associated values and some organizational principles and practices. But whether those professions that have evolved from bureaucratic organizations have more compatibility with those forms is still very much an open question, and it needs to be connected to issues of claims to professional status and competition between occupational groups for professional status.

The issue that Abbott (1988) sees as central, namely, interprofessional competition and jurisdictional disputes between occupational groups, should be related to the types of organizations within and between which such competition and disputes take place. The healthcare setting is a particularly good one for examining these kinds of issues because of the numbers of professional groups involved.

A second modification to the professional–bureaucratic opposition thesis lies in the variety of organizational settings and their changing nature. While the death of bureaucracy is much over-stated, there is no doubt that new organizational forms are emerging that emphasize knowledge acquisition, use, and dissemination, together with flexibility and autonomy in organizational working. We might argue that the organic, flexible design is the ‘new’ organizational form. But there is a range of established and emerging forms within which there are differing responses to expertise and professionalism.

A further development of these themes comes from our increased understanding of the role and nature of the professional service firm. Within the 1990s more and more interest and research has been centered on, *inter alia*, accounting firms, law firms, management consulting firms, and engineering consulting firms. These are, of course, the archetypal sites for the study of professionals within settings which should be the most accommodating because they are organized around professional work and managed by the professionals themselves. But they are also operating in changing institutional and market environments and face intra- and interprofessional competition. More research needs to be done on the way in which these professional fields are being restructured, new occupational grouping emerging, new organizational forms developing, and the organizational–professional relationship being changed. Part of this is also that there are important differences *within* as well as *between* professionals in terms of organizational setting.

Finally, an important and intriguing topic to be examined is the possible convergence of professionals in organizations and organizations of professionals. That is, on the one hand, many ‘nonprofessional’

organizations are becoming more knowledge-based and are experimenting with more flexible and autonomy-based organizational forms. On the other hand, professional organizations are moving into new markets, facing more competition, changing their knowledge base, and growing in size. In doing this they are becoming more managed, more strategic, and possibly decreasing some aspects of autonomy and flexibility. What they can offer is challenging work with major clients. This suggests a new kind of convergence, combining professionalism and managerialism (bureaucratization), due to the increasing role of knowledge in ‘postindustrial,’ service-based new economies. These changes present a real challenge for research.

C. R. Hinings

Professions, Sociology of

The sociology of professions is a branch of the sociology of work concerned with the analysis of expert occupations. It analyzes their patterns of organization, types of work, and social status. Because the sociology of professions first arose in the UK and the USA, it took its name and much of its early conceptual apparatus from the pattern of expert work characteristic of those countries. In recent years, however, the field has become more international, a change that is transforming both its empirical base and its theoretical superstructure.

1. Expert Occupations and the Sociology of Professions

The sociology of professions first arose to study the particular social form taken on by expert occupations in England and the USA in the course of the nineteenth century. This form was characterized by a combination of independent individual practice with some type of collective association. It usually involved specialized education, examination or licensure, service fees, and some form of autonomous discipline. By the early twentieth century, such a form was characteristic of medicine, law, accounting, architecture, and various other fields in the Anglophone world.

The first systematic analysis of these 'professions' was by Carr-Saunders and Wilson in 1933, who set

forth a typological analysis of occupations resting on various 'traits' that were taken to characterize the professions. The Carr-Saunders and Wilson analysis had a hard time with the military and the clergy, which were certainly 'professions' in the English sense of the term. Moreover, it made no effective contact with the quite different organization of expert work on the continent.

The French, for example, have no word with the denotation of the Anglo-American 'profession.' The French do distinguish *professions libérales*, but these include only experts in free individual practice, not all experts of a certain type. *Profession* itself has much broader purview than the English 'profession,' as does the parallel *métier*. Moreover, the organization of French experts has historically been far more state-dependent than has that of Anglo-American ones. Nor was France the only problem. The word and concept of profession were no closer to the German culture of expertism than to the French. Indeed, the characteristic pattern for organizing expert workers on the continent has more often been through quasi-civil service arrangements than through autonomous 'professional' ones. The sociology of professions thus began as a study of a particular kind of expert occupation. Only gradually have historical and comparative study made the limiting character of that approach clear.

2. Historical Development of the Field

From the Carr-Saunders book of the 1930s up into the 1970s, typology remained the dominant strategy of the sociology of professions. Millerson (1964) presented a comprehensive summary of all the various qualities that had been used to define 'professionhood.' The typological approach eventually strangled inquiry, as investigators worried whether or not various groups really were professions. Indeed, a substantial literature grew up in this period on the 'semiprofessions,' usually felt to include teaching, librarianship, nursing, and social work. These fit the typological model in some ways (advanced education, licensing) but missed it in others (independent practice). The so-called semiprofessions were all largely female occupations, a fact that would later become more emphasized, but engineering, although largely male, shared many of the same characteristics. Within typological thinking, salaried employment of professionals presented a problem. A small literature in the 1950s and 1960s considered this problem under the heading of 'professionals in bureaucracies,' viewing such professionals as being under strong role strain because of the conflicting demands of profession and organization.

The typological model enabled the sociology of professions to come to a rapprochement with structural functionalism. In a celebrated essay, Parsons (1954) argued that professions were rationalist (as

opposed to traditional), that they exercised functionally specific authority (as opposed to undifferentiated authority), and that they were universalist (as opposed to particularist). The later Parsonian tradition saw the professions as squarely anchoring the pattern maintenance sectors of crucial social subsystems. The typologists' focus on the organization rather than the content of professional work accorded better with the early Parsons, however, which kept them apart from the later structural functional interest in the professions.

Throughout the early postwar period, students of Everett Hughes and others in the Chicago tradition continued to amass case studies of professions and semiprofessions. Many of these fit the typological model badly. Their dependent nature often mocked the high role structural functionalists assigned to professions. One way around this problem was to argue that professionalization was a characteristic process that many occupations had not yet fully traversed. In the 1960s and 1970s, sociologists of professions argued for a characteristic professionalizing process, a sequence of stages through which all expert occupations developed. (Wilensky in 1964 provided the most famous analysis of such an argument.)

In the later 1960s, the sociology of professions, like many other subfields, turned towards skeptical interpretations. Major reinterpretations came from Johnson (1967), Freidson (1970) and Larson (1977). This new 'professional power' interpretation saw the professions in a different light. Freidson brought a generation of detailed studies of medical workplaces and medical knowledge together with a theory of professional organization to argue that the structures of professional organization were hardly the direct outcomes of rational and functionally specific universalism. The power of doctors over nurses suddenly seemed less a matter of advanced training than an enforced local division of labor. At a much more general level, Johnson recast professionalism as one among a number of modes of occupational control. This argument was carried further by Larson's reinterpretation of professions as collective mobility projects in which expert groups sought rewards through control of certain markets for services.

The rise of the power school coincided with a wide new interest in professions among historians, particularly in the USA. Scattered works had previously considered some major professions—English law and US medicine, for example. But the 1970s and early 1980s brought a flood of works covering various professions in the USA, England, and to a lesser extent France and Germany. These various works covered periods from the early twentieth century as far back as the seventeenth and eighteenth centuries. Although there were (and remain) important lacunae, theorists of professions began to work with a new empirical base. Perhaps more important, the historians turned

to the sociological literature for conceptual guidance and in many cases found little of use to them.

A number of other trends helped recast study of professions in the 1970s and 1980s. Most important was the steady drift of professionals away from independent practice and into corporate settings. On the one hand, this was simply a continuation of the trend towards larger and larger professional firms. In law, accounting, and architecture, sizable firms dated from the first half of the twentieth century, at least in the USA. Legal restrictions generally prevented this development both in the UK and on the continent. On the other hand was the development of multiprofessional firms, a pattern that had begun in architecture and now spread into areas like accounting, finance, and consulting. These largely professional firms were complemented by a much larger body of salaried professionals scattered throughout commercial and nonprofit organizations in the USA. By 1980, few US professions indeed were more than 50 percent made up of independent practitioners.

The rise of salaried professional work in the USA accomplished three things. First, it brought the US professional world much closer to the European pattern. The pattern of large-scale salaried employment by professionals had fascinated the French particularly, who had developed, in the concept of *cadres*, the notion of a technocratic intelligentsia as a new mode of occupational structure (see Boltanski 1982). Second, the new salaried professional work reawakened the interest in the 'professionals in bureaucracies' problem of role conflict. Third, the new pattern led to new concepts of 'deprofessionalization' and 'proletarianization of professionals.' Although the latter term obviously derived from the attempt to develop a Marxist analysis of professions, both concepts attempted to come to terms with the notion—an absurdity under the 'professionalization' concept—that occupations could lose the perquisites and possibly even the form of professions once these had been gained. A wide variety of studies appeared in the 1970s and 1980s examining the degree to which professions and professionals were losing control of work and cultural authority as well as enduring more mundane changes in salaries and tenure.

By the mid-1980s, then, the sociology of professions looked quite different. It had lost nearly all touch with structural functionalism. There was confusion over which professions would develop in which directions at which times. A large new body of research opened to theorizing not only a wide variety of quasi-professional occupations in the USA and England, but also the expert occupations of the continent. In many cases, this new data had extraordinary historical depth (see, e.g., the comparative work in Cocks and Jarausch 1990). In 1988, Abbott attempted to synthesize the entire area by refocusing the sociology of professions on actual professional work (both cultural and practical), turning away from the strong emphasis

on the social structures of professionalism that had become the center of the literature. He envisioned a world of interprofessional competition over jurisdiction of work. Changes flowed into this world both from within professions and from beyond them, recasting some professions, privileging others, destroying yet others. Professions attempted to claim control of work in the workplace, before the public, and within the state, and the course of professions' histories was determined by the ensemble of this melee of interaction. Abbott explicitly attacked the still-continuing typological tradition for eliding large areas of work. For him a profession was anything that competed like one.

Although Larson and others had attempted some international comparisons, Abbott's heavy reliance on European cases, particularly French ones, presaged what became the major development in studies of professions in the 1990s. This was the trend toward examining the relation of professions and the state. Much of the most interesting work came from Europe, for example, Jarausch's (1990) comparative analysis of lawyers, teachers, and engineers in Germany in the first half of the twentieth century. Krause (1994) has made the most general attempt at analyzing relations between the state and professions (and also capital), studying the USA, the UK, France, Germany, and Italy by means of case studies of law, medicine, engineering, and academics in each country. Krause's analysis focuses on the relative decline of professional autonomy and power in all these societies in the years after 1970. Both state and capital have increased their authority over professions.

The relation of state and professions has been underscored as an empirical question by the vast complications of creating standardized professional credentials in the European Union. The future of the sociology of professions will be greatly shaped by the theoretical developments necessary to analyse this process of internationalization of professional life. There is also a 'relations with capital' side to internationalization, encompassed in the largely unstudied complexities of the transnational corporations' use of professional services. There has been some study of 'offshoring' of professional services (e.g., of engineering services in telecommunications), but this particular capitalist attack on professional organization has not been studied in detail. In general, there is a startlingly small amount of work on expert occupations in the third world, with the possible exceptions of lawyers and, of course, the military.

3. *Current Problems*

The central present issue for the sociology of professions, then, is the question of how the professions will be reshaped by the economic reorganization that arose out of the crisis of the 1970s. Many of the recent

transformations have long antecedents, particularly the drift to salaried employment with its questioning of professions' cultural authority. Other trends, however, are new or newly important because of the economic conjuncture. Internationalization has been crucial. By the late 1980s the restrictions on professional firm size began to fall in Europe, largely under the onslaught of US firms, particularly law firms and multiprofessional consulting firms, which were the only firms able to manage some of the huge legal and financial projects characteristic of the new international economy. The new gigantism has transformed relations both within the professions, and, more important, between the professions and the state. It is in the international context, too, that the question of the profession-state relation is most clearly posed.

But there have been important internal effects to rethink as well. The decline of medical power from the pinnacle portrayed by Freidson has given new meaning to the phrase 'proletarianization of professionals.' This decline, driven by reorganizations of insurers and regulators, requires revising general theory about how expertise is organized in society. In that sense, the sociology of professions is again confronted with a functionalist question: how is expertise to be produced, controlled and reproduced in modern societies?

The issue of state and capitalist control is only one side of this question. On the other is the issue of commodification of professional knowledge. It is at present much too early to know the effects of computer-aided design systems, medical diagnosis systems, and other expert systems on the future of professions. But it is clear that new theory is required. It is also clear that commodification will be used to further reduce the status of professionals (see Abbott 1991).

Indeed, the field faces again the boundary question that has so long obsessed it. Earlier in this century, the boundary issue was 'what is a profession?' Given the new structure of employment relations, even in such highly professionalized surroundings as technological research firms and law firms, it is not clear what kinds of workers ought to be the subject of the sociology of professions. If the pattern of associational professionalism that gave rise to the field itself is either dead or transformed, then the field must retheorize its objects of scrutiny. Abbott's test—a profession is an occupation that competes by retheorizing others' work—presupposes fixed and organized occupations of a kind that simply may not exist under modern conditions of employment.

While the main focus of the professions literature has been on organizational and structural levels, some have insisted on a focus at the individual level, on the professionals themselves. The most general theme in this area has been a recurrent attempt to resolve the problem professionals (or expert workers) represent to Marxist theories of work. Originating in Djilas's book, *The New Class* (1957), the theme was continued in

Bell's *Coming of Post-Industrial Society* (1973), with its predictions of a knowledge world of the future. Attempting to synthesize this literature Brint (1994) recognizes the intense pressures brought on older structures of professionalism by modern economies. He sees a decline of 'social trustee professionalism' as professionals become mere private citizens with particular interests. Perkin's (1989) much broader analysis argues that the idea of profession became a model for modern societies generally in the middle fifty years of this century. The ideal of an individual with personal 'knowledge capital,' combined with the notion of just reward, was in Perkin's view fundamental to the conception of the modern welfare state. In that state's fall, argued Perkins, fell the professional ideal as well.

Perkins's argument provides a useful conclusion. In his article on 'professions' in the prior edition of this encyclopedia, Talcott Parsons (1968) closed with the confident assertion that 'the professional complex has already not only come into prominence but has even begun to dominate the contemporary scene in such a way as to render obsolescent the primacy of old issues of political authoritarianism and capitalistic exploitation.' Now that history has shown him wrong, the sociology of professions must develop a theory that can stand the test of major historical change.

A. Abbott

Program Evaluation

Evaluations are, in a broad sense, concerned with the effectiveness of programs. While commonsense evaluation has a very long history, evaluation research which relies on scientific methods is a young discipline but has grown massively in recent years. Program evaluation has made important contributions to various social domains; for example, to education, health, economics, and the environment.

This article gives an introduction to program evaluation by dealing with the following three questions: What is program evaluation? What standards can be set to enhance quality and fairness of evaluation? How to conduct a program evaluation?

1. What is Program Evaluation?

1.1 Definition, Distinction from other Activities, Users, and Evaluators

Evaluation, broadly construed, has a very long history. For example, in ancient Rome, tax policies were altered in response to observed fluctuations in revenues, and many thousands of years ago, hunters developed complicated procedures for fishing and trapping game. In recent years, commonsense program evaluation has evolved into evaluation research which relies on scientific research methods. The article focuses on the latter type of evaluation (for introductory texts on evaluation research see, e.g., Berk and Rossi 1998, Fink 1995, Pawson and Tilley 1997, Rossi and Freeman 1993). In the article, the terms evaluation, program evaluation, and evaluation research are used synonymously. Concerns for the first large-scale national evaluations of social programs in the USA had its origins in the War of Poverty, and the way of monitoring programs is still evolving rapidly. Evaluation has proven its usefulness to the extent that

most federal and state agencies require evaluations of new programs.

Programs are the objects of evaluation, sometimes also called projects or interventions. Program evaluation derives from the idea that social programs should have demonstrable merits and explicit aims by which success or failure may be empirically judged; for example, literacy programs for high-school students should lead to measurable improvements in their reading skills. Introductory texts on evaluation describe programs as systematic activities that are provided on a continuing basis to achieve preplanned purposes; for example, a national program to train teachers to work in rural and underserved areas, a campaign to vaccinate all children in a school district (e.g., Fink 1995, JCSEE 1994).

Evaluation systematically investigates characteristics and merits of programs. It is the purpose of evaluation to provide information on the effectiveness of programs so as to optimize outcomes, quality, and efficiency. Program evaluations are conducted by applying many of the same methods that social researchers rely on to gather reliable and valid evidence. These include formulating the study questions, designing the evaluation, setting standards to assess the program impact, ongoing monitoring of the program functioning, collecting and analyzing data, assessing program effectiveness relative to the costs, and reporting results. For examples of evaluation in various fields of clinical and applied psychology see, for example, Bickman et al. (1995), Gueron and Pauly (1991), Hope and Foster (1992), and Spiel (2001).

While few authors (e.g., Scriven 1991) take the view that theories are a luxury for the evaluator, since they are not even essential for explanations, the majority of researchers called for injections of theory into every aspect of evaluation design and analysis (e.g., Pawson and Tilley 1997, Berk and Rossi 1998). This implies that program evaluation capitalizes on existing theory and empirical generalizations from the social sciences, and is, therefore, after all, applied research.

By relying on the scientific method, program evaluation differs from e.g., newspaper reporting and social commentary. Program evaluation differs from the social sciences in its goals and audience.

Evaluation goals are defined by the client; that is the individual, group, or organization that commissions the evaluator(s), for example, policymakers. However, often programs and clients do not have clear and consistent goals that can be evaluated for effectiveness. Therefore, to meet evaluation standards, program evaluation should be conducted by professional evaluators who are experts in social sciences, using a broad repertoire of concepts and methods, but who have also expertise in project and staff management, and have at least basic knowledge of the evaluated domain.

While impetus for evaluation rests in policy, information from evaluations is used by the *stakeholders*, all individuals or groups that may be involved

in or affected by a program evaluation. There are at least five groups (Fink 1995): (a) federal, state, and local government, for example, a city, the National Institute of Education; (b) program providers, for example, the healthcare services, the curriculum department in a school; (c) policymakers, for example, a subcommittee on human services of the state; (d) program funders, for example, the Office of Education; (e) social researchers, for example, in government, public agencies, and universities. Therefore, program evaluation is also an interdisciplinary task where evaluators and stakeholders work together (see Cousins and Earl 1992).

1.2 Key Concepts and Assignment Criteria

Evaluation can and should be done in all phases of a program. *Baseline data* collected before the start of the program are used to describe the current situation; for example, the need for an intervention. In addition, baseline data are used to monitor and explain changes. For example, if the medical emergency services attempt to reorganize their service to better care for children, they may collect interim data to answer questions such as: In what cases did the emergency medical services fail to meet the needs of critically ill children? What are the differences to the needs of adults? What is the current performance of medical staff?

Before the start of the program a *prospective evaluation* can be employed to determine the program's potential of realisation, its effectiveness, and impact; that is, the scope of its effects.

In *formative evaluation*, interim data are collected after the start of a program but before its conclusion. It is the purpose of formative evaluation to describe the progress of the program and, if necessary, to modify and optimize the program design.

A *process evaluation* is concerned with the extent to which planned activities are executed and, therefore, is nearly always useful. For example, process evaluation can accompany implementation of a community-oriented curriculum in medical schools.

Outcome evaluation deals with the question of whether programs achieve their goals. However, as mentioned before, goals are often stated vaguely and broadly and, therefore, *program effectiveness* is difficult to evaluate. In practice, the concept of effectiveness must always address the issue 'compared to what?' Often it is difficult to distinguish program effects from chance variation and from other forces affecting the outcome. Berk and Rossi (1998) distinguish between *marginal effectiveness*, *relative effectiveness*, and *cost effectiveness*. Marginal effectiveness concerns the dosage of an intervention measure. For example, to prove the assumption that a better student-teacher ratio would improve student performance, the class size has to be reduced. In this case,

two or more different student–teacher ratios are the doses of intervention and their outcomes are compared.

Relative effectiveness is evaluated by contrasting two and more programs, or a program and the absence of the program. For example, lecture-based learning can be contrasted with problem-based learning in their effects on students' practical performance. Cost-effectiveness considers effectiveness in monetary units. Evaluation usually is concerned with the costs of programs and their relationship to effects and benefits. For example, in the evaluation of a physical education program, one can ask how much gain in monetary units can be expected from the reduced use of health services.

However, the entire impact of a program, for example, the extent of its influence in other settings, is very difficult, maybe impossible to assess. Therefore, *summative evaluations* are applied, that is, historical reviews of programs that are performed after the programs have been in operation for some period of time.

2. What Standards Can be Set to Enhance Quality and Fairness of Evaluation?

Because of the increasing number of evaluations and the high impact that decisions based on results of evaluations may have, there has been since the early 1970s an ongoing discussion about guidelines for effective evaluations. In the absence of any clear definition of what constitutes a reasonable program evaluation, the Joint Committee on Standards for Educational Evaluation (JCSEE 1994), in cooperation with evaluation and research specialists, compiled knowledge about program evaluation and established a systematic progress for developing, testing, and publishing evaluation standards. The Joint Committee began its work in 1975. In 1989 the progress for developing standards was adopted by the American National Standards Institute (ANSI), and became available worldwide.

Originally, the standards were developed to guide the design, implementation, and assessment of evaluations of educational programs, projects, and materials. However, in the new *Program Evaluation Standards*, published in 1994, new illustrations were included that feature applications of the standards in such other settings as medicine, nursing, the military, business, law, government, and social service agencies (JCSEE 1994). The standards are published for people who commission and conduct evaluations as well as for people who use the results of evaluations.

The Joint Committee defined an *evaluation standard* as a principle mutually agreed on by people engaged in the professional practice of evaluation, that, if met, will enhance the quality and fairness of an evaluation (JCSEE 1994). The standards provide advice on how

to judge the adequacy of evaluation activities, but they do not present specific criteria for such judgments. The reason is that there is no such thing as a routine evaluation and the standards encourage the use of a variety of evaluation methods.

The 30 standards are organized around the four important attributes of sound and fair program evaluation: *utility*, *feasibility*, *propriety*, and *accuracy* (JCSEE 1994).

Utility Standards guide evaluations so that they will be informative, timely, and influential. They require evaluators to keep in any phase of the evaluation the stakeholders' needs in mind. Seven standards are included in this category; for example, Stakeholder Identification, Evaluator Credibility, Report Clarity, and Evaluation Impact.

Feasibility Standards call for evaluations to be realistic, prudent, diplomatic, and economical. They recognize that evaluations usually are conducted in natural settings. The three standards included in this category are Practical Procedures, Political Viability, and Cost Effectiveness.

Propriety Standards are intended to facilitate protection of the rights of individuals affected by an evaluation. They urge evaluators to act lawfully, scrupulously, and ethically. In this category eight standards are included; for example, Service Orientation, Formal Agreements, Disclosure of Findings, Fiscal Responsibility.

Accuracy Standards are intended to ensure that an evaluation will reveal and transmit accurate information about the program's merits. They determine whether an evaluation has produced sound information. The 12 accuracy standards include Program Documentation, Valid Information, Reliable Information, Justified Conclusions, and Metaevaluation.

Validity refers to the degree to which an information or measure assesses what it claims to assess, while *reliability* refers to the degree to which an information is free from 'measurement error'; that is, the exactness of the information. *Meta-evaluation* is evaluation of an evaluation.

For each standard the Joint Committee summarized guidelines for application and common errors. In addition, one or more illustrations of the standard's application are given (JCSEE 1994).

However, the Joint Committee acknowledges that standards are not all equally applicable in every evaluation. Professional evaluators must select to identify those that are most applicable in a particular context.

3. How to Conduct a Program Evaluation?

Program evaluation typically consists of a chronological sequence of activities or tasks. The main tasks or activities are (see, e.g., Fink 1995, JCSEE 1994): Posing questions about the program and defining evaluation

goals, setting standards of effectiveness, designing the evaluation, collecting and analyzing information, reporting the results. In addition, an evaluation plan must be worked out that specifies each of the tasks to be accomplished and the personnel, time, and resources needed.

3.1 Posing Evaluation Questions and Setting Standards of Effectiveness

Based on the program's goals and objectives, evaluation questions are formulated. While goals are often relatively general, e.g., to improve the organization of an institution, objectives refer to the specific purposes of a program; for example, to produce a guidebook about how to review the literature. Evaluation questions may also concern the magnitude, duration, and distribution of effects.

Because program evaluations should provide convincing evidence concerning the effectiveness of a program, specific effectiveness criteria are set. Because these *standards of effectiveness* determine the evaluation design, they should be set prior to any evaluation activity. Information about standards came from the literature, from experts, normative data, and statistical analyses (see, e.g., Donabedian 1982).

Consider, for example, the program goal to teach students how to review the literature (see Fink 1995). Then the evaluation question is, whether students learned to do this. The standard of effectiveness can set, for example, (a) that 90 percent of students learn to review the literature or, (b) that a statistically significant difference in learning is observed between students in Schools A and B, with students in School A participating in a new program and students in School B serving as controls. The decision for either standard (a) or (b) can have consequences for the evaluation design, the selection of participants, and the statistical analyses of the data.

3.2 Designing the Evaluation

An *evaluation design* is a structure created to produce an unbiased appraisal of a program's benefits. The decision for an evaluation design depends on the evaluation questions and the standards of effectiveness, but also on the resources available and on the degree of precision needed. Given the variety of research designs there is no single 'best way' to proceed (for an overview see, e.g., Cook and Campbell 1979, von Eye and Spiel 1996).

Essential criteria for evaluation designs are internal and external validity. *Internal validity* is attained when the evaluator can decide whether a finding is due to the program and cannot be caused by some other factors or biases. *Randomized experiments* are the method of choice to reach this criterion; for example, when participants are by chance assigned either to program A, to program B, or to no program. *External validity*

concerns the generalizability of findings; for example, to participants of the program in other places and at other times.

3.3 Collecting Information

For collecting information an arsenal of methods is available; for example, questionnaires, performance tests, various kinds of interviews, record reviews, observations, etc. (see, e.g., Kosecoff and Fink 1982, Rosenbaum 1995). When selecting the methods of data collection, the evaluator must consider the evaluation questions, the available technical and financial resources, and the time needed to develop a new instrument. A 'good' measure is, in common terms, one that is likely to measure accurately what it is supposed to measure (Berk and Rossi 1998). In methodological terms, a good measure is reliable and valid.

Mostly, more than one measure is used to obtain the relevant information. For example, when health-related behavior of 14-year-old students is the variable of interest, possible methods of data collection include surveys of students, surveys of parents and teachers, observations of students, and reviews of health and medical records (Fink 1995).

3.4 Analyzing and Reporting Data

Program evaluators and social scientists employ statistical methods to analyze and summarize data. However, evaluators have to keep in mind that statistical significance does not always imply practical significance or educational meaningfulness. Standards of effectiveness that have been set in advance of the evaluation (see above) should guarantee that analyses of the data provide also evidence about practical effectiveness of the program (see, e.g., Fink 1995).

To combine results of evaluations that address the same questions or goals, meta-analyses can be conducted. A *meta-analysis* is an analysis of evaluation data from several studies. It is a statistical procedure which attempts to provide estimates of program impact by combining the results from a number of distinct evaluations to increase statistical power and the generalizability of results (see, e.g., Rosenthal 1991).

Reporting results is the last task for the evaluator. The evaluation report answers the evaluation questions, describes how the answers were obtained, and translates the findings into conclusions and recommendations about the program.

4. Concluding Remarks

The demands for sound program evaluation continue to grow in a way that some authors (Pawson and Tilley 1997) fear may become mandatory that everything

needs evaluating. Therefore, it is essential that quality control procedures and standards be introduced for all facets and tasks of evaluation and that the evaluation itself is evaluated against pertinent standards. However, there is also the risk of oversimplifying and only using a checklist of standards. There is no fixed recipe of how to run a successful evaluation.

Progress: History of the Concept

The idea of progress was integral to the project of creating social sciences in eighteenth-century Europe, and the relationship has continued since. During the nineteenth century, the idea that 'civilization has moved, is moving, and will move in a desirable direction' (Bury 1932) was the historical framework and central problematic of social science theory and practice. The idea of progress as inevitable collapsed in the vicissitudes of the twentieth century, although in mitigated forms, it continued, waxing and waning with historical expectations. One component, the idea of the progress of the social sciences, figured prominently as the ideology of the social science disciplines.

1. Eighteenth-century Origins

The idea of progress and the idea of social science were centrally involved in each other's origin. Both emerged as part of the historicist understanding of history as a realm of human construction, propelled ever forward in time and taking new qualitative forms. Modern society was thus decisively different from its feudal and ancient forerunners, engaged upon a novel historical course. Replacing earlier cyclical and supernatural views of historical time, progress instantiated in human history the teleological movement that governed the Christian drama of redemption. Progress was a universal journey, and the array of human differences sharpened for European thinkers the progressive character of their own society and the stages by which they had reached modernity (Meek 1976). The emergence of the social sciences was itself a lynchpin of progress. Science was understood as the most advanced form of reason and the extension of the progress of science into the realm of government and morals—barely begun—was central to the expectation of civilizational advance. By the same token, the task of the social sciences was to understand the forces that were propelling the modern European world and to guide it into the future.

The theories of progress propounded in the eighteenth century drew upon, and were often coincident with, the early formulations of social science. Associationist psychology explained the ability of human mental capacities to improve over time, while the studies of historians and economists and the observations of travelers set the trajectory of progress toward greater complexity and refinement: with increasing social differentiation and intercourse, came improving manners, morals, knowledge, and rationality. The guiding role of providence in this process was still visible, but it was understood to work through nature. Particularly in the UK and France, natural principles assured the existence and continuation of progress.

Several major theories of progress emerged in this context. Scottish 'philosophical historians' like Adam Smith and Adam Ferguson developed four- or five-stage theories of history in which the economic mode of production at each stage shaped political organization, customs, and moral temper. The expansion of population, the division of labor, and technological advance nonetheless emerged within a complex social process, as history was often the result of unintended consequences. In contrast, the *philosophes* of the French Enlightenment like Condorcet believed reason to be the key factor in historical progress. The rational acts of enlightened individuals, and particularly of utilitarian science, moved history forward, while ignorance and war held it back. In Germany, Kant and Herder made historical progress the work of philosophical and moral reason. History was the progressive fulfillment of humanity's moral and spiritual destiny, realized through the unique development of each historical people.

Emerging in contested political arenas, the early theories of progress staked out ideological positions of longstanding influence in politics and the social sciences. Designedly, Smith's view lent itself to a liberal presumption against state action; Condorcet's view, to a justification of the authority of social scientists in the guidance of society; and Kant's view, to a liberalism subordinated to idealist ends. If the reliance on progressive reason assigned all evil to its reactionary enemies, the Scottish view recognized that progress involved secondary losses. Smith's critique of the diminished life of industrial labor began a longstanding discourse that made progress itself responsible for the problems of modern society.

2. The Nineteenth-century Triumph of Progress

The French Revolution raised the stakes for both progress and social science as the millennial hopes it aroused were projected into the secular future. Progress became the dominant view of history among the educated classes of Europe and North America, while contesting versions of progress proliferated. Responding to rapid capitalist development and the continuing possibility of political and social revolution, theorists of political economy, sociology, and anthropology recast the eighteenth-century theories of progress and sought to specify the factors that controlled the course of history.

The classical political economy that developed from Smith focused on the natural laws of economic growth and, of equal importance, on how the expanded product would be distributed. The question of whether the average workman would be better off, despite growing inequality, became urgent as egalitarian, utopian versions of progress appeared. The Reverend Thomas Malthus argued that food supply would keep

wages at subsistence level. His political economy, informed by an Anglican reading of history, supported a cautious view of progress, incorporating cyclical movement and the necessity of suffering. The theories of David Ricardo were often pressed into this mold, though most practicing economists, including Ricardo, maintained a more optimistic scenario of growth based on capital accumulation. By mid-century, recognition of the role of technology in increasing productivity shifted the weight of economic opinion toward more optimistic predictions of growth (Berg 1990).

American exceptionalists and socialist radicals transformed this liberal political economy in opposite directions. Henry C. Carey argued that the uncultivated American continent would abrogate altogether the action of Malthusian law, vindicating America's utopian historical course (Ross 1991). Socialists, charging the capitalist economy with the degradation of workmen and the destruction of community, made capitalism an intermediate stage, to be superseded by socialism. In Karl Marx's formulation, history progressed by a process of historical contradiction between the forces and social relations of production: capitalism produced within itself the revolutionary proletariat that would destroy it and the technological basis of abundance that would support socialism (Cohen 1978).

August Comte, inheriting Condorcet's identification of historical progress with progress of the human mind, made social science its central agent. Civilization moved by necessary law from the theological to the metaphysical to the ultimate stage, the scientific, still struggling to be born. Although this trajectory was inevitable, action in accord with historical law could ease the transition. A new science of society, sociology, would objectively examine the world as it is and, based thereon, set out a plan for the rational ordering of society, opinion, and feeling (Lenzer 1975). Herbert Spencer's version of sociology, influenced by liberal political economy and Scottish philosophical history, removed the central planning role from sociology, but gave it the same power to discern the laws of historical progress to which successful social action must conform. More complacent about his own era, Spencer believed that the industrial age would encourage moral, intellectual, and social improvement. Spencer turned historical progress into a process of social evolution, drawing on biological notions of adaptation to the environment, the inheritance of acquired characteristics, and an embryological model of differentiation to form a cosmic law of evolution (Peel 1971).

Charles Darwin's *The Origin of Species* (1859) reinforced both the idea of progress and the use of biological analogy. Despite the radically nonprogressivist implications of natural selection, Darwin's theory, with its suggestion of the continuity of animal and human life, was often read in this era of faith in

progress—even by Darwin himself—as a proof of the progressive character of both evolution and history. The contemporaneous recognition of the long age of the earth created a space for ‘prehistory,’ solidifying the uniquely advanced position of European civilization (Segal 2000). Social scientists developed a ‘comparative method’ that sorted peoples and races on an evolutionary grid, assigning them to stages of a single evolutionary process by Euro-centered hierarchical standards, although that gradient was always subject to Romantic subversion (Bowler 1989).

3. *The Problem of Progress, 1890–1914*

During the late nineteenth and early twentieth century, the social sciences formed specialized, university-based disciplines, in part to grapple with the accelerating problems of modernity. As industrialization, democracy, and imperialism transformed society, Enlightenment hopes for modernity took chastened forms. At the same time, more stringent conceptions of science outlawed deterministic laws of history like those of Comte and Spencer as metaphysical constructions and called attention to the moral valuation inherent in the concept. By the early twentieth century, the rediscovery of Mendelian genetics attenuated the link between evolutionary biology and historical change, and critics, notably anthropologist Franz Boas, attacked the comparative method and its assumption of a single line of evolutionary advance. Progress no longer appeared to leading social scientists as an inevitable, universal process, guaranteed by natural or historical law. Yet the question of what form, and how beneficial a form, modern society would take remained central as did many nineteenth-century terms of discussion.

In economics, marginalism shifted the focus of attention from economic growth to allocation. Those who joined the mixed neoclassical discourse that resulted grounded capitalism in laws analogous to the laws of physical nature and retained optimistic assumptions of economic growth and its central role in social advance, but those assumptions no longer framed their specialized and dehistoricized discourse. Other economists who sought a qualitative change in capitalism worked within a self-consciously historical or institutional framework, like the socialist Thorstein Veblen, who asked in 1899 ‘Why Is Economics Not an Evolutionary Science?’ (Ross 1991).

Sociologists narrowed their focus to the tendencies of modern society. In Germany, where antimodernist attitudes flourished, sociologists were most pessimistic. For Ferdinand Tönnies and Max Weber, traditional community (*Gemeinschaft*) and modern capitalist society (*Gesellschaft*) marked polar modes of social organization. The impersonality and loss of spirituality of modern society were inevitable con-

sequences of its organizing principles. Weber, more than Tönnies, saw the positive advantages of instrumental rationality, yet termed the framework it built for modern society an ‘iron cage’ (Liebersohn 1988).

Emile Durkheim, like American sociologists, retained the more hopeful nineteenth-century formulation that placed the present troubled society in transition to a more harmonious modernity. Durkheim (1933, [1893]) argued that a new kind of functional and normative social integration was forming; the anomie of individuals thrown outside the regulative norms of society by the upheavals of social transformation would subside as modern society reached equilibrium. Edward A. Ross posited a transition from the natural social control of face-to-face community to the more fragile, ‘artificial’ controls of modern society, similar to the German model of *Gemeinschaft/Gesellschaft*, but he too expected that a harmonious adjustment would be reached (Ross 1991).

It was primarily in thinking about their own role in modern society that social scientists returned to, and reaffirmed, the central role of science in progress. In his presidential address to the American Psychological Association in 1899, John Dewey expressed both the anxieties of modernity and the solution favored by his colleagues. ‘With tremendous increase in control of nature,’ he noted, ‘we find the actual realization of ends, the enjoyment of values growing unassured and precarious.’ But, he added ‘the entire problem is one of the development of science and of its application to life.’ When the social sciences are further developed, ‘we can anticipate no other outcome than increasing control in the ethical sphere’ comparable to ‘the revolution that has taken place in the control of physical nature’ (Dewey 1976, 1: 149–50). That science itself progressed, that it produced increasing control over nature and social life, and that such control worked to the benefit of humanity remained unquestioned. This faith served as the ideological basis for the social science disciplines.

4. *Progress Dethroned, 1914–1945*

The most severe challenges to the idea of progress occurred in the decades spanned by the two world wars: economic depression, totalitarian politics, and wars that unleashed mass destruction made possible by modern science and technology. At the same time, the intellectual and cultural changes that had undermined the idea of progress in the late nineteenth century gathered force after World War I. A sharp sense of historical discontinuity, breaking off the new world of mass production, mass consumption, and mass politics from the past, also broke the sense of cumulative gain in civilization on which progress depended. Historians mark World War I as the end of progress both as an unquestioned public faith and as

an idea that social scientists could presuppose or hope to demonstrate.

What remained open was the possibility of limited lines of progress, as human constructions, and the hope, still carried by the Marxist and liberal traditions and in the USA by an exceptionalist historical faith, that limited the gains worked toward the larger progress of history. Thus the American sociologist William F. Ogburn explained that social scientists had dropped the term progress and were instead studying 'social change,' as a 'term free from dogmatic or moral implications.' Social change is caused by inventions, Ogburn argued, but inventions occur unevenly, creating 'lags' until society 'adjusts.' In his analysis, however, adjustments can always be made and society was always better off when they were. Progress was not so much abandoned as forced underground (Ogburn 1930).

The point at which it remained still vibrantly alive, especially in the USA, was the faith in science. The new understanding of science itself suggested that if science did not mirror reality, it could more readily reconstruct reality to human purposes (Porter 1994). While Ogburn was moderate in his hopes for prediction and control, other American social scientists of the 1920s, like the behaviorist psychologist John B. Watson and the political scientist Charles Merriam, expressed utopian faith in science and technology (Ross 1991). A more sober tone emerged throughout the West in the 1930s, but the possibility of historical progress through science remained a central feature of American social science theory and ideology.

5. The Return of Progress, 1945–1970

In the decades after World War II, the vision of a progressive modern society guided by science gained energy and urgency from the defeat of fascism, the disintegration of colonial empires, and the threat of communism. As the strongest power to emerge from the war, the USA embraced that vision with renewed self-confidence. In what was experienced as the 'American Moment' of an 'American Century,' the USA already appeared to stand at the summit of world history ready to embody the values its exceptionalist history promised.

This static notion of historical time was mirrored in social science theories of functionalist, cybernetic, and equilibrium systems that nonetheless incorporated the idea of progress. The sense of progress achieved was embodied most visibly in modernization theory, which measured the distance the underdeveloped world still needed to traverse to achieve the American or Western norm (Latham 1999).

Modernization theory also marked one of the many points in these decades at which the social scientists' ideology of progress through social science entered into the substance of social science theory. Thus modernization was defined as a 'process of social

change that seeks to govern itself by rational policy planning' for which social scientists were 'indispensable' (Lerner 1968). Talcott Parsons suggested that academic intellectuals and the practical professionals they trained had become 'the most important single component in the structure of modern societies,' displacing from leadership the older political and newer capitalist class (Parsons 1968).

The possibility of progress, along with the liberal and Marxist traditions in which it was imbedded, revived in Western Europe with postwar reconstruction, although with far greater circumspection. In Germany, Jürgen Habermas blended native Marxist traditions with American theories of pragmatism and democracy to project not a utopian future, but an ideal against which modern society might measure its defects (A. Giddens on Habermas, in Skinner 1985). The dehumanizing character of modern society remained a powerful, and sometimes dominant, theme in German sociology.

The idea of progress and its drawbacks also played a conspicuous role in the development of the social sciences in the non-Western world. As an arm of secular, Western-style development, the social sciences had been since the nineteenth century a major site of debate over whether Western or native paths to modernity should be chosen. After World War II, the developing world also served as a major source of critical revision of Western conceptions of modernization, recasting modernization as economic dependency, or redefining tradition and modernity as mutually transformative rather than diametrically opposed processes.

6. Postmodernism and Progress

Political conflicts in Europe and the USA in the 1960s shattered the American Moment, opening the way for longstanding discontents with modernity and reconsideration of the idea of progress (Salomon 1955). The most radical challenge—the postmodern critique of modernity—emerged in the home of the rationalist Enlightenment. Francois Lyotard attacked the idea of progress, with its universalist and rationalist premises, as the basis of the most oppressive, totalitarian impulses of modern Western society. Michel Foucault pointed specifically to the professions and social sciences as the source of the knowledge/power that disciplined the unruly masses of modern society in the name of enlightened rationality. The pluralistic and libertarian values that animated this critique gained power from the increasing reach of Western capitalism into every area of the world and the proliferation of multi-ethnic societies. Globalization in the post-modern reading was producing not a single narrative of universal progress, but a pluralistic, hybrid world of many historical narratives. However, as the term post-modern suggests this vision can be read as a liberationist narrative of progress, drawn from Romantic,

rather than Enlightenment, strains of modernity (McGowan 1991).

This pluralistic vision had some influence on the social sciences as a support of feminism and multiculturalism within the USA and as a counter to Americanization elsewhere. The liberal, Western-centered idea of progress revived, however, on the strength of the free-market neoclassical paradigm in economics, with its presumption of capitalist-led progress, and a revival of the narrative of American exceptionalism after the fall of communism. Globalization in that context defined progress as the Americanization of the world.

The most fundamental aspect of the postmodern critique of progress, however, was its critique of scientific reason. Here, postmodern critics joined broader currents of philosophical criticism of positivism and analysis of the linguistic and social construction of knowledge. Although Thomas Kuhn argued that *The Structure of Scientific Revolutions* (1962) did not destroy the idea of scientific progress, it did radically remove the sciences from a universalistic narrative of the progressive discovery of truth and resituate them in a social-historical world of shifting purposes and uncertain directions (B. Barnes on Kuhn, in Skinner 1985). Most social scientists in the USA have not paid attention to the philosophical debates around this work. Indeed, in those segments of social science identified most closely with mathematics and natural science, like economics, older positivist understandings of science are especially powerful (Backhouse 1997). However, the context of critique has weakened the self-confidence, and with it, the ideological construction of the progress of social science, among other segments of the social science disciplines. While the eighteenth-century formulation of historicism as the story of progress gave the social sciences their charter, the critical historicism of the late twentieth century called for a reformulation of both the historical assumptions and the self-understanding of the social science disciplines.

Progressive Education Internationally

Progressive education (*éducation nouvelle*, *Reform-paedagogik*) is an international movement which originated in Western Europe and North America by 1900 in different national contexts. It can be seen as a reaction to the decisive educational fact of the nineteenth century that, with the introduction of compulsory schooling, education had been achieved for everyone in the younger generation, even the inhabitants of the smallest rural villages, even the inhabitants of the working-class areas of growing big cities.

Education thus institutionalized as a system for the masses showed its deficiencies. Progressive education tried to overcome these defects while maintaining education for all.

1. *Origins and International Spread*

Progressive education started in the UK with the 'new schools' such as Abbotsholme, founded by Cecil Reddie in 1889; Bedales, founded by John H. Badley in 1893; and King Alfred's School, set up by a group of parents in northwest London in 1898. A generation later, Alexander S. Neill, a former teacher at King Alfred's, who had been in contact with child-oriented education in Homer Lane's self-governed 'Little Commonwealth,' and who had grounded his experiences in psychoanalytical theory, founded Summerhill in 1921 as an experiment of antiauthoritarian education.

Progressive education in the USA is linked with the practical and theoretical activities of educators, such as the Columbia University teacher trainer William H. Kilpatrick with his famous project method; the school superintendent of Winnetka, Illinois, Carleton Washburne, who successfully modeled the schools of his district on progressive principles; the Harvard psychologist William James, who was influential on progressive pre- and in-service teacher training; Helen Parkhurst, who in her Dalton Plan developed an institutional model of individualized learning; Jane Addams of Hull House, Chicago, who introduced progressivism into social work; and above all John Dewey (see *Dewey, John (1859–1952)*), who gave progressive education a sound foundation in pragmatist philosophy.

In the French-speaking countries of Europe the French primary schoolteacher Célestin Freinet, the inventor of the methodology of the *école moderne*, a prominent feature of which is 'the printing press in school,' the Swiss cofounder of the Geneva International Bureau of Education, Adolphe Ferrière, with his idea of the *école active*, where the children were to make their own textbooks as a result of their learning processes, and the Belgian medical doctor Ovid Decroly, the founder of the reform school L'Eremitage in Brussels, are key figures of the *éducation nouvelle*. In Italy, the most prominent representative of progressive education is the preschool educator Maria Montessori, who through her specifically designed didactic materials introduced the idea of self-directed learning into early childhood education. In Germany, the basic patterns of the English new schools were institutionalized by Hermann Lietz and Paul Geheeb in their 'rural education centers'; the Munich school superintendent Georg Kerschensteiner brought learning and practical work more closely together in his 'working school' concept; and the director of the Hamburg art gallery, Alfred Lichtwark, inspired the art education movement. In the Scan-

dinavian countries, the Swedish teacher Ellen Key published the 1900 programmatic pamphlet of progressive education 'The century of the child.'

With the school Lev Tolstoy had erected at his estate in Yasnaya Polyana, progressive education was prepared in the USSR. Stanislav T. Šackih, who had transferred the Anglo-American idea of the settlements into summer camps for children even before the Soviet revolution, built the bridge between progressive and Marxist ideas in the education of the early USSR. The main propagator of melting progressivism into a Marxist–Leninist perspective of education was Pavel P. Blonsky, with his program of the production school. For realizing these efforts in educational policies, even more influential was Lenin's wife, Nadeszhda Krupskaya. The Polish physician and orphanage educator, Janusz Korczak, sealed his view of the dignity of the child by accompanying the Jewish children entrusted to him into the Holocaust.

By the end of World War I, progressive education had grown from local and individual initiatives into national movements and even, despite the nationalist cleavages the war had evoked, into an international network. The founding of the American Progressive Education Association in 1919 and of the international New Education Fellowship in 1921 mark the beginning of that new phase of the movement.

Progressive education now spread from its countries of origin into other parts of the world. Theoretical forerunners, like Tomer Tanimoto and Kanjiro Higuchi, transferred progressive ideas to Japan which were later on institutionalized in experimental schools. Small group education, self-directed learning, and the working school were tried out by educators like Heiji Oikawa, Kishie Tezuka, and Taneichi Kitazama. Progressive education with its more individualist though socially responsible approach became an oppositional force against the nationalist imperialism that led Japan into World War II. Brazil is a good example of the adaptation of new education to the Latin American context. It was especially the 'three cardinals'—Lourenço Filho, who made efforts for a psychologically grounded theory of instruction, Fernando de Azevedo, who was envisaging the structural reform of the Brazilian education system, and Anísio Teixeira, who was striving for a democratic educational policy—that were defending educational progressivism against the conservative Catholic educational theory of the country. Later on, these progressive impulses merged with elements of the 'educação popular.'

On the African continent a mass education system in the 1920s was not yet developed. Consequently there was only a scarce influence of progressive education on the educational activities of the African countries. The school farms and school workshops of different missionary societies linked primary schooling for students and adult literacy programs to manual and agricultural activities. The Phelps–Stokes Com-

mission, which in 1919 evaluated the education situation in the British territories of Africa recommended a practical orientation toward basic education. The skills taught at school should be directly useful in family and community life. In Kenya in 1925 there was an attempt to train teachers as community development workers.

On the Australian continent progressive education was 'very much a series of side eddies, and not the main stream of education' (Connell 1995, p. 351), but teacher educators such as G. S. Browne of the University of Melbourne had acquainted their students with the Dalton Plan or the project method, or the educational philosophy of Dewey.

A quantitative content analysis of educational journals proved that by 1930 progressive education concepts had become the leading educational semantics worldwide; progressive education had indeed developed into an international movement (Schriewer et al. 1998).

2. *Core Elements and Comprehensive Principles*

The intertwining educational philosophies, political semantics, pedagogical programs, theories, projects, foundations of institutions, and teaching methodologies which progressive education consists of are not easily summarized. In spite of Cremin's verdict concerning a capsule definition of progressive education—'None exists, and none ever will' (Cremin 1961, p. x)—the common structural origin and the mutual international criticism of progressive educators, which distinguished between that which was pluralistically proven and that which was blinded by ideology, allow for pointing out some core elements or comprehensive principles and practical approaches of progressive education. These can be reconstructed by looking at the classic historical accounts of Cremin (1961), Boyd and Rawson (1965), Mialaret et al. (1976), or Roehrs (1998b), which together with Roehrs and Lenhart (1995) at the same time contain biographical and work-related references to the aforementioned progressive educators:

(a) Progressive education stood for the democratization of the industrial society by opening up chances of participation on an educational basis. This referred to the induction into technical-industrial processes of production and their social structuring as well as to the authorization to the exercise of political rights. Progressive education brought (sub)cultural group identities into focus. The concept of enabling the individual to cooperate included social feedback on the individual possibilities of action that were opened up by education. The interrelations of society as a whole were thus changed via the spheres of proximity of everyday life. An expression of this is the community-oriented approach of progressive educational endeavors. Education is conceived as an aid for everyone to cope with life.

(b) Progressive education is distinguished by its orientation toward the child's individuality. This means a child-centeredness that provides the educands with enough time to find and do things themselves while playing and learning. In life philosophy's metaphor of the 'opening of the eye,' the pedagogical effort is to let the children themselves experience and recognize 'things.'

Progressive education's intellectuality includes a new relationship to the body. The model is a simple, healthy life-style: there is no cult of athletics, but no neglect of the body either. The concept of human nature is rather pragmatic or positivist—Mialaret et al. (1976, p. 12), following Freinet, 'mechanize the functions (of the body) with the aim to free the vigor of life for the use of the higher activities of the mind.' It does not rule out an ultimate religious bond, but does not put it to the fore either.

(c) As a classical-modern reform movement, progressive education is (social and behavioral) science-oriented. It holds that a scientific foundation for and advice on practical education are both possible and necessary. The concept of science here is pluralistic, including different paradigmatic orientations. Progressive education above all refers to psychology, especially developmental psychology as it was constituted in empirical research and theoretical construction, for example in the works of Piaget (e.g., 1963). Next it refers to a sociology as it was put in concrete forms by J. Dewey (e.g., 1966) or G. H. Mead (e.g., 1967; see *Mead, George Herbert (1863–1931)*), for instance, with a pragmatic intention. Finally, it refers to education as an academic discipline as well, as this has, in its idealist-humanistic variant, become almost an accompanying theory of the German pedagogical reform projects.

(d) Progressive education at its heart is a school reform movement. The evolution of school as an educational institution is not completely to be reversed; still, teaching and learning at school is to be brought closer to the learning processes taking place in the family, workshop, workplace, and community. At the same time, the roles of those who encounter each other at school are changing. There is a friendly relationship between teachers and pupils, based on partnership and companionship, and the opportunities of involvement stretch as far as to the rights of participation ('government') in school communities. Progressive education disseminated into further educational fields apart from school: parallel to school and partly supported by the reform movement, kindergarten education, adult education, and social work were irreversibly institutionalized as fields of pedagogical action in their own right.

(e) As heritage of the philanthropist education of the Enlightenment, progressive education is concerned with a free relationship within educational interaction. This is especially manifest in teaching. The reformers invent, or at least accentuate newly, 'the teaching

dialogue, small group teaching, the various sorts of projects, (the) use of teaching aids, (they emphasize) self-governed activity..., (they aim at) a plurality of teaching methods, that (cause) as an “education by peers in the classroom” ...a change in the direction of the activity’ (Roehrs 1998, p. 319). The change of direction finds expression especially in those didactic models that transfer the planning of work and learning at least partly to the pupils. While acquiring and applying a basic knowledge on methodology the children prove their self-governing abilities.

3. *Progressive Education in Practice—Two Examples*

What internal reform of the school on progressive lines means in detail can be illustrated by the famous project method. This approach was theoretically explained by Kilpatrick (1918) and in the following decades practically spelled out worldwide in many variations (cf. Kliebisch and Sommer 1997). For Kilpatrick, a project was a ‘wholehearted purposeful activity proceeding in a social environment’ (Kilpatrick 1918, p. 330). This formal definition covers different project types which the educationist structures according to learning objectives and content matter, but he also gives hints to classify them into the categories of individual and group projects. A project has four phases: ‘purposing, planning, executing, and judging.’ The learners take all steps autonomously; the teacher only interferes if they are asked for advice or if the learning process is threatened by total failure. Later on, Kilpatrick embedded the project method into his philosophy of the school and of teaching procedures:

(1) Count that the school is properly a place of living. Work for the finest quality of living that teacher and pupils can together devise, reaching out as much as feasible into the community... (2) Let the principles of interest and purposeful activity set the predominant pattern... (3) Run everything on a basis of democracy and respect for personality... (4) Work in season and out, depending on pupil maturity and development, for the finest and most inclusive aims of life, these to be increasingly exemplified in everything done in school and out.’ (Kilpatrick 1959, p. 429)

Progressive education in its linkage to social work can be illustrated by the example of Jane Addams. Although she wrote several books and contributed articles to academic journals (e.g., the *American Journal of Sociology*), the focus of her activities was not the production of academic theory but practical political, educational, and social work efforts. These activities had their institutional basis in Hull House, a community center which Addams had set up in a Chicago slum area in 1889 after the model of the English ‘settlements.’ For 46 years the house under her leadership has been a center that has intervened in local educational policies to improve the educational

situation for immigrant children, organized its own educational activities—such as a Shakespeare Club or a Working People’s Science Club—provided meals for the poor, and improved hygiene standards by establishing public baths. Production and consumption cooperatives were operating; for some ‘residents’ common households were organized. Hull House built the first public playground in Chicago, and coinitiated the Juvenile Protection Association, which, through social activities and political pressure (e.g., on shop owners who sold alcoholic beverages to minors), tried to prevent youth delinquency. Addams and her friends succeeded in having a youth court set up that was no ordinary criminal court but acted *loco parentis*. The house was active in reducing child labor, and it fought against the ‘white slave trade,’ the ‘import’ of young women for prostitution. Hull House supported the trade unions, backing up the laborers in conflict situations, such as the big Pullman strike of 1894. The activities of Hull House finally contributed to the differentiation of sociology and social work theory and—against Addams’s intentions—to transform social work into a profession (Eberhart 1995).

4. *History or Ongoing Movement*

Historians of education dispute the question whether progressive education was a historical movement in its time or whether it is a continuous ongoing stream of theories and activities. US theorists such as Sol Cohen (1995) tend to see it as history (and the US school reform efforts of the 1990s even as a countermovement to restore the moral-intellectual discourse of education), while the German contribution of Oelkers (1996) doubts whether there was an epoch of progressive education at all, and that of Roehrs (1998b) conceives of it as a continuing story. The overt history of progressive education in the USA ended in 1955 when the Progressive Education Association was dissolved. In fascist Italy and Germany progressive education with its liberty-oriented and democratic tendencies was politically banned, and some of its German proponents, such as Kurt Hahn, the director of the famous Salem School, were driven out of their home country. A few others, however, such as Andresen, Lietz’s successor in the leadership of the rural education centers, tried to establish links to Nazi ideology, thus enabling several measures of progressive education to be abused by totalitarian educational practice. In the USSR progressive education was suppressed by Stalin’s dictatorship from the early 1930s. He even threatened Krupskaya with using another woman to ‘replace’ her as Lenin’s widow, unless she stopped publishing about polytechnic education.

Conversely, the New Education Fellowship, as the organization of the progressivists, made important contributions to the establishment of UNESCO (United Nations Educational, Scientific, and Cultural

Organization) within the United Nations (UN) system after World War II. Many progressive education institutions have continued their activities into the present. More important, perhaps, is the fact that since the 1950s progressive ideas and practices have trickled down into the day-to-day activities of education worldwide. In this reduced form the movement is still a reservoir of innovation, and this is reflected in the alternative schools that have been established from the 1970s onward. The progressive movement has even made contributions toward meeting the most recent educational challenges, such as peace education, multicultural education, and human rights education. These must now be transformed creatively to build the 'four pillars of education' enumerated by the International Commission on Education for the Twenty-first Century: 'learning to know,' 'learning to do,' 'learning to live together, to live with others,' 'learning to be' (UNESCO 1996, pp. 86–96).

Projective Methods in Psychology

Projective techniques is a term that encompasses any test or procedure designed to increase insight into individuals by allowing them to respond freely to ambiguous stimuli. The underlying assumption is that, when faced with unstructured or ambiguous stimuli, people will reveal aspects of their personality in their attempt to structure the material. In other words, the vague quality of the stimulus evokes free fantasy play and triggers projection on the part of the subject while simultaneously revealing aspects of psychological functioning in the nature of their responses. Many experts believe that everything said or written in response to a stimulus has dynamic meaning and that people reveal conflicts, anxieties, attitudes, beliefs, and needs in their attempt to structure or complete an incomplete stimulus. Projective techniques tend to have brief, general instructions that, when coupled with ambiguous stimuli, tend to elicit less defensive responses than more structured testing. It should be noted that a concern about conflicts, anxieties, attitudes, beliefs, and needs, and the usual attempts to blend these into a picture of a person, is most closely associated with one approach to personality, the psychoanalytic approach. A preference for psychodynamic theory is not required in order to use projective techniques, but it is frequently found. Perhaps this is because one of the hallmarks of the psychoanalytic approach is the prominent role assigned to unconscious processes, and projective techniques are designed with the intention, satisfied or not, of eliciting unconscious material. (see *Psychoanalysis in Clinical Psychology*).

1. Historical Overview

Historically, the turn of the twentieth century was a time when psychological testing was applied predominantly for the study of intelligence. The trend was

toward finding data or norms descriptive of groups of people (nomothetic data). At this time, personality measures tended to examine only a single trait at a time (e.g., introversion/extroversion, flexibility). The scope began to broaden about two decades later when interest surfaced in tests that yielded specific data about an individual (idiographic data). In the early 1920s, projective testing emerged when Rorschach ([1921], 1942) developed his now famous inkblots in an attempt to aid in the diagnosis of schizophrenia.

The notion of projection with these tests gave birth to the progression of projective techniques throughout the rest of the twentieth century and the belief that ambiguous stimuli can be used to gain insight into the dynamics of the respondent. Frank (1939) coined the term 'projective methods' to describe a variety of techniques used by clinicians with ambiguous stimuli that pull for projection. He postulated a projective hypothesis, namely that the world is structured according to internal needs and external demands, so that ambiguous external stimuli will elicit structuring based on internal factors. The 'Projective Movement' grew tremendously during the 1940s and 1950s, as clinicians moved away from the nomothetic approach to studying their patients toward the more idiographic approach. More recently, because of psychometric considerations, and possibly because of a reduction in the number of clinicians trained in psychodynamic approaches, the use of projective techniques has waned, leaving an open question and considerable controversy over the value of the projective approach.

Perhaps the most commonly used projective techniques are the Rorschach, the Thematic Apperception Test (TAT), figure drawings, and sentence completion tests.

1.1 Rorschach

The use of inkblots was not a new concept in the 1920s. In fact, a popular game among children at the time was Blotto, in which children used bought or handmade blots of their own. Rorschach's clinical interest in the use of blots was sparked in 1911, while working with Eugen Bleuler, his professor and supervisor, who coined the term schizophrenia and instigated the need to differentiate schizophrenia from other forms of psychosis. Rorschach believed that the process of perception, as a respondent struggles to make sense of an ambiguous stimulus, reveals the threshold of each respondent to assimilate or integrate the new stimulus with existing mental images. Rorschach happened to observe in his work that schizophrenic patients tended to respond differently in Blotto than patients with other forms of psychosis or dementia, and decided to study this phenomenon more systematically. By 1921, he had administered the test often enough to believe in its usefulness as a diagnostic aid in identifying schizophrenia, but noted

unexpectedly that increased frequencies of certain kinds of responses were consistent with certain personality traits or styles. Rorschach died in 1922, but his successors saw the potential of his tool as an idiographic, projective measure and worked over the next two decades to develop a standardized scoring system for responses to the inkblots.

Samuel Beck was a psychology graduate student who attempted, shortly after Rorschach's death, to do a standardization study as a dissertation topic. He began his work at the Institute for Child Guidance in New York and later took positions at both Boston Psychopathic Hospital and Harvard Medical School. Over the years he gained extensive experience with the use of the inkblots and became acutely aware of the need for more intensive work toward standardization.

Around the same time, Bruno Klopfer came to Zurich to work as a technician at the Zurich Psychotechnic Institute where Rorschach inkblots were routinely used in the screening of candidates for employment positions. After working there for several years, he emigrated to the USA in 1934 and began working at Columbia University. The psychology graduate students at Columbia, who were frustrated by the lack of formal training available in the use of inkblots, were eager to have him share his experience with them. Klopfer began giving informal seminars to students and, in his work with these students, began to develop new scoring codes that seemed necessary, especially those for unusual locations or shading responses. Thus, by 1936, Klopfer was working hard to expand the existing coding system.

At the same time, Beck was busy writing papers that criticized the existing scoring systems for their lack of empirical soundness. He approached Klopfer's attempts to expand the system with criticism. Over the next 20 years, the arguments continued and different scoring systems were attempted. Despite this controversy over scoring, the method of using the Rorschach continued to burgeon. By 1957, five vastly different scoring systems had emerged.

John Exner began to study the difficulty with using inkblots in 1968. Between 1968 and 1972, he found that most clinicians were scoring the tests in a haphazard manner. Many did not score it at all, and those who did tended to use features of different scoring systems. Only a small minority used one system to score an entire test. Exner set out to develop a system that integrated features of all the available scoring systems that had empirically defensible data, and a system that was not wedded to any single personality theory. Thus, he developed the comprehensive system that is still used by many clinicians and that includes the successful work and research that accumulated from the 1920s onward. The system developed by Exner (1993) is probably the most widely used at the beginning of the twenty-first century, but many clinicians continue to treat the Rorschach purely as a projective device, rather than as a psychometric

instrument, and simply interpret the content of the responses according to their understanding of personality. It should be noted that there are several sets of ambiguous stimuli, usually inkblots, that are in use, but the Rorschach is by far the most popular.

1.2 Thematic Apperception Test

In 1935, Morgan and Murray introduced the Thematic Apperception Test (TAT; Murray 1943), a series of provocative pictures used to explore the respondent's dynamics. The stimuli are more highly structured than inkblots and respondents are required to give more meaningfully organized verbal responses. Respondents are asked to describe the scene in the picture, the apparent emotional content and thoughts of the people involved, what led up to the scene, and what the outcome will be. This test was developed on the premise shared by other projective techniques that people reveal something of their own personality (i.e., their motivational and emotional condition), as well as their cognitive structure, when ascribing thoughts and feelings to ambiguously drawn characters. Just as with the Rorschach, many sets of pictures have been developed for use as an apperceptive approach, but the TAT remains the most widely used.

Perhaps the most popular scoring method for this test is that devised by David McClelland (McClelland et al. 1953). McClelland's work was devoted to measuring achievement motivation and he scored the TAT responses across seven dimensions: (a) stated need for achievement (someone in the story expresses a desire to achieve a goal); (b) instrumental activity (whether the outcome of the instrumental activity is successful, doubtful, or unsuccessful); (c) anticipatory goal status (whether the person in the story anticipates achieving the goal or being frustrated by it); (d) obstacles or blocks (whether the goal in the story is blocked by an obstacle); (e) nurturant press (whether there are nurturing forces aiding the characters in goal achievement); (f) affective states (emotions present associated with achieving or being frustrated by the goal); and (g) achievement themes (when achievement imagery is the focus of the story).

TAT responses have been studied and scored in a variety of ways, with McClelland's approach being only one example. By far the easiest and most commonly used method among clinicians is simply to read the responses, look for common themes, treat the stories as psychologically meaningful communications, and consider them as projective tools for understanding the patient's underlying conflicts and needs.

1.3 Figure Drawings

Figure drawings are a series of drawings by the respondent that the clinician uses to understand nonverbal expressions of the self. Respondents are

asked to draw a full person (gender not specified ahead of time), and then to draw a person of the opposite sex of the first drawing. The absolute and relative size of the persons are examined as well as details such as the position on the page, the quality of the lines, the sequence of parts drawn, the stance, position of the arms, and grounding effects. Clinicians have often found these drawings helpful in understanding the self-perception, motor expression, anxieties, and needs of the respondents. Variations of this task ask the respondent to produce other drawings, including drawings of objects such as a house or a tree. In general, regardless of what is drawn, the research with these approaches has not been very encouraging (Swenson 1968).

1.4 Sentence Completion

Sentence completion is another method for gathering information about personality dynamics. Respondents may be asked, orally or in writing, to complete sentences that are vague and ambiguous (e.g., What worries me ... ; Women ... ; My mother ...). In addition, there have been standardized written sentence completion tests developed by authors such as Rotter (Rotter and Rafferty 1950). As with the TAT and other apperceptive measures, the value of the task often is dependent on the particular set of items that is employed, and the more closely the items approximate the target being studied, the more valuable the responses can be shown to be.

2. Psychometric Considerations

A psychological test or assessment device is subject to evaluation on standard dimensions and, regardless of how compelling a rationale may be, must demonstrate that it meets the usual psychometric criteria before it can be considered to be useful. Foremost among these criteria are reliability and validity (for a more detailed explication of these critical concepts, see Wiggins 1973).

2.1 Reliability

Reliability refers to the extent to which a test provides a consistent measure of what it is measuring. If a test lacks reliability it is akin to using a rubber ruler, providing different measurements each time it is applied, and there is little credence that can be given to any of those measurements. One approach to the measurement of reliability is through retest, with the expectation that a test given on two occasions will produce the same response on both testings. A second approach is internal consistency, which assesses the extent to which every item in a test is measuring the same characteristic.

Although most projective techniques employ many items, the items often are designed to be responsive to different dimensions, and so a projective test may often be seen as a collection of disparate single items rather than a collection of redundant items. Unfortunately, in measurement, redundancy is often desirable, and it is well demonstrated that single items are subject to far more unreliability than collections of items, in which errors may cancel each other out. If there are indeed collections of single items, it can be argued that the test really is a collection of tests, each of which measures a single dimension (and therefore requires a separate assessment of reliability and validity), and does so in a way that reduces the reliability of each. A proponent of these tests would counter that the object being measured is personality, which contains several dimensions, and that the items should converge to produce a clear picture of the multidimensionality of the respondent. Whether or not this is so is a matter of validity.

2.2 Validity

Reliability is necessary but not sufficient for a test. An unreliable test cannot be valid, but a reliable test may not necessarily be valid. Validity is an assessment of the extent to which a test measures what it is intended to measure. This leads to a very interesting problem in assessing the validity of projective techniques. Most projective techniques purport to measure many different aspects of the person, and it is necessary to indicate the validity of every inference that a test draws. Thus, rather than asking, for example, whether the Rorschach is valid, it is necessary to ask, for each inference drawn from the Rorschach, whether or not that inference is valid. One statistical estimate cannot represent the validity of the test, and the general question cannot be answered (Stricker and Gold 1999).

It is not unusual for a research project to compare the validity of projective techniques with more objective, self-report, measures of personality (e.g., McClelland et al. 1989). The usual finding of such studies is that the two approaches do not correlate with each other. Some people have interpreted this as indicating a failure in the validity of the projective approach, a conclusion that assumes the validity of objective tests. Others have determined that this lack of correspondence indicates that each approach is valid, but that they are measuring different aspects of the person. This view suggests that objective tests are superior at measuring objective criteria, such as behavior, whereas projective approaches are superior at measuring more covert, unconscious aspects of the person (Hiller et al. 1999). This interpretation is consistent with the theoretical position that usually underlies each of the approaches to measurement.

It also is reasonable to ask whether the incorporation of a projective approach to a test battery adds anything to the process of assessment (incremen-

tal validity). If the conclusion about measuring different aspects of the person is accepted, then projective approaches do contribute incremental validity insofar as the assessor is interested in less overt aspects of the respondent. Given the length of time necessary for the administration and interpretation of projective techniques, the question of cost effectiveness also can be raised. The answer to this question probably is dependent on the individual circumstance. It should be clear, however, that validity, incremental validity, and cost effectiveness are separate questions, and the answer to one does not determine the answer to the others.

Finally, it should be noted that the subjectivity of the projective approach places great stress on the skill of the examiner, and any question of validity is equally a function of the ability of the approach to elicit material and the ability of the examiner to interpret it.

3. Concluding Comments

It can be concluded, with some certainty, that the original promise of the projective hypothesis (Frank 1939) has not been sustained, and that there are many limitations on the conclusions that can be drawn from ambiguous stimuli. However, there are instances in which such stimuli can be used to produce valid inferences, and inferences that cannot be drawn from other approaches to measurement. Whether these inferences are useful depends on the theoretical approach and goals of the examiner, whose skillfulness also must be considered in reaching a conclusion about the utility of projective methods. Because projective techniques do show the promise of providing valid information that is different than that produced by objective measures, it is a path worth pursuing. However, any pursuit will have to be marked by attention to psychometric considerations, a neglect of which has led to the excessive promise of past attempts.

Pronouns

Noun referents can be substituted by personal pronouns. In most contexts the pronoun is coreferential with and interchangeable with the noun to which it refers. Other pronouns determine nouns, some have the capability of doing both. In English, the personal pronouns substitute, the articles determine, and the demonstratives do both. These, together with indefinites, negatives, locatives, interrogatives, and relatives are grouped together as non-personal pronouns.

The word *tree* refers to an object in the real world (exophoric use), but *it* can have meaning only in referring to some noun such as *tree* by being coreferential with it (endophoric use). Within the linguistic context *it* can replace *tree* or any other noun of the same class—but not, for example, *man* or *trees*, which require special pronominal forms in English.

Pronoun sets can also be distinguished on the basis of case and emphatic differences. Not all pronouns are in fact interchangeable with nouns, such as the reflexives, the logophorics, and the sequentials. Pronouns may be morphologically free or bound, that is, they may be separate words or affixes.

Instead of treating pronouns as part of the lexicon, Everett (1996) argues for considering them to be composed of phi-features, such as case, gender, number, tense, and person. These phi-features are stored in the lexicon, their phonological shapes are given by postlexical or precompiled spell-out rules. (see *Clitics, Linguistics of; Morphology in Linguistics; Word, Linguistics of*.)

1. Personal Pronouns

The personal pronouns can be studied under the parameters of person, number, and gender distinctions, which vary considerably from one language to another.

1.1 Person

In the person parameter, the third persons (*he/she/it/they*) are usually used endophorically, whereas the first and second persons (*I, we, you*) are frequently used exophorically.

The only language with person but no number distinctions reported to date is Mura Pirahã, an unclassified Amerindian language (Brazil). First, second, and third constitute the only formal pronoun distinction this language has. One language has been found which appears to distinguish in the pronominal system two persons only: first and nonfirst. In the *Balante* variety spoken in Guinea-Bissau, *N*-(homorganic nasal) is used for 1sg, *ha-* for 2sg or 3sg, and *be-* for plural in any of the three persons.

Many languages have pronouns that combine 1 + 2 persons; that is, speaker and hearer, into an *inclusive* first person. This is in contrast to the 1 + 1 or first person *exclusive* category, in which the hearer is excluded explicitly. Some languages combine other categories as well, such as 1 + 3—that is, speaker plus one person not present; 2 + 3—grouping together one hearer and one person not present; and 3 + 3—grouping together two persons not present. In addition to binary combinations, the tertiary combination of 1 + 2 + 3 is sometimes used, where everybody is included explicitly (particularly the ancestors).

1.2 Number

The person distinctions are usually combined with number distinctions, singular and plural being the most common. When person categories are combined, making the smallest possible number two, or even three, it is more sensible to talk about a minimum-plural distinction. The most complex person-number combinations so far reported are found in Ghomala'

Table 1
Ghomala' subject pronouns

Person		Minimum	1pl	2pl	3pl
Mono	1	gǎ	pyǎ		
	2	o		po	
	3	e			wap
Double	1 + 2	pu		pə	
	1 + 3	pyǎ	pyayú		pyəapu
	2 + 3	poé		poayú	poapu
	3 + 3	pué			wap
Triple	1 + 2 + 3	pəayú	pəayú	pəayú	wəkpampu

(Bameleke, Cameroon). The plural categories have hierarchical order: first person comes before second, which comes before third.

Sursurunga (New Guinea) has what is probably the most complex number system in operation with mono, dual, triple, and quadruple, as well as four-person distinctions (Hutchisson 1986).

1.3 Gender

Gender distinctions are basically of two kinds: natural gender, such as masculine, feminine, and neuter (or animate/inanimate, human/non-human, for example), and grammatical gender having to do with noun classes. The latter is common in African and some Asian languages. Normally, gender distinctions are restricted to the third person, but may be found in other persons as well, particularly in possessive function.

1.4 Honorific Use

Many languages have special uses of pronominal forms for showing respect or social distance. Instead of the second singular, the plural may be used. Completely different pronouns can also be found. For Bangkok Thai, 17 different forms for first, 19 for second, and 10 for third person are in use, distinguished by such categories as power and status, kinship, friendship, occupation, ethnic-religious groups, age, sex, genealogical distance, solidarity, formality, presence of certain persons, emotional manifestations, and combinations of all these (Palakornkul 1975).

1.5 Special Meanings

There may also be unusual uses of person distinctions. Exclusiveness may be an added dimension to any of

the personal pronouns, though there are no special forms to mark the distinction. In several Amerindian languages the 1sg has the exclusive meaning of 'only I (speaker), but not anybody else,' whereas the second means 'only you (hearer) but not I' (speaker). The only pronoun which can be used inclusively is the 1pl form.

Other pronouns can have meanings which are not apparent from examining the system. In Kaingang (Je, Brazil) whenever a family unit is involved, the 3pl fem. form is used after the name of the man; the 3pl masc. is reserved for a group of men only (see *Classifiers, Linguistics of; Grammatical Number; Language and Gender; Language and Social Class; Numeral Systems; Politeness and Language*).

2. Nonpersonal

Nonpersonal pronouns are used in the third person only, but may vary in number and gender.

2.1 Definite

Demonstratives and articles are included in the series of definites. A distinction is often found according to where the determined noun is placed in relation to the speaker and/or the hearer, which gives a two- or three-way distinction, as when the locative adverbs are used pronominally.

In English:

- (a) *the* man is anaphoric: the already mentioned;
- (b) *this* man is close to speaker (often anaphoric);
- (c) *that* man is far from speaker (often anaphoric);
- (d) *this* makes me wonder if ...

This and *that* may be used as substitutes (exophorically) if the object is in sight (and in that case not necessarily anaphorically) or to replace arguments and other parts of discourse. In German the articles may substitute for the noun.

In Didinga (Nilo-Saharan, Sudan) separate forms exist for information that is generally known as against

exclusive knowledge of the speaker; or whether the pronoun refers to a happening long ago or recently, or whether the person was referred to recently or much earlier.

2.2 Indefinite

A number of languages also have indefinite pronouns, referring to no one in particular, but rather to everyone or certain unspecified individuals, such as *they* in English or *on* in French. The second person, singular or plural, might be used in this way also: *you don't beat children!*

Among the indefinite forms can be classed such words as *a, certain, other, such, few, some, many, any*, and others. Some languages class the distributives among the indefinite, such as *all, every, each, both, half, part of, some, another, other, either*, and others.

2.3 Negative

Certain forms are entirely negative. They are often subsumed under indefinite. In English they include *none, nobody, nothing, no, neither*. In many languages the negation is not expressed in a pronoun (or noun) but rather in the verbal expression.

2.4 Interrogative

In all languages, people ask questions with the aid of interrogative substitutes or determiners. Some of these are simple, others are constructed from simple forms. In English, the simple forms are *how? what? when? where? which? who? whom? whose? why?*, constructed forms *how many? whatever?*, and others.

Some languages form interrogatives from demonstratives, such as:

Fulfulde (Cameroon)

- (a) dewtere nde'e 'this book' (demonstrative)
- (b) dewtere ndeye 'which book?' (interrogative)
- (c) gorko o'o 'this man' (demonstrative)
- (d) gorko oyo 'which man?' (interrogative)

2.5 Relative

Relative constructions usually contain a relative pronoun, which may be a demonstrative or an interrogative, or an entirely different form, restricted in use to relative constructions. English: 'Here is the one *who* could help.' In Konzimé (Cameroon), the pronoun comes at the end of a relative construction and can be:

- either a special relative pronoun which varies according to the noun classes; or

- the demonstrative *ní* which is invariable.

In some languages the relative pronouns also indicate differences in tense and form part of the verbal paradigm:

Denya (Ekoid, Cameroon)

- (a) à-wá 'he killed' – á-wà-né 'he who killed'
- (b) à-wà-nè 'he kills' – á-wá-nè 'he who kills'

2.6 Pronominally Used

A number of adverbs have pronominal use, especially the indicators of space and time. The locative adverbs indicate at least three different localities: close to speaker, close to hearer (but far from speaker), and far from both, as in English *here—there—yonder*. There may also be other types of information, such as *inside, outside, underneath, above, before, after* that could be counted among them.

Nouns can also be used pronominally, especially (but not only) as honorifics. In Brazilian Portuguese, *a gente* 'the people' is commonly used instead of *nós* 'we'. (see *Adverbial Clauses; Anaphora; Grammaticalization; Negation, Linguistics of; Quantifiers, in Linguistics; Relative Clauses*).

3. Set Distinctions

In noun phrases and clauses, pronouns may be marked for any case distinction found in the language. Case indicators including circumstantial information may be fused to the pronouns causing different sets. English distinguishes *I—me, he—him, she—her, we—us, they—them*.

Yaouré (Ivory Coast) shows pronoun fusion with postpositions (Hopkins 1986):

i + lē → *jíé* '2sg + of → of you sg'

ká + lē → *ké* '2pl + of → of you pl'

3.1 Genitive

In genitive constructions the possessor can be replaced by a pronoun. The possessed item often takes the mark of the clause level function, whereas the mark on the possessor identifies it as such by the genitive case. The agreement rules of the associative noun phrase can be quite complex and varied.

English:

- (a) John's book – *his* book (agrees with John)
- (b) Mary's book – *her* book (agrees with Mary)

French:

- (a) le livre de 'the book of
Jean – *son* livre John – his (masc) book'
(agrees with book)

Table 2
Kabiye *subject + mode*

	Singular	Plural	Singular	Plural
1	mòn	dí	máá	díí
2	ñ	é	nn	éé
3	è	pà	éé	páá

Table 3
Rendille (Kenya) *subject + aspect*
(verb root: táx-, -e marks perfective, -a imperfective)

	Perfective	Imperfective	Person markers
1sg	táxe	táxa	
1pl	táxne	táxna	-n
2sg	táxte	táxta	-t
2pl	táxten	táxtan	-t..-n

- (b) la case de ‘the hut of
Jean – *sa* case John – his (fem) hut’
(agrees with hut)
- (c) les livres de ‘the books of
Jean – *ses* livres John – his (pl) books’
(agrees with books)

African class languages show a wealth of pronominal forms in all the cases. In the genitive, agreement holds in first and second person as well. The agreement may be with the possessor (as in English) or with the possessed item (as in French), or with both.

There may be different kinds of genitives, such as alienable and inalienable possession. The differences may be marked in the pronoun sets:

Lendu (Zaire)

(a)	<i>mà</i>	<i>ndzá</i>	<i>búkù</i>	'my book'	alienable/ possessive
	my	of-cl.	book		
(b)	<i>nì</i>	<i>dhí</i>	<i>búkù</i>	'your book'	
	your	of-cl.	book		
(c)	<i>mā</i>	<i>djō</i>		'my brother'	inalienable/ qualificative
	my	brother			
(d)	<i>n'ī</i>	<i>djō</i>		'your brother'	
	your	brother			

In the alienable construction, the tone of the possessor pronoun is different from the inalienable construction, and the alienable particle 'of' (which changes in form according to noun class) is absent in the inalienable construction.

3.2 Noun Phrase Substitution

The whole possessive noun phrase can be substituted by a pronoun or a nominalized or adjectivized pronoun, which functions on clause level and may carry case markers, as in German:

- (a) Mutters Garten – *ihr* Garten – *ihrer* – der *ihrige*
(b) *mein* Garten – *meiner* – der *meinige*

Table 4
Attie (Ivory Coast) *subject + mode + aspect*

	Perfective	Imperfective	Negative Perfective	Subjunctive
1sg	mě	mẽ	mẽ	mẽ
2sg	bù	bò	bù	bú
3sg	ò	wò	ò	ó

Table 5
Mundani (Cameroon) emphatic pronouns (simplified)

Person	1. Degree	2. Degree	Authoritative
1sg	mmʒ	mmʒ mbɔŋ	mmʒ mbɔŋ
1pl	bàá	bàá mbɔŋ	bàá tà mbɔŋ

3.3 Subject + Distinctions

Subject pronouns may contain, in addition to person, number, and gender information, a case marker, combined with verbal information such as mode—as illustrated from Kabiye (Togo), or aspect as illustrated from Rendille (Kenya), or a combination of these, as illustrated from Attié (Ivory Coast).

The Kabiye irrealis pronouns seem to be a fusion of the first series plus a suffix *-ka*, which is seen in its full form when following nouns.

The Attie imperfective can be reconstructed as a fusion of the perfective plus a suffix *-a*. In the negative perfective series, only two forms are different from the perfective: the 1sg and 2pl forms have high instead of low tone. Nevertheless, the whole set constitutes a new series. The subjunctive forms all have high tone.

3.4 *Emphatic*

Emphatic pronouns can be found in all languages, especially in subject function. These are usually focus forms, which can also be differentiated by degree. All of these differences can result in different pronoun series.

In Bafut (Grassfields, Cameroon), in addition to the location an insistence distinction adds member to the demonstrative set. These distinctions go from 0, the 'normal' form, to 3, where the people are actually shouting at each other. Since Bafut is a class language, the whole set includes corresponding forms for each class; class 5 forms are presented here. The location distinctions are: *nú* 'close to speaker'—*ní* 'close to hearer'—*nyá* 'far from both,' and all have corresponding forms:

- (a) nìbá nû 'this (here) wing' (0)
 (b) nìbá núà '(no,) *this* (here) wing!' (1)
 (c) nìbá núlà '(no, no,) *this (here)* wing!' (2)
 (d) nìbá núànuù '(of course not!) *this (here)* wing!' (3)

Table 6
Kobon SS/DS pronouns

Person	SS			DS		
	Singular	Dual	Plural	Singular	Dual	Plural
1	-em	-ul	-un	-nō	-lo	-no
2	-mön	-mil	-mim	-ö	-lö	-be ~ -pe
3	-öm	-mil	-öm	-ö	-lö	-ö

(see *Grammatical Agreement; Possession (Linguistic); Serial Verb Constructions; Sign Language; Tense, Aspect, and Mood, Linguistics of*).

4. Noninterchangeable

Some pronouns are not interchangeable with the nouns with which they are coreferent. *John hurt himself* cannot be replaced by **John hurt John* without changing the meaning.

4.1 Reflexive and Reciprocal

Reflexive pronouns are used to show that the agent and the patient of an event are coreferent:

- (a) John_i hurt himself_i
- (b) John_i and Mary_k hurt themselves_{i+k}
- (c) John_i and Mary_k hurt each other
/one another_{i <-> k}

If more than one participant is involved, and in the course of the action they exchange roles, the construction is reciprocal.

The relationship can hold between the subject (or agent) and the possessor:

- (d) John_i watched his (own)_i son reflexive
- (e) John_i watched his_k son not coreferent

4.2 Logophoric

Logophoric indicators, usually pronouns, are found in many African languages. Their primary use is in indirect reported speech. They express coreference between the quoted speaker and any participant in the quote content, but primarily the subject or agent.

Tupuri (Cameroon)

- (a) Pɔ_i rin Jan_k gá sɛ_i le'ɛ
Paul_i said to John_k that LOG_i fell
'Paul said to John that he (Paul) fell'
- (b) Pɔ_i rin Jan_k gá a_{k,i} le'ɛ
Paul_i said to John_k that he_{k,i} fell
'Paul said to John that he (John or someone else) fell'

In all the languages that have such a logophoric indicator, the relationship holds between the quoted

speaker and the subject of the quote content. Some languages use the same particle to show coreference between the speaker and other functions in the quote content, such as direct object, indirect object, or possessor.

The logophoric indicator is normally used in the third person, always singular, but sometimes plural as well. Some languages also use it in the second person, and in Lélé (Chad) it is used for all three persons, singular and plural. In languages with nominal classes, the marker may be distinguished according to the class of the noun to which it refers (Wiesemann 1986).

Logophorics are used with certain verbs related to speaking, especially the equivalent of 'say'. Verbs of thinking and feeling may also permit their use. In some languages, the logophoric pronouns can also be used with any verb, in which case the clause is one of intention or cause, which can be interpreted as truncated indirect speech.

Babungo (Grassfields, Cameroon)

- ɲwá nyiŋ lāā Kí vǝŋ sáN yí mē
3s_i flee that NEG 3p_k beat LOG_i not
'He fled so they would not beat him'

4.3 Sequential

In a sequence of clauses one may be the principal and the others subordinate to it. This relationship can be made explicit by the form of the subject pronoun. Any dependent clause in which the subject is coreferential with that of the principal one, the same subject (SS) is marked by a special sequential form of the pronoun. Or the converse may be true: any subject that is not coreferent with that of the main clause, the different subject (DS) is marked in some way. This relationship is also called switch-reference (Munro 1979).

Bafut (Grassfields, Cameroon)

- (a) á-ghèè ndá ŋ-kw érs fōrə
3s_i-go house SS_i-take rat
'... then he went home and caught a rat.'
- (b) á-ghèè ndá ŋ-kw érs fōrə
3s_i-go house gwa 3s_k-take rat
'... then he went home and gwa caught a rat'

In Bafut, the SS–DS difference is restricted to the third person subject. In Kobon (Papua New Guinea) all the persons have a different form for SS and for DS, as well as a 'normal' pronoun form. The actual use of such forms can be illustrated by:

kobon (Papua New Guinea)

- (a) kabö mjanu lau-ö in-a
stone that heat-DS3sg hot-3sg
'he heated the stones and they were hot'
(b) yad kaj pak-em ram ud ar-nab-in
1sg pig strike-SS2sg house take go-FUT-1sg
'I will kill a pig and take it home.'

Reflexives, Logophorics, and Sequentials can all be marked in the same language, either by the same markers or by different ones. In Mundani (Grassfields, Momo, Cameroon) the sequential pronoun is a homorganic nasal *N* in imperative and realis mode, and *e* in irrealis mode, the logophoric pronoun is *yè*, and the reflexive *vi*. They work together to keep the participants in a text straight (Parker 1986).

Property: Legal Aspects

Property encompasses the governance of resources—real property (land), natural resources, and personal property (chattels and intangibles, including copyrights, patents, stocks, claims of right). Natural law theory, beginning with Aristotle and perhaps best articulated in the writings of John Locke (1698), posits that 'life, liberty, and property' exist naturally as a

matter of fundamental principles of justice, irrespective of the state. Echoing Locke's formulation, the United States Constitution provides that a person may not 'be deprived of life, liberty, or property, without due process of law; nor shall private property be taken for public use, without just compensation.' By contrast, legal positivists, such as Jeremy Bentham (1789), assert that property rights arise only to the extent that they are formally recognized by the state: 'Property and law are born together, and die together. Before laws were made there was no property; take away laws, and property ceases.' Both views give content to what we understand as property. Legal positivism captures the practical reality that legislatures and courts define property rights in most societies, and that property rights have practical meaning only to the extent that they are enforceable. Nonetheless, natural law (and other philosophical frameworks) inform the content of property rules by providing the justification for state-created rights.

1. Philosophical Justifications for and Critiques of Private Property Rights

Waldron (1988) suggests that property is best viewed as a 'system of rules governing access to and control of material resources.' These rules are often characterized as a bundle of rights—in the case of land, the rights to possess (or occupy), to exclude, to use, to transfer, to enjoy fruits, and to alter or destroy—which can be allocated in different ways. Particular bundles represent different conceptions of property, which derive from one or more philosophical justification.

1.1 Labor Theory

John Locke (1698) offered a strong natural rights justification for private property, which remains a central pillar of property theory today. Beginning with the proposition that all humans possess property in their own 'person,' Locke argued that

[t]he 'labour' of his body and the 'work' of his hands, we may say, are properly his. Whatsoever, then, he removes out of the stat[e] that Nature hath provided and left it in, he hath mixed his labor with it and joined to it something th[at] is hi[s] own and thereby makes it his property. It being by him removed from the common state Nature placed it in, it hath by this labour something annexed to it that excludes the common right of other men. For this 'labour' being the unquestionable property of the labourer, no man but he can have a right to what that is once joined to, at least where there is enough and as good left in common for others.

Locke's theory is widely viewed as justifying first possession as a basis for acquiring property rights (Rose 1985, Epstein 1979). While useful as a basis for establishing rights in land and raw materials in a world of abundant unclaimed resources, Locke's theory significantly qualifies the laborer's claim in a world of scarcity—requiring 'enough and as good left in com-

mon for others.' Waldron (1988), Rose (1987), Ryan (1984), Becket (1977), and Schlatter (1951) elaborate and critique Locke's justification for private property rights.

1.2 Libertarianism

Drawing upon Lockean principles, libertarians emphasize individual freedom to control and alienate their private property. Nozick (1974) asserts that the state should play no role in distributing or redistributing property acquired properly, apart from respecting the voluntary transfers of property owners. Epstein (1985) argues for a broad interpretation of the government's obligation to compensate owners of private property for regulation and other governmental decisions interfering with private property rights.

1.3 Utilitarianism

First articulated by Jeremy Bentham (1789), utilitarianism judges the allocation of resources and the design of governance institutions on the basis of the utility or individual satisfaction that they produce. In applying this theory to property rights, utilitarian scholars have focused principally upon the inefficiency that can result from incomplete or shared resource ownership. In a now classic work, Hardin (1968) describes the 'tragedy of the commons,' whereby regulated access to a common pasture (or any other common resource such as air, water, or roads) results in overuse. Hardin suggested that private property or government regulation is needed to govern the commons. Economists generally prefer private property institutions (Posner 1998), although the efficacy of private property depends critically upon the costs of creating, monitoring, and enforcing such rights (Lueck 1995, Anderson and Hill 1975, Demsetz 1967). Government regulation often entails direct costs as well as inefficiencies attributable to rent-seeking by those interests affected by regulation. Although private property regimes often ameliorate the tragedy of the commons, shared governance institutions can maximize utility in a range of circumstances depending upon the cohesion and history of the community affected and the nature of the resources in question (Libecap 1994, Ellickson 1991, Ostrom 1990, Rose 1986).

1.4 Personhood

The personhood justification for private property, derived from Kant's *Philosophy of Law* and Hegel's *Philosophy of Right*, has been elaborated in modern legal discourse in the work of Radin (1982, 1993). 'The premise underlying the personhood perspective is that to achieve proper development—to be a person—an individual needs some control over resources in the

external environment. The necessary assurances of control take the form of property rights' (Radin 1982). The personhood justification for private property emphasizes the extent to which property is personal as opposed to fungible: the justification is strongest where an object or idea is closely intertwined with an individual's personal identity and weakest where the 'thing' is valued by the individual at its market worth. The personhood justification for private property is limited and highly subjective (Schnably 1993).

1.5 Distributive Justice

Theories of distributive justice seek to allocate society's resources on the basis of just principles. The process of determining such principles is the focus of considerable debate. Many theories incorporate utilitarian and Lockean principles. In perhaps the most influential work on distributive justice of the past century, Rawls (1971) offers an 'ideal contractarian' theory of distributive shares in which a just allocation of benefits and burdens of social life is determined by what rational persons would choose from behind a 'veil of ignorance,' which prevents them from knowing what abilities, desires, parentage, or social stratum they would occupy. Rawls concludes that people behind such a veil would adopt what he calls the 'difference principle': 'primary goods'—not only wealth, income, and opportunity, but also bases of self-respect—would be distributed to the maximal advantage of a representative member of the least advantaged social class. Rawls (1993) emphasizes that the difference principle does not call for simple egalitarianism but rather measures to assure that 'the basic needs of all citizens can be met so that they can take part in political and social life.'

1.6 Civic Republicanism

Republicanism rejects the view that individuals are wholly autonomous and that the public interest is just the aggregation of individual preferences. Republicanism stresses civic virtue and the role of participation in public discourse as essential to the realization of the common good. Civic republicanism relies upon the propertied independence of its citizens. Such ownership of capital affords citizens the competence to engage in meaningful discourse and protects against the subversion of democracy by a wealthy oligarchy or an aggressive state (Simon 1991).

1.7 Marxist Theory

Karl Marx viewed human history as an evolutionary process of class struggle leading, ultimately, to a classless society (communism) in which the state will wither away. In the capitalist phase of this evolution, private property provides the basis for the most important social relation: ownership of the means of

production. According to Marx, the class owning the means of production (bourgeoisie) acquires the property (capacity to work) of the labor class (proletariat) through the employment relation, thereby obtaining exclusive control of and hence power over the worker class. Such subordination, exploitation, and alienation sow the seeds of revolution, leading to the establishment of a proletarian dictatorship, socialism (productive resources owned by workers through participatory institutions), and eventually communism, a classless society without exploitation or inequalities in which property in land and rights of inheritance are abolished (Marx and Engels 1848).

1.8 Ecological Theories

As understanding of the connections between technology, land development, and the environment has deepened, many environmental scholars have increasingly viewed private property rights more skeptically (Sax 1983). Traditional reformist theories—which are anthropocentric in nature and draw heavily upon utilitarian and other traditional philosophical frameworks—favor internalization of the adverse impacts of development (Menell and Stewart 1994), Ellickson (1977, 1973). Building upon Leopold's (1949) call for a land ethic which seeks to 'preserve the integrity, stability, and beauty to the biotic community,' Freyfogle (1996), Sprankling (1996), and Sax (1993) propose a shift away from private property toward greater regulation and coordination of land and natural resource development. At the other extreme, Anderson and Leal (1991), drawing upon property rights and public choice literatures, advocate complete reliance on private property and free market principles as the best institutional choice to address substantially all environmental problems. Menell (1992) highlights the institutional limitations of both extremes and urges careful attention to the strengths and limitations of the broad spectrum of institutional alternatives in governing resources.

1.9 Pluralist and Hybrid Theories of Property Rights

The insights of the many philosophical perspectives have led some scholars to synthesize multiple strands into new and comprehensive theories for justifying and evaluating property. Munzer (1990), for example, constructs a theory of property built upon principles of utility and efficiency, justice and equality, and rewards based on labor. Simon (1991) synthesizes civic republicanism and socialism to advocate an intermediate form of property emphasizing enterprise and community-based democracy (cf. Hansmann 1996), offering a utilitarian explanation for worker owned and managed firms and organization).

2. The Emergence of Private Property Rights

Although no single philosophical theory provides a complete explanation for private property rights, utilitarianism has emerged as the dominant framework for understanding property rights systems. In a seminal article, Demsetz (1967) posited that private property regimes develop to internalize externalities. As the benefits of internalizing externalities rise (e.g., where a common resource becomes more valuable) or the cost of internalizing externalities fall (e.g., as technology reduces the costs of fencing or monitoring property rights), private property systems emerge to promote efficient management of the resource. As support for this thesis, Demsetz cites anthropological evidence suggesting that native Americans established private hunting territories following the arrival of Europeans and the development of the fur trade. By spurring the hunting of beavers, the fur trade threatened the productivity of this renewable resource, thereby creating social pressure to institute property rules that internalize the effects of resource exploitation.

Demsetz's theory explains the emergence of private property institutions across a broad range of contexts, including air (sulfur oxide emissions in the United States), water allocation, fishing, telecommunications spectrum, wetlands, roads (tolls), trademarks (causes of action for diluting famous marks), and publicity (commercial exploitation of a person's image, likeness, or voice). Nonetheless, by focusing exclusively upon private property institutions, Demsetz's theory overlooks much of the richness of property institutions and the complex social processes that affect their evolution. Libecap (1994), Ostrom (1990), Ellickson (1991), Rose (1986), and others contribute to the explication of a broad spectrum of property institutions lying between the poles of pure private property and the commons where informal and shared governance emerge and succeed in allocating resources.

The emergence and nature of property rights also reflect the political economy driving the legislative process and government agencies that administer property rights (Buchanan and Tullock 1962). Interest groups tend to form in those areas where government policies create concentrated benefits or impose concentrated costs (Olson 1965). Laws and agencies creating or affecting property rights (e.g., through regulation) attract substantial rent-seeking activity. Thus, the design of such property regimes often reflect political, as well as economic, considerations.

3. Evolution of Jurisprudential and Analytical Conceptions of Property

Although property rights are as old as human civilization, the modern jurisprudential conception of property traces its roots to the agrarian and early mercantilist economies that developed during the

decline of feudalism. Sir William Blackstone (1765), author of the first widely accepted legal treatise on English law, regarded property as an absolute right

which consists in the free use, enjoyment, and disposal of all acquisitions, without any control or diminution, save only by the laws of the land ...

So great moreover is the regard of the law for private property, that it will not authorize the least violation of it; no, not even for the general good of the whole community ...

Although some have questioned Blackstone's rigor and cogency (Burns 1985) few doubt his influence upon the jurisprudence of property in England and America. Maine (1861) reinforced the superiority of private property institutions through his historical account of the progress of civilization from primitive forms of shared ownership among kinship groups (status) to individual ownership and alienability of property interests (contract).

The industrial revolution and the shift from an agrarian economy to urban and other community structures changed the ways in which land and other resources were owned and exploited. The desire to restrict land through contract pushed courts to liberalize constraints on non-possessory interests, presaging the disintegration of the unitary bundle of sticks. Property came to be seen increasingly as a malleable concept that could be tailored to serve utilitarian purposes.

In the early twentieth century, Hohfeld (1913) developed a detailed descriptive framework for capturing the richness of legal rights reconceptualizing property as *relationships* among people relative to things. Recognizing four primary legal entitlements—rights, privileges, powers, and immunities—Hohfeld postulated four basic legal relations ('correlatives'): 'right-duty,' 'privilege-absence of right,' 'power-liability,' and 'immunity-disability.' Hohfeld provided the vocabulary and structure for representing the complexity of property relations—bundles of rights (and relations)—as well as the conceptual menu from which legislatures and courts could craft property rights.

Blackstone's conception of property as an inviolate, unified bundle of rights came under increasing assault with the proliferation of zoning and other public land use controls upon private property rights and the expansion of the role of government at all levels following the New Deal in the USA. Property rights, like much of the law governing the legal relations, came increasingly within the purview of political institutions, and accordingly gave way to the instrumentalist (utilitarian) nature of politics.

In a seminal article, Coase (1960) developed a new, instrumentalist framework for analyzing property rights. In much the way that a frictionless surface enables physicists to isolate and study the laws of physics, Coase hypothesized a world of zero transaction costs (costless bargaining and enforcement of

agreements), which provided valuable insights into the interplay of legal and market institutions. Coase demonstrated that in a world of costless transactions, an efficient allocation of resources will result regardless of how property rights are initially allocated. The desire of conflicting property owners to maximize their joint profit will lead them to bargain to an efficient allocation of resources. The initial allocation of entitlements will affect the distribution of wealth, but not the total level of wealth.

As with the frictionless surface, Coase recognized that costless transactions do not exist in the real world. His article fueled a deluge of scholarship exploring the implications of costly transactions for the allocation and design of property rights. Building upon Coase's construct, Calabresi and Melamed (1972) developed a framework that divides the analysis of property rights into two inquiries: (1) how should property rights be allocated; and (2) how should such entitlements be enforced—by a property rule (enabling property owners to enjoin interference with their entitlement and requiring consent for violation or transfer of the entitlement), a liability rule (allowing property owners court-determined damages for invasion of their property right, as in the case of eminent domain), or by a rule of inalienability (preventing transfer of a property right, as with prohibitions on the sale of body parts).

Calabresi and Melamed propose that entitlements and enforcement rules be based on economic efficiency, distributional goals, and other considerations of justice. Where transactions are costly, entitlements should be allocated so that the party who is best able to minimize harm (the least cost avoider) bears responsibility for the harm in order to promote economic efficiency. With regard to the enforcement of entitlements, Calabresi and Melamed demonstrate that the use of liability rules can minimize the costs of making an erroneous decision about the allocation of entitlements where transactions are costly. Subsequent scholars have refined and extended the framework and applied it in a range of contexts (Symposium 1997, Kaplow and Shavell 1996, Merges 1996, Radin 1996, Krier and Schwab 1995, Rose-Ackerman 1985, Polinsky 1980, Ellickson 1977, 1973).

In a provocative essay published in the early 1980s, Grey (1980) argued that the field of property 'ceases to be an important category in legal and political theory' as a result of the 'disintegration' of the conception of property. In his view, the dividing of property ownership into a 'bundle of rights' and the development of differing conceptions of property across disciplines has 'fragmented' property theory 'into a set of discontinuous usages.' Numerous scholars have questioned Grey's claims on a range of bases (Munzer 1990), yet the observation that provided the point of departure for Grey's essay, the 'disintegration' of property, resonates today. Property has lost the simplicity of Blackstone's conception—unitary, ex-

clusive, and omnipotent control—but a new conception of property integrating the many institutional structures governing resources, the cultural contingency of governance regimes, and the dynamism of governance institutions has emerged.

4. Property as a Triadic Relation

Menell (2001) and Dwyer and Menell (1998) present property as a dynamic system comprising three components: resources, institutions, and culture. Resources may be governed by background legal institutions (such as common law rules, or in civil law regimes, codes), social norms, markets (contractual agreements supported by the background legal institutions), political institutions (e.g., zoning), or some combination thereof. At any point in time, the mix of governance rules and institutions reflects the nature of the resources governed and the society or culture (knowledge, values, cohesion, technology) in which the resources are situated. Thus, in smaller, more cohesive social settings, we might observe more commonly particular resources are governed through social norms or other common property institutions whereas the same resources might be governed through formal private property institutions in a larger, more heterogeneous community. In this way, the triadic framework captures the economic and cultural dependency of resource governance as well as the richness of property regimes.

The triadic conception of property also incorporates the dynamic nature of resource governance. As reflected in Fig. 1, the framework incorporates causal connections and feedback mechanisms. Changes in the society (such as the value attributed to the protection of endangered species or technological advances reducing the costs of monitoring private property rights) generate changes in the design and mix of governance institutions. Such changes, by affecting the resource base, may generate further reactions within the overall system. The system may

Figure 1
Property

also be affected by external shocks, such as charges in the larger political atmosphere. Demsetz's (1967) positive account represents a special case of this dynamic process, but the triadic relation generalizes the dynamism of institutional evolution to account for a broader mix of governance institutions.

5. New Frontiers

Notwithstanding the settlement of substantially all significant land masses on the planet, the frontiers of property continue to expand and evolve. Among the most important resources in today's economy are intangibles—ideas, genetic code, cyberspace, telecommunication spectrum (Merges et al. 2000). The internet has significantly expanded opportunities to distribute expressive works, but has also threatened the ability of copyright owners to control their works. This new medium has reshaped perceptions about rights to reproduce and distribute expressive works. Advances in bioscience have spawned disputes over rights and control of human genetic code, cell lines, and indigenous plants. And even in the more conventional realm of land management, increasing pressures on natural resources, greater knowledge of ecosystem effects, and changes in attitudes toward the environment continue to alter the balance among private property rights, public ownership, and regulation (Dwyer and Menell 1998, Menell and Stewart 1994). Public rights in artistic treasures, historical documents, architectural works, archeological discoveries, and scholarly research present a further set of challenges for a system of governance built significantly upon a foundation of private property rights (Sax 1999). Just as the advent of rights in government benefits expanded our conception of property four decades ago (Reich 1964), advances in technology and changing social values continue to expand and alter our conception of property.

Property: Legal Aspects of Intergenerational Transmission

1. Wills and Succession Throughout History

Property exists essentially in two forms: movable (including intangible) and immovable (land). The transmission of that property at death generally occurs in one of three ways: by will, by customary or legal rules of succession, or by a combination of the two. An heir's right of succession by law or custom is an ancient and powerful right rooted in kinship ties. It was, for example, an attribute of early European feudal life, allowing family members to share that portion of the land vacated by a kinsman's death (see Chester 1982). By the twelfth century in England and many parts of Western Europe, lands were not partitioned, but descended to the eldest son of the landowner under the concept of primogeniture.

The right of a beneficiary to take property under a will is dependent on the legal power or right of the decedent to transmit this property at death to that beneficiary. This right was recognized relatively recently in Western thought and has often been regarded, at least by the positivist tradition, as having been created for society's convenience. Natural rights advocates by contrast might consider the right to bequeath an aboriginal attribute of property itself (see Chester 1998b).

In Western society, the legitimization of the right of bequest symbolized the shift from feudal to individualistic conceptions of property. Unknown to the early law of Greece, India, Egypt, Babylon, and Israel, the will was by no means a universal institution. The testamentary conception built upon by Europeans had its roots in Roman law and was resurrected after feudalism by ecclesiastical courts applying Romano-canonical law (see McMurray 1919).

In England the customary right of testamentary disposition was recognized in very early times, but land—the primary source of wealth—could not be willed until after the Norman invasion and the establishment of feudal tenures. Finally, in 1540, the Statute of Wills declared the right of an individual to leave real property to whomever the individual pleased by means of a duly executed will. This statute

confirmed a customary right long recognized for personal property (Chester 1982).

Once established, the right of an individual to leave property outside the family had to be reined in by providing protection from disinheritance for certain family members. For example, in England, primogeniture protected the eldest sons of landed decedents until well into the nineteenth century. Common law rights of dower and curtesy for surviving wives and husbands provided them with interests in the land of the decedent (see Chester 1982). Even though English women of the sixteenth, seventeenth and eighteenth centuries could not will property or own it in their own name, it could descend through them. However, married women's assets were also protected to some extent by courts of equity by means of trusts and other devices, especially toward the end of that period.

Children who were omitted from wills were not protected directly, except those benefiting under primogeniture. However, the wills of their parents were strictly scrutinized to ensure that they had not been left out unintentionally. One English rule derived from Roman law even stated that to cut off an heir 'without a shilling' raised a presumption that the testator was legally incompetent to make a will. Thus even in England, the family's right to inherited property was protected not only when the decedent died without a will (intestate) but to some extent when the decedent did leave such a will (see Chester 1982).

The entrenchment of the right of testation in England was associated with the movement from feudalism, with its emphasis on family and kinship, to free-market capitalism, with its emphasis on the individual. By the mid-nineteenth century, the adult male, Anglo-American owner of both realty and moveable property had nearly unlimited power of testamentary disposition. In contrast, countries such as France, Spain, and Germany on the European continent made the move to capitalism with a right of testation that, even when recognized, was much more sharply curtailed than that in Anglo-America by the requirement of fixed shares for surviving spouse and children.

In the eighteenth and nineteenth centuries, the principal difference between the Continental and Anglo-American systems of succession was the different attitude each displayed toward the right of family members to succeed to the decedent's property. Although the Spanish principle of mandatory heirship appeared in theory to be a significant curb on the Anglo-American concept of testamentary freedom, in practice the differences were not so marked. This reality stems from two separate phenomena: (a) in the majority of instances free testamentary power among the Anglo-Americans was exercised in favor of those who would be forced heirs under a mandatory system such as that in Spain; and (b) even where testamentary power appears absolutely undiluted, far more people

die without wills than with them, resulting in the passage of their property to those who, under Spanish law, for example, would be designated forced heirs (see McKnight 1996).

Spanish lawyers of the eighteenth and nineteenth centuries were trained in the Germanic tradition, which accepted only an extremely narrow testamentary power. Thus, while Anglo-American lawyers thought of both testate and intestate succession, the basic distinction for the Spanish was between those who were forced heirs and those who were not.

What is more, married women in the Spanish system not only had a much more extensive right to property than did those in Anglo-America, but they also had will-making power, which they did not have in Anglo-America. American women, for example, did not gain the power of will-making until the passage of the Married Women's Property Acts of the late nineteenth century.

In Spain the surviving spouse was also entitled to half of the gains of the marriage under what is today termed the community property system. Most of the property that was the decedent's alone passed to descendant forced heirs, despite any contrary testamentary provisions, and if there were no descendants, ascendants took as forced heirs, although in smaller shares than descendants. If the decedent died without a will, the estate passed to the forced heirs, or, if none, to other heirs as dictated by law (see McKnight 1996).

French law also maintained forced heirship under the concept of legitim. During the French Revolution, this concept was viewed as a means of eliminating the feudal principle of primogeniture in order to break up feudal estates. There was some relaxation in the strict adherence to forced heirship by the time of the Napoleonic Code, which announced the general French view of succession that is held even today. Under the Code, half of the testator's estate (after marital property has been distributed to the surviving spouse) was freely disposable if there was one child; one-third if there were two children, and one-fourth if there were three or more children (see McKnight 1996).

In general, since the early fifteenth century, the difference between Continental and Anglo-American views of succession, seen most strikingly in the Hispanic tradition, is that the Spanish adhered to the traditional Germanic tribal concept of familial right to property, whereas the Anglo-Americans took an individualistic view of who should succeed to the decedent's property (see McKnight 1996). By the mid-nineteenth century, this English individualistic notion had triumphed throughout the USA, with the exception of Louisiana which followed the French law of legitim. The Anglo-American system was, however, tempered by the concept of community property in states with a Spanish tradition and by dower and curtesy (mentioned above) in the others. The former

gave each spouse an immediate half interest in any property acquired during the marriage, while dower provided a surviving wife with a life interest in one-third of her dead husband's real property, and curtesy gave a surviving husband a life interest in all of the wife's real property.

2. Trusts

A particularly ingenious device for the intergenerational transfer of wealth was developed in Anglo-American courts of equity. Called the trust, it has sometimes been copied in other legal systems, for example that of modern Japan (see *International Law Digests* 1999). This form of property holding enabled the decedent to pass legal title to a third party who held the property for the benefit of its intended beneficiary. This third party trustee was subject to the equitable interest of the beneficiary, who generally received the income from the property for a period of time up to life. At the end of the designated period, the equitable title of that beneficiary would cease, transferring absolute ownership to that beneficiary or another chosen by the decedent.

The temporary division of legal and equitable title to property in trust allows, among other things, professional management of trust property assets. It also allows decedents to delay the actual vesting of full title to the property for a period of time up to and including a generation or more, during which period a beneficiary may receive a managed stream of income. Trusts in the USA that pay income to a decedent's children during their lives, and upon their deaths pay the principal to the grandchildren are called generation-skipping trusts. Estate tax advantages of these trusts (achieved because the children never received full title) were cut back by the Tax Reform Act of 1986 and subsequent amendments (which imposed a generation skipping transfer tax (see Johnson and Eller 1998, Dukeminier and Johanson, 1995).

3. Wills and Succession Among Nations in the Twentieth Century

The USA took freedom of testation one step further than did England and the countries of the British Commonwealth. While in varying degrees these nations developed flexible systems of family maintenance to protect surviving spouses and children (at least adult, competent children) from disinheritance, the USA maintained the right of testator to disinherit his or her children completely, even those children who were minors and/or had need. Thus, while surviving spouses in the USA are protected either by the elective share (in 'common law' states following the English tradition) or community property laws (in

those states following the Spanish tradition), children are theoretically left to the whims of unrestrained individualism.

Although this disparity has been attacked, it has also been noted that flexible concepts such as lack of testator competence, undue influence, and 'unintentionally' omitted children indirectly protect surviving children to some extent in most 'common law' states (see Chester 1997, 1998a).

That the USA's focus on the individual rights of the decedent, even to the exclusion of children and other descendants, is unusual in the world can also be seen by examining the systems of the Soviet Union (before its dissolution) and China. Traditionally, the Soviet law of inheritance did not differ substantially from that of the civil law countries of Western Europe (see Dukeminier and Johanson 1995). Although there was an attempt by the Bolsheviks to change this in their takeover of power in 1918, it failed. Nearly unique in the modern history of humankind, a 1918 Soviet Union law read: 'inheritance, testate and intestate, is abolished. Upon the death of the owner his property (moveable and immovable) becomes the property of [the state]' (1 *Sob. Uzak.*, RSFSR, No. 34, item 456, Apr. 26, 1918). This attempt to abolish inheritance proved so unpopular with the people that inheritance was reestablished within four years (see Foster-Simons 1985).

At present, inheritance law in Russia and the republics of the former Soviet Union generally follows the civil law views of Western Europe. In this way, it is similar to the law in modern China (see Dukeminier and Johanson 1995). In that country, if first order heirs (spouse, children and parents) inherit, then no second-order heirs (brothers, sisters, and grandparents) will inherit. Following a kind of community property system, all property in China acquired during marriage is joint property, unless the marital partners have executed a contract to the contrary (see *International Law Digests* 1999). Since much of China is still rural and nonindustrial, custom plays an important part in the actual distribution of estates (see Foster-Simons 1985), just as it does for example, in tribal Africa. This distribution depends partly on the law and the terms of any will and partly on the social and economic facts relevant to the intestate, or the testator and his heirs (see *International Law Digests* 1999).

4. Free Testation and Capitalism

It is tempting to view the relatively free testation of the USA as coincident with that country's status as the exemplar of capitalism. Except for the elective share (typically one-third) provided for surviving spouses, testation in America is predicated on protecting the free will of the testator. While England and the Commonwealth countries are certainly capitalistic,

their laws show, on the whole, more of a socialist's regard for protection of society (and family) than do those of the USA. While family protection is achieved in these countries by reposing a great deal of discretion in probate judges to ensure family maintenance (as distinguished from the use of fixed shares in the Continental system), this still provides a strong check on the whims of the testator. The governmental intrusion into testation is, of course, even pronounced on the continent where fixed shares for the family are the norm.

In its 1987 decision in *Hodel vs. Irving* (481 US 1987), the USA Supreme Court even seemed ready to protect *constitutionally* the right of an individual to transmit property at his death in any manner that he or she chooses. While that decision has been criticized and not extended beyond its facts (which involved government confiscation of noneconomic land parcels descending at the death of American Indians), it symbolizes America's fierce protection of individualism, even after the individual's death (Chester 1995, 1998b). Interestingly, the occasion for that decision was the government's attempt to save Indians from the disastrous economic effects of the Anglo-American individual property system which had been forced on the various tribes. Without imposition of the notion of individually held property in the first place, functioning Indian tribes, much like the tribes in sub-Saharan Africa, might have continued to treat property, which is chiefly in the form of land, as a family, and by extension community asset, which was never the individual's to transmit at death in the first place.

5. Implications of Inheritance and Taxation Policy for Equal Opportunity and the Distribution of Wealth

Allowing large amounts of capital to pass between generations without significant taxation is problematic for those countries such as the USA which profess a belief in equal opportunity. Taxation of estates and gifts is widely seen as an intrusion on the freedom to transmit property at death—a freedom that Americans particularly seem to cherish. While the American estate and gift tax has high nominal rates, its high exemption levels and numerous loopholes, including a deduction of up to 100 percent for all property left to a surviving spouse, may make it in effect a 'voluntary tax' (see Cooper 1979).

Countries such as France and Spain have both an inheritance tax and an annual tax on accumulated wealth. Perhaps not coincidentally, these countries do not have so strong a tradition as does the USA of allowing testators to do almost anything they want to do with their money at death.

Commentators (e.g., see Ascher 1990, Chester 1976, 1982, 1998a, 1998b) have noted that the policies of free wealth transmission and equality of opportunity

coexist very awkwardly in the USA. Although legal systems cannot control differences in natural ability or the luck of being born into a family that values, e.g., culture and education, they *can* curb that form of luck represented by inheritance. If equality of opportunity is truly a key goal, then children fortunate enough to have been reared and educated by wealthy parents need not be allowed the additional luck of inheriting their parents' property. Strong and effective taxation of inheritances would contribute significantly to this goal of equal opportunity.

Whatever the logic of this point of view, in countries like the USA there appears to be little public support for more effective taxation on postmortem (or even lifetime) transmission of wealth to heirs. In fact, at the beginning of this twenty-first century bills in Congress relating to the estate tax generally call for its softening or its abolition. Those supporting such bills argue that low or nonexistent taxation of inherited wealth is good for the economy because it preserves large blocks of investment capital in private rather than government hands. However, it might also be said that untrammelled inheritance saps the initiative both of those who receive it and of those who cannot possibly compete on equal terms with those who do (see Chester 1976, 1982).

6. The Future

In looking toward the future of intergenerational wealth transmission in the twenty-first century, one might begin by considering the changing nature of the family itself. Particularly in advanced capitalist nations such as the USA, the family is showing signs of disintegration. Traditional heterosexual marriages often end in divorce and several forms of non-traditional relationships are being legitimized. Since advanced capitalist nations offer many forms of wealth that are obtainable by individuals, there is no longer a critical need for children to succeed to a parent's land. Thus, the strict family protection practiced by the inheritance systems of many capitalist nations may seem outdated to some.

US law, unlike that of many nations, does not directly protect children from disinheritance by their parents. However, other nations may not desire to aggravate by such a legal stance the atomization of family and society toward which many of them are already heading. Their common judgment may be that, even in the twenty-first century, some homage to the family, traditional or otherwise, still needs to be paid in the field of intergenerational wealth transfer. Whether the restraints on individualism that such a judgment entails will become the norm as this century progresses remains an open question.

Property, Philosophy of

The philosophy of property concerns itself with the distribution of benefits, entitlements, and responsibilities associated with goods in a society. Most major Western political philosophers have constructed theories of property rights and property ownership including the limits and justification of property (e.g., Plato, Aristotle, Hume, Locke, Mill, Marx). Philosophical inquiry into property rights is closely associated with distributive justice, the role of the state, and the fundamental tensions between contemporary socialist and liberal political theory. Philosophical interest in property and property rights involves conceptual analysis of what property, own-

ership, and property rights are, as well as critical evaluation of the justifications given for property systems. In this entry the meaning of property, property rights, and ownership are addressed, before providing an examination of the contexts (historical and intellectual) within which property theories arise, an overview of competing approaches to justifying property and, finally, a discussion of current (and potential) debates concerning property in political philosophy and philosophy of law.

1. The Term 'Property'

Property is probably best understood relationally. Property rights involve relations among people concerning benefits and responsibilities which often are (but need not be) associated with particular objects in the world. In ordinary speech, however, the term 'property' is often used to describe the objects over which property relations are held themselves. Although it is common to speak of property as concerning objects in the world, philosophical discussions of property concern themselves with property understood as social, legal, and moral relations with regard to objects, benefits, responsibilities, and their control, within given legal and social contexts. The law of property concerns the legally recognized distribution of rights, responsibilities, and benefits associated with objects of property (both physical and immaterial). Social and moral relations of property, however, are not bound by legally recognized understandings of the limits and extent of property rights.

The range of legally recognized property rights and responsibilities vary from jurisdiction to jurisdiction. Similarly, social and moral property rights vary between cultures and across history. It can be difficult to identify whether a particular claim to a benefit or attribution of responsibility is best characterized as a property right or some other form of legally or socially recognized benefit or responsibility. In jurisprudence, clear distinctions between property, contract, and tort bases for legal entitlements or legally protected interests may be impossible to make (see *Property: Legal Aspects*). In this way, philosophical discussions of property are bound inevitably with broader discussions of distributive justice, social justice and with normative discussions of the role of the state in protecting or promoting certain kinds of interests.

The extent and limits on property rights vary along three dimensions: the range of objects over which property rights can be held (for example, whether water, air, or titles can be held as property); the range of specific property rights over an object that are recognized (for example, whether property can be bequeathed on death or whether property rights can be leased to others); and the entities that can bear specific property rights (for example, individuals and corporations, communities, the state). In capitalist

states, there is a presumption that anything could be conceived of as property and that anything which is property could be alienated, although there may be good moral grounds for the state to limit property rights in the public interest (for example, prohibitions against the sale of human beings, or prohibitions against the purchase of insurance against some legal responsibilities like legal culpability for criminal conduct). In pre-capitalist and socialist states there may be limits to the kinds of property which can be privately owned (for example there may be state or collective ownership of land, factories, or other means of production), with some presumption of a state interest in limiting private property rights for the purpose of redistribution of benefits and burdens through, for example, taxation, control over prices, limits on rights of sale, and control over wages.

1.1 Property as a 'Bundle of Rights'

In the conceptual analysis of property, it is generally understood as a term which refers to a bundle of rights, or rights and responsibilities. In liberal democratic theory and jurisprudence, specification of the bundle starts with the full array of rights and responsibilities enjoyed by a private owner of a thing. Minimally these are taken to include Hohfeldian rights of exclusion, rights of use, the power to alienate property and immunity from expropriation (Hohfeld 1919). Theorists have provided a number of ways of enumerating the different aspects (rights and responsibilities) of ownership, most are now heavily influenced by Honoré's (1961) list of the 11 'incidents' which together constitute 'full, liberal ownership.' These incidents are the rights of use, possession, management, income, capital, security, absence of term, residuary, and the responsibilities of prohibition of harmful use and liability to execution. Honoré's analysis applies most readily to property in material objects, but is intended also to apply to immaterial property such as future production, control over labor and copyright. The terms 'thing' and 'object over which property rights are held,' then, are not meant to exclude these forms of property.

Honoré's analysis allows that the constitutive rights which together make up ownership could be identified differently (that finer distinctions could be made, for example between the right to capital through sale and through consumption of property). He also recognizes that for any given object over which property rights may be held (for example, a car) the range of property rights which a person must hold to be deemed the owner of that object may differ from what is required to own another kind of object (for example, a pharmaceutical company). Other theorists provide distinct analyses of property which are less extensive, but draw on Honoré's list: for example, Becker (1977)

and Snare (1972) (see *Property Rights; Property: Legal Aspects*).

1.2 'Ownership'

Within liberal capitalism, philosophical discussion of property is often understood as a discussion of 'ownership'. Ownership can be seen as a kind of legal trump with regard to other property rights, but not necessarily with regard to other kinds of moral or social claim.

Many writers seeking to analyze the concepts of property and ownership as social and legal institutions have focused on the rights an owner has regarding a thing, with which nonowners may not interfere. 'Ownership' is the relation one is in (characteristically in a private property system), when one has 'the greatest possible interest' in a thing (Honoré 1961). That is it is the title given to the person who has the widest range of property rights over the thing. It may be more correct to say that the owner is the person who holds the most socially or legally significant property rights over a particular kind of thing. The specific property rights which are seen as most significant will vary with the kind of thing owned and the possible uses of those rights: rights of control over production and rights to income from profits will be relevant in identifying the owner of an industrial business, while rights over control of access and use may be more significant in identifying the owner of a retail space; rights of possession and use may be more important in identifying the owner of personal property (such as a car). In legal contexts, the person who is deemed to be an 'owner' has a stronger legal claim than any other holders of property rights over the thing. Nonetheless, there are many cases where it is unhelpful to try to determine who has rights of ownership, as property rights may be separated and limited in a huge number of ways. Further, the terms 'owner' and 'ownership' most naturally arise in discussion of private property. In the justification of property theories where relative merits of private, communal, state or mixed systems of property are to be assessed, it is frequently more helpful to refer to the range of property relations recognized within the theory, rather than attempting to specify relations of ownership.

1.3 Property Systems

Property systems, or the legal and social institutions concerning property a society are frequently divided into three kinds: private, collective, and common property systems. Waldron (1988) describes property systems as systems of 'rules governing access to and control of material resources' and distinguishes between private, collective, and common property

systems in terms of the different 'organizing idea' around which each kind of system is framed. 'In a system of private property, the rules governing access to and control of resources are organized around the idea that resources are on the whole separate objects each assigned and therefore belonging to some particular individual.' Collective property systems are characterized by the organizing idea or a 'social rule that the use of material resources in particular cases is to be determined by reference to the collective interests of society as a whole.' In common property systems, the organizing idea of the rules of allocation of rights to resources is the idea that 'each resource is in principle available for the use of every member alike' (Waldron 1988). For Waldron, kinds of property systems are distinguished according to their organizing ideas, yet Waldron's concept of an organizing idea for property systems is not meant to be reductive. Most property systems in actual societies contain elements of each system: some resources, e.g., sunlight, are understood as common property; some, e.g., state-run utilities, are held as collective property and some resources, e.g., clothing, are held privately.

2. The Context of Debates Surrounding Property

Within political philosophy debate about property rights and the justification of property are closely connected with debate about the legitimacy of state authority, national sovereignty, individual rights against the state and justice. Historically the shift from feudalism to representative democracies in Europe coincided with debate about the source and nature of the justification of property rights. Broadly speaking, feudal modes of production were agricultural. In feudal regimes all property in land was held by the sovereign and rights to use of that land were allocated in accordance with the sovereign will. The sovereign then levied taxes or required some form of payment for the use of the land and had ultimate authority to determine the use of the land and the income generated from the working of that land. Land obtained through conquest or treaty similarly came under the sovereign power. With the rise of representative democracies, the scope for exercising sovereign rights over land and determining taxes and other levies on the use of the land became constrained by the popular will and claims of the citizenry. What remained, however, was the idea that ultimate authority over grants of land, the use of land, and taxation rested with the sovereign, whether that be an individual monarch or the sovereign authority of a parliamentary government.

2.1 Property, Patriarchy, and God

An early debate about the source of legitimate property rights and its relation to political authority was

between Filmer (1680) and Locke (1690). Filmer had argued that the king's sovereignty could be traced directly back to God's gift of the earth and its bounty to Adam. The patriarchal lineage of the king gave him and no other person ownership of the world, and authority over all those living therein. Locke's refutation of Filmer rested on three propositions: the fundamental moral equality of all men; the gift by God of the earth and its fruits to all men in common (and not exclusively to Adam and his descendants); and that individual appropriation of property from the common could be legitimate, in the absence of the universal consent of all the other common owners. Filmer's argument tied the ownership of land and the political authority of the king together through Adam's sovereignty. Locke's argument separated the two, as he argued that legitimate property rights could be held in the state of nature (outside of political societies). However, he argues that political societies would not be entered into with the consent of the citizens unless the sovereign authority protected the pre-political property rights. Thus, the legitimacy of the state depends, in part, on its protection of property rights.

2.2 Property and Liberalism

Within liberal political philosophy more generally, the recognition, enforcement, and protection of private property rights is viewed as a function of the state (Rawls 1971), and as a source of its legitimacy. Private property is understood by many liberals as providing a realm within which individuals can exercise personal liberty, free from interference by others. If something is owned by a person, others must not interfere with the harmless exercise of the property rights held over the thing. Some liberal theorists, particularly those who emphasize the significance of 'negative freedom' argue that expansion of personal liberty depends on private possessions through which liberty can be exercised. Other liberals, however, recognize that the unequal distribution of private property rights limits the equal enjoyment of liberty and therefore argue that property rights must be limited to protect against gross inequalities in freedom (see *Freedom/Liberty: Impact on the Social Sciences*).

2.3 Equality and Justice

Because systems of property distribute goods among individuals within a state, discussion of property is closely linked with concerns about distributive justice and equality. Significant inequalities between individuals or groups which result from the unfettered exercise of property rights can be addressed within the justificatory structure of a property system (placing

limits on what can be owned or how property rights can be exercised) or through separate appeals to equality or justice within a broader political theory. Rawls (1971) provides the 'difference principle' as part of his two principles of justice to protect against significant inequalities which might emerge through the various political institutions of his just state. The difference principle can be applied to any form of inequality within the state; applied to property it holds that differences in property rights are justifiable only if they are of the greatest benefit to those who are least advantaged. This would allow some inequalities within a property system, such as those which are required to provide sufficient incentive for some people to engage in risky, dangerous, or socially stigmatized activities where those activities benefit the least advantaged. It would also require that there be some decent minimum level of welfare for all members of the society and would limit the extent of difference between the most and least advantaged (see *Justice: Philosophical Aspects; Equality: Philosophical Aspects*).

3. Property and Justification

Although conceptual analysis of property, property rights, and ownership have concerned philosophers and students of jurisprudence, by far the greater philosophical interest in property concerns its justification. The array of property rights identified by Honoré as jointly constitutive of full ownership could be justified as a whole or separately. Some justifications of property are for mixed systems; so some specific property rights are justified by appeal to one kind of grounding while others may be justified by appeal to another grounding.

Proudhon (1890) famously argued that no private property could be justified. In writing '*La propriété c'est le vol*' (property is theft), he argued that any plausible justification of private property would both demand equality and would, thereby, prove self-defeating. On Proudhon's view, whatever justified one person's exclusive right to a thing, equally justified a similar right for all others. Given the scarcity or at least physical limits on potential objects of property, exclusive rights to property entailed unequal rights, hence one person's exercise of private property rights constituted theft of another's (potential or actual) property.

Despite Proudhon's skepticism that any adequate justification of property could be developed, many political theorists have attempted to provide normative justifications for property. The justification of property rights has taken a number of (sometimes overlapping) forms, these include property rights justified by natural law; property rights justified by acquisition; property rights grounded in the desert of the laborer; property rights justified by appeal to

utility; and property rights as necessary for the development of personality.

3.1 Natural Law

Locke (1690) offers both a natural law theory of property and a labor theory of property in the Second Treatise. First he argued that the earth and its bounty were given to mankind in common by God, such that each individual had the right to take some of the common bounty of nature to provide for life, preservation and comfort. The individual comes to own what is taken from the common, through the exercise of his natural liberty, the labor of his body. In the state of nature, property rights are limited: fruits taken from the common are for the individual's use and must not be allowed to waste in a person's possession. Further, the appropriator must leave 'enough and as good' bounty in the common for others. In the transformation from the state of nature to the civil state, property rules are formalized and the state takes on the responsibility of enforcing the property rights of citizens. Macpherson (1962) and Tully (1980) offer two interpretations of Locke's argument: Macpherson arguing that Locke's argument is essentially possessive individualist, so that the natural law grounding of property is de-emphasized and the protection of exclusive private property is emphasized. Tully, in contrast, argues that natural law limits to property extend into the political state, thus providing significant limitations to individual acquisition.

3.2 Acquisition

Nozick (1974) offers a contemporary libertarian justification for property drawing on Locke's argument, with three significant differences from Locke's argument. For Nozick, the earth and its products are initially unowned. Each individual comes to have legitimate private property rights in those things which he or she has legitimately acquired. Without the premises of common ownership or the aim of legitimate acquisition being the life, preservation and comfort of the acquirer, Nozick's argument justifies largely unrestricted property rights and unlimited property acquisition. Nozick's sole limitation of property rights is what he calls his 'lockean proviso' property rights can be limited if 'the position of others no longer at liberty to use the thing is thereby worsened' (Nozick 1974, p. 178). The situation of others is not worsened, however, by the restriction of liberty which they experience as a result of the thing becoming privately owned. Moreover, 'worsening' the situation of others through acquisition requires compensation, it does not curtail acquisition of the thing in question. Nozick is notoriously vague about which acts constitute acts of legitimate initial acquisition of

unowned objects. Nozick's view is further criticized for failing to provide an argument for the unilateral imposition of duties on all other individuals which follows from an act of acquisition (see *Libertarianism*).

3.3 Labor and Desert

Contemporary arguments which justify limited property rights grounded in labor and desert can be found in Becker (1977) and more recently Munzer (1990). On both accounts, a person's (morally legitimate) labor to create, make available, or to improve something which was unowned grounds a claim to property. The person deserves some recompense for the labor expended, and this will often justify property rights in the improved thing or in the surplus value so generated. For Munzer, the laborers' use of their bodies in the production of something or in the provision of a service gives them the basis for a property claim on the product or on wages. These claims are *prima facie* claims, they are qualified by the needs or rights of others, and by scarcity. Munzer recognizes that the work involved in production is a social activity, and thus argues that payment of wages should be commensurate with desert. It is unclear, however, how desert is to be measured against labor, given the great differences between individuals in capacity, talent, and opportunity.

3.4 Utility and Efficiency

Hume (1740) and Mill (1891) offer utilitarian justifications for property. A system of property rights which distinguishes what is one person's from another's is required for the efficient use of the earth's resources. What the extent, limit, and scope of property rights should be, on a utilitarian account, is a matter of expediency and frequently involves balancing stability of expectations against efficient production and distribution. Hume favored custom and a fixed prescription of property rights, even if that approach allowed for considerable inefficiency. For Hume, inheritance and rights to alienate (sell, bequeath, or give) property acted as incentives for individuals to develop useful habits and accomplishments. Mill, by contrast, argued that the law of property ought to be used by the state to promote greater efficiency and a greater level of communal production of the goods needed within a society. Mill favored private property, but with limited rights of exclusive access and enjoyment of land so as to promote efficient exploitation. Mill recognized that property rights formed a bundle; each property right associated with ownership of a particular kind of property needed to be justified independently on the grounds of utility.

More contemporary utilitarian justifications of property concern themselves primarily with questions of efficiency in allocation of property rights. Economists in particular favor property systems grounded in efficiency, and argue for (somewhat moderated) capitalist relations of production and exchange as the most efficient way to respond to individual wants and needs. Philosophers emphasizing utility, rather than efficiency, are likely to justify mixed property systems (some public as well as some private property) which are roughly egalitarian, as the principle of utility can be directed to make interpersonal comparisons of individual preference satisfaction (see *Economics and Ethics*).

3.5 Property and Personality

Hegel (1821) argued that property is justified as an expression of human freedom. It is important to note, however, that Hegel does not ground property in natural freedom as natural law theorists, like Locke, sought to do. Property relations involve both a relationship between material objects and persons and relations among persons. In taking up an unowned object as property, the acquirer expresses his or her personality upon the object and gives the object value. In the absence of human actions of acquisition and use, material objects have no value and are useless. A human being can only develop—as a free moral agent—in the context of a community of other persons. To be a person is necessarily communal, it depends on recognition by others (Ryan 1984, p. 121). Each individual's will can only be recognized by others through the individual's impression of it on objects of property. Private property, then, is essential for personality. Ownership involves the impression of one's personality on what is possessed, to the exclusion of others. One's will or personality is embodied in the object. Waldron argues that Hegel's account is a general-right based justification for private property: that private property is something which it is important for every person to have, so that the poverty and propertylessness of some individuals is something a property system ought to protect against (Waldron 1988). Property rights justified on Hegel's account included possession, use, and alienation.

Radin (1993) offers a contemporary personality justification of property rights. Radin does not provide a fully developed argument for private property, but rather uses her argument to describe and evaluate existing property relations. Radin argues that at least some private property is required for the development of personhood, and that some things are so closely tied to personhood that they ought not to be commodified as property at all. Radin emphasizes a distinction between property relations based on personal attachment, property constitutive of personality as opposed to the more readily commodified, 'fungible' relations

of property. Radin's view is not entirely Hegelian, as it is strongly influenced by more traditional liberal conceptions of freedom and individualism, yet it is clearly distinguishable from utilitarian emphasis on economic efficiency and Lockean labor justifications of property.

3.6 Marxist Critiques

Most contemporary theorists writing on property, write against the backdrop of the Marxist critique of private property and its centrality to capitalist modes of production. Marx (1971) argued that private property systems presuppose and reproduce inequalities in power between those who have amassed sufficient wealth to become owners of capital (the means of production of goods) and those who are forced to sell their labor power in order to purchase those goods needed for life. Given the equal needs of all humans for the material necessities of life, workers who sell their labor power are open to exploitation by those who own capital. The capitalist pays the worker at the rate required for the subsistence and reproduction of labor, but sells the product produced through the worker's labor at a price which exceeds the cost of the labor and the cost of the resources required to produce the product. The value added by the laborer's efforts (surplus value) is taken by the owner of capital as profit. The degree to which workers are exploited depends on how much surplus value is appropriated by the capitalist. Further, capitalist modes of production involve various forms of alienation including the alienation of people from nature, of workers from the products of their collective labor, and of workers from their own labor power. This alienation, for Marx, is a distortion of human relations. The supposed expansion of freedom offered by private property which some liberal and libertarian theorists argue to defend private ownership, must be reconciled with the alienation and loss of freedom suffered by the propertyless under capitalism (Cohen 1981) (see *Analytical Marxism*).

4. Ongoing Debates About Property

Current debates about property rights raise both fundamental questions about the relationship between property rights and state sovereignty and contextual questions about the appropriate limitation or expansion of property rights. One source of this discussion is response to the demand for recognition of indigenous people's prior ownership of colonized lands in the New World and Australasia. Tully (1995), for example, argues that proper recognition of indigenous peoples, their forms of government, and their legal systems, including their property systems is required for the current legitimacy of states such as

Canada, Australia, and the USA. This area of debate ties the justification of property systems to state legitimacy as well as demanding an account of international relations between states and justice in recognition of other states' property systems.

Another current area of debate concerns conflicting interests in protection of property rights and protection of environmental values. Environmental ethicists have argued for greater limitation of property rights where those rights risk serious damage to the environment and have also argued for increasing the responsibilities of owners for long term damage to environmental values (Dodds 1994). Debate about whether 'pollution taxes' on factories that produce effluent unfairly constrain property rights or can act as an effective deterrent against pollution are among the issues concerning property and the environment.

A third area of considerable current debate about property involves the range of entities which are properly understood as property and as commodities, including ideas, human body parts, reproductive capacities, organisms, and electronic commodities. Radin (1996) challenges the ready extension of property rights allowing for sale and purchase of human tissue, embryos, sexual services, and other forms of property which she views as incompatible or threatening to personality. Other theorists argue that whether property rights are formally recognized over these things or not is irrelevant as there exists a market for these 'goods' and that will determine what is property, regardless of legal or moral attempts at constraining property (e.g., see *Market and Nonmarket Allocation*). Finally, with the growth of electronic commerce, a new field of property debate is also opening up as there will inevitably follow a need for legal determinations about property relations involving purely electronic commodities.

Property Rights

1. The Nature of Property Rights

A property right is the right to use a particular item of property in a particular way. An item of property can be used in more than one way, as long as those

different uses do not exclude each other. Therefore, there can be more than one property right attached to one item of property.

There are various types of property over which property rights can be exercised: water (e.g., extracting water from a river), intellectual property (e.g., authorship of a book), moveable property ('chattels'), and immovable property (land and buildings). For this article (property rights in connection with urban studies and planning), we restrict ourselves to immovable property (alternatively called landed property, real estate, or real property).

It is customary to classify the various types of rights in immovable property which can be attached to one item:

- (a) according to the type of use (e.g., easements);
- (b) according to the division of the space (i.e., special purpose boundaries within the general purpose boundaries of the item of property, such as an office in an office block);
- (c) according to the time (temporary, such as usufructs or leases, or in perpetuity).

There are some other classifications of property rights which cut across those given above:

- (a) superior/inferior (the owner of the superior right is entitled to acquire the inferior rights under certain circumstances);
- (b) alienable/inalienable (the owner of an alienable right is entitled to transfer it to someone else of their own choosing);
- (c) material/contractual (this distinction is derived from Roman law. Material rights, or 'rights in rem,' are attached to the property irrespective of the (legal) person exercising the right and can therefore be freely traded. Contractual rights, or 'rights in persona,' are attached to the property but may be exercised only by the (legal) person specifically named in connection with that right: they cannot, therefore, be traded).

2. Separate Property Rights

It follows from this that it is not an item of property which is owned or exchanged but rights in property and, because there can be many different rights attached to one item, it is possible that one right is owned separately from other rights in the same item (e.g., owning a lease to use a building 'owned' by another).

Where the property right may be traded (and this does not apply to rights which are inalienable and 'rights in persona'), this will have a market value equal to the 'present worth of rights to future benefits arising from ownership' (Jaffe and Sirmans 1989). The owner of more than one right over an item of property might have the choice between selling those rights to one person (keeping the bundle of rights intact) or to several persons (splitting or decomposing the rights). If the total value is greater undivided than divided, the

seller will probably decide not to split the rights. Conversely, if the rights over one item are divided and if the total value of all the rights would be greater if they were amalgamated (there is a 'marriage value'), then one person will try to gain possession of as many rights as possible.

3. The Right(s) of Property Ownership

Because it is a right in property rather than property itself which is owned, it is possible to conceive of a situation in which rights over one item of property were so dispersed that no one person could direct or manage the way in which the item was used. This is not found often: there are inferior and superior rights and there are temporary rights which revert to the owner of perpetual rights. Clearly, it is found to be socially (and economically) desirable that one (legal) person should be able to act as owner of the property (and for this purpose it does not matter whether the legal person is a private or a public entity).

In countries where the law on property is still strongly influenced by the feudal past, property ownership is regarded as being ownership of a full 'bundle of property rights' (fee simple, in Anglo-Saxon legal terms): the starting point is many rights in one item of property, which have been bundled and are in possession of one person. In countries where the Napoleonic legal code shapes the present system, the starting point is that property ownership is complete and that partial rights can then be split off from it. For example, in Dutch law, which is based on that code, ownership is defined as 'the most comprehensive right that a person can have over an object' (Civil Code, article 5.1).

The particular set of rights which constitute 'property ownership' varies from society to society. Nevertheless, it has been suggested that ownership of a property item always includes:

- the right to exclude others from that property;
- the right to dispose of (to alienate) that property;
- the right to derive income from that property.

4. Restrictions on the Exercise of Property Rights

There are many restrictions on the exercise of property rights, most of them accepted voluntarily by the owner when entering into a contract (e.g., someone acquires a building lease from the owner of the fee simple). In addition, there are restrictions imposed by the public administration. These latter can be politically very contentious, when the right(s) of property ownership are constrained.

The owner of an item of property might wish that, 'It is my land and I can do what I like with it' but in practice the legislature always restricts the right of

ownership. Again we take the example of Dutch law (Civil Code, article 5.1) where the definition of ownership quoted above is followed by:

- ‘the owner is entitled freely to use the object and to exclude others from that object, as long as this use does not infringe the rights of others, nor the constraints imposed by written and unwritten law’;
- ‘the owner of the object is owner also of the benefits arising from that object, apart from any rights that others may have.’

A restriction on property rights commonly found is expropriation (the state may acquire the ownership against the wishes of the owner). Another restriction is land-use planning by a public authority (see Sect. 7). It is interesting to note that although, under the US Constitution (5th amendment), ‘nor shall private property be taken for public use, without just compensation,’ the courts have ruled that public actions which restrict the rights of property owners, as long as this does not take 100 percent of the economic value of the property, falls under ‘police powers’ which allow regulation in the interests of ‘public health, safety and morals.’ Such ‘taking’ does not need to be compensated.

5. Property Rights as a Social Creation

In order that a property right can be exercised, it is necessary to delineate the right (define the limits of the property item and the limits of the particular property right), to register who is entitled to dispose of the right, and to determine how the right can be enforced or defended. Establishing those regulations is a matter for the legislature, enforcing them a matter for the courts. It follows from this that property rights are a ‘social creation’: there can be no property rights without agreement on what they entail and without the possibility of enforcing them legally. It is not that something is protected because it is a property right, but that something becomes a property right by being protected (Bromley 1998, p. 25).

From this it follows that property rights can be changed by act of the legislature. This can take the form of restricting an existing right. Introducing a law on noise zones provides an example: henceforth, the owner of land may build upon it only if noise levels on that land are lower than a certain level. Property rights can also be changed by identifying a use which was previously included in a wider right, and making of it a separate right. A well known example is the nationalization of development rights in Britain. The right to develop property was part of the right to own property: in 1947 the British parliament separated the right to development from the right to ownership, nationalized the right to development (which became ownership of the state), and compensated owners of the ownership right for the loss of the right to development. Yet another way of changing property

rights is to establish private rights over something which previously could not be owned. It has been suggested, for example (and see Sect. 7), that the owner of a right to use land in a particular location should have also the right to clean air at that location, whereby that is a right which could be traded.

6. Property Rights Regimes

The statement that property rights are a social creation does not mean that they can be created only by the formal legislature (the law-making institutions). Many societies had property rights before they had such a legislature. The Dutch, for example, set up water boards with legislative powers over rights to use land and water long before they had a general purpose government at any level.

Moreover, a society has often developed its formal legal systems in close connection with its system of property rights: the wish to define and enforce property rights has influenced the legal system. Alternatively, a society may reform its legal system deliberately in order to change the existing system of property rights (as happened after the French Revolution and in the United States after the declaration of independence).

It is for such reasons that it is common to talk about a society having a ‘property rights regime’ (or a land regime), an amalgam of law and custom as distinct from the formal law on property. A regime can be characterised by the way in which it regulates three aspects of property rights:

- who may exercise the right (and may exclude others from exercising it);
- how the right may be used (including restrictions on that use); and,
- how the right may be transferred.

(It will be seen that these are the same three aspects used to define the minimum set of rights that constitute property ownership—see Sect. 1.) Two sorts of regime have already been mentioned: the Anglo-Saxon and the Napoleonic. Others have distinguished in addition (‘legal families’ in Europe, see Newman and Thornley 1996): the Germanic, the Scandinavian, and the East European regimes.

It is sometimes claimed that there are social laws which explain the creation of property rights regimes and changes in them (that is, the regimes do not arise accidentally). These laws have the form of a ‘positive’ theory which can be tested empirically. In an influential article, Ellickson (1992/3) put forward an ‘efficiency thesis’ that ‘land rules within a close-knit group evolve as to minimise its members’ costs.’ The costs he identifies as ‘deadweight’ (net external costs of individual actions) and transaction costs. A change in land rules is efficient when it reduces the sum of these two sets of costs.

7. The Politics of Property Rights

Because a property rights regime is a social creation, it can then be evaluated socially, with a view to changing it in some desired way. That is not new: property rights have always attracted intense political attention.

One strand in the political argument may be called the dyadic view of property rights: private versus public. At one level, the issue is: who should own property rights (in particular, who should own land), the individual (or the family unit) or some collectivity such as the state? Some regard private ownership of property as a bulwark against state despotism, at the other extreme are those who claim (with Proudhon, 1809–1865) that ‘property is theft’ and that it should be owned collectively.

At a more refined level, the issue in most present-day Western societies is: to what extent and in what ways should the state intervene in the exercise of private property rights? Most Western societies agree that the private exercise of property rights cannot be unconstrained (see Sect. 4) and even the most fervent defenders of private property rights usually want the state (or some collectivity) to own land and build roads upon it if this gives access to their land.

Another strand in the political argument about property rights regimes can be called triadic. Then there are not two parties—a private person versus the state—but three—one person who, in the exercise of their property rights can affect another person, and the state as an arbiter in that private/private relationship. Most property law and custom is, in fact, civil law: a collectivity regulates the relationships between (private) legal persons in the use of their property.

Much of the current debate about property rights and land-use planning can be interpreted in terms of dyadic/triadic. To the extent that land-use planning by a public body is justified in terms of welfare economics, it is usually the arguments of Pigou (1932) which are invoked. The market in which private persons exchange property rights has certain characteristics which mean that a welfare optimum (in a Paretian sense) will not necessarily be reached. There are ‘market failures.’ This is seen as a problem, which is resolved when a public body intervenes in the market for property rights. Examples include: restricting the right to use a plot of land in the way that the land owner wants, expropriating the ownership right, public ownership to provide ‘public goods.’

In 1960, Coase argued that market failures arise mainly because of transaction costs and because property rights are not clearly delineated. Examples of this latter are the right to clean air (see Sect. 5) and the right to graze cattle on common land. Incomplete separation of rights creates common property, i.e., in the public domain (Barzel 1898) and, if these rights are valued, resources are spent on capturing them. This can lead to rent-seeking and ‘common-property dissipation’ (of which the best known description is

Hardin’s (1968) ‘tragedy of the commons’). According to this argument, the problem of market failures can be tackled not only by government intervention to restrict property rights (Pigovian measures: moreover, these can make matters worse by creating ‘public failures,’ see Wolf 1979) but alternatively by public measures to enable markets in property rights to function well, to reduce transaction costs and to delineate exclusive property rights.

The economic argument is that helping the market in private property rights to work better will reduce risks, which will stimulate investment, which will achieve a better allocation of resources than through public land-use planning. The political argument is that a property rights regime should be created in which—in dyadic terms—most property rights are held privately and in which—in triadic terms—the role of the public administration is to regulate private transactions in property rights in ways described above. If this is not possible (because, for example transaction costs are high and cannot be reduced, as is the case with roads in urban areas) then ‘Pigovian’ measures can be justified. This approach to land-use planning is called the ‘property rights model’ (see e.g., Lai 1997).

D. B. Needham

Prophetism

Prophetism may be defined as a religious current or movement promoted by the activities of a prophet. A prophet in turn may be defined as a leader of or key participant in a movement or group who proclaims a religious mission on the basis of personal revelation. While many prophets have been founders of religious movements they are not necessarily so but may be significant figures within a revitalization of a religious group or simply play a central role in the religious life of a group or community by pronouncing upon religious matters through revelatory insights or experiences. Neither is the foretelling of future events a necessary component of prophecy but is not uncommonly associated with it. A prophet may or may not convey a message from the gods or be the mouthpiece of divinity. They may express the word of God or the gods or may simply convey religious truths to their followers, which are not claimed to stem from such supernatural sources. Buss (1980) puts the point usefully in the following terms: 'The role of a prophet or seer can be characterised as the receiving and transmitting of communications not available to ordinary conscious sensitivity which are held to come from a source (the divine) or through a form of perception transcending normal spatio-temporal limitations.' Prophets may or may not claim spiritual or supernatural powers themselves and may or may not receive revelation through the experience of states of trance or possession.

What is essential to the notion of prophecy, then, is the relatively emotional proclamation of a religious message that has been revealed personally in a non-routine and nonmundane manner. Prophets are called to their mission and compelled to follow it whether voluntarily or, as is not uncommon, very reluctantly.

The category of prophet as a religious specialist or type of religious figure is one which owes much to Weber who gives it a central role in his sociology of religion (see *Religion, Sociology of*). For Weber a prophet is 'a purely individual bearer of charisma, who by virtue of his mission proclaims a religious doctrine or divine commandment' (1965). Weber distinguishes the prophet from the category of priest. The priest commands religious authority on the basis of a position within a sacred tradition or religious organization and dispenses salvation by virtue of holding an office while the prophet commands religious authority on the basis of personal charisma and recognition of a personal calling to a mission through revelation. The term 'charisma' is used by Weber to refer generally to extraordinary powers essentially of a magical or non-mundane nature (see *Charisma and Charismatic*). The priest for Weber is thus the upholder and guardian of tradition while the prophet is a religious innovator or at least a radical revitalising force (see *Religious Specialists*).

Weber is careful to distinguish the prophet from a number of other types of religious specialist. While the authority and following of prophets may be based upon magical charisma they are not primarily magicians or workers of miracles. The prophet is concerned primarily with doctrine and commandment. It is this that distinguishes the prophet from the mystagogue whose following is based purely upon attribution of magical powers. Yet it is rare that prophets are not expected to give proof of their particular gifts and such proof has more often than not taken the form of possession of magical abilities. Reflecting the fact that charisma may be either inherent or acquired through undergoing extraordinary experiences or practices, these capacities may be inherent in the person or may be acquired through, e.g., ascetic regimes or cultivation of ecstatic states.

Again, while prophets engage, in many instances, in divinatory activities, as was the case, e.g., with the Biblical *nebiim* (singular *nabi*), they may be distinguished from diviners on the basis that it is normal for the latter to be economically recompensed for their services. Prophets provide their spiritual revelations gratuitously and, indeed, often unbidden. To do otherwise would be to undermine their distinctive claim to religious and spiritual influence.

Likewise, Weber distinguishes the prophet from related or similar religious specialists such as legislators, arbitrators, social reformers, orators and teachers on the grounds that lacking in the case of all of them is the proclamation of a religious truth on the basis of personal revelation. Later usages of the term 'prophet' are often less precise and looser than Weber's but in general at the root of them is this specific emphasis upon a purely personal revelatory impulse and calling.

Weber distinguished between two fundamentally different types of prophecy. In the 'ethical' or 'emissary' type, exemplified most clearly by figures such as Zoroaster or Muhammad, the prophet is an instrument for the proclamation of the message or commandments of a god. The doctrines proclaimed by such a prophet take the form of ethical duties. In the 'exemplary' type, most clearly exemplified by the Buddha, the prophet proclaims a soteriological message by personal example and demonstration of the means or path to salvation which others are free to follow to their personal benefit if they wish or ignore to their personal detriment.

In both cases the prophetic revelation acts to promote a meaningful understanding of life in relation to the whole of reality to which conduct must be brought into alignment if salvation is to be attained. It involves the construction of a cosmos as a meaningfully ordered totality. As Parsons (1965) says 'the prophet is above all the agent of the process of breakthrough to a higher, in the sense of more rationalised and systematised, cultural order, an order at the level of religious ethics, which in turn has

implications for the nature of the society in which it becomes institutionalised.' While there is such a stress in Weber's characterization of the prophet upon the construction of a more rationalized and systematized meaningful order, prophecy, Parsons is careful to point out, is not fundamentally an intellectual or theological enterprise but frequently takes emotional and sometimes even violent forms.

Weber's most extensive analysis of specific prophetic activity and prophetic movements occurs in his study of the development of Judaism, in his *Ancient Judaism* (1952), a development in which the Biblical prophets are given a crucial role (see *Judaism*). Weber traces the emergence of a new type of prophet towards the end of the period of the confederacy that he distinguishes from the earlier ecstasies or *nebiim* and the *roeh* or oracle givers. These new prophets saw themselves as called upon to transmit the will of Yahweh to the people and to the rulers. Early prophets of this type did not pronounce unless solicited but progressively they spoke independently and increasingly critically of the political authorities. From the time of Elijah onwards prophets spoke as much to the masses as to the rulers culminating in a situation in which the prophets became the intellectual leaders of the opposition against all that monarchy was perceived to stand for—centralization of power and government, heavy taxation, and social injustice.

Not that Weber considered social justice to be their primary concern. It was the destiny of the state and of the people that motivated their essentially religious yet inextricably political message. It was their purely religious concerns with fulfilling the commandments of Yahweh that brought upon them the opposition of the authorities. For Weber the Biblical prophets represented the values and ethos of the presettlement confederacy.

Classical Biblical prophecy in Weber's analysis is characterized by independence, spontaneity, and disregard for popularity among any sector of Israelite society. It was indifferent to economic, material, or other reward in contrast to other types dependent for their livelihood upon prophecy and prediction. They were at best tolerated and not infrequently persecuted.

While not primarily diviners and seers the classical Biblical prophets nevertheless stressed the dire fate that Israel would suffer if it did not keep the terms of its covenant with God. Such was the precarious situation of the Israelite states in Palestine that gloomy predictions were not uncommonly fulfilled. The religious conduct of the Israelite people was linked intimately by the activities of the prophets to their material and political fate and to that of the state.

The conditions which promoted the development and impact of prophetic currents of this type were those of military and political insecurity and unpredictability. Weber considers that new religious insights rarely occur in the main centers of civilization but rather in areas on their periphery which are subject

to their influence and pressure. Those who live in such regions repeatedly are given reason to question the meaning of events that affect them. Unlike the inhabitants of long stable, politically secure, and settled regions who tend to take the world for granted, those outside these areas constantly are puzzled by the turn of events; 'the possibility of questioning the meaning of the world presupposes the capacity to be astonished about the course of events' (Weber 1952).

Subsequent research on Biblical prophecy has often been critical of aspects of Weber's analysis and by implication of his analysis of prophecy and prophetism in general. Berger (1963) and Turner (1974) have questioned whether the Biblical prophets were the independent force based upon pure charismatic authority and motivated entirely by religious concerns that Weber portrays them as being. In fact, the classical Biblical prophets are more likely, according to some recent research, to have occupied official positions in the cult of Yahweh. The conclusion that writers such as Turner draw from this, that it requires us to reconsider Weber's understanding of prophetic charisma as an autonomous and personal force and to recognize that it arises from the incumbency of positions in an established social institution is, perhaps, rather extreme. It is likely that there were several different types of prophet in ancient Israelite society. Emmet (1956), who considers that Weber equates prophecy with charismatic authority which she finds too restrictive, usefully differentiates a number of types of prophet. First, there is the institutional prophet who fulfils a traditional and established role. Second, corresponding to Weber's charismatic prophecy, there is the leader of a movement which seeks radical change. Finally, there are prophets who do not attract a personal following but who act as independent critics, advocates of reform or who provide moral leadership. While the prophets associated with the Temple in Jerusalem, whose function was an institutionalized one within the Temple cult, were perhaps more numerous, the classical Biblical prophets with which Weber was concerned may be considered to be of a different type. Whether they enjoyed greater autonomy and independence stemming from personal charisma is still, however, open to question.

Weber's stress upon the charismatic authority of the classical Biblical prophets has been challenged by Petersen (1979) on the grounds that there is no evidence that they were leaders with a group of followers, which he claims is implied by Weber's notion of charismatic authority. Neither is it useful, in his view, to characterize Biblical prophets as office holders. The dichotomy between charismatic leader and office holder is, in any case, he argues, far too strictly drawn. We are led, therefore, to question whether the Israelite prophets could have provided the breakthrough that Weber attributes to them. In a later work Petersen (1981) argues that we may get a better

understanding of the Biblical prophets if we see them as having a specific role. He applies role theory in an analysis of their position in Israelite society based upon a close examination of the use of a variety of terms in Hebrew used to refer to such figures. The results show that there was more than one type of prophetic role in this society. Some held established positions in the official cult and operated also by offering a personal service for a fee. Others, termed central morality prophets, pronounced as individuals at times of crisis but in order to uphold established values and institutions. Still others, peripheral prophets, operated outside institutional contexts and established values.

Also doubtful of the simple dichotomy of functionary vs. autonomous charismatic is Lang (1983). The prophetic tradition, he argues, was largely an institution of the land-owning nobility that enabled them to express publicly their political views. He attempts to show that the prophets were largely from a land-owning, noble background. While they were not chosen by formal procedures but simply emerged, they nevertheless, according to Lang, had to learn how to be an acceptable prophet and to observe the rules governing appropriate behavior for prophets. They were closer, however, to Emmet's third type, in Lang's view, and not wholly established functionaries within the cult. The contrast between charisma and tradition in discussions of prophetism is indeed often overstated. Lang points out that they are often bound up with one another in complex ways such that prophetic charisma can be seen as a force for renewal which emerges within traditional structures at certain times. It is a force that changes and reforms without destroying.

While the Weberian view of Biblical prophecy has, in recent decades, been questioned by some, it has for others stood the test of time and deeper scrutiny rather more robustly. Williams' analysis of sources (1969), e.g., supports the view that many of the classical prophets were independent of the official cult. A detailed study by Wilson (1980) is alert to the complexities and differences between periods and regions. He contrasts the premonarchical Ephraite tradition of the North with the monarchical period in both the Northern and Southern kingdoms and also different periods and circumstances in the South. In the premonarchical North, prophetic behavior was expected to conform to familiar patterns regarding the stereotypical linguistic style in which pronouncements were made and to customary behavioral patterns. This clearly suggests that these prophets occupied a defined position and role within the central religious institutions of the society. In the monarchical period prophets seem to have become figures of less central significance but rather more peripheral to the established religious institutions and rather more concerned with producing change. In Judah, however, political circumstances and alliances differentially

affected the type of role and significance that prophets had. Some, standing outside the established cult, were more critical of the status quo while others exercised a more supportive function. This reminds us that prophetism, at least of this type and in these circumstances, may not simply refer to a movement or development led by a prophetic figure but to a dynamic situation of struggle to define or lay claim to the accepted interpretation of a religious tradition or interpretation. Lang (1983) points out that, like many prophets in various traditions and cultures, Jeremiah engaged in conflict with rival prophets opposed to his policy of accommodation with the Babylonians and who advocated total resistance.

Such debates highlight the extent to which Biblical prophecy, and it is an observation applicable to all prophecy, is associated with crises which, while differing extensively in kind, generally call forth a questioning of the status quo and of established institutions and patterns of power and authority. This point has been made by Carroll (1979) in the case of ancient Palestine and Weber's analysis. The religious-political factions that tend to emerge in such circumstances may understandably become aligned with pro-regime and anti-regime types of prophecy.

Not that this necessarily means that prophetism is really a form of politics under the guise of religion. As Albrektson (1972) notes, Weber may well be correct in attributing to the Biblical prophets motives which were primarily religious. Circumstances often made their pronouncements political in tone but at root they were essentially utopian and idealistic rather than pragmatic or designed to stir up political opposition for its own sake.

The political element in prophetism is a factor that comes to the fore most notably in studies of those forms of prophetism that can be described as millennial. It is in the context of the quite extensive studies of such movements that prophetism has been most systematically examined (see *Millennialism*). Not all prophetic movements are millennial and not all millennial movements are prophetic, though most are. It is prophetic millennial movements, however, that have received most attention (see, e.g., Wilson 1975). The role of the prophet in millennial movements varies. Such movements may be initiated by the visions, revelations, and activities of a prophet. Once underway they may call forth a prophet who focuses relatively disordered and uncoordinated activities of participants and who gives coherent expression to previously vague, inchoate, and diverse ideas. The appearance of the prophet transforms millennial ferment into a millennial movement.

The role of the prophet in the millennial movement generally has been found to reflect Weber's emphasis upon prophetism being associated with social and political crisis or radical social change. On the other hand, it is rarely a complete break with the past and more often a process of bridging past and present, the

traditional and the new. The prophetic message in such movements tends to reinterpret old understandings in ways appropriate for an altered situation while at the same time adding new elements and opening up the imagination to new possibilities. The prophet gives concrete expression to what are often inarticulate feelings and ideas and channels them into a program of action promising redemption from current ills. The prophet helps those who are confused by circumstances of change, uncertainty, and instability to comprehend and grasp the meaning of their situation by offering insight derived from special revelation which through understanding points the way forward for remedying what is unsatisfactory. Prophetic movements frequently are found in circumstances of disaffection in which a population is subject to foreign or colonial rule or have little comprehension of the mechanisms and structures of power or how to operate within them in order to ameliorate their situation. The prophet provides the missing knowledge and means of finding solutions. It is significant that many prophetic leaders of such movements are more knowledgeable than their followers as a result of wider experience through travel, limited education, or access to information. The prophet, by providing a focus, is often able to bring together otherwise fragmented communities and diverse groups previously unable to operate in concert in the pursuit of common aims. What is promised, however, is not simply material but also usually, and more significantly, moral and emotional redemption through the recovery of lost personal and cultural dignity and sense of self-worth.

Prophylaxis in Psychiatry

In psychiatry, prophylactic drug therapy includes the use of medication for both prevention and maintenance. For the sake of clarity prevention is measures used in order to prevent the occurrence of a first illness-episode in a group of high-risk individuals (primary prevention), or the occurrence of subsequent illness episodes following the occurrence of a first one (secondary prevention). While secondary prevention is used in a variety of psychiatric disorders, primary prevention, especially for the psychotic disorders, is still under investigation. In order to familiarize the reader with both the concept of primary and secondary prevention, the following paragraphs will discuss a variety of strategies suggested for implementation of primary and secondary prevention focusing on their use in schizophrenic illness.

In the absence of current curative treatments in psychiatry, the use of maintenance therapy—which is associated with long-term control of symptoms and illness-episodes—is especially important. Some of the current drug-prophylactic-maintenance strategies will be described that are used to control abnormal behavior and symptoms in three major psychotic disorders: schizophrenia, major depression, and bipolar illness. Since a knowledgeable choice of a proper maintenance drug treatment necessitates a set of predictors for the success or failure of a given drug, this issue will be exemplified below while discussing maintenance treatment for bipolar illness.

Drug therapy, whether preventive or maintenance, depends on patient compliance. This in turn depends on several variables and certain measures can be taken to maximize compliance. This issue will be discussed as well.

Finally, future directions in prophylactic medication treatment for psychiatric disorders will be discussed focusing on strategies for primary prevention.

1. *Primary Prevention in Schizophrenia*

There is as yet no consensus as to the nature of a subgroup of individuals carrying a high risk for the development of schizophrenia. Research designs used toward this aim involve both retrospective and prospective methods.

Prospective research projects mainly apply long-term follow-up of selected high-risk groups of subjects. Such prospective strategies assume that biological and psychological data obtained from subjects who will later develop the disease will help to identify markers associated with this disease. This, it is hoped, will enable a knowledgeable prediction as to who will develop a schizophrenic illness. One example of such a prospective approach is the follow-up of offspring of schizophrenic patients or their family members (Mednick et al. 1987, Weintraub et al. 1987, Asarnow et al. 1988, Erlenmeyer-Kimling et al. 1993). Another is the examination of psychomotor and neuropsychological variables in large cohorts of individuals while identifying variables associated with later development of psychotic illness and schizophrenia. Yet, another prospective strategy is the study of a variety of factors and early symptoms associated with a transition phase—that is, the phase leading from ‘normal’ into a psychotic state—in order to identify relevant risk factors. All the above strategies require long-term follow-up. Interestingly, there is also a suggestion for a short-term prospective strategy employed by Yung et al. (1998) aiming at identifying a very high risk group of subjects for the development of psychosis. This strategy utilizes a 6–12 months follow-up of selected subgroups of individuals demonstrating high risk for a manifestation of a schizophrenic episode.

In general, retrospective and prospective studies have identified a host of markers increasing the risk for future psychosis including a family history of schizophrenia, distressed family functioning, early separation and institutional rearing, neurobehavioral deficits, delivery complications, maternal exposure to influenza during the second trimester of pregnancy, along with certain behavioral and personality patterns. The latter are mainly reported by teachers and caregivers. Also, a variety of biological findings were identified, all of which still need to be verified in further research. An example of a biological finding is that of small amygdala-hippocampal complex or thalami in people at high risk of developing schizophrenia (Lawrie et al. 1999). Another finding is that of increased plasma homovanillic acid that is negatively correlated with performance in arithmetic tasks in a group of subjects

demonstrating prodromal phase of schizophrenia (Shimushi et al. 2000). All the markers discussed above should be taken at the moment with caution until further research is done. Also, it is our opinion that the use of certain combinations of the above markers for the initiation of antipsychotic treatment in high-risk individuals—although suggested by some (Phillips et al. 1999)—is not recommended at this time as routine treatment.

2. *Maintenance Treatment in Schizophrenia*

Maintenance therapy in schizophrenia is provided by long-term treatment. Based on accumulated experience, it was suggested that schizophrenic patients could be looked at as two groups. One in which maintenance therapy seems to play a ‘suppressive role,’ and its discontinuation leads to a rapid re-appearance of psychotic symptoms, and another group in which the treatment has more of a ‘prophylactic’ role. In this last group discontinuation of treatment leads to a more gradual and remote in time relapse of symptoms (see Gelenberg et al. 1991).

It is estimated that about 10 percent of remitted medication free schizophrenic patients will relapse in any given month. That means that after 6 months roughly about half of these patients will relapse whereas after 12 months about 70 percent will do so and only a small portion of these patients will not relapse at the end of 2 years.

Several strategies of maintenance treatment are suggested for these patients. The first consists of a continuous maintenance treatment. This strategy applies relatively lower doses of antipsychotic treatment as compared with that used for acute exacerbation.

The second maintenance strategy includes ‘drug holidays,’ that is, treatment periods interrupted by drug free periods. This strategy was suggested in order to lower the incidence of side effects while retaining drug efficiency. However, such a strategy is not recommended nowadays since research studies could not support its effectiveness. A third strategy suggests ‘intermittent’ treatment or ‘targeted dose’ for chronic schizophrenic patients. In this case, patients are treated during the acute episode only, while monitored for the appearance of prodromal symptoms (first symptoms anticipating the appearance of an exacerbation). Once prodromal symptoms appear, pharmacological treatment is initiated.

In general pharmacological treatment in schizophrenia includes the use of a group of drugs collectively called ‘antipsychotic drugs.’ These drugs have the ability to block neurons using the neurotransmitter dopamine to transmit messages to other neurons.

In the 1980s, a second generation of drugs came into use. The prototype was clozapine, a drug that besides its ability to block some types of dopaminergic

neurons can also exert a blocking effect on certain serotonergic neurons—(labeled as 5HT-2 neurons) in the central nervous system. This drug was shown to have a lower side-effect profile compared to the more traditional drugs, especially it had minimal extrapyramidal signs (a set of abnormal motoric signs that interfere with daily activities) and it did not elevate plasma levels of prolactin (the lactating hormone). However, clozapine also has several distressing side effects including the lowering of white blood cell count that may expose these subjects to severe infections. Clozapine seems to affect not only the positive illness symptoms but also the negative symptoms of schizophrenia (a set of symptoms characterized by impaired volition and motivation, apathy and paucity of speech) and it may also improve some neurocognitive impairments demonstrated in this disease (see Kane et al. 1988). Beside clozapine, other second-generation antipsychotic drugs were also developed of which mainly olanzapine and risperidone are in use. However, there is still a question whether all these second generation antipsychotic drugs or only some of them can mimic clozapine's effect and if so to what extent.

3. Maintenance in Bipolar Illness

This illness course is characterized by the appearance of manic episodes with or without the occurrence of depressive episodes. It is estimated that the majority of patients who had a manic episode will have one or more recurrences. Since both manic and depressive episodes may be associated with progressive deterioration of interpersonal and occupational functioning and may also carry the risk of harming oneself or others, an adequate maintenance drug treatment for bipolar illness is of utmost importance. Several mood stabilizers—that is, drugs designed for maintenance of the euthymic (normal) state while preventing the appearance of both manic and depressed episodes—are now available. The first mood stabilizer to be used was lithium, a drug still considered by many to be the gold standard treatment for bipolar illness. Other commonly used mood stabilizers are valproic acid and its derivatives, and carbamazepine whereas newer drugs such as the anticonvulsants lamotrigine, gabapentin, and topiramate are still under study. This article will mainly address data published for lithium.

Three open trials suggested that lithium may be effective in the prophylaxis of bipolar disorders (Baastrup 1964, Hartigan 1963, Baastrup and Schou 1967). During the 1970s, a series of double blind studies were conducted to examine the possible efficacy of lithium in the prophylaxis of bipolar disorder. Goodwin (1994) summarized these studies calculating the recurrence rates over a one year period for placebo (a nonactive treatment) to be 81 percent, but only 34 percent for lithium. These reports included two types of studies. Prospective studies treating patients with

either lithium or placebo and discontinuation studies where one group of patients continues with lithium treatment for a given period of time, whereas the other discontinues treatment for a similar time period.

From the 1980s and on more prospective and discontinuation studies were conducted. These studies basically confirmed lithium's efficacy as maintenance treatment for bipolar disorder. They also suggested that there may be an advantage in keeping maintenance lithium blood levels at about 0.6 meq/L as it may lead to less side effects and increase compliance (Coppen et al. 1983) and that lithium plasma levels of 0.8–1.0 meq/L seem to be associated with less relapse (Gelenberg et al. 1989). In general, although many authors still suggest that lithium is an efficient drug for bipolar illness, especially in the classic bipolar patient (Grof 1999), some authors now point to the fact that there is a group of patients who are less responsive to this drug or that demonstrate a decreased response throughout the years.

One important issue associated with long-term maintenance therapy is the finding of predictors for a beneficial, or lack of, response for a given drug. Several predictors of lithium response were offered. Grof et al. (1983a, 1983b, 1999) suggested a better response to lithium treatment in a group of patients demonstrating a course of illness with periods of euthymia (normal range of mood), followed by mania, depression, and then euthymia. These authors also suggested that the absence of rapid cycling (four and more illness episodes per year), the absence of personality disorder, and the diagnosis of primary bipolar disorder (i.e., not secondary to street drugs or organic cause) predict a good prophylactic response to lithium. Faedda et al. (1991) in agreement with Grof suggested that mania-depression-euthymia course is associated with a good response to lithium. Others suggested that good response to lithium in relatives and a family history of mood disorders carry a good response. Aagaard and Vestegaard (1990) suggested that bipolar patients tend to demonstrate decreased response to lithium treatment when they have a lengthy episode, they are young or of female gender. Abou-Soleh and Coppen (1990) suggested that positive prophylactic response to lithium over 6–12 months predicts further good response in the future. Patients with dysphoric and mixed mania (manic episode associated with some depressive symptomatology) were suggested to respond less to lithium treatment and some studies suggest this is also true for rapid cycling bipolar disorder. Hopefully, a knowledgeable use of predictors may help the physician to choose selected subgroups of patients, which will benefit from lithium maintenance treatment.

4. Maintenance in Major Depression

Depression is a serious illness. It carries high suicidal risk. It is estimated that the recurrence of major depression is between 70–85 percent. Two types of

studies report the efficacy of antidepressants to prevent relapse in the first year after remission from a depressive episode. The first is that of a cross-over design, whereas the second is that of a continuation design. In the first design patients are first brought into remission with a given medication and are then maintained on this medication for a period of 2–3 months. Patients who respond are then entered into a double blind design for up to another year, in which they receive randomly either the same antidepressant or placebo. In the continuation design, acutely depressed patients are assigned randomly to either active drug or placebo. Patients who respond continue with the same treatment. Eighteen studies compared a group of antidepressants collectively called tertiary amine tricyclics (this name describes the common molecular structure characterizing this group of drugs), finding that while 50 percent relapsed on placebo only 23 percent relapsed on the active drugs. Three studies compared another group of newer antidepressants collectively called selective serotonin reuptake inhibitors (SSRIs) (this name describes the hypothesized mechanism of action of this group of drugs) finding that the relapse rate for the active drug was between 13–26 percent whereas for placebo it was 46–57 percent (see Janicak et al. 1997).

In general, it is agreed that prevention of relapse in major depressive illness is of major importance and every effort must be taken to address this. Contrary to previous reports that supported the use of low doses in the prophylactic treatment of major depression, several authors now recommend that the full dose be used, that is, a similar dose to that used for the acute treatment of a major depressive episode.

In general, it is recommended to continue maintenance treatment after a first episode of major depression for about 6 months and then to taper the drug gradually. If another episode occurs the recommendation is to continue treatment for several years and after a third episode a lifetime maintenance treatment is recommended.

5. *The Issue of Compliance and its Importance in Prophylactic Drug Treatment*

Compliance to drug treatment is defined as adherence to an agreed treatment schedule between a physician and the patient. It is estimated that no more than 50 percent of patients fully comply with their treatment and we suspect that the magnitude of non-compliance may be even greater in the case of long-term maintenance treatment. Various factors seem to influence compliance including the nature of the patient-physician relationship, the patient's set of beliefs and expectations as well as the occurrence of side effects. Issues relevant to compliance in psychiatric disorders are: (a) the occurrence of delusions and severe cognitive distortions about the index drug, its effect and

side effects, (b) the patient's cognitive functioning and motivation, which may be impaired in certain psychiatric disorders, and (c) the patient's general attitude toward mental illness. Especially important in this context is the level of stigma felt by the patient; the greater the stigma, the less compliant the patient will be.

Several remedies can be offered to enhance compliance and they should be tailored according to the patient's condition and level of understanding. First, an empathic approach, one that builds basic trust with the patient and their family is of utmost importance. Second, whenever possible, the patient with the guidance of their physician should be an active participant in decisions made for the treatment plan. This does not mean that the patient decides or guides such decision making, but that they are presented with several treatment alternatives and an educated decision is agreed upon with the guidance of the physician. Third, the patient should be educated as to side effects and ways to cope with them once they appear (i.e., lower the drug by a certain degree and contact your physician). Treatment diaries and involvement of family members whenever necessary can also be of help. Since maintenance treatment is a long-term treatment, it is our opinion that a responsible physician should renew such a drug treatment 'agreement' at least every several months, discussing it with the patient and perhaps with relevant family and community members if needed. The physician should also actively ask in each meeting with the patient about side effects as well as examine whether there is any change in the patient's set of beliefs about the drug and its action that may need renewed education.

6. *Future Directions for Primary Prevention of Psychiatric Disorders*

Genetic epidemiological studies have shown that genes play a major role in several psychiatric disorders including schizophrenia, bipolar illness, and major depression. It is now believed that these disorders are not related to a single gene, but rather are determined polygenetically. In general, it seems that gene-environment interactions are involved in the causation of many psychiatric disorders. Interestingly, the vulnerability to environmental influences may also be genetically determined (see Owen et al. 2000 for review).

The human genome project, now completed, is expected to contribute to the finding of genes responsible for the susceptibility, occurrence, and maintenance of these disorders. The sorting out of genetic variations in the population, which are related to these psychiatric disorders, may open new avenues to genetic medical interventions prior to the manifestation of these diseases. Such interventions may alter the course or even prevent these diseases from

occurring. Although this project is still far off, one cannot ignore it at the dawn of this new era, which started with the recent completion of the decoding of the human genome.

J. Levine and S. Gershon

Proportional Representation

As a standard for making political evaluations, 'proportional representation' implies that members of a group (R_g) participate in a governmental entity in numbers that bear the same ratio to the total membership of that body (R) as persons identifying with the group (P_g) have to the total population governed (P)—thus, $R_g/R = P_g/P$. The group in question may be supporters of a political party, adherents of an ideological or policy tendency, or persons sharing an identity based on race, ethnicity, religion, language, or gender. 'Proportional representation' also, and more commonly, refers to methods of electing representatives designed to achieve, or at least approximate, the ideal of proportionality in converting citizens' votes into legislative seats. In this article 'proportional representation' (PR) will indicate electoral systems, while the standard at which they aim will be referred to as 'proportionality.' (For related articles, see *Electoral Systems*; *Parliamentary Government*; *Political Representation*; *Voting: Tactical*; *Voting: Turnout*.)

1. PR Electoral Systems

There are two basic types of PR electoral systems—list PR and the single-transferable vote (STV). All PR systems require multimember districts—constituencies from which voters elect more than one representative. Thus, except in the trivial sense that the winner should have more votes than any loser, proportional representation does not apply to elections that choose a single winner, such as for executive posts or legislatures based on single-member districts (SMDs). The degree to which a PR electoral scheme can approximate perfect proportionality depends on the number of representatives elected per constituency, or district magnitude (M). In the limiting case, the entire nation constitutes a single constituency, as in Israel and The Netherlands, where $M = 120$ and 150, respectively.

1.1 List PR

In the pure form of list PR, the closed list, political parties designate before the election a rank-ordered list of M (or fewer) candidates. Electors vote for a party, not for individual candidates. Parties winning seats select representatives from their lists according to the predetermined ranking.

The number of seats each party wins is determined by a formula that employs one of two basic mechanisms—quotas or divisors. In quota (or largest remainder) formulas, parties receive an initial allocation of seats equal to the number of quotas achieved in the vote for their list. The quota is determined by dividing total votes by M (Hare or natural quota), $M+1$ (Droop quota), or $M+2$ (Imperiale quota). Any remaining seats are assigned according to largest remainders—i.e., by the size of parties' leftover votes after subtracting the quotas they have used. In divisor (or highest average) methods, seats are assigned sequentially. Each seat goes to the party which, at that point in the allocation, has the largest quotient after its votes are divided by a number that varies with the seats the party has already received (S). Well-known divisors include $S+1$ (1, 2, 3, ...), the *d'Hondt* formula, and $2S+1$ (1, 3, 5, ...), the *Sainte-Laguë* formula.

Formulas inspire political controversy, because different quotas and divisors favor large, medium, or small parties. Nevertheless, district magnitude has a more powerful effect on parties' fortunes; small parties generally do better as M rises. Some list PR systems incorporate another element to exclude small parties—a threshold of votes (e.g., five percent) that a party must achieve to win seats.

List PR systems are employed for national parliamentary elections in most countries of Latin America and continental Europe.

1.2 The Single-transferable Vote

STV, also known as the quota-preferential system, depends on a preferential ballot, in which voters rank individual candidates from most to least preferred. A quota of votes, Q , is established, usually by dividing the total number of voters by $M+1$. All candidates receiving Q or more first preferences are elected. To determine the remaining winners, two types of transfers are carried out. In downward transfers, surplus votes (those above Q) received by winning candidates are reallocated to voters' second (or, if necessary, subsequent) choices. In upward transfers, the candidate ranking last in votes is eliminated, and ballots giving first preferences to him or her are reassigned to the voters' second (or subsequent) choices. Transfers are iterated until M candidates have achieved the quota.

Perhaps because of its complexity, both in balloting and selecting winners, STV is employed in national elections by just a few countries—Ireland, Malta, and (for the Senate only) Australia.

1.3 Parties and Candidates in PR Voting Systems

In its pure form, list PR assigns control over the fate of individual candidates to parties' internal decision processes, whereas STV reserves that power for voters. In addition, list PR forces voters to choose just one party (or sometimes an electoral alliance of parties), whereas STV allows voters to move back and forth across parties while ranking candidates. Thus, list PR strengthens party organization and promotes party discipline in the legislature, whereas STV is conducive to intraparty electoral competition and individualistic behavior among legislators.

In practice, however, these differences may be blurred. Many list PR countries use open lists, in which electors are permitted (or, as in Finland, required) to indicate preferences for candidates as well as a party. In the *panachage* system of Switzerland and Luxembourg, electors may even distribute votes for candidates across different party lists. Conversely, in STV systems, unless district magnitude is kept low (on the order of three to five representatives per constituency), the task of ranking numerous candidates becomes so difficult that most voters will depend on instructions from parties. Thus, if it imposes excessive cognitive demands, a system intended to maximize the autonomous power of individual voters may end up functioning rather like list PR.

2. Mixed-member Proportional

In an effort to combine the virtues of proportionality and local representation, Germany after World War II pioneered the mixed-member proportional (MMP)

electoral system. In MMP, a share of representatives (half in Germany) are elected from single-member districts, and the remainder are elected from party lists. Electors cast two votes—one for an individual constituency representative and one for a party. Seats that parties win from constituencies are subtracted from their list allocations to make overall delegations proportional to party votes. This crucial compensatory feature makes MMP a truly proportional system.

3. *Semi-proportional Systems*

Another mixed type, easily confused with mixed-member proportional, is the parallel system. Like MMP, parallel systems elect some legislators from single-member constituencies and some from PR lists. Parallel systems diverge from MMP by not compensating for constituency victories in allocating seats to party lists. In effect, the legislature is chosen by an amalgamation of two separate electoral systems, only one of which aims at proportionality. If, as is usually the case, seats chosen by PR comprise no more than half the assembly, then the parallel system is appropriately classified as semiproportional. Japan and Russia adopted parallel systems in the 1990s.

The term semiproportional is also applied to electoral systems that are intended to achieve a degree of proportionality, but do not employ PR formulas to do so. These systems use multimember districts (of low magnitude), voting for individual candidates, and the plurality formula. The opportunity for proportionality arises from their balloting rules. The limited vote requires electors to cast fewer than M votes. In the extreme version case, the single-nontransferable vote (SNTV), electors may vote for only one candidate, even though M will be elected. Japan employed SNTV until 1993. Cumulative voting systems give electors M votes, but allow them to cast multiple votes for a favored candidate or candidates. Limited voting and cumulative voting, which have similar underlying strategic properties, enable well-coordinated minorities to win seats. However, because parties must avoid dispersing votes among too many candidates, these systems tend to reduce competition, and such competition as does occur tends to be within parties or voting blocs, causing internal conflict and factionalism.

4. *Effects and Evaluations*

The obvious intended benefit of PR systems is to establish what advocates consider an essential condition of electoral fairness—a close correspondence between parties' votes and seats. The use of a PR formula, however, does not preclude significant deviations from proportionality when thresholds exist or district magnitudes are low, especially if parties have

not yet adapted strategically to the parameters of the electoral system.

Although the immediate effect of list PR is to promote proportionality for political parties rather than underlying population groups, most parties will compete for votes of minority groups by placing members in electable list positions. If they do not, groups large enough to surpass the threshold can win representation by organizing their own parties. Consequently, list PR systems usually offer improved representation to minorities. The same incentives apply to electing women. Where they have become politically active and ambitious, women generally win more legislative seats under list PR than under single-member district (SMD) systems.

Because PR is less likely than SMD to waste votes cast for smaller parties, it usually results in multiparty parliaments (see *Party Systems*). The association between PR and multipartyism must be regarded as permissive rather than automatic. Within the constraints imposed by the electoral framework (district magnitude, threshold, and formula), the number of parties depends on the number of societal cleavages and on the willingness and ability of politicians to exploit them by organizing parties (see *Cleavages: Political*). Proportionality and multipartyism together make one-party majorities rare, so parliaments elected by PR typically form coalition governments or minority governments that must get support from other parties to pass legislation.

Critics of PR usually concede its representational advantages, but they contend that it produces a fragmented party system, unstable coalition governments, and excessive influence by extremist parties. Their favorite negative examples include Italy (before 1993 reforms), Israel, and Weimar Germany. In response, defenders of PR recommend 'moderate PR' with significant thresholds or districts of intermediate magnitude, rather than the pure forms those three cases exemplify. They defend the need for coalitions under PR as fostering consensus politics and stable policies, if not always stable cabinets.

5. *Historical Development*

Because PR methods are non-obvious and complex, their development stands as one of the key intellectual achievements in the history of democracy. The Marquis de Mirabeau enunciated the principle of proportionality in 1789, but methods designed to achieve it were not refined until well into the nineteenth century. In 1834 Victor Considérant devised a list PR system that Antoine Morin of Switzerland developed further in 1862. In 1885 an international conference on proportional representation in Antwerp recommended the list PR method proposed in 1882 by the Belgian Victor D'Hondt. In 1899, Belgium adopted D'Hondt's system and thus became the first country to use list

PR. By 1920 most countries of western Europe had adopted versions of PR (Carstairs 1980).

Beside the intellectual and moral appeal of proportionality, two practical motives spurred the turn to PR in Europe. In societies divided along linguistic or religious lines, such as Switzerland, Belgium, and The Netherlands, PR offered all groups a stake in democracy (see *Consociationalism*). For countries about to expand the franchise, PR assured ruling conservative parties that they would not be shut out of parliament, as might have occurred under existing electoral systems once previously disenfranchised citizens became a majority of voters. These motives also influenced later decisions to adopt PR, including the notable case of South Africa in 1994.

Perhaps because of their continuous history of elections predating the development of PR, the UK and the USA (as well as some countries they influenced) have clung to the older, simpler method of single-member districts and plurality rule (see *First Past the Post, in Politics*). Proponents of PR in English-speaking countries have usually favored STV, reflecting its invention by the Englishman Thomas Hare in 1857 and John Stuart Mill's enthusiastic advocacy. That tradition was broken in 1993 when New Zealand adopted MMP.

Agreement on a list PR system was often a key ingredient in democratizations during the late twentieth century, as in Portugal, Spain, South Africa, and Indonesia. However, in the 1990s the global trend shifted to mixed electoral systems, both the semi-proportional parallel version and fully proportional MMP. By 1997, of the world's 211 independent states or semiautonomous territories, 75 (35 percent) used PR systems (list, MMP, or STV) to elect the principal chamber of the national legislature. Countries using PR comprised 46 percent of states respecting political rights and civil liberties, and 59 percent of well-established democracies (Reynolds and Reilly 1997). In many other nations, PR is used for elections to upper chambers, regional and local councils, or supranational authorities, such as the European Parliament.

Propositional Representations in Psychology

In cognitive psychology the term 'proposition' refers to a truth-valued unit of meaning that is represented symbolically in the human cognitive system. Propositions have two important components. First, they consist of semantic information structures that represent aspects of experience (e.g., events, states), real and hypothetical situations in the world, and abstract conceptual knowledge. Second, they include truth value and modality information that represents an attitude or belief on the part of a speaker, writer, or any holder of the proposition, with respect to the truth or falsity of the semantic relationships that are represented by the proposition. Propositions function as a semantic base for natural language where they represent types of semantic information that are distinguished in natural languages; and they function as a base for reasoning, serving as truth-valued and quantified predicates to which logical reasoning operations may be applied. This article examines propositional representations from a psychological point of view, the functions of propositions in the human cognitive system, models of propositional representations, and a closely related discourse analysis and model-building technique in cognitive science known as 'propositional analysis.'

1. Propositional Representation in Cognitive Systems

1.1 Propositions as Cognitive Representations

Like all cognitive representations, propositions are a form of semantic representation. As such, they may be used to represent concrete situations of cognition and action in the world, or they may represent more general or abstract conceptual knowledge that is a part of one's long-term store of knowledge about the world and how to act in it. However, in contrast to propositions, systems of cognitive representation are usually thought of as large networks of concepts and relations that reflect a person's comprehension and knowledge. Such networks are often referred to as 'mental models,' 'situation models,' 'conceptual or semantic networks,' 'schemata,' 'knowledge frames,' or in terms of other similar constructs (see Rumelhart and Norman 1988 for a review).

For example, when a visual scene is interpreted, it is represented semantically in the cognitive system as a

network in which objects are identified and represented (as nodes), their properties are represented by links to attributes, and their relationships to each other are represented by particular types of semantic links. To talk about a scene requires the construction of propositions. These consist of truth-valued assertions about information from this network. The validity of these assertions can be evaluated and they can consequently serve as a basis for discussion, inferences, and reasoning. A major task for a theory of cognitive representation is to identify the types of concepts and relations that are used by humans to interpret and represent their physical world as it is interpreted and described through natural language.

An essential property of systems of cognitive representation is their relationship to the particular situation or situations in the world that they represent. Thus, systems of cognitive representation must support evaluations of their validity as representations of (real or hypothetical) situations in the world, or in relation to bodies of shared abstract or concrete knowledge (e.g., in a scientific field). This semiotic property of cognitive representations underlies the truth value and modality information present in propositions, since it is information about asserted truth conditions that permits discussion and reasoning about perceived situations in the world. Consequently, the study of propositional representations in natural language processing, and of reasoning and inference through natural language, has provided psychologists with models of semantic representation that have had a large impact on theories of cognitive representation in general (see Frederiksen 1975, 1986, Kintsch 1974, Rumelhart and Norman 1975, van Dijk and Kintsch 1983).

1.2 The Influence of Other Disciplines on Cognitive Theories of Propositional Representation

Propositions are closely associated with the production and comprehension of natural language, where they represent semantic information that is asserted by a speaker or writer and explicitly encoded in language structures and discourse. Researchers studying language comprehension have shown that in addition to interpreting the propositions encoded in lexical and syntactic structures, understanding discourse also involves construction of inferred propositions. Inferences are used to complete, elaborate, and connect local propositional information into a coherent text representation, and relate a text's meaning to prior knowledge and to its situational context (Denhière and Rossi 1991, Graesser and Bower 1990, Kintsch 1998). The construction of propositional representations, whether through interpretation of natural language or through reasoning about situations in the world, is a fundamental aspect of the cognitive processes that enable us to understand and interpret the world. Thus, propositions are a fundamental aspect of the human

cognitive system where they function in a variety of ways by providing the basic representational units of meaning in cognition and language.

Cognitive theories of propositions as units of semantic representation have been influenced by work from many fields including: linguistics (case grammar, linguistic semantics, text linguistics, pragmatics, systemic linguistics); logic; model theory; situation semantics; philosophy of language (speech act theory, semiotics); and computer science (artificial intelligence and language understanding, conceptual graph and semantic network representations, frame theory, scene analysis, and computational linguistics). Other relevant disciplines include ethnography of communication (conversational inference); cognitive sociology (conversational analysis, ethnomethodology); and cognitive linguistics. For further reading on work in computer science, see Brachman and Levesque 1985; for a multidisciplinary overview, see van Dijk 1997. Fauconnier (1997) discusses recent work in cognitive linguistics and related fields.

1.3 The Role of Propositions in the Architecture of the Cognitive System

The architecture of the cognitive system consists of its general properties as an information-processing system (e.g., Simon 1996 and other papers in the same volume). These include systems for: processing input information; constructing and storing internal symbolic codes; interpreting input information; accessing, using, and modifying stored prior knowledge; operating on internal representations (e.g., to understand, reason, and solve problems); and producing appropriate actions and results (including language) as output. The cognitive architecture that supports natural language processing capabilities consists of a stratified semantic processing system in which propositions are intermediate semantic units that are involved in producing and comprehending natural language in relation to its situational context and to the participants' long-term store of conceptual and relational knowledge. Figure 1 identifies the major elements of this stratified processing system and the central role that propositions play in comprehending and producing natural language discourse. The major levels of representation and processing are:

Natural language discourse: phonetic or lexical patterns; word/morpheme sequences; syntactic structures; linguistic forms signaling discourse cohesion; linguistic and extralinguistic markers (e.g., gestures, stress, intonation) that relate discourse constituents to events, states, and representations in the spatio-temporal environment and signal the situational cohesion of the discourse; and (if the discourse is interactive) speech acts and conversational structures.

Propositional representations: representations of concepts and relational semantic information explicitly encoded in natural language expressions (the text

Figure 1

Levels of processing in the production and comprehension of situated discourse

base); inferred propositions that elaborate and connect local propositions in the text and resolve anaphoric references; coherence inferences; macropropositions that summarize content; propositions generated by logical rules to represent the logical structure of arguments; and propositions that resolve extralinguistic references to the situational context.

Active mental representations of situations and knowledge: conceptual networks constructed to link propositional information into a contextually appropriate connected and coherent cognitive representation—a currently active mental model, situation model, or knowledge structure that is constructed based on the text propositions, situational information, and prior knowledge.

In a stratified semantic processing system, these multiple representations are constructed in a situational context that includes a physical environment (of things, states, actions, events, processes, sequences, etc.) and a representational environment (of symbols, language, icons, images, texts, etc.). They also reflect an individual's use of prior conceptual and relational knowledge that is potentially relevant to the situation and content of the discourse.

2. Cognitive and Communicative Functions of Propositions

2.1 The Semantic Content of Linguistic Expressions

Propositions represent the semantic content of linguistic expressions. For example, in 'The airplane was rising swiftly,' the proposition would represent the structure of an event involving an action (rising), an object undergoing change as a result of the action (the airplane), and an attribute of the action (swiftly). It

would also specify how the airplane is determined (definite) and quantified (singular), and the truth assertion about the proposition (positive truth value). To see how this can become more complex, in 'Laura felt the airplane rising swiftly,' the previous proposition would have to be embedded so as to reflect its semantic role as the thematic content of a process (feel) of a patient or experiencer (Laura), and this proposition would have its truth value specified and objects (Laura) quantified. As can be seen in Fig. 1, producing utterances in a language involves the specification of propositions that 'chunk' conceptual and semantic information taken from situation or knowledge models into propositional units so that the information can be encoded morphologically and syntactically in a particular language.

2.2 Units of Meaning for Comprehension, Inference, Reasoning, Thinking, and Learning Processes

In comprehension, the end product is a mental representation of a situation and knowledge. The direction of processing can be data-driven (when the flow of processing is from semantic interpretation of language units, to propositional inferences, to the construction of a situation model), or it can be knowledge-driven (when prior conceptual knowledge or knowledge frames are applied to guide and constrain the construction of a situation model that incorporates propositional information from a text base). Processes of inference and logical reasoning can operate on propositional predicates, or they may be based on mental models that are constructed to facilitate a more inductive style of reasoning based on concrete examples (Johnson-Laird 1996). Thinking processes involve the construction, activation, and modification of situation models and propositions, and learning involves the incorporation of propositions and information from active situation and knowledge models into a more permanent knowledge structure.

2.3 Building Blocks for Systems of Cognitive Representation

Propositions provide the building blocks for systems of cognitive representation. If knowledge is to be communicated through language or treated as an object of logical reasoning, then it must at some point be propositionalized. Consequently, there should be a close relationship between propositions and systems of cognitive representation. Thus, cognitive psychologists have adopted the strategy of building models of knowledge structure to incorporate semantic relationships that are present in the propositional semantic structures that are expressed in natural language (Frederiksen and Breuleux 1990, Rumelhart and Norman 1988).

2.4 The Semantic Representation of Situations and Knowledge

The propositional information that we construct to describe situations through language is similar to the semantic structures we use to interpret and construct cognitive representations of situations and knowledge. Thus, a primary function of propositions and situation models is to represent and continually update our representations of knowledge and of the currently experienced situational contexts in which we are participating.

2.5 Communication, Conversational Inference, and Situated Cognition

In social environments of collaborative action, reasoning, and problem solving, the main channel of communication is conversational dialog. Participation in such task-oriented dialogs demands conversational inferences by the participants, and these are based on comprehension of the propositional content of the speech as it occurs within the situation and with reference to relevant domain knowledge. Communication and collaborative action in such environments depends on comprehension of the propositions asserted by the participants in the conversation. Thus, propositional representations play a central role in such situations of conversational interaction and socially situated cognition (see Koschmann 1999 for an example).

3. Models of Propositional Representations

3.1 Types of Propositions

Propositions represent a variety of types of semantic information that may be expressed in language. Types of propositions have been defined in terms of the particular semantic relations and concepts that are involved in a particular type of situation that is being represented. A listing of some of the types of propositions that have been identified can help convey the richness of propositional representations.

Events: Events are structures involving an action that produces a change, its causes, results, goals, instruments, and other information specifying the participants and objects effected, the internal structure of an event, and properties of the action, e.g., 'The man walked from the top of the hill to the cemetery gate.'

Processes: Processes identify a process and the objects or persons who experience or are involved in the process; they include cognitive processes having thematic content (e.g., know, believe) and represent the structure of a complex process and its properties,

e.g., 'The war raged.' 'John knows Sally.' 'Laura felt the airplane rising gradually.'

States: States identify objects and specify properties of the objects (e.g., attributes, parts, set relations) as well as their determination and quantification, e.g., 'The painting is beautiful.' 'All of the visitors were tourists.' 'The painting is on the wall.'

Abstract relations: Abstract relations identify abstract concepts (corresponding to propositions) and their properties, e.g., 'This theory is complex.' 'The diagnosis was not obvious.'

Identities: Identity relations link objects or propositions into identity sets, e.g., 'The American President is George W. Bush.'

Algebraic relations: Order and equivalence relations are involved in comparative statements and apply to variables that represent values identified in other propositions, e.g., 'John is taller than Mary.' 'His temperature is normal.'

Functions: Functions represent operations defined on variables that return values, e.g., 'Ottawa is close to Montreal.' 'Montreal is closer to Toronto than to New York.' 'The mean height of the team members is six feet.'

Dependency relations: Dependency relations make one proposition depend on another, such as by causal, conditional, and logical implication relations, e.g., 'He won because he had trained intensively.' 'If you finish your supper, then you can have dessert.'

Conjoint relations: Conjoint relations, such as 'and,' alternating 'or' and exclusive 'or,' specify intersecting, alternating, or mutually exclusive sets of objects or propositions.

Tense and aspect components: These specify temporal properties of propositions, e.g., 'He was attending the opera.'

Modality and truth value components: These specify the asserted truth conditions of propositions, e.g., 'He may not have been at the Opera.'

Determination and quantification components: These specify the determination and quantification of concepts, e.g., objects, and of abstract concepts, e.g., 'Six of the men volunteered,' 'All people are mortal.'

3.2 Predicate-argument vs. Conceptual Graph Structures

Two sorts of formalisms have been used to represent propositions: predicate-argument notation, and conceptual graphs (Sowa 1984). Predicate-argument formalisms use a list notation in which a proposition is represented as a predicate (e.g., event) followed by a list of its arguments (the components of the event: the action, the object of the action, the result, etc.). Information about the determination and quantification of objects may be embedded in its argument slot. For example, consider the following sentence taken

Figure 2

Conceptual graph of 'Collect the samples in an airtight bottle' (adapted from Frederiksen and Breuleux 1990)

from a procedural text in chemistry: 'Collect the samples in an airtight bottle.' An event proposition for this sentence might be as follows (in predicate notation):

7.1 Event: Act (*collect*), Object (*samples*: Def, Plural), Result (7.2, 7.3), Truth.Value (Positive);

The result consists of pointers to two embedded state propositions representing the location of the samples after the action has taken place and a property of the bottle:

7.2 State: Object (*samples*: Def, Plural), Locative. Relation (Object (*bottle*: Token, Singular)), Truth.Value (Positive);

7.3 State: Object (*bottle*: Token, Singular), Attribute.Relation (*airtight*), Truth.Value (Positive)

The alternative conceptual graph notation for this example is given in Fig. 2. Conceptual graphs are equivalent but have the advantage of helping to visualize the semantic relationships being represented by the propositions. This notation is particularly useful in developing models of knowledge structures in particular domains being studied.

3.3 Propositions as Canonical Frames or Semantic Grammars

If propositions are constructed in interpreting and producing language, and in making inferences, how can we explain how they are generated? Two types of explanation have been considered: the canonical frame explanation, and the semantic grammar explanation. It is possible to think of propositions as a vast collection of frame structures which contain 'slots' (or variables) that can be 'bound to' particular conceptual information.

If we replace the arguments in the event proposition by variables, we have an event frame for the action collect which can be applied to many different situations by 'binding' the variables to particular 'values':

'Collect the butterflies in the jar' (Y = butterflies, Z = a state representing the butterflies' location in the jar).

Event: Act (*collect*), Object (Y: Determiner, Quantifier), Result (Z), Truth.Value (Positive);

A conceptual frame theory requires a very large store of such frames in memory and processes to apply them to new linguistic or situational data.

Others have argued that representing propositions as a set of frames is insufficiently powerful to represent the full range of propositional representations that can be constructed. It is argued that like natural language structures, propositional structures reflect rules of formation, and propositional representations need to be defined in terms of knowledge representation languages or semantic grammars. Semantic grammars provide a way of precisely defining a language of propositional representation, and provide rules to guide the generation of propositions and semantic parsing of linguistic expressions. Both canonical frames and semantic grammars appear to be plausible as cognitive mechanisms for the construction of propositional representations (see Brachman and Levesque 1985, Frederiksen 1986, Rumelhart and Norman 1988 for discussions of both perspectives).

4. Propositional Analysis

Theories and models of propositional representation have provided a principled basis for the development of precise methods for analyzing the semantic content of texts as representations of knowledge, developing models of expert domain knowledge, and analyzing the cognitive representations and processes underlying cognitive processes in discourse comprehension and production, inference, reasoning, and other cognitive processes that are reflected in verbal protocols. Propositional analysis is essentially a method for analyzing the propositional content of texts, verbal protocols such as text recalls, responses to questions, reasoning, or talk-aloud protocols, and even task-oriented dialog in collaborative situations of learning or performance (see Frederiksen 1986 and Kintsch 1998).

Propositional analysis normally begins with transcription and segmentation of textual material. Linguistic analysis of the text segments may be undertaken in terms of the linguistic structures previously cited. Semantic parsing rules or propositional frames are applied to specify the propositions explicitly encoded in the sentences. The generation of propositions can be guided by computer tools that enable the application of semantic parsing rules or apply frames to analyze the propositional content of text segments. Inferred propositions may be added to the model to fill recognized gaps in the text information or argument structure, relate the text to aspects of the context or task, summarize the macrostructure of the text, provide responses to questions, etc. Inference analysis can

be based on data from subjects who verbally recall, discuss, or analyze a text. Models of situation and knowledge models may be constructed applying conceptual network formalisms to the propositions. Finally, texts can be analyzed in terms of high-level conceptual frame structures such as underlie procedural texts, problem-solving or reasoning protocols, argument structures, narratives, and story plot structures.

Prosecution

In its broadest sense, 'prosecution' signifies an aggrieved party's initiation and pursuit of a legal case through the court system. It begins with the filing of a complaint document and continues through trial, awarding of remedies, and appeal. While this term technically applies to both civil and criminal matters, it is most commonly used in the criminal law context. In a criminal case, the term 'prosecution' may refer to the process of handling a dispute in criminal court or to the aggrieved party who files the complaint in criminal court.

This article addresses both definitions of criminal prosecution using comparative data to illuminate differences and similarities among prosecution systems throughout the world. Prosecutors have been called the 'gate-keepers of criminal justice' because without their actions, judicial intervention and sanctions could not occur (di Federico 1998). However, a study of prosecution should not be limited to assessments of the prosecutor's role in individual cases. One must instead consider the ways in which countries deal with competing needs and limited resources when they establish and operate their prosecution systems. Because prosecution contributes substantially to the definition and implementation of criminal policy, any comprehensive examination of prosecutors' functions must include an analysis of their relationship to the state.

This article considers six of the most salient features of prosecution systems: (a) the degree to which prosecution is handled by public officials or private parties; (b) the degree to which the prosecutor's office is centralized or decentralized; (c) the political accountability of the prosecutor; (d) the prosecutor's relationship to and with the police; (e) the prosecutor's filing standards; and (f) the prosecutor's role in court. The content of this essay will be limited to the role of prosecution in democratic countries; for a discussion of criminal courts in nondemocratic nations, see *Trials: Cultural; Nazi Law; Socialist Law; Political Trials; War Crimes Tribunals*.

1. Public or Private Prosecution

In many legal systems, criminal law was once a branch of what scholars now call 'torts,' (see *Torts in Law*) and prosecution was initiated and pursued by the injured parties. With the rise of the modern state, crime became a distinct offense against the state itself, and responsibility for prosecution was assumed by the

state (Langbein 1974). This trend emerged earlier and more sharply in Europe than in England, where crimes were defined as offenses against the state, the system of privately initiated and financed prosecution remained in place well into the nineteenth century.

1.1 Prosecutors as Public Officials

On the European continent, public prosecutors play a much larger role in the criminal process than they do in the United States and England. Continental prosecutors control the investigation of crime, often having direct supervisory powers over the police, and typically oversee the execution and disposition of almost all criminal arrests. This tradition derives largely from the institution of the *ministère publique* from the Napoleonic Code. Furthermore, some civil law countries combine the role of prosecutor and judge, allowing officials to move back and forth between the two positions at different points in their careers and sometimes within the same case. A number of non-western countries that have based their criminal justice systems on German or French models (such as Japan) also permit role flexibility to varying degrees (see also *Trials: Cultural; Judges* for the relationship between prosecutors and judges). Recent developments in France and Italy, however, suggest the use of more clearly defined boundaries between criminal justice system actors.

Common law countries reject this expansive conception of the prosecutor's office and formally prohibit any degree of fluidity in roles, regarding such interchangeability as in conflict with due process and separation of powers principles (see also *Due Process in Law; Civil Rights*). In common law countries such as the United States, the public prosecutor unilaterally (with very few exceptions) makes filing and case-processing decisions. The investigative work is typically left to the police and judging is the domain of elected or appointed members of the judiciary. (Of course, in actual practice, the discretion with which each of these actors is vested allows some flexibility in task performance; see also *Plea Bargaining* and *Policing* for examples.) In England and Wales, the newly developed Crown Prosecution Service, comprised exclusively of professional prosecutors under the leadership of the Director of Public Prosecutions and the Attorney General, handles the prosecution of most crimes. Like their American counterparts, British judges and police officers function independently of prosecutors, although they do coordinate their activities.

1.2 Elements of Private Prosecution

Since the mid-nineteenth century, public prosecutors everywhere have become more powerful and inde-

pendent. However, since the 1970s, with the growth of the victims' rights movement in many countries, legislatures have begun to provide victims with a greater voice in criminal proceedings. The degree of victim empowerment varies tremendously among countries. For example, Belgian law recognizes that certain crimes (i.e., defamation) require a formal complaint by the victim in order for the public prosecutor to initiate a criminal case. Even in that event, however, the public prosecutor is not obligated to file charges. In Germany, a victim may act as a private prosecutor if the public prosecutor does not file charges, or he may join the public prosecution as a joint plaintiff and support the prosecutor's case. A French crime victim who feels ignored by the authorities may file a civil case based on the criminal behavior. This action automatically initiates a criminal case, thereby forcing an otherwise reluctant public prosecutor to become involved.

American crime victims generally have no formal right to participate directly in criminal cases; their role is limited to testifying as witnesses and to receiving restitution as part of the final case disposition. Nonetheless, victim enthusiasm or willingness to participate (or lack thereof) may greatly influence the prosecutor's decision to proceed with a case; cooperative victims are not a prerequisite to a successful prosecution (given the expansive laws of evidence), but they often bolster an otherwise shaky case. Victims of crime in the United States can also file a civil lawsuit against the defendant based on the same conduct at issue in the criminal case, although the remedies available remain limited to civil damages. Interestingly, the role of private interests in prosecution has made a comeback in the United States, as scholars have recently debated the legitimacy of allowing private victims to finance investigations or prosecutions which are conducted by public officials (Kennedy 1997).

2. Centralized or Decentralized Office

Centralization or decentralization of oversight affects all aspects of the prosecutorial function, from the hiring and training of staff, to the implementation of policies for filing and processing cases, to levels of responsiveness to public opinion. Scholars can distinguish between those highly centralized systems that place prosecutors in an national civil service hierarchy led by the Ministry of Justice, and those decentralized systems that consider prosecutors to be locally selected (and often elected) political officials. Overall these structural and institutional features are likely to be closely related to the larger structure of government and to make a difference (Damaska 1981). Needless to say, variations exist between these extremes, and even within each category, according to hiring practices or filing control.

At one extreme is the American experience. The vast majority of criminal cases—both serious and minor—in the United States are filed and processed at the state level. However, ‘State Control’ is something of a misnomer, because most American state prosecutors are county officials who enforce state law. The chief prosecutor of each office (usually called the district attorney) is elected by the people, while the deputies or assistants may be either career civil servants or employees of a specific administration. State attorneys general have little control over their behavior or filing practices, handling mostly training and appeals (Flemming et al. 1992). Each county operates its own hiring system and typically recruits graduates from local law schools. There is little advance training for the job; on-the-job training occurs locally, within the office or in short courses run by the state. As a result, each office sets its priorities according to the demands of its electorate and according to the interests of its leaders; this can produce great diversity in policies among prosecutors’ offices, even within the same state (Utz 1979, Feeley 1979).

At the other end of the spectrum lie countries like France and Japan, where the procuracy is tightly controlled and pyramidal in shape. For example, at the apex of the Japanese system sits the Supreme Public Prosecutors Office, followed by eight High Public Prosecutors Offices and then fifty District Public Prosecutors Offices. At the base are 452 Local Public Prosecutors Offices, located in major cities throughout Japan. The Local Offices prosecute only relatively minor cases, while the District Offices handle all serious crimes. Moreover, Japanese prosecutors are an elite subset of the population; they have graduated from top law schools, passed an extremely rigorous bar exam, and endured two years of training at the Supreme Court’s Legal Training Institute. Because they are overseen by the Supreme Court, Japanese prosecutors at all levels have close association with judges; indeed, prosecutors can transfer to judicial work if they like and vice versa. As a result of their training and the hierarchy within which they work, and perhaps their close association with the judiciary, Japanese prosecutors value consistency in case-handling to a degree which other nations’ prosecutors find almost inconceivable (Johnson 1996, 1998).

Centralization also affects the extent to which prosecutors can be influenced by public opinion. Officials in decentralized offices are often vulnerable to intense local political pressures and media criticism. In contrast, where public prosecutors’ offices form part of a civil service hierarchy headed by the Ministry of Justice, prosecutors may consider themselves more immune from public opinion. They contend that this immunity is crucial in order for the prosecutor to remain objective and impartial; it allows him to more easily dismiss cases for insufficient evidence, or to prosecute popular or famous citizens, without fear of

retaliation on election day. These claims to immunity should not be taken at face value, however; some modern prosecutors in Italy, Spain, France, and Portugal will actively court the media to generate public interest and support for their cases. Prosecutors in civil service countries are also much less likely than American prosecutors to leave government work for private practice; hence, they are less concerned about keeping good relations with the local defense bar. However, the existence of tight governmental controls provides a different sort of pressure: at least one scholar has noted that Japanese prosecutors have been severely criticized for failing to prosecute corrupt politicians (Johnson 1996).

3. *Accountability to the Public*

As the previous comments regarding public opinion and corrupt politicians reveal, prosecutors in most countries must answer to someone for their unpopular decisions. As discussed above, some countries have responded to this issue by providing victims with the right to initiate private prosecutions after the public prosecutor declines to file charges. While there is not much data on the degree to which these provisions are used by private citizens, the existence of these policies serves (at least in theory) as a check on the prosecutor’s monopoly over charging decisions.

Where the prosecutor is an elected official, as in the United States, accountability is likely to come from another source: re-election pressures. A prosecutor who wishes to be re-elected must present herself as an ethical, fair, and supremely competent attorney and administrator who is responsive to the demands of the local community (Flemming et al. 1992). She is thus not likely to file charges for technical violations about which the local community cares little (such as prostitution in some places), and she may press for rigorous prosecution and sentencing for those crimes which inspire publicity, political lobbying, or protest (such as drunk driving or domestic violence in the latter part of the twentieth century).

Where the prosecutor is a career civil servant, accountability is usually to his superiors or to the Ministry of Justice. Decisions not to file charges will be reviewed by prosecutorial superiors, who tend to be conservative in matters of discretion not to prosecute (Damaska 1981). Japanese prosecutors, for example, must seek the approval of two or three superiors before making any charge decision (Johnson 1996, 1998). Yet some civil servant prosecutors have found another source of leverage; as noted above, prosecutors in Latin European countries often attempt to use media coverage to pressure office superiors into filing or pursuing controversial criminal cases. Hierarchical control is not unproblematic, though, particularly when it affects a prosecutor’s career advance-

ment. France, for example, enacted reforms in 1993 and 1994 to limit the discretionary powers of the Minister of Justice, with regard to both his hierarchical supervision of prosecutorial activities and his decisions concerning the status, promotion, and discipline of public prosecutors (di Federico 1998).

Assessments of accountability must acknowledge context: prosecutors are, *inter alia*, employees of large organizations. As such, they must advance the interests of the organization in order to advance their own careers. Hence, prosecution policy and behavior are likely to follow bureaucratic dictates or public demands, despite (or within) the constraints provided by formal law.

4. Relationship to and with Police

Is a prosecutor a justice official or a member of law enforcement? While Langbein (1974) reports that English justices of the peace served as both investigators and prosecutors in the fourteenth and fifteenth centuries, most countries today have formally separated the roles of police and prosecutor. Nonetheless, prosecutors vary in the degree to which they control or participate in the investigative phase of a case. A prosecutor may bring a high level of control to police activities by formally supervising a police investigation (before or after bringing charges), by interviewing witnesses, or by attending the execution of search warrants. In contrast, a prosecutor may manifest low levels of control by simply filing charges in response to documents and evidence collected and submitted by investigating police officers.

In code-based countries with strongly centralized prosecution agencies, high control is the norm. Police may be statutorily required to notify prosecutors of an ongoing investigation or the detention of suspects, and the prosecutor can directly interrogate suspects or collect evidence. While prosecutors often delegate these decisions to police officers, the existence of prosecutorial investigative authority may serve as a useful check on police power (Johnson 1996, Frase 1990, 1999).

Low levels of control characterize common law countries like the United States; police typically handle the investigation and arrest phases of a criminal matter and notify the prosecutor only after arrest. While federal prosecutors often become far more involved in the investigatory phases, coordinating wire-taps, search warrants, and witness interviews, most state prosecutors do not interrogate suspects or assist in the collection of evidence (Leo 1996). Hence, police often control the flow of information on which prosecutors must rely in order to decide whether and what crimes to charge. This has led some commentators to conclude that prosecutors do little more than ratify police decisions (Feeley and Lazerson 1983), rendering the arrest itself far more significant than the prosecutor's

filing decision. The same tendency has been observed in Canada (Grosman 1969).

The division of labor between police and prosecutors is not always clear-cut or unproblematic, as police behavior can influence both the onset and eventual disposition of a criminal case (Skolnick 1975). These tensions are manifest in the British experience. The police were Britain's public prosecutors from 1829 to 1986, due to the absence of a suitable alternative; in this time period, they developed a vested interest in controlling all stages of criminal cases—from investigation to arrest to prosecution (Fionda 1995). The Crown Prosecution Service was created to separate police and prosecutorial functions in order to remedy a perceived lack of police objectivity in prosecutorial duties, such as the filing and disposing of cases. However, in the fifteen years since the creation of the CPS, police officers have continued to fight for control over filing decisions and have been accused of manipulating files and witnesses to influence prosecutors' options (Nduka-Eze 1995). (See *Policing* for more about police discretion.)

5. Filing Standards and Guidelines

With respect to filing policies, scholars are principally concerned with whether a nation imposes a program of mandatory or compulsory prosecution on the one hand, or officially allows its prosecutors discretion in filing charges on the other. Nonetheless, whether a country actually requires its prosecutors to file charges is often hard to ascertain; the official codes may dictate one practice while informal policies allow others. For example, the American criminal prosecution system gives vast discretion to prosecutors; many continental systems, in contrast, maintain a formal policy of 'full prosecution' and explicitly make no provision for individual discretion. However, most American systems have placed some restrictions on their prosecutors' discretionary powers, while most continental systems permit discretion in hidden (or not-so-hidden) forms. This paradox has led observers to conclude that 'the rule of compulsory criminal prosecution ... may foster a wider use of discretion without responsibility if no control is at work' (Guarneri and Pederzolo 2001).

Mandatory prosecution, which requires a prosecutor to bring a charge whenever there are sufficient grounds to suspect a person of having committed an offense, is a more common feature of civil law countries, whose provisions and requirements are strictly controlled by the criminal codes. Civil law countries typically choose to address undesired consequences by amending their codes, rather than openly permitting the prosecution to use discretion in enforcement. For example, Germany, Sweden, and other countries have handled their increased crime problem by legislatively downgrading or decriminalizing certain offenses, and by making

others subject to administrative (rather than criminal) sanctions (Sessar 1979, Feeley 1979). However, Germany also recognizes the 'principle of opportunity' for petty offenses, which gives the prosecutor discretion to drop the charge, to issue a penal order (which allows a person to pay a fine in a minor case), or to bring the case for summary trial in order to expedite proceedings (Herrmann 1992, Felstiner 1979).

In France, the opportunity principle works somewhat differently. While the public prosecutor is not obligated to bring a prosecution, once she initiates a prosecution she no longer has a choice regarding whether to pursue the case (Frase 1999). In Italy, compulsory prosecution exists without the concurrent opportunity principle, but discretion reigns nonetheless (Gaurneri 1996, Corso 1993). When a prosecutor does not wish to file a case, she may neglect to investigate and ask the judge to declare the evidence insufficient, or she may allow the statute of limitation to lapse.

The Italian prosecutor's manipulation of formal criteria to justify a non-filing decision raises the issue of discretion: in countries which officially allow some discretion, are prosecutors subject to any formal rules regarding its exercise? For example, Israeli and British prosecutors must prosecute when the evidence is sufficient, unless they find that prosecution would not be in the public interest (Harnon and Stein 1999, Fionda 1995). Notably, British prosecutors may be using this public interest criterion as an informal presumption against prosecution in relatively minor cases, especially where the defendant has no previous criminal record (Fionda 1995).

In the United States, where there is no official 'public interest' component to the filing decision, prosecutors have an enormous amount of discretion; they need to justify filing decisions only to their superiors, as victims have no legal rights to intervene. As a result, prosecutors allow informal social criteria, including victim characteristics, to influence their charging decisions. Cases involving victims who are related to defendants, or who are otherwise 'undesirable' people (such as prostitutes or gang members) trigger larger societal issues, and thus appear less distinctively 'criminal' to American juries. Because these cases pose conviction problems, prosecutors concerned about their personal 'win rates' are reluctant to file them (Frohmann 1997, Vera Institute of Justice 1981). American prosecutors have also been accused of overcharging cases, filing multiple charges in the complaint with an eye towards plea bargaining later. Overcharging gives the prosecutor leverage in the plea bargaining process, but it has been called a coercive, corrupting, and deceptive technique to get the defendant to agree to virtually the same sentence he would receive after trial (Alschuler 1968) (see *Plea Bargaining*).

Discussion of filing policy necessarily leads to consideration of alternatives to prosecution, because

many cases which are not technically prosecuted are also not fully dismissed. Rather, they are redirected into other channels, alternatively called diversion, penal orders, or summary procedures. These programs arose in response to demands to keep minor offenders and unimportant cases out of the already overworked court systems. However, they have all been accused of 'widening the net' of criminal social control, as prosecutors are more inclined to divert a minor offender into this type of alternative program than to drop his case altogether.

6. Roles in Court

The final point of comparison concerns the prosecutor's role during the trial of a criminal case. Her role will largely be determined by the type of trial system in which she works (adversarial, inquisitorial, or some mixture thereof; see *Trials: Cultural*). She may be an active adversarial participant striving to win a conviction, or a more passive, impartial actor charged with ensuring that justice results.

Where the trial depends largely on the contents of a written dossier (in countries such as Japan, Argentina, France, and Germany), the prosecutor is generally more passive; she submits the dossier containing the investigative reports to the judge (or to the panel of judges) before trial, but she generally relinquishes control over questioning of witnesses. In many of these systems, the prosecutor is obligated to ask the judge for an acquittal following trial if the evidence merits this result, and the prosecutor typically has the right to appeal both the outcome of the case and the sentence.

In systems that require oral testimony (including Italy, Great Britain, Israel, and the United States), the prosecutor is the principal player in the courtroom. He may sit near the factfinders or judges to establish rapport; he controls the majority of the witnesses and the presentation of evidence; he argues his case both first and last, providing both the initial opening statement and the final closing argument. For this reason, prosecutors in oral-trial systems feel personally invested in the outcome of a case and often place tremendous pressure on themselves to win convictions (Heilbroner 1990, Baker 1999). They generally have no right to appeal acquittals.

A final consideration is the prosecutors' input into the sentencing decision. Prosecutors are often said to have tremendous influence over sentencing based on their charging and plea bargaining policies. Because each crime is associated with a specific minimum and maximum sentence, the prosecutor can control the type of sentence a defendant will receive by filing or making him plead guilty to certain charges. This power is exacerbated by mandatory sentencing guidelines; by eradicating the judge's discretion to sentence appropriately after conviction, these guidelines give

the prosecutor the ability to control the sentence through his charge-bargaining practices. Furthermore, some nations, such as Great Britain and Germany, limit the ability of certain courts to impose certain punishments; hence, the mode of trial pre-determines the maximum sentencing powers of the court in a given case. The prosecutor may thus indirectly control sentencing by filing the case in a particular type of court.

Prosecutors might also influence sentencing directly, although nations differ concerning the degree to which they allow prosecutors to make sentencing recommendations after trial. In many European countries, prosecutors can assist judges in navigating complex sentencing formulas, while in the United States the sentencing hearing is regarded as another phase of the adversarial process in which the prosecutor may present both witnesses and arguments. In Great Britain, the prosecutor has no legal authority to recommend an appropriate sentence; indeed, some commentators believe such a power would be an unconstitutional infringement on judges' power (Fionda 1995). However, British prosecutors have a duty to correct a judge who is in danger of imposing an illegal sentence, and the British Attorney General, like prosecutors in South Africa and the United States, may appeal any sentence imposed by the trial court on the grounds of undue leniency or statutory error.

7. Conclusion

Given the vast array of criminal prosecution systems existing at the close of the twentieth century, it no longer seems useful to rely on the broad categories of adversarial and inquisitorial systems to illustrate similarities and differences. A number of axes exist that better describe the elements of various prosecution systems; to ignore these dimensions in favor of simple dichotomies provides us with too superficial a view of the prosecutor's role in court, in public life, and in political affairs. Moreover, the prosecutor is not an isolated actor: her responsibilities, relationships, and roles depend on social, legal, and political contexts. In order to truly understand the role of prosecution from a social scientific perspective, we must commit ourselves to understanding these environments and to accepting the cultural differences which exist among the world's nations.

K. Levine and M. Feeley

Prosocial Behavior and Empathy: Developmental Processes

Research on helping others in distress took off with the brutal murder of a young woman in Queens, New York in the mid-1960s, which was witnessed by 30 people from their apartment windows. The initial research on why witnesses do not help (Latane and Darley 1970) focused on the context and found that the presence of other bystanders can interfere with a person helping by activating certain assumptions—'diffusion of responsibility' (I'm sure someone has called the police) or 'pluralistic ignorance' (no one is doing anything, so it can't be an emergency). There was also research on when people do help, which showed among other things that the tendency of bystanders to help increases with age.

Recent research has focused more on prosocial motivation and emotion. It highlights empathic emotion, sympathy, and guilt. This article is concerned with developmental processes in empathic emotions and their contribution to helping. Also covered is the role of cognition in arousing, developing, and shaping empathic emotion and enlarging the individual's perspective on prosocial behavior. Finally, the article deals with the contribution of socialization especially by parents and peers, and gender differences.

1. Definition of Empathy

Empathy has been defined in two ways: (a) the cognitive awareness of another person's internal states (thoughts, feelings, perceptions, intentions); (b) the vicarious affective response to another person. This chapter deals with affective empathy, because of its motive properties (see Ickes 1997 for cognitive empathy).

Affective empathy was initially defined as a match between the observer's and the model's feeling. It is now defined as it is here, more in terms of the processes that make an observer's feelings congruent with the model's situation not his own (Hoffman 1978, 2000). There may be a match, but not necessarily as when one feels empathic anger on seeing someone attacked even when the victim feels sad or disappointed rather than angry. Most of the research on affective empathy as a prosocial motive focuses on empathic distress because prosocial moral action usually involves helping someone in discomfort, pain, danger, poverty, and the like.

2. Modes of Empathic Arousal

Five empathy-arousal modes have been identified (Hoffman 1978). Three are primitive, automatic, and preverbal. (a) Mimicry, which has two steps: one spontaneously imitates another's facial, vocal, or postural expressions of feeling, producing changes in one's own facial or postural musculature; these changes trigger afferent feedback to the brain, which results in feelings that resemble the other's feelings. (b) Classical conditioning, in which empathic distress becomes a conditioned response to distress in others through observing others in distress at the same time that one is in actual distress. (c) Direct association of cues from others or their situation with one's own painful past experience. The empathy aroused by these three modes is passive, involuntary, based on the pull of surface cues, and requires little cognitive processing. Nevertheless, these modes are important because (a) they show that a person's distress can indeed result from someone else's painful experience; (b) they make empathy arousal possible in the early preverbal years of childhood; and (c) they give empathy an involuntary dimension throughout life.

Two empathy-arousing modes are higher order cognitive. (a) Verbally mediated association: language communicates the other's distress and connects the other's situation to one's own painful past experience. (b) Perspective-taking: one feels something of the victim's distress by imagining how one would feel in the victim's place and/or trying to imagine directly how the victim feels by using information one has about him or her. These higher order cognitive modes may be drawn out over time and subject to voluntary control, but they may also be triggered immediately on witnessing another's distress. What they contribute to

empathy is scope; they also allow one to empathize with others who are not present.

Multiple modes are important because they enable observers to respond empathically to whatever distress cues are available (Hoffman 2000). Cues from the victim's face, voice, or posture can be picked up through mimicry, situational cues, through conditioning or association. If a victim expresses distress verbally or in writing, or someone else describes the victim's situation, one can empathize through verbally mediated association or perspective-taking. Empathic distress is thus a multidetermined hence reliable human response, which fits the argument that it survived natural selection and has a hereditary component (Hoffman 1981, Zahn-Waxler et al. 1992).

3. Developmental Stages

Mature empathy has a metacognitive dimension: one knows one's feeling of distress results from another's plight and how the other presumably feels. One thus has a sense of oneself and others as separate beings with independent inner states (that are only partly reflected in outward behavior), separate identities, and separate life conditions. Before 6 or 7 years children can empathize but without this metacognitive dimension. This suggests that empathic affect develops along with cognitive self/other development. Five stages of empathy development have been hypothesized (Hoffman 1978, 2000).

(a) Global empathic distress: newborns show a vigorous, agitated distress response to another infant's cry. (b) Egocentric empathic distress: one responds to another's distress as though oneself were in distress. This occurs when children can be empathically aroused by the three preverbal modes but still lack a clear self-/other distinction. (c) Quasiegocentric empathic distress: one knows the other is in actual distress but confuses the other's inner states with one's own and tries to help by doing for the other what would comfort oneself. (d) Veridical empathic distress: one's feeling is closer to the other's because one realizes the other has inner states independent of one's own. (e) Empathy for another's experience beyond the immediate situation (e.g., chronic illness, economic hardship, deprivation): this high empathy level is possible when children realize that others have an identity and a generally sad or happy life condition; and empathy with an entire group (homeless; Oklahoma City bombing victims).

4. Causal Attribution's Shaping of Empathic Affect

Humans spontaneously attribute causality to events (Weiner 1985) and they presumably do this when witnessing someone in distress. If they blame the victim, empathic distress is of course reduced. Other-

wise, depending on the attribution, empathic affect may be shaped into four empathy-based moral affects (Hoffman 2000). (a) Sympathetic distress, when the cause is beyond the victim's control (illness, accident, loss). (b) Empathic anger, when someone else is the cause. (c) Empathic feeling of injustice, when a discrepancy exists between the victim's character and the victim's fate (a good person fares badly). (d) Empathy-based guilt over inaction, when one does not help or one's efforts to help fail and the victim's distress continues; here one's empathic distress combines with blaming oneself not for causing the victim's distress but allowing it to continue.

5. Empathy as a Prosocial Motive

Empathy correlates positively with helping. There is also experimental evidence that arousal of empathic distress leads to helping; and that observers help more quickly the greater the victims' pain and the higher the observers' empathic distress. Furthermore, observers' empathic distress becomes less intense and they feel better if they help, but not if they don't help or if despite their best efforts and through no fault of their own, the victim's distress is not alleviated, which implies that the main objective of empathy-based helping is to alleviate the victim's distress. There is also evidence that empathy reduces both aggressive and manipulative (Machiavellian) behavior. It thus seems clear that empathic distress is a prosocial motive. See reviews by Hoffman (1978, 2000) and Eisenberg and Miller (1987).

Empathy has limitations, however (Hoffman 1984, 2000). (a) Egoistic motives may intervene and one may not help, even at the price of feeling guilty afterwards. (b) Empathic distress increases with the level of victims' distress, but empathic distress can become aversive enough to shift one's attention from the victim's to one's own personal distress (empathic overarousal). (c) People empathize with almost anyone in distress (the victims in research are usually strangers), but they empathize more with kin, in-group members, friends, and people who share their personal concerns (familiarity bias)—which may not be a problem except when intergroup rivalry contributes to intense empathic anger (hatred, ethnic cleansing) toward outgroup members. (d) People empathize more with victims who are physically present (here-and-now bias), probably because most empathy-arousing processes require immediate situational and personal cues.

6. Socialization by Parents and Peers

The role of parent as socializer has three facets: model, disciplinarian, nurturer. Each contributes to children's empathy and prosocial behavior, although discipline has been the most studied (Hoffman 2000). The

discipline method most likely to contribute to empathy, helping, and guilt over harming others is a type of reasoning called induction, often used by educated middle-class American parents when children harm or are about to harm someone. Inductions direct the child's attention to the victim's distress and may thus engage the empathy-arousing modes noted above. They also highlight the child's role in causing the victim's distress, which may lead to empathy-based transgression guilt. Power-assertive disciplines (physical force, threats, commands) are associated with low empathy, low helping, and low guilt, although some power assertion may be needed at times to get children to attend and process an induction's message.

Parents' behavior outside discipline encounters may provide prosocial models that reinforce children's empathic proclivity and legitimize helping (Eisenberg and Fabes 1998, Hoffman 2000). Examples are expressing compassion toward people in difficult straights such as the homeless; linking a television protagonist's feelings or situations with the child's own experience; pointing out similarities among all humans such as sadness due to separation and loss. Parent models may thus reinforce children's empathic dispositions especially when they are bystanders and someone needs help. Parent models may also make children more receptive to inductions, and, along with inductions, make children more receptive to claims of their peers (Hoffman 2000).

Piaget suggested in the 1930s that interaction with peers (not parents, who are too powerful) fosters prosocial moral development in children (Piaget 1932). Cognitive-developmental psychologists have recently elaborated this view (Turiel 1998), briefly as follows: children 'co-construct' and discover moral norms in the give-and-take of peer interaction (disputes, arguments, negotiations). These peer conflicts put pressure on children to take different points of view and to consider and coordinate the needs and rights of self and others (for example, regarding claims to ownership and possession of objects). This is a compelling hypothesis that merits research. Hoffman (2000) suggests that the peer interaction processes involved can serve to add the finishing touches to the prosocial outcomes of having inductive, nurturant, prosocial models as parents.

7. The Role of Cognition

Though we deal with empathic affect, cognition's importance is evident in two empathy arousal processes (verbally mediated association and perspective-taking): in the key role of self/other differentiation in empathy development; in the production of empathic anger and empathy-based guilt through causal attribution; and in children processing the information in inductions. Beyond that, cognitive development enables humans to form images, represent people and

events, and imagine themselves in another's place; and because represented people and events can evoke affect, victims need not be present for empathy to be aroused in observers. Empathy can be aroused when observers imagine or read about victims, discuss or argue about economic or political issues that involve victims, or make moral judgments about hypothetical moral dilemmas (see *Moral Reasoning in Psychology*) in which there are victims. See Hoffman (1987, 2000) for discussion of the importance of cognition, including the cognitive dimension of moral principles, in empathy's development and prosocial functioning.

8. Gender Differences

Girls are socialized more than boys to be kind and feel responsible for others' well-being. Girls are thus expected, increasingly with age, to be more empathic and prosocial and less likely to harm others. The research supports these expectations but in varying degrees (Eisenberg and Fabes 1998). Girls show more kindness and consideration for others and, to a lesser extent, are more likely to help and share. They are less likely to harm others and more apt to feel guilty when they do. They are also more empathic than boys, but this is clear only with self-report, especially questionnaire measures, in which it is obvious what is being assessed and responses are under the subject's control. It is not clear with unobtrusive naturalistic observations or physiological indices of empathy. The empathy findings may thus reflect subjects' conceptions of what boys and girls are supposed to be like. Whether they reflect gender differences in actual behavior is a matter for future research to decide.

Prosopagnosia

Prosopagnosia is a neuropsychological condition involving loss of ability to recognize familiar faces. Prosopagnosic patients instead rely on voice, context, name, or sometimes clothing or gait to achieve recognition of people they know. The problem in face recognition is not due to blindness (the person with prosopagnosia can still see) or general intellectual impairment (people are still recognized from nonfacial cues). Yet even the most familiar faces may go unrecognized: famous people, friends, family, and the person's own face when seen in a mirror.

Face recognition impairments are socially disabling, and most patients develop strategies for tackling the problem. They may note carefully what clothes someone is wearing, ask relatives always to wear a particular distinctive item, or become adept at initiating or maintaining a conversation whilst they work out who they are talking to. These strategies are not completely effective. One prosopagnosic patient lost a legal action when he discussed his case with his opponent's lawyer—he thought it was his own advocate because he was wearing similar court clothes.

Prosopagnosia should not be confused with other types of impairment that can compromise face recognition (Young 1992). In prosopagnosia, recognition from other cues than the face is usually possible. In contrast, cases of inability to recognize people from face, voice, and name have been described—these

seem to reflect loss of semantic information about the identities of individuals. There are also reports of problems of name retrieval (anomia), in which familiar people are successfully recognized and appropriate semantic information is accessed, but their names cannot be recalled. Face recognition impairments therefore reflect damage to an underlying system which can break down in different ways.

Although reports of problems affecting face recognition after brain injury can be traced back to the nineteenth century, prosopagnosia was identified as a distinct neuropsychological problem by Bodamer in 1947 (Ellis and Florence 1990). Whilst it is generally considered a rare deficit, there are now several hundred case descriptions in the literature. These include cases where brain injury early or late in life has led to inability to recognize previously familiar faces, and developmental cases where the disorder is present from birth. People with prosopagnosia know when they are looking at a face, and can describe its features, but the loss of any sense of overt recognition is often complete, with no feeling of familiarity. In contrast, other aspects of face processing, such as the ability to interpret facial expressions, or to match views of unfamiliar faces, can remain remarkably intact in some (though not all) cases. The ability to recognize everyday objects other than faces may also remain good, and many prosopagnosic patients are able to read without difficulty. In one of the cases of early acquired deficit, a child who had remained unable to recognize any faces since suffering meningitis and subsequent complications in infancy was nonetheless able to learn to read (Young and Ellis 1989); this underlines the implication that reading and face recognition depend on different types of visual analysis.

Deficits commonly associated with prosopagnosia include a visual field defect in the left upper quadrant, achromatopsia (loss of color vision), and topographical disorders (inability to find one's way about). These are useful clinical pointers, but they are thought to be due to anatomical proximity of otherwise unrelated processes rather than having any direct functional significance; cases of prosopagnosia without each of these associated deficits have been described, and they have also each been reported in the absence of prosopagnosia.

Studies of prosopagnosia initially concentrated on the location of the lesions responsible, and to what extent the problem is specific to face recognition. More recent work has asked whether there exist different underlying forms of deficit, and has explored the implications of findings of covert recognition.

1. Lesions Causing Prosopagnosia

The underlying pathology involves lesions affecting ventromedial regions of occipitotemporal cortex; these include the lingual, fusiform, and parahippocampal

gyri, and more anterior parts of the temporal lobes. Functional imaging studies of normal observers have confirmed the importance of these regions to face perception (Kanwisher et al. 1997). Bilateral lesions are usually present in the relatively small number of cases that have come to autopsy (Damasio et al. 1982), but cases involving unilateral lesions of the right cerebral hemisphere have been reported in several computerized tomography (CT) and magnetic resonance imaging (MRI) studies, and the functional imaging findings with normal people also emphasize the importance of the right hemisphere.

2. A Face-specific Deficit?

Prosopagnosia involves a severe impairment of face recognition, yet a number of prosopagnosic patients can read and can recognize many everyday objects, so the deficit does not compromise all aspects of visual recognition. But is it only face recognition that is impaired?

In most cases, the answer is clearly 'no.' So, for example, recognition of familiar buildings, flowers, types of car, or animal species may all pose difficulties. Like faces, these are all visual categories with a high degree of interitem similarity.

This has led to the hypothesis that what is lost in prosopagnosia is the ability to recognize the individual members of categories that contain several items of similar appearance. Ability to identify the general category to which the items belong (face, building, flower, etc.) is preserved, but within-category recognition is defective. Although attractive, this idea has been undermined by (rare) reports of highly circumscribed impairments. One of De Renzi's (1986) cases could find his own belongings when they were mixed in with similar objects, identify his own handwriting, pick out a Siamese cat among photographs of other cats, recognize his own car without reading the number plate, and sort domestic coins from foreign coins. In all of these tasks he was therefore able to identify individual members of visual categories with high interitem similarity, yet he could not recognize the faces of relatives and close friends. Just as strikingly, the deficit can affect mainly *human* faces: when McNeil and Warrington's (1993) prosopagnosic patient took up farming, he was able to learn to recognize his sheep, and correctly identified several of them from photographs of their faces!

Although they are exceptionally rare, such cases imply that the possibility of face-specific deficits must be taken seriously. However, it may be important to reconsider the underlying issue. The presumption behind the interest in face-specific deficits has been that these might indicate whether the brain has an evolved neural substrate for the important social task of face recognition. But this rationale would only be

valid if the organization of the evolved substrate was so rigid that it could not become involved in other important visual discriminations. Studies of the properties of visual cells in the primate brain (Logothetis and Pauls 1995) and acquired expertise in humans (Diamond and Carey 1986) suggest, in contrast, a more plastic organization. It is possible that much of our visual expertise involves extending the sphere of involvement of cells that would otherwise become dedicated to face recognition.

3. Different Forms of Prosopagnosia

There has been much discussion as to whether prosopagnosia can have more than one different underlying cause. Often, a distinction is made between cases that seem to reflect defective face perception and those that are more like a loss of face memories. When face perception is defective, patients may be poor at telling male from female faces, or matching photographs of unfamiliar faces, whereas patients with a face memory problem may remain able to perform such tasks fairly normally.

For many years, this debate proved inconclusive because it was conceivable that the so-called perceptual cases simply reflected a more severe form of the same impairment. However, studies of ability to form mental images of premorbidly familiar faces have shown that someone suffering from the perceptual form of prosopagnosia can perform better than someone with a loss of face memories (Young et al. 1994). A plausible interpretation is that this happens because we need the same representation to conjure up a mental image of someone's face that we need to recognize that face. In perceptually based cases of prosopagnosia, these stored representations of familiar faces could remain intact, but a seen face could not access them because it is not perceived sufficiently accurately; imaging faces which cannot be recognized would then remain possible. In memory-based cases, stored memories cannot be used for imagery or for recognition—either because they are themselves damaged or because access to the store is defective.

4. Covert Recognition

The interpretation of some cases of prosopagnosia as a domain-specific impairment of face memory is strengthened by findings of covert recognition, which show clear parallels to priming effects found more generally in amnesia. Prosopagnosic patients usually fail all tests of overt recognition of familiar faces. They cannot name the face, give the person's occupation or other biographical details, or even state whether a face is that of a familiar person (all faces seem unfamiliar).

Surprisingly, however, there is substantial evidence of covert recognition from physiological and behavioral measures (Bruyer 1991).

Bauer (1984) measured skin conductance whilst a prosopagnosic patient, LF, viewed a familiar face and listened to a list of five names. When the name belonged to the face LF was looking at, there was a greater skin conductance change than when someone else's name was read out. Yet if LF was asked to choose which name in the list was correct for the face, his performance was at chance level. Hence, there was a marked discrepancy between LF's inability to identify the face overtly and the relatively good recognition shown using the indirect skin conductance measure.

A number of other indices of nonconscious, covert recognition in prosopagnosia have also been developed. Matching of familiar faces is better than for unfamiliar faces, priming has been found from familiar faces onto the recognition of name targets, and learning of correct face-name pairings is better than learning of incorrect pairings (Bruyer 1991). All of these effects can be demonstrated when overt recognition of the faces is at chance level.

Not all prosopagnosic patients show covert recognition, however. As might be expected, when there is evidence of substantial impairment of face perception, covert as well as overt performance can fall to chance level.

There is a parallel between preserved covert recognition abilities and those aspects of recognition that operate automatically for normal people. We cannot look at a familiar face and decide not to recognize it—the mechanisms responsible for visual recognition are not open to conscious control in this way. It seems that some of these automatic aspects of recognition continue to function in some cases of prosopagnosia. A simulation of this pattern can be made by halving some of the connection strengths in a computer model of the architecture of the recognition system (Young and Burton 1999). The network is then no longer able to classify face inputs as familiar, yet it continues to display priming effects. This helps us to understand how covert responses can be preserved when there is no overt discrimination, but it does not solve the more difficult issue of what is involved in being aware of recognizing a face.

Despite the extensive range of covert effects demonstrated in the laboratory, prosopagnosic patients do not act as if they recognize faces in everyday life. Instead, most are acutely conscious of their problems in face recognition. However, some patients lack insight into their disability and show unawareness of impairment (anosognosia). Case SP was very poor at recognizing familiar faces, yet she maintained that she recognized faces 'as well as before,' even when directly confronted with her failure to recognize photographs of familiar faces (Young et al. 1990). In contrast, SP showed adequate insight into other physical and

cognitive problems produced by her illness—her lack of insight into her face recognition impairment involved a deficit-specific anosognosia. Such deficit-specific anosognosias may reflect impairment to mechanisms used for monitoring performance in everyday life; we can all make occasional errors of recognition, so we constantly monitor our own performance to correct these errors quickly and avoid embarrassment whenever possible.

Remarkably, the deficits of overt recognition noted in prosopagnosia need not be absolute. Sergent and Poncet (1990) found that their patient, PV, could achieve overt recognition of some faces if several members of the same semantic category were presented together. This only happened when PV could determine the category herself; otherwise she continued to fail to recognize the faces overtly even when the occupational category was pointed out to her. Sergent and Poncet (1990) suggested that the simultaneous presentation of several members of the same category may have temporarily raised their activation above the threshold at which recognition could be achieved.

Such findings in prosopagnosia show that the boundary between awareness and lack of awareness is not as completely impassable as it seems to the patients' everyday experience. However, the circumstances under which this has been found to happen are at present very limited, and it has not yet proved possible to find a way to provide significant remedial assistance in real life.

A. W. Young

Prosopography (Collective Biography)

Prosopography, or collective biography, has developed considerably since the 1960s, expanding in the fields of modern and contemporary history, after the tool was invented and applied primarily in ancient and medieval history. The method's principle is simple: defining a population on the basis of one or several criteria and designing a relevant biographical questionnaire containing a range of variables or criteria which serve to describe it in terms of social, private, public and/or cultural, ideological or political dynamics, depending on the population under scrutiny and the questionnaire that is being used. In the words of Lawrence Stone: 'Prosopography is the investigation of the common background characteristics of a group of actors in history by means of a collective study of their lives (Stone 1971, p. 46) Once the documentation has been compiled, which is the most time-consuming aspect of the work, the data can be evaluated with the help of a number of techniques, both quantitative and qualitative, including manual counting or computerized processing, statistical tables or factor analyses, depending on the scope and sophistication of the questionnaire and the sample.

To appreciate the success of this method and demonstrate its extension to different branches of history, several historiographic references are cited in Sect. 1. To gain insight into its merits and limitations, it is necessary to analyze a few examples of its application, taken primarily from recent periods see Sect. 2 where other social history methods can be used, permitting us to weigh the advantages and disadvantages of both alternatives. An attempt is made to define the heretofore untapped potential of the method in the area of comparative studies in Sect. 3. This possibility has been the least explored to date.

1. Historiographic References

Ancient history scholars claim to be the fathers of prosopography (Chastagnol 1970, Nicolet 1970). The term was conspicuously used in the modern sense by T. Mommsen in the announcement of the *Prosopographia Imperii Romani*, published in 1897 (Groag and Stein 1897, Lalouette 1999). This serial was imitated for other periods of ancient history throughout the twentieth century, both in collective works and in individual monographs. Prime examples are *The Prosopography of the Later Roman Empire* by A. H. M. Jones and J. R. Martindale (1971–92), and *Prosopographie chrétienne du Bas-Empire*, of which two volumes have appeared, edited by André Mandouze (1982) and Charles Pietri and Luce Pietri (1982). Countless monographs contain prosopographies of elites of antiquity. One of the earliest is Jean Kirchner's *Prosopographia attica* (1901), followed by Paul Poralla's 1913 work on the Lacedaemonians and the classics by Friedrich Münzer (1920), Ronald Syme (1939) and Claude Nicolet (1966), etc. The application of prosopography to medieval times started to develop between the world wars. Studies focus on administrative personnel and the entourage of the sovereigns of the principal Western European states. Since the 1960s, the body of literature has become quite copious, as various surveys (Bulst 1986, Griffiths 1986) reveal. The same goes for modern history, where the initiator was Sir Lewis Namier (1929, 1930), who studied English political elites. His works inaugurated an ongoing series of studies on the House of Commons from the Middle Ages to 1832 (Cruikshanks 1986). French and Italian investigation has concentrated on diverse selections of officials taken from public administration and the judiciary as well as on ecclesiastical, intellectual, financial and commercial elites (see Charle et al. 1980, Nagle 1986).

In the area of contemporary history, work began during the second half of the 1960s. Most of it was inspired by the perspective on elites introduced by sociologists, particularly American, influenced by the theses of Pareto and Mosca beginning in the 1950s. In France, one of the issues that stimulated research of this kind was the debate on the French Revolution opened by the theses of F. Furet and D. Richet (Richet 1969, discussed by Vovelle 1974), proposing an alternative to the Marxist interpretation then dominant in France, founded on prosopographic study of elites before and after the upheaval. This is the background of the investigation by L. Bergeron and G. Chaussinand-Nogaret on notables of the Napoleonic Era (1979). Similar works on prominent figures of the nineteenth century and the bourgeoisie since the 1960s have relied on the prosopographic method. This approach was inspired by Ernest Labrousse (Tudesq 1964) (for an overall survey, see Charle 1992). French sociology of education, influenced by the works of Pierre Bourdieu (Bourdieu and Passeron 1970,

Bourdieu 1989), has also been the source of numerous intellectual and academic prosopographies (Karady 1972, 1973). In Britain, Germany, and the USA and more recently in Italy, Spain, and Switzerland, collective biographies of political, economic, religious, intellectual, artistic, and militant elites have proliferated. They are an outgrowth of great national historiographic debates on subjects such as the foundation of political rifts in the British parliament, the evolution and function of English nobility, the distinguishing characteristics of German, Swiss, and Italian bourgeoisies (Kocka and Frevert 1988, Tanner 1990, Augustine 1994, Malatesta 1995), the formation and reproduction of American elites (Baltzell 1958, Jeher 1973), and so on. In contemporary history, the method has also been applied to larger groups than elites, which are the sole focus of prosopography in the spheres of ancient, medieval and modern history because records on other segments of the population are not available. The history of women, the middle classes, lower classes and even marginals have also availed themselves of collective biography in recent decades thanks to abundant printed sources, oral history and new assessments of large biographic files which already existed (Dreyfus et al. 1996, Omnès 1997).

2. *Merits and Limitations*

The proliferation of studies in contemporary history and historical sociology using the prosopographic method is due to intellectual trends and techniques developed since the 1970s. The concomitant decline of global statistical methods and of the intellectual impact of Marxism, which featured social classes with huge populations, and the desire, typical of societies focused more and more on the individual, to come to grips with individual experience and the diversity of social patterns have inclined historians of recent times to emphasize social microhistory, which gives priority to prosopography or collective biography. Finally, the widespread advance of computerization has facilitated complex processing of bigger and bigger databases (Stone 1971, Millet 1985). Whereas in former times the lack of mass documentation required patient gathering of data on the individual level before any collective generalizations could be made, in recent periods resorting to prosopography has been construed as a change of perspective from traditional social history based on serial documentation.

Thanks to this technique, since the 1970s historians have increasingly set their sights on gaining intimate knowledge of small problem-related constituencies. Thus, S. W. Serman's study of officers of the Second Republic and the Second Empire traced the long-lasting confrontation in nineteenth century France between the aristocratic ideal and the rising democratic tide (Serman 1978). Investigations of elites

(high-ranking personalities of the July Monarchy (Tudesq 1964, Girard et al. 1976), the business leaders of the Second Empire (Plessis 1985, Barjot et al. 1991–1999), ruling circles of the Third Republic (Estèbe 1982, Charle 1987), and deputies to the national assemblies in Paris and Frankfurt in 1848–49 (Best 1990)) were attempts to understand the evolution of models of reproduction dominant in one regime toward those prevailing in other systems, the disparity between myths justifying the social order and sociological mechanisms, the possible social impact of political revolutions, reasons for the unique French road to industrialization, the peculiar German path to an incomplete parliamentary system, and the relations between English entrepreneurs and previously dominant elites (Berghoff 1991). In short, these collective biographies allow us to revamp our answers to some major questions as well as to conduct an in-depth reassessment of cherished tenets of social history without confining ourselves to the preconceived structure of serial and quantifiable sources. In these new approaches, groups define themselves with reference to relational characteristics or their reciprocal images or even their capacity to impose an image of themselves on others and on the majority of their members. The notion of construction of the object thus becomes decisive in this microhistory based on collective biographies.

This is precisely the point which since 1971 has triggered premature criticism of prosopography, summed up by Lawrence Stone with reference to modern history studies inspired by Sir Lewis Namier: the biases of official sources on which the biographies rely lead to a partial view of reality, the delimitation of populations is largely arbitrary, and criteria applied for the biographies are often restrictive. All this contributes to an elitist, cynical and conformist perspective on the spheres of leadership and their relations with society at large (Stone 1971). These criticisms are not valid unless the historians confuse the method with its objective and forget that they can never consider more than a fraction of reality as determined by the sources which they select and the limitations of their biographical questionnaires. They are less likely to fall into these traps for recent periods, where the findings of collective biographies can be confronted with other sources, where partial prosopographies can be compared and merged, and where the diversity of groups readily available for investigation goes well beyond the scope of the elites to which earlier studies were confined.

The prosopographical historian navigates permanently between two reefs: the undefined biography of individuals (with the risk of losing sight of the collective dimension) and the opposite: the expansion of prolific samples to the scale of the entire society (with the risk of reducing the questionnaire to its lowest common denominator). To escape from this dilemma, collective investigation by means of large

research teams, adopting common principles, has been applied with varying success in different countries. Examples include the ongoing study of the British House of Commons (Namier and Brooke 1964), the study of mayors in France (Agulhon et al. 1986), the investigation of members of parliament of the French Third Republic (Corbin and Mayeur 1995), the collective biographies of legislators by the Zentrum für Historische Sozialforschung in Cologne (Schröder et al. 2000, Best and Cotta 2000). These surveys require a long-term institutional financial commitment, which has become more and more difficult to find since profitability criteria were introduced in academic research. They also assume long-term involvement of loyal research personnel, which is less and less compatible with normal levels of staff turnover. This is why the principle of coordinated monographs, being more flexible and decentralized, appears to be more realistic in the contemporary university environment. It also overcomes the need to sacrifice the originality of each individual's work in the anonymity of a hierarchic endeavor. However, to avoid the risk of dissipation or non-comparability of partial results, it posits a minimum of harmonization and entails meetings to fine-tune the common questionnaires, coding systems and evaluations. In exploiting collective biography, one is not only forced to gauge the conditions of sample validity. One must also recognize the limits of the categories applied *a priori* to the data. Since the responses to the questions which are included involve social stakes, the process of interpretation of prosopographic data is characterized, more so than in other methods, by historians who consciously or unconsciously put their mark on the results at all stages of the study: sampling, data gathering, coding, and processing.

3. Toward Comparative Prosopography

In France and increasingly in most other developed countries, nearly all groups that lend themselves to collective biography have been adopted by a biographer: aristocracies, dignitaries, urban bourgeoisies, administrative elites, financial, commercial and entrepreneurial elites, intellectual and university elites, artists, middle-class professionals (physicians, jurists, journalists, professors), students, officeholders at all levels, labor leaders and militant feminists, even marginals, etc. Is a decline of the method of collective biography imminent? Will it be stopped in the name of the unyielding law of diminishing returns and as a result of the resurgence of historiographic topics which are less amenable to this approach (cultural history, history of memory, history of collective sensibilities)? Three considerations allow us to reject this premature diagnosis of a decline in the advantages of a method which has been so fruitful in the area of recent social history.

First, apart from elites, other social groups which are beginning to revise their social history thanks to insiders' collective biographies (middle classes and, increasingly, lower classes, not only through the eyes of their militant elites, but also in the form of life stories of privileged witnesses) (Ozouf et al. 1992, Pudal 1991, Gribaudi 1987) are far from being thoroughly investigated. Application of the method to these new fields requires new reflection on the composition of samples (which can no longer be exhaustive) and on the relations between individual paths and morphology: the internal diversity of the configurations is directly proportional to the size of the target population. This again raises the issue of sample representativeness, which had disappeared when investigators employing prosopography of elites resorted to exhaustive polls. All these groups are transitory, while elites, by definition at the top of the heap, are target groups; hence characteristics of the individuals of which such groups are composed cannot be viewed in isolation, but must be understood as vectors of multiple strategies.

Second, European historiographers are acquainted with the adjustments required to enable them to merge complementary studies to arrive at a homogeneous scrutiny of comparable groups from different societies. Thus, the comparative research coordinated by Jürgen Kocka on European bourgeoisies has demonstrated that not all of the difficulties in analyzing this group at an international level are due to the unequal advancement of studies; above all they arise from the collateral persistence of divergent investigations—some inspired by classical methods of social history, particularly in Germanic and Anglo-Saxon countries, others, particularly in France, primarily involving research based on collective biographies, which result in different approaches to different problems, and at times to inappropriate comparisons (Kocka and Frevert 1988, Charle 1990).

Collective biography, therefore, still has a nearly unexploited field at its disposal: that of comparative prosopography. The principal, eternal objection to comparative historical study is the necessity, given the abundance of material, to conduct secondhand research, using monographs prepared by other scholars, with the compounded risks of hasty generalization of conclusions taken out of their unique context and of the permanent lack of correspondence in the compared data, particularly in social history, on account of the recurring coding problem. Despite these obstacles, German researchers have already forged ahead, and certain French historians and specialists in England have followed suit since the 1990s (Best 1990, Berghoff and Möller 1994, Charle 1994, Siegrist 1995, Cassis 1997, Ruggiu 1997). Collective biography is an extraordinarily demanding methodology in terms of research time and rigorous organization of data. Comparative prosopography multiplies the time it takes to assemble the data by at least two—for two

countries—or more, if one wants to compare a greater number of cases. The problem is compounded by the extra time needed to design the research and evaluate the data. In order to test the initial hypothesis of feasibility and fruitfulness of a comparative project, it is convenient to start in a domain where one of the two countries involved already has a critical mass of usable data allowing researchers to define an analogous scope of investigation in the other selected country, which must possess a comparable, evident interest in the chosen elite. This explains the fact that comparative prosopographies deal primarily with the best-documented and most frequently studied elites (in big business, politics, higher education and high society), as in the cases mentioned previously. Collective biographies at a national level have permitted us to better understand the internal rifts in the various groups which have been studied as well as their social and generational dynamics. In certain favorable cases, it has been possible to relate these rifts to political, ideological or religious stances or apply them to better understand certain failures or successes. Comparative prosopography should allow us to go even further in this interpretive analysis by relativizing correlations which were taken for granted in a given national or social setting. They should account for common trends which transcend borders and the peculiarities of one moment in time, of one milieu or one nation. For instance, the generally accepted notion that the expansion of higher education translates into an opening of university teaching positions to a wider segment of society is disproved if one compares the collective biographies of the professors of the University of Berlin (Arts and Sciences) with their counterparts at the Sorbonne at the turn of the nineteenth and twentieth centuries. The major divergence accounts for the misunderstandings between the two academic communities even when they attempt to cooperate, and goes a long way toward explaining their widely varying relations with other elites during political crises (Charle 1994).

The goal of comparative prosopography, as with any kind of prosopography, is to employ collective biographies to portray the real social behavior of the institutions or the milieus in which the individual subjects of the study interact (Genet and Lottes 1996). The main danger in applying comparative prosopography is therefore, as with many erudite ventures, that one will discover nothing but well-established or generally acknowledged truths in each country concerned. One usually arrives at this impasse or this disappointing result when one deals with samples that are too vast to lend themselves to controlled comparisons which would allow the study to qualify any dominant feature or put it into perspective. In light of this danger it is essential to make a particularly judicious choice of variables to be compared. We face a series of common methodological issues which transcend historical periods.

Their resolution would allow us to launch a wider debate on the possible foundations of a comparative sociocultural history of European society.

Prospective Memory, Psychology of

Prospective memory refers to remembering to perform an action in the future such as remembering to pick up a loaf of bread on the way home, to give a friend a message, to send a birthday card to your aunt, to take your medication, and to pick someone up at airport at 4 p.m. Ellis (1996, p. 1) defines it somewhat more precisely as the 'realization of delayed intentions and associated actions.' Prospective memory can be contrasted with retrospective memory, which is memory for past events.

Examples of retrospective memory include remembering the name of your eighth grade teacher, the causes of the World War I, the formula for the area of a circle, what you had for lunch yesterday, and a list of words learned in an experiment 15 minutes earlier. In thinking about the distinction between prospective and retrospective memory, it is worthwhile considering that many of the same processes may be involved in retrospective and prospective memory tasks. It is interesting to note that all prospective memories are to some extent retrospective in the sense that you have to have retrospective memory for the action that is to be performed and when it is to be performed in order to remember to perform it on time. For example, in order to remember to give a friend a message, you have to remember the message and to whom it is to be given. In addition, however, successful prospective memory requires that you actually remember to do this when you see your friend, and this is the prospective component of the memory. One fairly common error that is made in this situation is that upon seeing your friend, you remember that you have a message to give but forget the message (a retrospective memory problem). Another is that you forget to give the message even though you have good memory for it (a prospective memory failure).

1. Contrasts with Retrospective Memory

When studying retrospective memory (at least explicit forms of retrospective memory) in the laboratory, the experimenter presents some materials for learning. After a delay of some duration, the experimenter puts participants in a retrieval mode and asks them to recollect intentionally as they perform a designated criterial task such as free or cued recall. By contrast, when studying prospective memory, the experimenter asks participants to perform an action or several actions at a later point in time (either at a particular

time or when a certain event occurs; see Sect. 2.2 for examples). The interest is in whether participants remember to perform the task at the appropriate time/event and without an external agent (e.g., the experimenter) prompting participants to remember at the critical period. A key difference then between retrospective and prospective memory is that while the process of remembering is initiated by the experimenter in retrospective memory, it is initiated by the participant in prospective memory.

This self-cueing feature of prospective memory, along with the fact that retrieval needs to occur sometime in the future, places a different and perhaps more complex combination of demands (than typical retrospective memory tasks) on our cognitive systems. Indeed, many researchers have argued that prospective memory involves much more than memory processes (Dobbs and Reeves 1996, Ellis 1996, Burgess and Shallice 1997, Marsh et al. 1998b). They make the case that plan creation, plan modification, monitoring or rehearsal of the conditions for performing the action, and output monitoring, as well as individual factors such as working memory resources and personality variables, are all essential to a complete understanding of prospective memory.

Despite the differences just mentioned, it is likely that prospective and retrospective memory share similar memory processes and, accordingly, our vast understanding in the retrospective memory arena will be useful for understanding prospective memory. For example, given that many prospective memory tasks involve realizing a connection between an event (seeing a friend) and an intended action (giving a message), our basic understanding of associative memory processes should prove useful in understanding prospective memory. Also, as in retrospective memory, it seems that the level of processing of the target event is critical for good prospective memory as is the overlap between processing of the target event at encoding and retrieval (McDaniel et al. 1998).

2. Research in Prospective Memory

2.1 Historical Overview

Nearly all memory research conducted thus far has focused on retrospective memory, and this seems inconsistent with the nature of our everyday memory demands. Our lives are replete with prospective memory demands such as fulfilling an appointment, giving a message, remembering to flip the pancakes at the appropriate time, and returning a library book. To get some sense of the prevalence of prospective memory in everyday life, for several years G. O. Einstein asked students in his classes to write down the last thing they remembered forgetting. Interestingly, 62 percent of college-age students and 54 percent of older students (60 years and older) listed responses that were prospective memory failures. Given its prevalence in

everyday living, there is a real gap in our scientific understanding of prospective memory. It is difficult to overemphasize this gap as Kvavilashvili and Ellis (1996) in a recent review found only 45 prospective memory papers published over the prior 20 years, and only a small percentage of these papers consisted of rigorous experimental work in major journals. However, as evidenced by the inclusion of prospective memory in this volume, there now appears to be strong interest in the area.

2.2 Experimental Paradigms

Initial research in prospective memory required prospective memory responses to be initiated outside of the laboratory. For instance, subjects were asked to return postcards (e.g., Meacham and Singer 1977) or make telephone calls at specified times (Moscovitch 1982). Although these paradigms were valuable in producing the first investigations of factors thought to influence prospective remembering (like a person's age), they did not allow control of extraneous factors that affect prospective remembering. For instance, in these experiments there may have been variation in the degree to which subjects used external aids such as calendars to help complete the prospective memory task.

Empirical and theoretical work in prospective memory has increased significantly with the introduction of laboratory paradigms that bring experimental control and precision to the study of prospective memory. One influential paradigm, developed by Einstein and McDaniel (1990), requires that the subject be busily engaged in a primary task that serves as a cover task for the prospective memory component. During the instructions for the primary task, subjects are also instructed that they are to remember on their own to perform another action (e.g., press a special function key on the keyboard) at some designated point after they begin the primary task.

Sometimes the designation is an event embedded in the primary task (e.g., a particular word, a particular type of question) and other times the designation is a period of time that has elapsed (e.g., after 5 minutes). In this paradigm, the retrospective memory demands are designed to be simple and well remembered so that the major focus is whether participants remember to perform the intended action at the appropriate point. Other paradigms that focus on planning involve having participants remember to perform multiple sets of activities, each with their own constraints (e.g., Kliegel et al. 2000).

2.3 Principal Findings and Theoretical Perspectives

The general theoretical orientation guiding prospective memory research has turned on potential differ-

ences between prospective memory processes and retrospective memory processes. Unique features of prospective memory seem possible at encoding, storage, and retrieval stages of memory.

Encoding refers to rehearsal and elaboration of information so as to enter or commit that information to memory. People may use different encoding strategies for prospective memory tasks than they use for retrospective memory tasks. Consistent with this possibility, Koriati et al. (1990) found that actions encoded to be executed later are better recalled than actions that are encoded for a later recall test. It is likely that additional encoding processes found in prospective memory tasks are related to the requirement to remember to perform the intended action. Most prominently, during encoding of a prospective memory intention people often construct plans for how and when the intended activity will be accomplished (Ellis 1996, Marsh et al. 1998b). These plans may also anticipate the conditions or arrange the conditions under which the intended action must be retrieved, information that may not typically be considered when engaged in encoding for a retrospective memory task.

Only a few studies have examined the planning processes in prospective memory, but it is already clear that individuals vary in their prospective memory planning in several ways. People vary in the extent to which they use external aids like notes or lists to keep track of their plans (Marsh et al. 1998b). The complexity of the plans also varies and for older adults especially, more complex plans seem to be related to the effectiveness with which the intention is eventually executed (Kliegel et al. 2000).

Storage refers to maintaining information in memory during the retention interval. It would be adaptive if the storage of prospective memory were somewhat special so that the intended action would be remembered at the time it needed to be performed. Evidence to date suggests there may indeed be several ways in which prospective memory storage is different from retrospective memory storage. First, it may be that prospective memories (intended actions) enjoy greater and more persistent activation in memory (Goschke and Kuhl 1993, Marsh et al. 1998a).

Theoretically, memories in a more activated state more easily come to mind when one comes across cues in the environment that are related to those memories. It would also be adaptive if these memories for intentions would be deactivated after the activity was performed, so that they would not come to mind later. Preliminary findings suggest that such deactivation may occur (Marsh et al. 1998a), although for older adults under demanding conditions it appears that the memory for the intention may persist so that they inappropriately repeat their performance of the intended action (Einstein et al. 1998).

Another special storage feature of prospective memory suggested in one study is that prospective mem-

ories may actually become stronger as the retention (storage) time lengthens (Hicks et al. 2000). This is in dramatic contrast to the well-known finding that retrospective memory often declines with increased retention intervals. Additional research is needed to explain this provocative finding that prospective memories become better as the retention time increases. One clear possibility is that people remind themselves about the intended activity during the retention interval, especially as the duration increases between the formation of the initial intention and the point at which the intention can be performed. Reminders would presumably refresh the memory of the intended activity, thereby increasing the memorability of the intended action and its likelihood of being successfully performed at the appropriate time (Guynn et al. 1998).

Retrieval refers to accessing information in long-term memory so that it can be brought into awareness and used in a conscious fashion. As noted earlier in this article, a critical feature of prospective remembering is that retrieval must be initiated by the individual performing the prospective memory task. By contrast, retrieval in a retrospective memory task is initiated by somebody else (e.g., an experimenter) who prompts the individual to retrieve the target information. Accordingly, retrieval processes in prospective memory are thought to be somewhat different from those that are characteristic of retrospective memory retrieval.

Cognitive psychologists are not in agreement about how prospective memory retrieval operates. Consistent with the above analysis, one view proposes that prospective memory tasks are very high in self-initiated retrieval (Craik 1986) and therefore require a high level of cognitive resources to support retrieval. Another view proposes that initiating an intended action is not so much a memory process as it is an attentional process in which the person monitors the environment for signals that indicate that it is appropriate to perform the action (e.g., Burgess and Shallice 1997). By these views, prospective memory tasks should be especially difficult for older adults because of declines in cognitive or attentional resources that accompany aging. In support of this expectation, age-related decrements have been reported in time-based prospective memory tasks (Einstein et al. 1995, Park et al. 1997), tasks for which the intended action must be performed after a certain period of time has elapsed.

However, in some studies, older and younger subjects have surprisingly demonstrated equivalent prospective memory performance in event-based prospective memory tasks (Einstein and McDaniel 1990, Einstein et al. 1995). In an event-based task an external event signals that it is appropriate to perform the intended action. This event (or cue) might be the appearance of a friend to whom you have to give a message or a particular word in an experiment to

which you have to give a special response. The absence of age differences in event-based prospective memory suggests that prospective memory retrieval can be a relatively automatic process. One idea is that the environmental cue may automatically stimulate the retrieval from memory of the intended action, after which the action can be performed (McDaniel et al. 1998).

More research is needed to understand completely prospective memory retrieval. Based on the literature it seems likely that prospective memory tasks may vary such that those with very few environmental cues (such as time-based tasks) may rely heavily on self-initiated retrieval and attentional processes, whereas prospective memory tasks with salient environmental cues may be supported by more automatic retrieval mechanisms. In addition, future work in prospective memory will no doubt increasingly focus on the planning processes that are involved in prospective memory (e.g., Dobbs and Reeves 1996, Burgess and Shallice 1997, Kliegel et al. 2000) and the potential special storage dynamics of prospective memories.

M. A. McDaniel and G. O. Einstein

Prostitution

Prostitution is simultaneously a sexual and an economic institution, and it is also highly gendered. The majority of prostitutes are female, and an even larger majority of customers are male. While men's prostitute use is widely tolerated, female prostitution is popularly viewed as a form of social and sexual deviance, and mainstream social scientists have traditionally reproduced such attitudes in their research on the topic. Feminist theorists, by contrast, have long been concerned to explore parallels between marriage, prostitution, slavery, and wage labor, as well as the sexual, political, and economic relations that underpin these institutions. They do not speak as one on the subject, however, and the division between feminists who are concerned with prostitution as a sexual institution and feminists who approach it first and foremost as a form of economic activity is particularly sharp. This article provides a brief overview of prostitution in the contemporary world and highlights the theoretical and actual problems it poses for gender scholarship.

1. Prostitution: A Stigmatized and Criminalized Activity

A profoundly negative stigma is almost universally attached to prostitute women. Religious thinking on men's prostitute use varies, but there is no major world religion that actively sanctions female prostitution and, in secular societies, 'scientific' thinking has done little to displace traditional attitudes. Mainstream medical, psychological, psychoanalytic, and sociological research on the topic has generally assumed that while men's prostitute use is based on natural, biologically determined sexual drives, women who prostitute are somehow abnormal, unnatural, a threat to public health and order. Prostitution law varies from country to country and even within individual nation states, but typically enshrines this kind of stigma by treating female prostitutes as a distinct class of persons, separate from other workers and/or women in terms of their rights to protection, privacy, and/or self-determination (Walkowitz 1980, Bindman 1997).

Law enforcement almost invariably focuses upon female prostitution, ignoring men's prostitute use (often also male prostitution), and is generally informed by one of two basic models: prohibition/abolition, or regulation/registration. The prohibitionist model has historically led to an emphasis on controlling public manifestations of prostitution through the criminalization of (usually street working) prostitute women. The regulation/registration model, which legalizes prostitution providing it takes place in licensed brothels or designated geographical zones, has been associated with a variety of civil rights violations, such as requirements for prostitute women to register with the police and/or other authorities, have compulsory health checks, and so on. In some countries, there have been moves to deregulate prostitution either explicitly or by default, a shift which is taking place largely for reasons of 'financial exigency, prosecutor indifference, court deadlocks, and resistance to the overreach of the criminal law among some social sectors' (Davis 1993, p. 8).

2. The Economic Significance of Prostitution

Because female prostitution is ideologically and legally construed as a form of deviance, states do not officially recognize or regulate prostitution as an economic sector like any other. It is therefore extremely difficult to obtain accurate data on the size and earnings of the sex trade. However, research indicates that sex commerce is a significant feature of economic life in many nations, regardless of their overall level of economic development. Studies suggest that, for example, in London, prostitution generates around £200 million annually (Matthews 1997); that in New Zealand, almost one in every 150 women aged between 18 and 40 is employed in some form of sex work (Lichtenstein 1999); and that in Thailand, the Philippines, Malaysia,

and Indonesia, the sex sector accounts for between 2 percent and 14 percent of gross domestic product (Lim 1998). Research further suggests that a fairly consistent set of factors underpin prostitution labor markets. Gender discriminatory social practices are structural 'push' factors in economically developed and underdeveloped nations alike (Davis 1993).

As part of an unofficial and often criminalized economic sector, prostitution is frequently connected with corruption, organized crime, and drug abuse, but it is often simultaneously integrated into mainstream economic structures, such as the entertainment and the tourism industries (Lim 1998). This draws attention to the increasingly international nature of the sex industry.

3. *Global Politics and Markets and Prostitution*

Prostitution is affected by global politics and market trends in three main ways. First, there are countries in which the development of the sex sector has been directly shaped by the military and economic interests of external powers. Thailand, for example, was used for 'Rest and Recreation' by the US military in the 1950s, 1960s, and 1970s, and a highly sexualized entertainment sector developed to meet demand from legions of young men. Western financial institutions and businesses soon recognized that such an entertainment industry was also suited to serve one particular segment of the long haul tourist market, and economic initiatives based on a 1975 World Bank report 'led to what is routinely described today as a \$4-billion-a-year business involving fraternal relationships among airlines, tour operators, and the masters of the sex industry' (Bishop and Robinson 1998, p. 9). Similar developments have occurred elsewhere in South East Asia, as a result of either US or Japanese military or economic interventions in the region.

Sex commerce in poorer countries has also been affected by a set of linkages between international debt, price fluctuations in global commodity markets, economic development policy, and prostitution. Since the 1970s, world financial institutions have encouraged indebted nations to respond to economic crisis by developing tourism and/or 'nontraditional' export industries such as gold, diamonds, and timber. One side effect of such development policies is the creation of highly concentrated, effective demand for prostitution: affluent tourists seeking 'entertainment' and predominantly male, migrant workers in isolated mining and logging regions with cash to spend on 'recreation.' Meanwhile, structural adjustment measures have expanded the prostitution labor market. It is women and children who have been most adversely affected by the sudden introduction of cash economies into what were formerly subsistence economies, currency devaluations and concomitant falls in the price of labor, and the redirection of subsidies away from social spending and basic commodities towards debt

servicing. In such climates, prostitution has often become the best or only economic alternative for large numbers of women and teenagers (Chant and McIlwaine 1995, Clift and Carter 1999, Kempadoo 1999). Third, the sex trade is international in the sense that many of those working in prostitution have either voluntarily migrated in order to prostitute or have been trafficked by third parties for that purpose. Migrant prostitutes are especially vulnerable to abuse and exploitation by third parties and, as both illegal migrants and prostitute women, particularly likely to be denied legal protection and civil rights (Bindman 1997).

Ideological, as well as economic and political factors underpin the globalization of sex commerce. Racist discourses, which typically construct the 'Other' as sexually debased and/or exotic, have long fueled desire for 'racially' Other prostitutes and continue to shape demand today (Shrage 1994).

4. *The Diversity of Prostitution*

Prostitution varies enormously in terms of its social organization and the power relations it involves. In virtually every country of the world, hierarchies exist within both female and male prostitution (West 1992, Aggleton 1999). At their apex are independent, self-employed adult prostitutes who exercise a relatively high level of control in transactions with clients and whose earnings are relatively high. At their base are individuals who gain little or no financial reward from their prostitution and exercise little, if any, control over it (including control over condom use). This may be because they are physically forced into a given work regime by a third party pimp or brothel-keeper, but it may also be because extreme economic and social marginalization, and/or youth and/or drug addiction renders them horribly powerless within transactions.

Between the two extremes are prostitutes who either work independently or enter into some form of employment relation with a third party. The degree of control they exercise over whether, when, how often, and on what terms they prostitute varies according to a range of factors, including their level of economic desperation; the contractual form of the prostitute-client exchanges they enter into; and the specific legal, institutional, social, political, and ideological context in which they prostitute. There are, for example, settings in which prostitution law so heavily penalizes independent prostitution that it effectively operates as a pressure on prostitutes to enter and remain in third party controlled prostitution no matter how exploitative the third party may be. Equally, in contexts where certain social groups (for instance, women, children, homosexuals, migrants, particular 'castes' or racialized minorities) are generally devalued, and/or denied full juridical subjecthood, and/or denied independent access to welfare support, their

vulnerability to prostitution and to third party exploitation and abuse within it is increased. It should also be noted that people come to prostitution as individuals of a certain age and with particular personal histories and experience, and this leaves some more open to exploitation and at higher risk of violence and sexually transmitted disease than others (O'Connell Davidson 1998).

5. *Conceptualizing Prostitution*

One approach to the task of conceptualizing prostitution is to examine how it simultaneously resembles and differs from other social institutions. In prostitution, as in the institution of marriage, the sexual and the economic are conjoined. Unlike marriage, however, prostitution does not construct long term, mutual, or diffuse relations of dependency between individuals and their kin. Instead, sexual interaction between prostitute and client takes place on the understanding that some immediate economic benefit will accrue to either the prostitute or a third party as a result, and the client's obligations are thus discharged by payment in cash or kind. To this extent, relations within prostitution resemble market relations.

However, prostitution does not involve any ordinary commodity exchange. The client does not wish to purchase the disembodied means to an orgasm, a 'thing' that can be detached from the prostitute's person. Rather clients part with money and/or other material benefits in order to secure certain powers of sexual command over the person of the prostitute. Thus, although prostitution is often thought of as the exchange of *sex* or *sexual services* for money and/or other benefits, it is better conceptualized as an institution which allows certain powers over one person's body to be exercised by another. In this sense, prostitution has something in common with slavery, wage labor, and relations between buyers and self-employed sellers of services. All are institutions through which certain powers of command over the person are transferred from one individual to another, conferring a right upon the client/slave holder/employer/buyer to require that the prostitute/slave/worker/seller acts in ways that she/he would not otherwise choose to act.

Yet the relationship between prostitute and client differs from that between slave and slave holder or worker and employer in crucial respects. Not only is it generally brief and transitory, but also, clients enter into it as consumers, not producers. Clients do not depend upon prostitutes for their economic well being in the way that slave-holders and employers depend upon slaves and workers for their material existence. And even where the prostitute is self-employed, the prostitute-client exchange is made unlike other exchanges between independent sellers and purchasers of

services by the social meanings that are popularly attached to sexuality.

In monetary economies, sexual and economic relations are typically imagined, explained, and justified in very different ways. The products of human labor, human labor power, sometimes even human beings themselves, have been and are imagined as commodities to be bought and sold on the basis of rational economic calculation and/or in pursuit of status and social prestige. Human sexual interaction, by contrast, is generally regulated and given meaning through reference to premarket or nonmarket ideas, such as those pertaining to honor, shame and duty, and/or romantic love, and/or recreation, pleasure, and desire. Prostitution thus occupies a troubled and troubling space between two quite different symbolic domains. It does not readily fit into popularly understood categories of 'sex' or 'work,' and this tension has been central to much feminist debate on the subject.

6. *Feminist Debates on Prostitution*

Though sharing a common concern with the welfare of prostitute women, feminists are often deeply divided on the question of whether to view prostitution as a sexual or an economic institution. For 'radical' feminists, who foreground the sexual domination of women by men in their analyses of women's political subordination, prostitution is the unambiguous embodiment of male oppression. In this view, as a sexual institution, prostitution reduces women to bought objects, allows men temporary, but direct, control over the prostitute, and increases their existing social control over all women by affirming their masculinity and patriarchal rights of access to women's bodies. For such commentators, prostitution is always and necessarily damaging to women, there can be no distinction between 'forced' and 'free choice' prostitution, and in tolerating, regulating, or legalizing prostitution, states permit the repeated violation of human rights to dignity and sexual autonomy (Barry 1995, Jeffreys 1997).

Feminists who adopt a sex workers' rights perspective generally reject the idea that prostitution is intrinsically or essentially degrading, and view links between prostitution and patriarchal domination as contingent, rather than necessary. Treating prostitution as an economic institution, they make a strong distinction between 'free choice' prostitution by adults and all forms of forced and child prostitution. While they believe the latter should be outlawed, they hold the former to be a type of paid work, a job like any other. Since sex workers' rights feminists view free choice prostitution as a mutual voluntary exchange, they see state actions which criminalize or otherwise penalize those adults who make an individual choice to enter prostitution as a denial of human rights to self-determination (see Nagel 1997).

Because hierarchies exist within prostitution in terms of earnings, working conditions, vulnerability to violence and exploitation, and autonomy as regards specifying, limiting, and retracting from contracts with clients, these two very different interpretations of prostitution can each be partially supported empirically. Radical feminists point to research which indicates that around the world, the average age of entry into prostitution is very low (often under 18 years); that it is often precipitated by the experience of rape, sexual assault, and/or incest; and that the experience of prostitution can be extremely damaging psychologically, as well as associated with drug and solvent abuse, various forms of sexual and physical violence, and suicide (Hoigard and Finstad 1992, Kelly et al. 1995). Radical feminism's emphasis on a link between prostitution and systems of patriarchal domination is supported by the strong historical and contemporary association between the military and organized prostitution, while the persistence of highly abusive and slavery-like practices within prostitution and the significant presence of children aged between 12 and 18 in mainstream prostitution, even where prostitution is legally regulated rather than proscribed, lends further credence to a view of prostitution as a hugely problematic institution (Ennew 1986, Enloe 1989).

Sex workers' rights feminists point out that slavery-like practices and child labor persist in other industries, and that historically, such abuses have been most successfully addressed through collective struggle for workers' political representation, international conventions guaranteeing minimum rights to various groups of workers/persons, national employment laws outlawing abusive practices, and so on. They cite research which suggests that prohibitionist legislation increases, rather than reduces, prostitutes' vulnerability to violence, third party coercion, and extortion, and emphasize empirical studies in which adult women and men in prostitution describe themselves as perfectly content with their chosen occupation (Bindman 1997, Kempadoo and Doezema 1998).

Though certain feminist commentators remain rigidly wedded to a view of prostitution as either work or sexual violence, many theorists and activists (including some feminist abolitionists and sex workers' rights feminists) place a growing emphasis on the need to develop analyses of prostitution which can embrace its diversity and its particularity as both a sexual and an economic institution (see, for example, Shrager 1994, Chapkis 1997, O'Connell Davidson 1998).

J. O'Connell Davidson

Protein Synthesis and Memory

A role for proteins in memory formation was invoked by early neuroscientists in their search for the 'engram', an envisioned physical manifestation of stored memory. It was recognized that measured electrical activities were too transient to endure for a

lifetime, and chemically stable macromolecules such as proteins seemed more likely candidates, perhaps as metabolically stable bricks that comprised the structures of altered synapses (Gerard 1953). It eventually became evident that proteins are constantly being produced and broken down, necessitating more complex models of the molecular basis for memory storage than a simple accretion of structural molecules.

The nature of protein synthesis in the brain became of particular interest for behavioral scientists as a result of demonstrations in a number of vertebrate and invertebrate species that chemical agents that inhibit protein synthesis in the brain block the formation of long-term memory (LTM) of a variety of training tasks, yet do not block acquisition of the task (Agranoff et al. 1999). More recently, analogous effects of protein synthesis inhibition have been reported in a reductionist model of learning and memory, termed long-term potentiation (LTP) (see *Long-term Potentiation (Hippocampus)*).

For the purposes of this article, learning and short-term memory (STM) formation are defined by experimental measures of improved performance of an adaptive response observed during or shortly after a training session (acquisition), while LTM formation is evidenced by retention of the learned response in a subsequent training session, typically administered some days or weeks later. An experimental advantage of using an interventive agent such as a protein synthesis blocker in studying learning and memory is at the same time its great disadvantage: while it can establish the timing of an inferred molecular mechanism taking place in an otherwise intact animal, it does not specify cells or even brain regions critical for LTM formation, nor does it identify specific proteins on which memory formation is presumed to be dependent. Such proteins could hypothetically be identified by complementary correlative studies, for example, by examining the nature of newly synthesized proteins on the basis of their incorporation of radio-labeled precursor amino acids during the period of LTM formation. Together, the interventive and correlative approaches have proven useful in establishing the molecular bases of other complex cellular processes.

1. Proteins Defined

Proteins are biological macromolecules consisting of a linear array of 20 component L-amino acids. The amino acids are joined in chemically stable peptide linkages that are not easily disrupted by thermal, chemical or mechanical stresses encountered by living cells. A protein typically consists of several hundred amino acids in a precise sequence (termed its primary structure), much like a very long word written in a 20-letter alphabet. The secondary and tertiary structures

of a protein refer to how the polypeptide chain is folded into helices, ribbons and sheets. This overall conformation of proteins is largely dictated by the chemical properties of the individual amino acids in its primary structure.

Proteins play both structural and functional roles in cells. Membranes, consisting of lipid bilayers in which proteins are embedded, define a neuron and its intracellular organelles, such as the nucleus, mitochondria, synaptic vesicles, and endoplasmic reticulum. Proteins may be primarily structural, adding integrity to the membrane, or serving as a bridge to other membranes or to one of a group of fibrillar proteins including tubulin, actin and neurofilament proteins, known collectively as the cytoskeleton. Functional roles of proteins are exemplified by the enzymes, which are generally soluble proteins, present in a globular conformation. Hundreds of enzymes have been characterized and shown each to be a chemical catalyst that accelerates the rate of a specific biochemical reaction, without itself being consumed. Structural and functional proteins together catalyze and otherwise mediate the business of the cell (Voet and Voet 1995), expressing its genetic phenotype, including its appearance, its metabolism and its repertoire of responses. Knowledge of the primary structure of a protein is useful in determining its relation to other known proteins, in some instances yielding information about its evolutionary lineage as well as providing insight into its function. Short amino acid sequences within proteins (domains) identify probable catalytic active sites, the number of times a protein chain spans a membrane and the probable site of a protein's binding to other known proteins. There are also short amino acid sequences that identify the nature and likely sites of 'decoration' of proteins with small chemical groups following their synthesis. In addition to acting as catalysts, proteins can mediate recognition of a variety of small molecules that are intracellular chemical messengers. Membrane proteins on the cell surface may also act as receptors that recognize a variety of small molecules, including extracellular neuromodulators, hormones, neurotransmitters and environmental chemical signals (odorants) (see *Neurotransmitters*; Siegel et al. 1999). Proteins can recognize other proteins, even xenobiotic (novel) ones, as in the immune response. While proteins are clearly the arbiters of all cellular activities, not all cellular actions depend on ongoing protein synthesis, as will be seen.

1.1 Proteins are Synthesized on Ribosomes from Messenger RNA

The primary structure of a protein ultimately is determined genetically by linearly coded triplet deoxy-nucleotides in DNA in the cell nucleus, which are

transcribed to a complementary sequence of nucleotide triplets in the messenger RNA (mRNA) for the protein. The newly synthesized mRNA is *translated* ('decoded') into the new protein on polyribosomes in a cellular region near the nucleus, the RNA triplets establishing the primary structure of the new protein. The entire process, beginning with the availability of DNA template for transcription and ending with protein synthesis, generally takes minutes to hours (Voet and Voet 1995). Antibiotic inhibitors of protein synthesis such as puromycin and acetoxycycloheximide are structurally unrelated, and block translation by different molecular mechanisms, yet each has been shown to block LTM formation, confirming that their behavioral effects are indeed the result of their inhibition of protein synthesis rather than of some unknown side effects of the agents. Inhibition of RNA synthesis has also been found to block LTM formation.

Upon release from the polysomes, newly synthesized proteins may be subjected to *post-translational modification*, typically the addition of stable, small chemical substituents, such as fatty acid, isoprenoid, carbohydrate, and phosphate or methyl groups. These modifications are catalyzed by specific enzymes, and may also require cofactors such as calcium ions or cosubstrates such as ATP. Phosphorylation of a protein by ATP requires a protein kinase, although some proteins can autophosphorylate themselves. As a consequence of such modifications, a protein may be tagged with a chemical 'zip code' that designates its intracellular destination. For example, a lipid substituent will target a protein to a membrane site, while phosphorylation could direct a protein to a nuclear site. The overall conformation of proteins can be affected by these post-translational changes. A newly formed protein may be inactive until it is cleaved by a specific protein-splitting enzyme that removes a built-in inhibitory sequence.

Many proteins are part of intracellular messenger systems that act sequentially to produce multiplicative cascades, resulting ultimately in a cellular response, such as hyperpolarization, depolarization, contraction, or secretion. Unlike the ribosomal synthesis of proteins, in which the translation of proteins is measured in tens of minutes, post-translational modification can occur rapidly, even in milliseconds, and unlike typical protein synthesis, is not restricted to the perinuclear region of the cell. Post-translational modification of proteins can occur at any time in the life of a protein, and can even target proteins for degradation.

1.2 Brain Proteins are in a Dynamic State of Formation and Degradation

The thousands of protein species present in a brain cell are in a metabolically dynamic state, i.e., they are

continuously being synthesized by ribosomes and are then broken down into their component amino acids by the action of enzymes called proteases. The released amino acids may be metabolized or can be reincorporated into new proteins. Turnover studies employing radiolabeled amino acid precursors show that a given cellular protein in a specific cell type is turning over with a characteristic half-life of minutes to weeks. Each protein is present at a characteristic steady state level, i.e., the rate of synthesis of the protein is equal to its rate of degradation. Even though most neurons are formed early in life and remain in a postmitotic state through adulthood, their component structures are nevertheless in a dynamic metabolic equilibrium at a molecular level. A neuron may thus maintain an unchanging microscopic appearance throughout life, yet, with the exception of DNA, every component molecule, including all of its neuronal proteins, is constantly being replaced. There is considerable evidence that the cell's morphology and other cellular modifications of long duration are maintained by continual feedback to nuclear DNA, signaling initiation of transcription of mRNAs for constitutive proteins as they are depleted, or the induction of novel proteins, as occurs in cellular differentiation during development and in nerve regeneration. Thus, changes in synaptic connections might be similarly maintained by such transcriptional feedback loops in LTM storage. Translational and post-translational feedback loops that mediate memory formation have been proposed (Lisman and Fallon 1999).

1.3 Temporal Considerations in Establishing the Role of Protein Synthesis in Memory Formation

Since acquisition of a new behavior can occur within seconds, it is immediately apparent that it cannot be either directly or indirectly mediated by the relatively slow process of *de novo* protein synthesis. Acquisition could, however, involve a sustained post-translational modification at the synapse, which can occur within milliseconds and at any cellular locus. As noted, the macromolecular process of protein synthesis requires initiation of transcription in the nucleus followed by ribosomal translation, and takes minutes to hours, a time frame compatible with LTM, but not with STM formation. Additional time may be required for a putative chemical message from the presumed site of STM formation in the synaptic region (see *Memory: Synaptic Mechanisms*) to be transported to the nucleus in the neuronal cell body and to initiate transcription and translation. Still more time may be required for newly synthesized proteins to be transported from the cell body to a synaptic destination, where they could mediate long-term neuroplastic changes.

Rates of protein flow away from the cell body (anterograde axonal transport) and from the dendrites and axons toward the cell body (retrograde axonal

transport) were established in neurons with long processes. The amount of time required for trafficking of a chemical signal from a synapse to the nucleus and of a newly synthesized protein back to the synapse hypothetically could be extrapolated from known rates of axonal transport, together with knowledge of the morphology of the neuroplastic neurons hypothesized to be mediating the process. Ribosomal protein synthesis at a distance from the nucleus (Steward 1997) could shorten the calculated transport times. As will be addressed in the following section, the advent of antibiotic agents that selectively block protein synthesis offered the opportunity to study these complex issues experimentally.

2. Agents that Inhibit Protein Synthesis Block Formation of Long-term Memory

In the early 1960's, the excitement over the identification of the genetic code spurred renewed speculation and experimentation directed at the possible molecular nature of the engram. In 1962 Flexner and co-workers reported that intracerebral injection of the antibiotic puromycin, an aminonucleoside that prematurely cleaves the growing peptide chain from ribosomes, blocked brain protein synthesis in the mouse brain and could also block formation of memory of a Y-maze shock avoidance task (Flexner et al. 1962). This was followed by studies in the goldfish in 1964 (reviewed in Agranoff et al. 1999), and subsequently in a variety of other vertebrates and invertebrates.

2.1 Effects of Protein Synthesis Blockers on LTM Formation in Experimental Animals

Injection of puromycin into the cranial fluid (intracranially; IC) surrounding the goldfish brain produced a profound block in brain protein synthesis for several hours. Studies on acquisition (STM) and on LTM formation of a light-coupled-to-shock shuttlebox task revealed that a block in brain protein synthesis had no effect on acquisition of avoidance behavior during an initial multitrial training session, but eliminated retention of the improved performance that would otherwise have been seen in a second session administered a week later. The depth and duration of the inhibition of brain protein synthesis and the effectiveness of the block of LTM formation correlated well. Injection of the blocker into the fish body cavity rather than IC was without effect on LTM formation. IC injection of acetoxycycloheximide, another inhibitor of protein synthesis, was equally effective in blocking LTM formation.

The behavioral effects of inhibition of protein synthesis differ from that of a number of neurodisruptive agents and treatments, such as electroconvulsive

shock, in that animals exhibit normal behavior during the action of the interventive agent. This permitted an exploration of STM decay. It was known that fish injected IC with puromycin before the first training session would show increasing avoidance scores, comparable to those seen in uninjected control fish; yet in a second training session a week later, such fish performed at a naïve level, i.e., had formed no LTM of the first session. Groups of fish trained under conditions of blocked protein synthesis (and that nevertheless demonstrated normal acquisition, as noted above) were then retrained at various times following the initial session. It was found that performance gradually dropped to the level of naïve fish over a 2–3 day period, providing evidence for the decay of STM for this task. Block of protein synthesis immediately after training also blocked LTM formation, whereas if animals were returned to their home tanks and injected with puromycin a few hours later, there was no detectable effect on LTM. This period of LTM susceptibility was comparable in its duration to that seen with electroconvulsive shock and other disruptive agents administered after training. When fish were detained in the training apparatus following the first training session, the consolidation time was prolonged, suggesting that the onset of LTM formation required an 'environmental trigger.' This phenomenon, in which continued exposure of an experimental subject to its training environment delays the onset of LTM formation, has also been termed 'detention.'

Behavioral studies with numerous other species, including young chicks and rats (for review, see Davis and Squire 1984), support the general hypothesis that LTM formation requires ongoing protein synthesis, while STM formation does not. Among vertebrates, studies in *Hermessenda* and in *Aplysia* (Bailey et al. 1992) support this hypothesis (see Agranoff et al. 1999). *Drosophila* have proven useful in behavioral studies, with genetic mutants in which selected proteins are mutated, deleted or overexpressed, implicating various neurotransmitter-related and second messenger system proteins in memory formation (see Agranoff et al. 1999). Effects of protein blockers on human memory have not been reported, but the possibility did not escape the imagination of a novelist (MacDonald 1968).

2.2 Protein Synthesis Inhibition in Long-term Potentiation, a Reductionist Model of Learning and Memory

Attempts to identify specific proteins, the synthesis of which are crucial to LTM formation in the brain, have been beset with many experimental problems, not the least of which is knowledge of the precise anatomical sites of the presumed altered molecular events underlying an observed altered behavioral performance

interpreted as LTM formation. LTP (see *Long-term Potentiation (Hippocampus)*) can be induced and studied *ex vivo* in localized tissue preparations such as brain hippocampal slices, and has been proposed as a cellular model of LTM formation. Blockers of protein synthesis have been shown to prevent LTP formation, a result taken by some as its validation as a model of LTM formation. Numerous pharmacological, biochemical, molecular, and genetic studies have been performed to implicate one or another structural protein, enzyme, receptor, or intracellular messenger pathway in the development of LTP, as a result of which over 100 known molecules have been implicated in LTP formation, including intracellular messengers, vesicular trafficking proteins, proteases, kinases, etc. (Sanes and Lichtman 1999). Eventually it may prove to be the case that the ongoing synthesis of one or only a few of these proteins is indeed necessary and sufficient for LTP formation, and can account for the observed block of LTM formation by protein synthesis inhibitors. It would seem more likely that the synthesis of many such proteins is necessary for the complex process of LTM formation to proceed. This embarrassment of riches in candidate compounds continues to grow as additional previously undiscovered cellular proteins become implicated in neuroplasticity, in that their selective deletion or inactivation prevents LTP or LTM formation. Further information regarding the temporal sequence of the observed molecular events accompanying LTP may prove useful in establishing whether they are indeed causal or epiphenomenal in its formation.

2.3 Protein Nutrition and Mental Function

Half of the 20 amino acids of which proteins are composed can be synthesized in the human body, while the remaining 10, termed 'essential amino acids' (EAAs), must come from the diet, principally in the form of ingested proteins that are degraded to their component amino acids in the gut and absorbed into the bloodstream. Eventually some will cross the blood/brain barrier, which has efficient EAA uptake systems. Also, as the brain's own proteins are broken down, the released amino acids are conserved and become a rich source of EAAs for new brain protein. Thus, under conditions of dietary EAA deficiency in adults, as occurs in starvation, brain protein metabolism is relatively protected. This is not true for the developing brain in infancy and early childhood, periods during which the brain must grow. For this, the brain relies on an exogenous source of EAAs, without which permanent cognitive deficits can ensue, as in kwashiorkor, a protein deficiency disease of children encountered in impoverished tropical countries. A blood amino acid imbalance is seen in the genetic defect phenylketonuria in which there is a high

blood level of the amino acid phenylalanine, while blood levels of the other EAAs are normal. This imbalance overloads and blocks the amino acid transport system at the blood/brain barrier and effectively prevents entry of the other EAAs, eventually resulting in mental retardation. If infants with this genetic defect are raised on a diet deficient in phenylalanine, the brain develops normally, and as they mature, the toxic effect of dietary phenylalanine is much reduced.

3. Summary

It is apparent from the foregoing that in a number of animal species, disruption of protein synthesis in the brain for a period of hours has no effect on acquisition of a behavioral task, but blocks the formation of LTM. Since all brain proteins turn over metabolically, it is presumed that positive feedback loops are induced during LTM consolidation that involve transcription and/or translation of new protein, but how and where these loops function and are distributed in the complex structure of the brain is not yet known. Selective inhibition or elimination of various proteins by genetic means has been shown to block memory formation, but the salience of each new finding is dampened by the increasing number of identified genetic defects or deletions that can be shown to lead to a defect in memory and learning. The synthesis of many proteins each may prove necessary (but not sufficient) for LTM formation.

STM formation, as defined in human and primate learning and memory studies, may be measured in fractions of seconds, with lifetimes that are compatible with the durations of electrophysiological measurements of neuronal activity. Other forms of STM formation, primarily in lower vertebrates and invertebrates, may be long-lived (seconds to hours or even days) as indicated in Sect. 2.1. Intermediate stages in STM formation have been proposed in studies on taste aversion in the chick (Gibbs and Ng 1979). It is possible that the longer lasting forms of STM reside in synaptic regions and are mediated by post-translational feedback loops between proteins, and thus would not be affected by the protein synthesis blockers, as has been observed. It must be remembered that the various molecular, pharmacological, behavioral, and electrophysiological interpretations of memory formation are not mutually exclusive and in many instances may reflect observation of the same neurobiological phenomenon from dissimilar vantage points.

B. W. Agranoff

Protestantism and Gender

At the beginning of the twenty-first century, the term 'Protestant' is used to designate any group of Christians that does not acknowledge direct loyalty and connection either to the Roman Catholic hierarchy, or to the many catholic churches rooted in Euro-Asian cultures known collectively as Eastern Orthodox Christianity. In contemporary discourse the term 'Protestant' has come to apply to a broad range of spiritual communities. While this discussion of Protestantism and gender focuses on older Protestant 'denominations,' it should be remembered that by the late nineteenth century, Protestantism had expanded and changed greatly. By then, the majority of Prot-

estants were chiefly in movements whose historical development occurred outside of Europe, particularly in the Northern Hemisphere of the so-called 'New World.' Beginning in the nineteenth century, new forms spontaneously generated indigenous Christianities emerged in the Western Hemisphere, and by the early twentieth century, on the continents of Latin America, Africa, and Asia. The newer indigenous movements, identifiable as Christian by their emphasis on personal conversion, by the centrality of Jesus to their doctrine and practice, and by their fidelity to those texts broadly recognized as Christian scriptures (often called 'The Bible'), nevertheless bear little resemblance to the movements and cultures of Protestantism that had their roots in European history. Such Protestants now constitute the fastest growing edge of Christianity. It is too early to describe how such faith-communities will affect the future of gender relations, or reshape the historical directions of the original Protestantisms described here. And as will become clear, all Protestantisms, including these newer forms, are racked with conflict over gender issues, including the roles of women in churches and the nature of Christian attitudes toward sexuality. Today, strong forces within Christianity seek to reverse the clear directions toward gender equality and greater parity between men and women that have slowly shaped most Protestant belief and practice.

The origins of Protestantism are much debated. Deep resistance to the existing western Catholic sacramental system, loosely organized through the leadership of the bishops of Rome, appeared in late medieval Christianity. Much of this resistance presaged issues raised in the Protestant Reformation. However, Protestant beginnings are usually dated from the work of the German Reformer, Martin Luther, early in the sixteenth century. The four main trajectories that shaped the social formations of early Protestantism became differentiated and broadly identifiable 'traditions' of Protestant Christian belief and practice. The earliest, emerging under Luther's leadership, prospered chiefly in regions of Central Europe and quickly moved northward into Scandinavia. Almost simultaneously, a second major tradition emerged from Swiss Reform movements led by Zwingli, and was quickly joined by French-speaking groups under the leadership of John Calvin. These churches came to be known as 'Reformed.'

A third Continental stream of Protestantism emerged from the even more ardent and diverse dissenters within agrarian and peasant communities. These reforming groups were known in the first eras of Protestantism as Anabaptists. They were antihierarchical and egalitarian, and would eventually profoundly shape Protestant culture. However, initially the Anabaptist movements and communities generated hostility both from Lutheran and Reformed groups and from the Roman Catholic Church. The tensions generated by religious conflict on the Con-

tinient also reached the UK and also sparked a prolonged English Reformation struggle. The fourth Protestant tradition emerged from the settlement that created the Church of England and Anglicanism, which claimed to be a 'bridge' between Catholic and Protestant spirituality. It needs to be remembered that for three centuries Europe experienced a prolonged period of political, economic, and cultural turmoil as Christianity changed dramatically. This period is sometimes referred to as 'the Wars of Religion.'

By the late eighteenth century these realignments and newly-reordered ecclesial communities stabilized into clear cut 'denominations' with differences in doctrine and ritual practice that became matters of ongoing public dispute in cultures where Christianity predominated. Importantly, doctrinal differences were paralleled to differing normative views of how reforming Christian ecclesiastical culture and institutions should be related to political order and state power. Such differences are important to the topic of gender because Protestantist groups that were opposed to religious establishment and church support of state power would also become more egalitarian about issues of gender. But where the new Protestantisms became aligned with state power, they joined in suppressing dissent from their doctrine and practice as Roman Catholics frequently did during the Counter Reformation. As a result Anabaptist and Reformed Protestants migrated to seek refuge in any area of Europe or the New World of the Americas where they could find toleration or freedom from persecution.

Through these historical dynamics, Protestant reform seeded and reseeded itself, both in Europe and by the eighteenth century in North America. Migrations of many language groups also created hybrid Protestant churches that were Lutheran and Reformed. Lutheranism came to speak all the northern European languages, and 'Reformed Churches' from Switzerland, France, and the Netherlands dramatically flourished in the UK where the Church of England, or Anglicanism, had many rivals. Early European settlements in the Western Hemisphere often also brought multiple 'denominations' of the same Reformation traditions to North America. Dutch Reformed groups and Scottish and British Reformed communities created several separate denominations. Later European colonialism carried the four European-generated forms of Protestantism to areas of Africa, Asia and to parts of the sections of the Western Hemisphere previously colonized by Roman Catholic nations.

Reformed and 'Anabaptists,' sometimes called left-wing Protestants, in particular migrated in search of religious freedom and to escape state religious coercion. These traditions especially prospered in North America. Their emphasis on 'believers' communal equality' in the task of overseeing church life, in doctrinal discernment, and in scriptural interpretation, fit well with the democratizing tendencies of immigrant life. As a result, North American Prot-

estantism took on a dynamic life of its own that quickly produced new 'schisms of reform' that rebounded back to Europe. For example, Episcopalians, Anglicans in the USA, quickly generated a major division led by John Wesley that became known as 'Methodism.' Anabaptist or 'free church' movements that especially emphasized the priesthood of all believers and local autonomy of believing congregations came forth in great profusion, often spontaneously. Protestant denominationalism came to have indescribable diversity. Many such groups came to be known as Baptists. Baptists included forms of 'slave Christianity' that enabled African-Americans in slavery to generate a religious culture independent of the slave owners' 'white Christianity' imposed on them and designed to keep them in their place. Methodism and white Baptist practice spread in rural and frontier communities throughout the northern hemisphere. Even in the twenty-first century, the two largest Protestant churches in North America are Black and white Baptist denominations. Cultural historians now recognize that gender was never a theorized social reality until the modern period of western cultural history. This means that an accurate assessment of Protestantism's impact on gender cannot be uncovered through exercises in intellectual history alone. More recent methods of historical-material historiography enable us to see that the major impacts on gender relations within Protestantism were actually the result of changes in the religious practice initiated by the new Protestant churches. Slowly these changes produced concrete redirections in gender relations and, more slowly, reshaped how Protestants theorized gender.

Not surprisingly, early Protestantism continued what may be called 'traditionalist' Christian notions of gender. After the high Middle Ages, Catholic (now Roman Catholic) Christianity had made the moral theology of Thomas Aquinas its formal moral-theological standard. Thomistic thinking formalized Catholic moral teaching so that it came to presume two normative sources of moral knowledge: revelation and reason. Though what was meant by either revelation or reason differed in specific theological accounts, western Christians came to assume that both of these sources contributed to a proper knowledge of gender. What the resulting 'traditionalist Christian' view of gender presumed, roughly following Aristotelian biology, was that males and females differed by nature (science or reason) and divine will (revelation). Such thinking supported notions widely held in popular culture that made deep challenges to traditional gender relations difficult. Throughout Christian history women's roles varied and were frequently changed by resistance to existing traditionalisms. Well before the modern advent of women's organized efforts at political change, forms of what today are called Christian feminism existed and should be read as expressions by women of refusal of domination. Contemporary critical historiography confirms these continuous chal-

allenges but given the strength of patriarchal control, the point of visible institutional strain was never reached.

Even so, the full relevance of the Reformation to gender change is frequently missed because only formal teaching on gender is noted. The alternatives in communal form, ritual, and teaching in the Protestant traditions under discussion here were simultaneously shifts both in ecclesial/social forms and in Christian communal life. It was these new social formations and forms of ritualized communal practice that slowly changed gender relations in churches and in the broader culture.

The closing of the clergy and monastic-centered penitential systems, including the break with clerical celibacy brought the Christian parish, or in left-wing parlance, the Christian congregation, into the center of Protestant Christian faith practice. As a result, the primary units of Protestant spirituality soon became the local community (parish or congregation) and especially the family. In particular the patterns used to socialize persons as Protestant Christians dramatically altered gender relations. The Protestant family was theorized as an arena where both men and women, albeit initially in varied ways, were called to be agents of the formation of Christian communal life. Men were chiefly responsible for the public and the most authoritative ecclesial roles, but men and women alike were teachers of the faith, leaders of prayer, and witnesses to divine presence.

Protestantism particularly flourished in tandem with the invention of the printing press, which made Luther's, Calvin's and the Anabaptists' formal emphasis on scripture as the central theological source for Christians an actualizable reality. In all Protestant communities the locus of prayer, ritual practice, and theoretical (i.e. theological) formation shifted to the congregation and the family. None of the new Christian duties articulated by the Reformers were considered more important than that of transmitting the new 'knowledge of faith,' whether as scriptural literacy, or as newer catechism (doctrine). While none of this resulted in immediate transformations in female social roles because of the deeply gendered nature of the sex role systems, the new practices increased women's direct participation in matters of faith discernment. They also situated women within the central sacral systems of Protestant life. Prior to the Reformation, in spite of women's creativity and resistance, a lack of formal clerical power and women's remoteness from male-monopolized institutionalized hierarchies of ecclesial power prevailed. Pre-reformation Christian women certainly had created powerful gender alternatives, in particular monastic institutions for women. These enabled some women ('nuns') to live in an alternative social space where intellectual, artistic, and spiritual gifts could be cultivated. The impact of such efforts was severely marginalized structurally, however, and could be

easily manipulated by male hierarchies. Historians have also recognized that some initial Reformational changes had negative impacts on women's roles and status. For example, Luther's closing of nunneries and his and Calvin's insistence on clerical marriage, especially when gender dislocations led to arranged marriages between priests and nuns, robbed women of crucial existing social space. However, the need for alternatives also led the Protestant movements to create new gendered sub-cultures for women, usually in the form of Deaconess Orders or catechetical offices that enabled women to work with women and children in initiating them into 'the fullness of faith.'

The trajectory of changes in gender practice and, with the rise of modernity, gender theory, within these Protestant movements cannot be traced in detail. However, by the late nineteenth and early twentieth centuries, when gender began to become a contested political issue and calls for gender justice emerged widely in public discourse, calls for justice for women were voiced in all but the most 'traditionalist' Protestant Christian communities. It is erroneous, as some 'secular' historians as well as conservative Christians have done, to imagine that demands for change in gender roles occurred primarily outside of, and apart from, the life and practice of Protestant communities. Christian feminisms fed public political feminism and Christian anti-feminist resistance testifies to the militant presence of feminist agitation within Protestantism throughout the modern period. Feminism is perceived as secular in origins only because contemporary historians tend to discount the role of religion in positive social change and because feminist discourse within Protestantism was initially less confrontative than later feminist political rhetoric. But in Protestant cultures by the late nineteenth century, women's energies were powerful within the churches and pressure for change escalated simultaneously with the rising public efforts of women for political change. It is not too much to say that by the end of the nineteenth century Protestant churches were thoroughly feminized and women had gained considerable financial and organizational power. Within Christianity, antifeminism should be read as a symptom of increased pressure for change from women. A review of historical gains for women make clear that change came fastest in nations where Protestantism was strong but where the churches did not aspire to state-enforced establishment.

Even as many male church leaders reasserted Christian gender traditionalism against the claims of Christian feminisms, gender parity slowly increased in Protestant communities, and on-going feminist contentions did not disappear. On the contrary, by the twentieth century, contentions over gender exploded into nearly all Christian communities. Because feminist pressures were more muted in Anglican and Lutheran traditions until well into the century, and because controversies over ordination when they did

erupt were especially strident there, public awareness of church gender debates became widespread only at that historical moment. However, nearly all nations where Protestantism has had a clear religio-cultural role were the first to adopt explicit legal and moral norms of equality between men and women both within churches and in the wider society. Furthermore, because the congregation and the family have remained the cultic center of Protestant life and practice, active patriarchal misogyny is rarely overtly expressed within it. Protestant pastoral practice is invariably more egalitarian than official theologies would suggest so women are more likely to be pedestilized than criticized in Protestant rhetoric.

The ways in which clergy-lay ritual practice and power were realigned and the patterns by which Protestants groups related to state political power are also crucial to the pace of gender change. Where Protestant denominations replicated Roman Catholic efforts at church-state establishment as in the Church of England, in sectors of Lutheranism and in some Reformed churches such as those in early New England, USA, or predemocratic South Africa, Protestant leaders sought to reassure Christian rulers that the churches would officially conform to 'traditional values' and to the stability of social order. Efforts in support of keeping the Christian family 'traditional' were frequent among male leaders, though much more common in established churches than elsewhere. Gender change came much more rapidly where Reformed churches broke with theories of the divine right of kings and endorsed democratic political theory and where the 'free churches,' actively refusing religious establishment, sought to actualize a theology of universal priesthood. In fact, it was these free-church Protestants who demanded, on theological grounds, that religious toleration become the public stance of the just state. Left-wing Protestants militantly insisted that church-state separation is a matter of constitutional or political 'right' and in the USA they were successful.

Today it is often these Protestant movements, the first to ordain women and the strongest critics of identification with state power, who have become the most conservative on gender. This is because in the late twentieth century the locus of Protestant traditionalism in relation to gender change shifted dramatically. Until recently, theological progressivism had slowly carried the day in the older Protestantisms under discussion here. Over time, newer forms of knowledge prevailed and the historical-critical or hermeneutic sciences prevailed. The main dynamic of Protestant theological development was towards recognition that the 'two' sources of religious and moral knowledge—revelation and reason—supported the central Protestant historical/theological emphasis on 'continuing reformation.' Such 'theological liberalism,' as conservatives called it, was comprehended by most Protestants as the heart of their faith-claims.

Even when Protestant theological polemics included charges that gender justice was 'heresy' the trend was toward equality. In recent debates, however, the peculiar Protestant theological reaction of Biblicism has begun to alter older historical directions that embraced historical-critical readings of scripture.

In the late nineteenth century Protestant reaction to change began to take the form of what is called, somewhat misleadingly, 'biblical literalism.' So-called literalists do not seek to replicate ancient sex role patterns, but they project current traditionalist views to suggest that the Bible does not support gender justice. Such change, they contend, is impious because women's 'place' is forever set by what 'the Bible' teaches. This refusal of all truth except that found in 'the Bible' produced what in modern parlance is known as 'Fundamentalism.' Fundamentalism is a reactionary historical dynamic intrinsic to Protestantism as a text-based religion. Today many claim that other major religious movements are also becoming 'fundamentalist,' but such charges should be approached cautiously. Fundamentalism was generated by the particularities of Protestant inter-religious conflict. The refusal of gender justice within Protestant Christianity has parallels in other contemporary religions that accounts for the glib extension of the term. However, such usage is seriously misleading as to what is occurring within other religion. Even when reactionary Protestants and the Papacy attempt to enlist conservatives within Judaism, Islam, and even the great Asian religions against gender justice movements, Christian fundamentalist justifications for resisting such justice are not readily generalizable to other groups. Political and economic dynamics profoundly different than those occurring in older Protestant cultures are taking place elsewhere. For example, many former progressive left-wing Protestants in North America, are today for the first time, strongly aligned with global capitalist political power, whereas Islamic religious reaction is often aligned with anti-colonialism and resistance to capitalist 'modernizing' dynamics. Failure to notice such disparities may pit justice-seeking activists within the religions against each other.

In spite of the rising tide of fundamentalist anti-feminist attack within Protestant cultures and communities the struggles for justice continue in all of them. However, today even some moderate Protestants portray debates on gender justice as 'trivial.' Arguments about women's ordination, Christian sexual ethics, including Christian positions on gay, lesbian and transsexual lifestyles, and debates about reproductive choice and abortion are not understood, as earlier Protestant thought understood them, as aspects of the Protestant theological struggle towards genuine moral discernment and responsibility in a complex world. Most Protestants continue to espouse 'continuous and on-going reformation,' as the proper theological norm of Christian ecclesial and communal

life but the new fundamentalism has been chillingly successful in obscuring the connection between progressive Protestant theological principles and these particular issues. This is why in spite of the historical directions outlined here the question of whether continued movement toward equality in male and female relations among Protestants remain salient. Progressive moral change is always difficult to sustain both within religious communities and in the wider society. The fundamentalism now aligned with conservative political and economic power enjoys considerable success in part because of better political mobilization on the right. Even reputable media-spokespersons and scholars, who surely should know better, occasionally mislead in their interpretation of these contemporary controversies. For example, until the last decades of the twentieth century most Protestant churches from the traditions discussed here, emphatically embraced family planning and took no role in efforts to criminalize abortion. In ongoing debates legal abortion came to be embraced on various theological and moral grounds by major Protestant churches. However, the Christian Right has now succeeded in efforts to construct an 'unbroken' Christian anti-abortion tradition out of a pastiche of traditionalist Biblical pronatalism, Roman Catholic teaching, and post-sonogram technical imagery. To be sure, a few Protestant moral-theologians have been strongly anti-abortion on Biblicist grounds, but until recent efforts to 'reconstruct' Protestant history, it is not accurate to portray Protestants as anything other than committed to family planning and as moderately supportive of safe and legal abortion. Today, no reputable theological spokesperson would criticize family planning or embrace Roman papal doctrines that sex is chiefly for procreation, but fewer and fewer Protestant leaders recall the active debates that led to the embrace of reproductive choice for women in their communities. As a result the slow but dramatic march of Protestantism toward inclusion of women in 'the priesthood of all believers' may be reversed and the historical vocation of protestant theological reform rendered unrecognizable.

Protocol Analysis in Psychology

Protocol analysis is a rigorous methodology for eliciting verbal reports of thought sequences as a valid source of data on thinking. When psychology emerged as a scientific discipline at the end of the nineteenth century, the majority of psychologists were interested in consciousness. They sought to examine the structure and elements of their thoughts and subjective experiences through introspective analysis. Within a few decades, the introspective method was discredited, and introspective descriptions were rejected as scientific evidence. Psychology turned away from studies of individuals' descriptions of their thoughts and first-hand experiences, and focused on observations of how other adults performed tasks in the laboratory. The rejection of introspection made the study of thinking come to a virtual halt until the 1950s, when the

technical innovations such as the computer led to the emergence of cognitive and information processing theories of psychological phenomena. In the new research approach to the study of thought processes, subjects were asked to 'think aloud,' leading to a new type verbal report of thinking that differed from the earlier introspective methods and became the core method of protocol analysis. The next section describes the fundamental problems of introspection and general solutions offered by protocol analysis.

1. Problems with Introspective Descriptions of Thinking and Proposed General Solutions

Adults describe their subjective experience, such as dreams, memories, and mental slips, on a regular basis, so why are observations of one's own experiences and thinking problematic as psychological data? The fundamental problem with descriptions of inner experience is that they are private and known only to the person who experienced them. There are no methods to verify the accuracy of these experiences independently. Consequently, protocol analysis is restricted to situations where the scientist has other types of information about the participant's thinking that can be used to validate the verbal reports.

The other major objection to introspection is that the mere act of observation of one's thoughts and experiences changes them. For example, when someone examines a single visual image appearing during thinking to search for specific associated details, this analysis tends to make the desired details emerge and thus changes the content and structure of the original image. This extended analysis also interrupts the normal flow of visual images, so it is impossible just to resume the thought process where it was interrupted. To minimize this type of interference in protocol analysis, research participants are instructed to think aloud while problem solving so they can concentrate on the experimental task, and let verbalization of thought be secondary.

2. Historical Background

Self-observation of thinking has a long history, which helps explain the controversies surrounding introspection, as well as the development of less controversial methods for eliciting verbalizations of thinking. The first systematic attempts to understand the structure of thinking by observing one's own spontaneous thoughts have been traced back at least as far as the Greeks. Based on observation of his thoughts, Aristotle argued that thinking corresponds to a sequence of thoughts (see Fig. 1), where the brief transition periods between consecutive thoughts (see the arrows in Fig. 1) do not contain any reportable information.

Aristotle's general account of thinking as a thought sequence has never been seriously challenged (Ericsson and Crutcher 1991). The controversies about introspection have all involved attempts to go beyond the immediately observable aspects. For example, Aristotle tried to infer the unobservable processes that control the thought sequence (see the arrows in Fig. 2). By examining his memory of which thoughts tended to follow each other, Aristotle concluded that previously experienced associations between thoughts were the primary determining factor. Philosophers in the seventeenth, eighteenth and nineteenth centuries (Ericsson and Crutcher 1991) asked questions that required more involved inferences and introspective analyses. For example, can every thought be described as an amalgam of memories? In order to evaluate these claims empirically, philosophers would typically relax and daydream, allowing their thoughts to wander. Once in a while they would try to freeze an image and inspect it carefully to assess its sensory modality and components. Based on such detailed observations, the famous British philosopher David Hume came to the surprising conclusion that thoughts were as detailed as original perceptions—we cannot have a visual image a printed page of text without imaging every letter on the page at the same time.

By the nineteenth century, philosophers generally rejected Hume's claim and agreed that the process of analyzing a visual image changes its original appearance. For example, when a person has an image of a rose and then decides to inspect its petals, the whole mental image changes. Consequently, the process of examining mental images is fundamentally different from observing solid objects in the real world. A real rose can be looked at repeatedly from different directions without being changed, even its petals can be inspected with a looking glass without any change. In contrast, extended introspective analysis of a mental image changes its content and structure and cannot therefore be used to study thoughts as they emerge during spontaneous thinking.

In the beginning of the twentieth century, psychologists at the University of Würzburg tried to minimize this form of reactivity by training introspective observers. These observers were given thought-provoking questions and asked to respond as fast as possible. Only after their answers had been given would the observers start to recall the thoughts that they had had while answering the questions. The observers were trying to recall the most basic elements of their thoughts and visual images. Most reported thoughts consisted of visual and auditory images, but some subjects claimed to have experienced thoughts without any corresponding imagery—imageless thoughts. The alleged existence of imageless thoughts had far-reaching theoretical implications and led to a heated exchange between the psychologists who claimed to have observed them and others who argued that these reports were artifacts of inappropriate

Figure 1

An illustration of Aristotle's view of thinking as a sequence of states with reportable thoughts, while the processing responsible for transitions between consecutive thoughts remains inaccessible

Figure 2

An illustration of a covert sequence of thoughts and the associated overt verbalizations of most thoughts passing through attention during the performance of a task

reporting methods and theoretical bias of the observers. A devastating conclusion arose from this controversy: the existence of imageless thoughts could

not be resolved empirically. This finding raised fundamental doubts about analytic introspection as a scientific method.

Reacting to the methodological and theoretical problems of the introspective method, psychologists redirected their research from conscious experience and thinking and towards observable behavior, and focused on basic learning processes shared by adults, children, and animals. For example, some of the tasks involved learning the path from a starting location to a goal location in an arbitrary maze, where the benefits of prior experience and knowledge would be minimal. Similar learning tasks required participants to memorize 'meaningless' materials, such as nonsense syllables like XOK and ZUT, where the memory performance was measured objectively by scoring the sequence of recalled syllables for accuracy. The hypothesis that memory for nonsense syllables was based only on basic associations, and was later rejected in studies by cognitive psychologists showing that during memorization subjects reported thinking of words that were similar to the studied nonsense syllable, such as 'cozy' for KOZ and 'payment' for PYM (Prytulak 1971). When subjects were able to associate the nonsense syllable with a word, the speed and accuracy of memorization improved (Montague 1972), which provides validation for the reported thoughts.

The cognitive revolution in the 1960s renewed interest in higher-level cognitive processes and how thinking allows individuals to generate solutions to novel tasks. Cognitive theories describe how individuals are able to apply acquired knowledge and procedures to novel problems, such as mental multiplication of any combination of two two-digit numbers. Information processing theories (Newell and Simon 1972) proposed computational models that could reproduce the observable aspects of human performance on well-defined tasks through the application of explicit procedures.

One of the principle methods of the information processing approach is task analysis. Task analysis specifies the range of alternative procedures that people could use, in light of their prior knowledge of facts and procedures, to generate correct answers to a task. Let me illustrate how task analysis can be applied to mental multiplication. Most adults have only limited mathematical knowledge: they know their multiplication table and only the standard 'pencil and paper' procedure taught in school for solving multiplication problems. Accordingly, one can predict that they will solve a specific problem such as 36×24 by first calculating $4 \times 36 = 144$ then adding $20 \times 36 = 720$. More sophisticated subjects may recognize that 24×36 is equivalent to $(30 + 6) \times (30 - 6)$ and use the formula $(a + b) \times (a - b) = a^2 - b^2$, thus calculating 36×24 as $30^2 - 6^2 = 900 - 36 = 864$. The choice of alternative procedures participants use to generate the answer can be inferred by the time needed and verbal reports of their thoughts during problem solving.

In conclusion, the theoretical and methodological controversies about verbal reports have never cast doubt people's ability to recall part of their thought

sequences. The controversies have centered around efforts to go beyond the sequence of thoughts (see Fig. 1), to analyze their detailed structure through introspection, and to infer the processes controlling the generation of new thoughts. In fact, all major theoretical frameworks concerned with thinking have advocated the use of verbally reported sequences of thoughts (Ericsson and Crutcher 1991). For example, the behaviorist John B. Watson pioneered the use of 'think aloud,' and the gestalt psychologist Karl Duncker established it as a major method.

3. Protocol-analysis Methodology

The central assumption of protocol analysis is that it is possible to instruct subjects to verbalize their thoughts in a manner that doesn't alter the sequence of thoughts mediating the completion of a task, and can therefore be accepted as valid data on thinking.

3.1 Elicitation of Nonreactive Verbal Reports of Thinking

Based on their theoretical analysis, Ericsson and Simon (1993) argued that the closest connection between thinking and verbal reports is found when subjects verbalize thoughts generated during task completion (see Fig. 2). When subjects are asked to think aloud, some of their verbalizations seem to correspond to merely vocalizing 'inner speech,' which would otherwise have remained inaudible. Nonverbal thoughts can also be often given verbal expression by brief labels and referents. For example, when one subject was asked to think aloud while mentally multiplying 36 by 24 on two test occasions one week apart, the following protocols were obtained:

(a) OK, 36 times 24, um, 4 times 6 is 24, 4, carry the 2, 4 times 3 is 12, 14, 144, 0, 2 times 6 is 12, 2, carry the 1, 2 times 3 is 6, 7, 720, 720, 144 plus 720, so it would be 4, 6, 864.

(b) 36 times 24, 4, carry the—no wait, 4, carry the 2, 14, 144, 0, 36 times 2 is, 12, 6, 72, 720 plus 144, 4, uh, uh, 6, 8, uh, 864.

In these two examples, the reported thoughts are not introspectively analyzed into their perceptual or imagery components, but merely verbally expressed and referenced, such as 'carry the 1,' '36,' and '144 plus 720.' Similarly, subjects are not asked to describe or explain how they solve these problems. Instead, they are asked to remain focused on solving the problem and merely to give verbal expression to those thoughts that emerge in attention while generating the solution under normal (silent) conditions.

If the act of verbalizing subjects' thought processes does not change the sequence of thoughts, then subjects' task performance should not change as a result of thinking aloud. In a comprehensive review of

dozens of studies, Ericsson and Simon (1993) found no evidence that the sequences of thoughts (accuracy of performance) were changed when subjects thought aloud as they completed the tasks, compared with subjects who completed the same tasks silently. However, some studies showed that think-aloud subjects would take somewhat longer to complete the tasks—presumably due to the additional time required to produce the overt verbalization of the thoughts.

The same theoretical framework can also explain why other types of verbal report procedures consistently change cognitive processes. For example, when subjects are instructed to explain or carefully describe their thoughts, they are not able merely to verbalize each thought as it emerges, they must engage in additional cognitive processes to generate the thoughts corresponding to the required explanations and descriptions. This additional cognitive activity changes the sequence of mediating thoughts. Instructions to explain and describe the content of thought are reliably associated with changes in ability to solve problems correctly (Ericsson and Simon 1993).

In sum, after brief training in giving verbal reports, subjects can think aloud without any systematic changes to their thought process (see Ericsson and Simon 1993 for detailed instructions and associated warm-up tasks recommended for laboratory research). This means that subjects must already possess the necessary skills for verbalization of thoughts.

3.2 Validity of Verbalized Information from Think Aloud

When adults are able to perform tasks while thinking aloud without sacrificing accuracy and speed, the verbalized information would almost have to reflect some aspect of the regular cognitive processes. By analyzing the information expressed as verbalized thoughts, it is possible to assess the validity of the verbalized information. In protocol analysis, the verbalized thoughts are compared with intermediate results generated by different strategies that are specified in a task analysis (Ericsson and Simon 1993). The sequence of thoughts verbalized while multiplying 24 by 36 mentally (reproduced above) agrees with the sequence of intermediate thoughts specified by one, and only one, of the possible strategies for calculating the answer.

Even when subjects think aloud with its close connection between thoughts and reports, correspondence between verbalized thoughts and intermediate products predicted from the task analysis is not perfect (see Fig. 2). The lack of one-to-one correspondence is due primarily to the fact that not all thoughts which pass through attention are verbalized and some processing steps (thoughts) may be short-circuited with acquired skill. However, there is persuasive

evidence of validity for the thoughts that are verbalized (Ericsson and Simon 1993). Even if a highly skilled participant's think-aloud report in the multiplication task only consisted of '144' and '720,' the reported information would still be sufficient to reject many alternative strategies, because these strategies did not involve generating both of the reported intermediate products. The general finding that a task analysis can identify *a priori* the specific intermediate products that are later verbalized by subjects during their problem solutions, provides the strongest evidence that concurrent verbalization reflects the processes that mediate the actual generation of the correct answer.

More generally, verbal reports are only one indicator of the thought processes that occur during problem solving. Other indicators include reaction times (RTs), error rates, patterns of brain activation, and sequences of eye fixations. Given that each kind of empirical indicator can be separately recorded and analyzed, it is possible to compare the results of such independent data analyses. In their review, Ericsson and Simon (1993) found that longer RTs were associated with verbal reports of a larger number of intermediate thoughts than those corresponding to shorter RTs. Furthermore, there seemed to be close correspondence between subjects' thoughts and what information that they looked at—when subjects verbalized thoughts about objects in the environment they very frequently looked at them.

Finally, the validity of verbally reported thought sequences depends on the time interval between the occurrence of a thought and its verbal report, where the highest validity is observed for concurrent, think-aloud verbalizations. For tasks with relatively short response latencies (less than 5–10 s), subjects are able to recall their sequences of thoughts accurately immediately after the completion of the task, and the validity of this type of retrospective reports remains very high. However, for cognitive processes of longer duration, the problems of accurate recall of prior thoughts increases, with a corresponding decrease in validity of the verbal reports.

3.3 Explanations of Validity Problems with Other Types of Verbal Reports

Protocol analysis specifies the constrained conditions necessary for valid, nonreactive verbalizations of thinking. Many of the problems with verbally reported information obtained by other methods can be explained as violations of protocol analysis methodology. The first problem arises when the investigators ask subjects to give more information than is contained by the their recalled thought sequences. For example, some investigators ask subjects why they responded in a certain manner. Sometimes subjects will have deliberated and their recalled thoughts will

provide a sufficient answer, but typically the subjects need to go beyond any retrievable memory of their processes to give an answer. As subjects can only access the end products of their cognitive processes during perception and memory retrieval, they cannot report why only one of several logically possible thoughts entered their attention, so they must confabulate to answer such questions. In support of this argument, Nisbett and Wilson (1977) found that subjects' responses to 'why' questions were in many circumstances as inaccurate as those given by other subjects who merely observed and tried to explain another subject's behavior.

Second, scientists are interested primarily in the general strategies and methods subjects use to solve a broad class of problems in a domain, such as mathematics or text comprehension. They often ask subjects to describe their general methods after solving a long series of different tasks, which often leads to misleading summaries or after the fact reconstructions of what subjects think they must have done. In the rare cases when subjects have deliberately and consistently applied a single general strategy to solving the problems, they can answer such requests easily by recalling their thought sequence from any of the completed tasks. However, subjects typically employ multiple strategies, and their strategy choices may change during the course of an experimental session. Under such circumstances subjects would have great difficulty describing a single strategy that they used consistently throughout the experiment, thus their reports of such a strategy would be poorly related to their averaged performance. Hence, general strategy descriptions are usually inadequate, even when reports after each trial are valid descriptions of thought sequences.

Similar problems have been encountered in interviews of experts (Hoffman 1992). When experts are asked to describe their general methods in professional activities, they have difficulties, and there is often poor correspondence between the described methods and their observed behavior. However, when experts perform challenging representative problems from their domain of expertise while thinking aloud, their verbalizations consistently reveal a valid and informative account of their thought sequences during complex thinking and planning (Ericsson and Lehmann 1996). In sum, to obtain the most valid and complete trace of thought processes, scientists should strive to elicit those verbalizations that most directly reflect the subjects' spontaneous thoughts generated while they perform tasks that are representative of the studied phenomenon.

4. Range of Application

Protocol analysis has emerged as one of the principal methods for studying thinking in cognitive psychology (Crutcher 1994), cognitive science (Simon and Kaplan

1989), and behavior analysis (Austin and Delaney 1998). As further evidence of its validity, protocol analysis now plays a central role in applied settings, such as in the design of surveys and interviews (Sudman et al. 1996) and user testing of computer software (Henderson et al. 1995). Finally, several interesting adaptations of verbal-report methodology are emerging in the study of text comprehension (Pressley and Afflerbach 1995) and education (Renkl 1997).

Psychiatric Assessment: Negative Symptoms

Negative symptoms comprise, among others, flattening of affect, reduction of speech, and social withdrawal. They occur in different psychiatric diseases, but especially in schizophrenia, where they are traditionally seen as an important part of the symptomatology. In the last decade, they have evoked a special research interest due to the fact that novel/atypical antipsychotics have been developed with an improved therapeutic efficacy in negative symptoms of schizophrenia.

1. Definition of Negative Symptoms

Negative symptoms in schizophrenia comprise broadly of blunted affect, apathy, attentional impairment, poverty of thought or speech, incoherence, loosening of association, thought blocking, and social withdrawal. However, there is no unanimous agreement on the concept of negative symptoms in schizophrenia: some authors adhere to a broad interpretation (Meltzer and Zureick 1989, Rösler and Hengesch 1990), while others prefer a narrow approach (Crow 1985, Strauss et al. 1974, Wing 1989). The controversy centers on incoherence, loosening of association, and thought-blocking, since these are also attributes of positive symptoms. This disparity in the selection of items also manifests itself in the outcome of patient testing with different rating scales. Different authors use different concepts and definitions for the type and number of symptoms implicated (Rösler and Hengesch 1990).

These problems of definition can also be identified in the rating scales used for measuring negative symptoms.

2. History of the Term 'Negative Symptoms'

The origins of the positive/negative distinction are usually attributed to Jackson (1887), the British neurologist who drew the distinction in order to delineate primary from secondary neurological phenomena. Accordingly, positive symptoms are defined as the presence of a behavioral function that is otherwise not normally present in an individual. Negative symptoms are defined as the absence of a behavioral

function that is usually present in the normal individual. Negative symptoms all appear to be characterized by the loss of an important cognitive or behavioral function, while positive symptoms represent an exaggeration or distortion of a normal function.

3. Standardized Assessment and Dimensional Differentiation of Negative Symptoms

To improve the reliability of diagnostic assessment of negative symptoms, several scales have been developed, mostly in the last two decades (SANS: 1981, PANSS: 1987, SAPS: 1991).

Standardization of the assessment of negative symptoms through rating scales had a positive effect on reliability. For example, the interclass correlations for the Scale for the Assessment of Negative Symptoms (SANS) and the Scale for the Assessment of Positive Symptoms (SAPS) complex global ratings range between 0.70 and 0.88. Principally, the negative symptoms can be rated with as much reliability as positive symptoms.

Rating scales applied in the past decade include, among others, the anergia score of the Brief Psychiatric Rating Scale (BPRS), the Manchester Scale and Crow's modification of this scale, the negative score of the Positive and Negative Scale (PANSS), the SANS, and Abrams and Taylor's Rating Scale for Emotional Blunting. Nowadays, the SANS and the PANSS are the most frequently used rating scales.

In nearly all studies in which a broad spectrum of negative symptoms was investigated by a factor analytical approach, two or three dimensions of negative symptoms were found. This emphasizes the inadequacy of a unidimensional concept of negative symptoms in the complex phenomenology of this domain (Meltzer and Zureick 1989).

4. Symptomatic Overlap with Parkinsonism and Depression

The differentiation between depression and negative symptoms is difficult on the basis of both clinical phenomenology and rating scales, and therapeutic effects on depressive symptoms might be misinterpreted as successful treatment of negative symptoms and vice versa. Gaebel (1989) reported a correlation of $r = 0.34$ – 0.57 at different measurement points for the BPRS scores depression and anergia. In a follow-up study on schizophrenic patients, the correlation between the scores for depression and retardation/apathy in the Inpatient Multidimensional Psychiatric Scale (IMPS) amounted to $r = 0.35$ (Möller and von Zerssen 1986).

Another problem in the interpretation of rating scale data from studies in this field is that the negative symptoms score correlates positively with the drug-

induced Parkinson syndrome. Furthermore, there is a correlation between negative symptoms and hyperkinetic neurological symptoms such as akathisia and dyskinesia. One could therefore conclude that drugs without extrapyramidal side effects in general may appear to be more advantageous in treating negative symptoms.

5. Negative Symptoms in Schizophrenia

Both Kraepelin and Bleuler described a core of schizophrenic symptoms corresponding to the modern concept of negative symptoms (Table 1). Later, this position was gradually displaced by an emphasis on productive features as being pathognomonic of schizophrenia, in fact, as being a prerequisite for its diagnosis. This is exemplified in the diagnostic criteria for schizophrenia put forward by Schneider 1959, Feighner et al. (1972), in the research diagnostic criteria (Spitzer et al. 1978), and in the *Diagnostic and Statistical Manual DSM-III*, *DSM-III-R*, and *DSM-IV* criteria.

The need to incorporate both negative and positive features into a model of schizophrenia was brought out by the factor analytic studies of the 1960s and in particular by the research of Strauss et al. (1974), who adapted Jackson's (1887) terminology for classifying different profiles in schizophrenia.

Whereas Crow's (1980b) model viewed the positive and negative symptoms as annulated facets of schizophrenia that may reflect separate pathological processes, Andreasen (1982) proposed instead a typological model. They described positive and negative symptoms as opposing features that characterize different subtypes.

Which symptoms of schizophrenia are considered positive or negative varies across different authors. Nearly all authors include flat affect and poverty of speech among the negative symptoms, and hallucinations and delusions among the positive symptoms. Most regard anhedonia, apathy, avolition, or abulia

as negative symptoms. Thought disorder, bizarre behavior, and inappropriate affect, however, are variably classified as positive or negative.

6. Negative Symptoms in other Psychiatric/Mental Disorders

Anergia, anhedonia, poverty of speech, and affective flattening, which occur as part of the negative symptoms in schizophrenia, were also observed in patients severely ill with depressive disorder. Although negative symptoms of schizophrenia may be different from depressive symptoms in depression, they do overlap, thus making negative symptom complexes and psychomotoric retardation, lack of energy, anhedonia, and other symptoms of depression significantly associated. On the other hand, it was observed that a distinct hypokinetic syndrome involving anhedonia, depressed mood, and cognitive impairment existed not only in negative schizophrenia and retarded depression, but also in Parkinson's disease, suggesting that reduced dopamine turnover might play a role in the pathophysiology of each.

7. Primary and Secondary Negative Symptoms

The differentiation between primary and secondary negative symptoms, as proposed by Carpenter et al. (1985), seems of great theoretical and clinical relevance. While primary negative symptoms are the consequence of a moribogenic deficit state, secondary negative symptoms are the consequence of:

- (a) positive symptoms (e.g., social withdrawal because of paranoid ideas);
- (b) extrapyramidal effects (e.g., motor retardation as an indicator of neuroleptogenic akinesia);
- (c) depressive symptoms (e.g., postpsychotic or pharmacogenic depression); or
- (d) social understimulation (e.g., hospitalization).

Table 1
Relationship between the concept of basic symptoms and the concept of negative symptoms (Klosterkötter 1990)

Kraepelin (1904)	Bleuler (1911)	Wing and Brown (1970)	Strauss et al. (1974)
Cognitive decline ('Stultification,' 'Dementia')	Association disorder	Schizophrenic thought disorders Slowness of thought Poverty of speech	Certain kinds of formal thought disorders, such as blocking
Flatness of affect	Affective disorder	Flatness of affect	Blunting of affect
Loss of intentional power	Autism Ambivalence Abulia Lack of initiative	Social withdrawal Low motivation	
Loss of energy	Lack of interest	Lack of initiative Underactivity	Apathy

According to this distinction, the treatment of negative symptoms has to be differentiated concerning the different causes.

Angst et al. (1989) underlined the necessity of discriminating negative symptoms according to different stages in the course of schizophrenia, i.e., the prepsychotic period, the productive psychotic period (characterized by a mixture of positive and negative symptoms, whereby negative symptoms may be hidden at this stage), and the postpsychotic period (characterized by residuum or defect with or without positive symptoms, postpsychotic endogenous, or reactive depression, postremissive exhaustion).

Crow (1980a) postulated the stability of a specific subtype of schizophrenia with positive symptoms (type I) and a subtype with negative symptoms (type II), explaining this by different biological causes. Most other authors stressed the point that negative and positive symptoms can be combined cross-sectionally or longitudinally and cannot be taken as indicators for a specific biological or phenomenological subtype of schizophrenia.

8. Relationship between Positive and Negative Symptoms in Schizophrenia

The positive/negative distinction may represent different manifestations of the common underlying process. It may also suggest the existence of different pathophysiologies in schizophrenia. Hints about the inter-relationships of these processes may be gleaned from the intercorrelations among their final common expressions as symptomatic phenomenology. An initial effort by Andreasen (1982) showed that the positive and negative symptoms clusters were significantly correlated within clusters and inversely correlated between clusters, suggesting a bipolar construct with positive and negative symptoms at the opposite ends of a continuum. This was replicated by another group. However, later investigations showed little or no relationship between positive and negative symptoms, strongly suggesting that they are independent processes within schizophrenia.

Since both positive and negative symptoms are frequent in schizophrenia, they are likely not to be completely independent (Möller et al. 1995). However, some findings have been controversial. For example, Rosen et al. (1984) failed to find a positive/negative symptom correlation.

9. Course of Negative Symptoms in Schizophrenia

Findings on the course of positive and negative symptoms over time have aroused considerable controversy. In acute and/or first episode cases, negative symptoms are sparse and linked tightly to the presence of other manifestations of psychoses, especially to

positive symptoms (Möller and von Zerssen 1986). In the North American Risperidone Study (Marder and Meibach 1994), in which risperidone was compared to haloperidol, both drugs improved positive and negative symptoms significantly. Similar results were obtained in clinical trials on other novel/atypical neuroleptics such as olanzapine, sertindole, amisulpride, etc. Clearer results may be obtained if more sophisticated designs are used for psychopharmacological trials on negative symptoms. A European collaboration group therefore made some suggestions (Möller et al. 1994), focusing on patients with predominantly negative symptoms (Table 2).

During the acute phase, negative symptoms can often be unstable. For example, McCreddie (1989) studied schizophrenic patients suffering a first episode at three points in time (admission, one- and two-year follow-up). The percentages of patients with positive and negative symptoms were 96 and 23 percent at admission, 22 and 40 percent at the one-year follow-up, and 21 and 25 percent at the two-year follow-up, respectively. Other studies with acute patients have shown that negative symptoms are more stable over time. Ragin et al. (1989) found an increase in the level of poverty of speech between index admission and seven months after discharge. Wagman et al. (1987) found that the anergia score of the BPRS was significantly correlated across four months of repeated measures in patients with deficit symptoms, but not in patients without deficit symptoms.

Overall, negative symptoms appear to be more stable in subacute/subchronic patient samples. Pogue-Geile and Harrow (1985) recorded high and stable levels of anhedonia one and three years after episodes of schizophrenia. Biehl et al. (1986) found that negative symptoms had significant retest stability between years two and five in a sample from the International Pilot Study of Schizophrenia.

In a follow-up study of schizophrenia carried out in Munich (Möller and von Zerssen 1986), patients were rated using the IMPS at admission, discharge, and at a five-year follow-up. A decrease was observed in the mean score of positive symptoms and also in syndrome retardation as an indicator of negative symptoms. The correlation for the retardation score between discharge and follow-up was 0.36. In a similar 15 years follow-up study on first hospitalized patients with schizophrenia, a decrease of negative symptoms was found between admission and discharge, and an increase between discharge and follow-up (Möller et al. in press).

Many authors came to the conclusion that, in contrast to the views of Crow (1980b), the negative subtype and the positive subtype of schizophrenia are not stable conditions during the short- or long-term course of the disease. Most authors stressed the point that negative and positive symptoms can be combined cross-sectionally or longitudinally, and cannot be taken as indicators of a specific biological or phenomenological subtype.

Table 2

Suggestions of the working group on negative symptoms in schizophrenia (Möller et al. 1994)

Aim: evaluating treatment effects on negative symptoms in schizophrenia

Patient selection.

- Positive symptoms not dominating the actual clinical picture, e.g. PANSS negative type
- Duration of negative symptoms > 6 months
- Stable condition of the schizophrenic illness > 6 months
- Flat affect and poverty of speech as core symptom of negative symptoms
- No/low depression score

Design: double-blind comparison to placebo or active drug

Efficacy parameters: BPRS or SANS or PANSS

Other scales: depression scales, EPS scales

Statistical analyses

- End-point comparison
- Interaction with productive symptoms, depression, EPS

BPRS: Brief Psychiatric Rating Scale; EPS: extrapyramidal symptoms; PANSS: Positive and Negative Syndrome Scale; SANS: Scale for the Assessment of Negative Symptoms

10. *Biological Correlates of Negative Symptoms in Schizophrenia*

The most prominent biochemical finding in schizophrenic patients with negative symptoms appears to be the reduction in central dopaminergic, serotonergic, and noradrenergic activity, and, if at all, a general common pattern can be described. This decrease in amine activity tends to be associated with structural brain abnormalities, i.e., cortical atrophy or enlarged ventricles. There are indications that typical neuroleptics reduce at least those negative symptoms of schizophrenia that are secondary to positive symptoms when the positive symptoms are effectively treated. However, negative symptoms of schizophrenia that occur independently of positive symptoms may also be reduced, especially through treatment with atypical antipsychotics or with antidepressants. The efficacy of drug treatment of negative symptoms seems to be related to their pharmacological profile, i.e., their interference with dopaminergic, noradrenergic, and serotonergic receptor systems. As to atypical antipsychotics, among others the 5-HT_{2A} blockade was hypothesized as being a relevant mechanism for the efficacy of atypical antipsychotics in treating negative symptoms.

As mentioned above, there is a considerable overlap in the symptomatology of psychiatric disorders with respect to negative symptoms. Also, different types of negative symptoms in schizophrenia have to be considered. In addition, the lack of homogeneity in the definition and assessment of negative symptoms in schizophrenia can be a problem. All these difficulties have consequences for research and explain some of the inconsistencies in biochemical and pharmacologic schizophrenia research (Meltzer and Zureick 1989). The results of biochemical investigations as well as of positron emission tomography and magnetic resonance imaging studies on negative symptoms, warrant

further research efforts in this field to find, among others, a rationale of neuroleptic drug treatment in negative symptoms of schizophrenia.

11. *Treatment of Negative Symptoms in Schizophrenia*

There has been a strong debate in the literature on whether neuroleptics can really reduce negative symptoms, and especially whether they can reduce primary negative symptoms and not just secondary negative symptoms. An earlier review found evidence that some neuroleptics, especially some atypical neuroleptics, can reduce negative symptoms. However, since most of the trials were carried out in patients with negative and positive symptoms during acute exacerbations of schizophrenic psychoses, the question arises whether only those negative symptoms were reduced that were secondary to positive symptoms. In addition, the overlap between negative symptoms of schizophrenia and extrapyramidal side effects and depression has to be taken into account. As an alternative hypothesis to the direct effect of a drug on negative symptoms, the possibility that a drug reduces depression, akinesia, sedation, etc., and in this way also reduces negative symptoms, must be considered seriously.

One possibility of differentiating between direct and indirect drug effects on negative symptoms is to use statistical procedures. Formerly, only two studies had used an elementary statistical approach to account for the possibility of indirect effects on negative symptoms. Meltzer (1985) used a covariance analysis and found that the neuroleptic effect on negative symptoms could not be explained via a neuroleptic effect on positive symptoms alone. Van Kammen et al. (1987) used a regression analysis which showed that

the neuroleptic effect on negative symptoms could be explained by the effect on positive symptoms.

More complex statistical approaches were not used until the mid-1990s. Möller et al. (1995) applied a complex statistical model, a path analysis, to the data of the North American Risperidone Study (Marder and Meibach 1994), including effects on positive, negative, and extrapyramidal symptoms to determine whether risperidone had a more potent direct effect on negative symptoms than haloperidol. The aim was to determine whether a (direct) effect on negative symptoms remains after the effects which are possibly caused through the reduction of positive and extrapyramidal symptoms have been excluded. The estimate from the path model showed that even after statistical control for indirect effects on secondary negative symptoms, risperidone improved negative symptoms to a greater extent than haloperidol.

H.-J. Möller

Psychiatric Care, Economics of

A discussion of the economics of mental health care cannot take place without considering the epidemiological characteristics of mental illness and its cost to society.

1. Epidemiology of Mental Illness

1.1 The Burden of Mental Illness

Mental disorders are among the most prevalent and disabling illnesses worldwide. Unipolar major depression is the leading cause of disability globally in 1990, both in high-income and in low- and middle-income countries. It has been estimated that depressive and anxiety disorders account for 20–30 percent of all primary care visits worldwide. Approximately 29.5 percent of the US population is estimated to experience a diagnosable mental or addictive disorder in a 12-month period, which is comparable to the 20 percent rate for cardiovascular disorders (Kessler et al. 1994). Prevalence estimates of schizophrenia from studies in low-income countries vary from 0.8 per thousand reported from rural China to 5.9 per thousand in Calcutta, India. There were about 23 million people with schizophrenia in the world in 1985, three quarters in the less developed countries. Severe and persistent mental illnesses (as defined by diagnosis, disability, and duration) affect about 4 percent of the

population each year. These disorders are long lasting, produce significant level of disability, reduce an individual's ability to function in major social roles, and interfere with the creation and maintenance of social networks (Desjarlais et al. 1995).

These national and international statistics do not reflect the enormous toll of misery from mental disorders. Neuropsychiatric conditions have been ignored for a long time as they are absent from cause of death lists. However, disease priorities change dramatically as measurement of disease burden shifts from simple mortality indicators to indicators that incorporate disability. When disease-burden measurement includes time lived with disability, several of the neuropsychiatric disorders become a leading cause of disease burden worldwide. The World Bank estimates that neuropsychiatric diseases account for 6.8 percent of the Global Burden of Disease (GBD), measured in disability adjusted life years (DALYs), a toll greater than that exacted by tuberculosis, cancer, or heart disease. For adults aged 15–44 in developing economies, neuropsychiatric diseases account for 12 percent of the GBD. When intentional, self-inflicted injuries are added, the total constitutes 15.1 percent of the GBD for women and 16.1 percent for men. Because of the limited mortality consequences, this burden has been previously underestimated (World Bank 1993).

According to a 1999 estimate, neuropsychiatric conditions account for 10 percent of the burden of disease measured in DALYs in low and middle-income countries and 23 percent of DALYs in high-income countries. In comparison, cardiovascular diseases are responsible for 10 percent of DALYs in low and middle-income countries and 18 percent of DALYs in high-income countries. In high-income countries, one out of every four DALYs is lost to a neuropsychiatric condition. Of the ten leading causes of disease burden in young adults (in the 15–44 year age group) four are neuropsychiatric conditions. Alcohol dependence, bipolar disorder, and schizophrenia are among the leading causes of disease burden in this age group in 1998 (World Health Organization 1999).

1.2 The Social and Treatment Costs of Mental Illness

Society pays a high price for mental and addictive disorders—in both direct and indirect costs. Indirect costs (lost productivity, lost earnings due to illness or premature death, accidents, absenteeism) are twice the direct costs of care, adding to the actual economic impact of mental and addictive disorders. The total costs for the United States for 1990 for all mental disorders was \$148 billion (Rice et al. 1990). The direct cost of care for all mental disorders was \$67 billion, which represents 10 percent of the total \$670 billion direct cost of all health care in the United States

in 1990 (Levitt et al. 1991). In comparison, the total cost for all cardiovascular system diseases in US for 1990 was \$159 billion. More recent estimates show the full economic cost of alcohol and drug abuse in USA in 1992 to be \$246 billion. The cost burden from depression is about the same as that from heart disease. In the experience of one Fortune 100 company, mental health was ranked number two in the company's 10 most costly diseases, topped only by ischemic heart disease in terms of direct cost. If the same 10 diseases were ranked according to the full burden of disease, indirect costs drove mental health to the number one position and ischemic heart disease to the number 10 position (NAPHS 1999).

Spending on treatment is concentrated on those people with the most disabling conditions. Although individuals with severe and persistent mental illness represent only 5–10 percent of all the individuals who have mental illness, they account for approximately 40 percent of the specialty care expenditures (Steinwachs et al. 1992). Another estimate shows that 30 percent of the spending on mental health and substance abuse care is accounted for by 5 percent of the users of care (Frank et al. 1994). The total cost of severe and persistent mental illness in 1990 was estimated to be \$74 billion (accounted for by the dollar costs of treatment, lost productivity, shortened lives, and the costs incurred in the criminal justice and social services systems), with \$44 billion of the total being indirect cost (Rice et al. 1990).

However large, the dollar cost of mental illnesses does not account for the enormous emotional cost and pain that these illnesses exert not only on the affected individual but also on their family and on society. Mental disorders are often chronic conditions that create substantial disability. It is estimated that approximately 20–25 percent of the single adult homeless population suffers from some form of severe and persistent mental illness (Jencks 1994). Mental illness is correlated with other costly social problems: unemployment, crime and violence (Steadman et al. 1998), child abuse and neglect (Kelleher et al. 1994), and auto accidents (Rice et al. 1990).

1.3 Utilization of Services

It is not clearly established what proportion of individuals with mental disorder need, or want, treatment. Unlike other physical illnesses, not everyone with diagnosable mental illness perceives a need for treatment, and not all who seek treatment have a diagnosable disorder. Thus the under treatment and the over treatment of mental health problems can coexist within the same system (Regier et al. 1998).

In the United States, of the 30 percent of the population that has a mental illness at some point during the year, only 17.3 percent get some treatment in the health care sector with an additional 7.4 percent getting their only treatment from a human service

agency or a self-help group. Thus, only about 25 percent of those with a diagnosable condition get some form of treatment over a twelve-month period. Low rates of treatment characterize the most severely ill. Only 36 percent of the people diagnosed with bipolar disorder or major depression in a year are treated in any health sector, only 25 percent of those with substance abuse are treated, and 57 percent of the patients with schizophrenia are treated. At the same time 4.5 percent of individuals with no disorder, as assessed with a diagnostic instrument, receive mental health care (Kessler et al. 1997). According to Frank and McGuire (1999) nearly 38 percent of the users and 28 percent of all visits for mental health are not associated with a diagnosable disorder.

Two conclusions particularly relevant to the economic analysis of mental health care can be drawn from the above data on the epidemiology of mental illness and its cost to the society. First, mental and addictive disorders are prevalent and disabling and associated with a variety of social costs. Second, the social costs of mental and addictive disorders are concentrated in the 4 percent of the population that experiences severe and persistent mental illness, making this subgroup of people with mental illness 'undesirable' to insurers, employers, and neighbors.

2. The Market for Mental Health Care Services

Economics is the science and art of the distribution and allocation of scarce resources. The allocation of resources and rationing of scarce goods and services are guided by the market economy prices. The appropriate price for a product is determined by the relationship between *demand* and *supply* for this product. In the context of the market economy, health care in general and mental health care in particular can be conceptualized as a product. The classic relationship between the demand and the supply can be applied to mental health care as well. However, mental health care does not conform to the traditional rules of a marketplace. Several factors account for this. The nature of mental illness, the use of treatment services, and the supply side of the market differ from the general health sector. Plus, there are a greater variety of organizations and professionals with different theoretical orientation that supply mental health services. These include the specialty mental health sector (psychiatrists, psychologists, psychiatric social workers, psychiatric nurses, and counselors), the general medical sector (primary care physicians), self-help groups, and the clergy. Despite efforts to quantify mental health services and make them more objective, there is greater clinical uncertainty compared to the rest of medical care. Many mental disorders affect a person's ability to make decisions in their own best interest. Markets for other goods normally consist of a straightforward transfer of goods between the provider and the consumer. However, in the health sector,

in addition to this arrangement, funds from patients often flow through an intermediate funding body (either the government or an insurance agency). Market economics in mental health care are strongly influenced by *externalities*, that is the value that society derives from the health of its individual members.

Health care markets suffer from some kind of *market failure* but the mental health care market is subject to more failure than most. The most common market failures affecting the health care sector are due to lack of incentive to supply 'public goods,' neglect of externalities, and absence of well informed consumers. Failures in the market can be explained also by *adverse selection* (persons more likely to use coverage choose better coverage) and *moral hazard* (those who are insured will tend to overuse insured services). Evidence suggests that the forces of adverse selection and moral hazard work are at work in mental health (Frank and McGuire 1999). The special effort that is needed to reduce moral hazard and adverse selection in mental health care markets is one of the reasons why mental health services are organized and paid for differently than other types of health care (for review see Sharfstein et al. 1992, 1995).

3. Financing of Mental Health Services

Health care in general and mental health care in particular can be financed by public or private sources, the funds can be managed by public or private entities. Funds can be raised through taxes, mandates, private health insurance, out-of-pocket payments, grant assistance, charitable contributions, and borrowing. Funds can be managed by government, for-profit or not-for-profit private organizations, or consumers. Funds are then used to purchase health services that can be publicly or privately provided. A number of issues related to both public and private sources of financing are predicated on government's goals (allocational, distributional, and economic) and the policies utilized to correct market failures and instabilities.

3.1 Relationship Between Finance and Provision of Mental Health Care

It is important to distinguish between financing and provision of services. There is no absolute connection between the way mental health care is paid for and the way it is delivered. Public finance does not imply public provision. It is possible for services to be publicly financed yet privately provided or vice versa. Three major forms of relationships exist between the providers of mental health care and those who finance it, reimbursement, contract, and integrated approaches. Under the reimbursement approach, providers receive retroactive payments for services that they have supplied. Reimbursement can be found in systems with multiple private and public insurers and

multiple suppliers as in the United States. In low- and middle-income countries reimbursement is rarely combined with public finance with the exception of Chile. Contract involves an agreement between third-party payers (insurers) and health care providers. It is found in social insurance systems. Preferred provider organizations (PPOs) in the United States also use this form. In integrated health care systems the same agency controls the funding and the provision of health services. Medical providers are paid salaries and the budget is the main instrument for allocating resources. Integrated public systems are used in the Nordic countries and in developing countries as well. Health maintenance organizations (HMOs) in the United States are an example of an integrated private system. In countries with national health systems, the purchaser of care and the provider are commonly one and the same, namely, the government. In Europe there has been increasing interest in separating provider and financing functions in national health systems in order to promote competition.

3.2 Inequities in the Financing of Mental Health Care Services

A key characteristic of the mental health care service system is the inequity in financing mental health services compared to the coverage for other disorders. Resources available to mental health care have been eroding over the past decade (Buck and Umland 1997). Discriminatory limits on treatment of mental disorders characterize both the public and private sector. This discrimination against mental illness is based on arbitrary and often artificial distinctions between mental and physical illness.

3.3 Insurance and Managed Care

Health insurance is a system in which the prospective consumers of care make payment to a third party, which in the event of future illness will pay for some or all of the expenses incurred. Health insurance is a mixed source of finance, as it often draws contributions from both employers and employees, and sometimes from government. The existence of risk is the fundamental rationale for insurance. Insurance reduces risk by improving the predictability of adverse events through the pooling of a large number of similar risks. The few who become ill are covered for care by the many who remain well. Thus, risks that are unpredictable for the individual become predictable for the group and can be estimated.

Insurance markets are characterized by inherent instability. Adverse selection occurs in private insurance markets. Private insurance markets attempt to counter adverse selection by excluding the riskier customers and adjusting premiums which undermines the value of insurance altogether. This is one of the main arguments in favor of *public insurance* which can

be made universal and force everyone to share the risks. Cost sharing (deductibles, copayment), limits of benefits, total expenditures limits on policies, all are ways to deal with moral hazard. Despite the use of these mechanisms, the increased cost of health care and mental health care in particular has led to the introduction of other cost-containment mechanisms known as *managed care*. Managed care includes various organizational arrangements, such as HMOs and PPOs in the United States. Managed care organizations integrate the three functions of managing, financing and providing care. Managed care also includes financing mechanisms (capitation and risk-sharing contracts) that have strong incentives to reduce the amount of mental health care provided. The essence of managed care is its ability to ration care without imposing undue financial risk on consumers. Managed care principles can be utilized by public and private financing entities (see Mechanic 1997, 1998).

Managed care mechanisms are intended to affect rationing through establishment of a network of selected providers, contracts with providers that include incentives to limit care, introduction to the concept of medical necessity, and directing individuals to levels of care. Managed care plans also use various strategies to select good (profitable) risks from an insurance pool thus undermining the very existence of insurance and precluding effective risk pooling (Cutler and Zeckhauser 1998). They may prevent or discourage high-cost individuals from joining the plan or distort the services they provide in order to attract good and deter the bad risks. Supply-side management mechanisms to reduce costs include preauthorization requirements, utilization review, case-management for high utilizers, reducing access to specialty care providers, and substituting low cost providers for high cost providers.

Managed care has been shown to reduce overall mental health and substance abuse costs and service utilization. However, there has been concern about how the cost-containment strategies affect the access to care and the quality of care for patients. Cost-containment strategies can lead to excessive denial of care and under utilization of services, thus limiting access to care. Financial incentives to providers to reduce specialty referrals, hospital admissions, and length and amount of treatment can ultimately contribute to lowered quality of care.

Some demand-side cost-containment mechanisms, such as higher deductibles, copayments, visit- and day-limits, used by managed care can be reduced by introducing parity for mental health services with all other medical services. However, the introduction of parity generates incentives for insurance plans to replace the demand side cost-containment mechanisms with such mechanisms on the supply side. According to Frank and McGuire (1998) parity in insurance benefits for mental health care is not sufficient to guarantee equality in access to mental

health services if managed care-rationing devices such as 'medical necessity' denials cannot be controlled. Nevertheless, introducing parity for mental health services is a step towards overcoming the discrimination of mentally ill, reducing the financial barriers to treatment of mental disorders and improved access to services. Parity in private insurance benefits may result in some public-to-private sector cost shifting.

3.4 Private Financing

Private financing can be direct (personal payments) or indirect (payments for health services by employers). Private insurance, out-of-pocket payments for direct purchase of services, medical savings accounts, and charitable contributions are all sources of private financing of health services. Private financing is an essential part of health care financing given government's limited ability to raise enough resources to finance health services. Reliance on private financing is a necessity in many low-income countries.

The combination of price competition and the ownership incentives that the private sector offers may contribute to improved efficiency in the sector as a whole. However, instabilities in private insurance markets necessitate public financing of services or, in some cases, government regulation of private insurance markets. Except for a few countries (Switzerland, the United States) private health insurance is a minor source of finance. In developing countries this is because most of the population cannot afford private insurance. In high-income countries it is because the state has assumed most of the insurance function (Schieber and Maeda 1997).

No industrial country relies exclusively on free markets to produce and allocate health care in general and mental health care in particular. Government intervention is justified, in order to improve the efficiency and equity with which the private market produces and allocates its services. Public regulation of private markets is also essential to ensure effective risk pooling, affordability, informed choice, and continuity of coverage.

3.5 Public Financing

The main argument for public financing of health services is the achievement of universal access. This argument is based on efficiency (arising from market failures of the private market) and equity considerations (financing should be according to the ability to pay, and the distribution according to need). Public financing of health services can be of two types, a national health-service approach and social insurance funds. In both models collective risk pooling is achieved through compulsory taxation. There are a few major differences between the two systems.

National health services are usually financed by general taxes and other public revenue sources and thus they are subject to annual budget processes. Social insurance funds are generally financed through payroll taxes and tend to be more independent of annual political machinations. Public finance accounts for 75 percent of health care financing in high-income countries with the exception of The United States where public finance covers about 50 percent of the overall health care financing. In developing countries public finance is less important and accounts for about 20 percent of the total health care financing with out-of-pocket payments accounting for most of it. The composition of public finance varies in high-income countries. France, Germany and The Netherlands rely on social insurance while Canada, the Nordic countries and the United Kingdom use general taxation. United States operates both kinds of publicly financed systems (Johnson and Musgrove 1997).

3.6 Financing of Services for Severe and Persistent Mental Illness

Direct public services for the most severely ill people is a common feature of health systems that may otherwise be organized to provide and pay for other health care with a range of approaches (Hollingsworth 1992). The public mental health system in the United States, Germany, Canada, UK, and France are quite similar despite vast differences in their approaches to health care financing. The responsibility for mental health care is assigned to sub-national government and tends to rely on local tax funding. The role of local government-provided mental health care tends to emphasize providing care to the poor and disabled. The commonality can be explained partially by the fact that provision of mental health care has a public safety component and, therefore, the locality has a greater interest in assuming more direct control over the delivery of certain forms of mental health care to fulfill its obligation of public protection. Most countries have laws that tend to favor society's interests (externalities) over individual liberties of the mentally ill. This can explain partly the greater role of the government in provision of mental health care, including public hospitals and clinics.

Treatment programs aimed at people with severe and persistent mental illness are concerned not only with the acute care of symptoms but address also housing needs, income support, rehabilitation, social contacts, and social control of the affected individuals. The nature of severe and persistent mental illness requires coordination of services from various providers. Many of the successful innovations in the treatment of this group of people with mental illness involve new ways of organizing and coordinating the various elements of care.

4. Setting Priorities and the Role of the Government

There is little consensus or empirical evidence as to the right level of financing for health care and for mental health care in particular. Policymakers face the perpetual challenge of raising sufficient revenue for the health sector in an equitable and efficient way. Decisions about health spending cannot be isolated from a country's political, social, and economic characteristics. People's values, the responsiveness of the political system to public preferences, and the resources available are all reflected in the pattern of financing of health care. In the context of scarcity, mental health services are seldom given high priority by national governments or by international aid programs. Despite changing public attitudes towards mental illness and trends towards integration of the mentally ill into the mainstream of the health care system, the fact remains that, in terms of public and private policy, mental illness and substance abuse are not treated the same as other illnesses. In most countries today priorities are set in ways that exclude large numbers of people from access to organized care. Ability to pay appears increasingly to be the mechanism rationing access to care. In middle and upper income countries, health-financing policy is driven frequently by the need to increase coordination, reduce fragmentation, and exert better control over total health care costs. Countries in this group are often worried that their level of health spending will threaten economic growth and competitiveness by making their labor force, and therefore goods and services, more expensive. If universal access to affordable and effective mental health care is to be achieved, priorities have to be agreed upon and implemented. Choosing public priorities is how economic reality becomes an integral part of mental health system development and reform.

Psychiatric Disorders: Culture-specific

1. Introduction: Development of the Concept and Definition

The concept of 'culture-bound syndromes' has been the focus of an ongoing debate in the field of transcultural or comparative cultural psychiatry between psychiatric universalists who interpret these conditions as cultural elaborations of universal neuro-psychological or psychopathological phenomena, and cultural relativists who see them as generated and expressive of distinctive features of a particular culture. The 8th edition of Kraepelin's textbook of psychiatry in 1909 was the first handbook describing clinical pictures which were later labeled 'culture-bound syndromes,' namely *latah*, *koro*, and *amok*. In the past the term 'exotic' was used to emphasize the non-Western character of culture-related conditions. It was not anticipated then that a disorder such as *anorexia nervosa* in young women would become common due to sociocultural factors operant in modern Western society, so that it has now been recognized as a Western culture-reactive syndrome (DiNicola 1990). The concept of culture-specific psychiatric disorders was originally introduced into psychiatric literature in the 1950s and 60s by Yap, who also made the first attempt to order what he called 'culture-bound reactive syndromes,' known under a great variety of folk names, in a diagnostic classification schema (Yap 1967).

A list of 168 so-called culture-bound syndromes was compiled in a glossary by Hughes (1985), while the *Diagnostic and Statistical Manual* of the American Psychiatric Association, 4th edition, contains a glossary with 25 entries. These listings also include colloquial and local names for some well-known ubiquitous conditions. The Diagnostic Criteria for Research of the 10th Revision of the *WHO International Classification of Diseases* list 12 examples of 'culture-specific disorders' and suggest diagnostic codes while also stating that these conditions cannot be easily accommodated in established psychiatric classifications. Indeed, attempts at a nosological classification of culturally related syndromes have never been quite satisfactory due to (a) the overlap of diagnostically relevant symptoms, and (b) the fact that the various indigenous terms for similar syndromes are charged with different culture-specific meanings and traditional interpretations that codetermine the illness behavior of the patient and the reaction of the human environment.

On the basis of the data to be presented in this article, culture-specific psychiatric disorders are defined as clusters of symptoms and behaviors that can be plausibly related to specific cultural emphases, or to specific sociocultural stress situations, which are typical of a particular population.

2. Local Folk Idioms of Distress

Local folk idioms of distress for psychologically stressful situations that can occur in any culture are not signifiers of culturally specific disorders although the manifestations are influenced by the local culture. *Susto*, *espanto*, *miedo* are colloquially equivalent Spanish terms implying an experience of fright or scare, widely used among Hispanic populations of the Western hemisphere for a great variety of symptoms (Rubel et al. 1985). The conditions so labeled frequently resemble neurotic or somatoform syndromes but may also be caused by other kinds of disorders, including organic pathology. The Spanish word *nervios* is often used among Hispano-American and Caribbean populations, as is the English term *nerves* among rural Anglo-American groups, to denote chronic dysphoric mood states with various somatic manifestations especially in postmenopausal women under psychosocial stress, as is commonly encountered also in other cultures. The Spanish term *ataque de nervios* is, among Hispanic populations of Central and North America and the Caribbean, applied in reference to women showing a brief episode of behavioral discontrol as immediate reaction to any emotionally traumatizing experience (Oquendo 1994). Middle-aged Korean women, like those in other cultures, may react to stressful life situations and ongoing marital or family problems, with depressed mood, feelings of

anger, and somatizing complaints, typically of a sensation of an epigastric mass. This chronic dysthymia is known among Koreans and Korean-Americans as *hwa-byung*, 'fire disease,' and traditionally treated by female shamans (Lin 1983).

3. Culturally Stereotyped Reactions to Extreme Environmental Conditions

Certain behavioral reactions to extreme environmental conditions are culturally stereotyped although they are not truly culture-specific. This is the case with conditions generally subsumed under the heading 'arctic hysteria,' a term used by outside observers for the often dramatic behavioral reactions shown by indigenous inhabitants of arctic and subarctic areas in stress situations in which the person affected experiences a temporary state of dissociated consciousness induced by acute anxiety (Foulks 1972). Physical deprivation, mineral and vitamin deficiencies, as well as the psychological stresses of surviving in an extreme climate, were adduced to explain these phenomena which have practically disappeared as the traditional Eskimo way of life has largely been abandoned.

Frequently cited in the ethnological literature are *pibloktoq* (Inuit, 'crazy') among Eskimo in Greenland, arctic Canada, Alaska, and Siberia, and *kayak-svimmel* (Danish, 'kayak dizziness') also called *kayak-angst*, among seal-hunting Greenlanders. *Pibloktoq*-type attacks usually affected younger women who after a prodromal phase of anxious and irritated behavior started imitating animal calls, then suddenly became agitated and, screaming loudly, rushed into the snow or even into icy water, albeit not too far off so that they were easily rescued. The motor excitation ended with collapse or sometimes with convulsive movements, followed by deep sleep. There was only a vague recollection of the event which, in traditional culture, was attributed to possession by evil spirits.

Attacks of *kayak-svimmel* occurred among seal hunters experiencing extreme isolation and sensory deprivation when sitting lonely and motionless in the kayak, surrounded by the monotonous whiteness of the arctic sea, waiting for a seal to appear. In this situation the hunters might suddenly fear the kayak was filling with icy water when they had a sensation of coldness in the legs. In a state of mounting anxiety they felt dizzy and unbalanced; were trembling and sweating, paralyzed with panic anxiety and subject to illusionary perceptions. With help coming in time they could reach shore safely but more intense attacks followed on other trips so that they had to give up kayak hunting.

In the past, frequently referred to as a culture-specific condition of the Algonquin Indian tribes of northern Canada, was the '*windigo* (*witiko*) psychosis,' described as an obsessive murderous desire for human

flesh under the delusion of being possessed by, or turning into, the mythical cannibalistic *Windigo* monster with a heart of ice, said to appear during severe subarctic winters. The struggle for survival in the harsh northern climate may have led to isolated instances of famine cannibalism but a critical examination of the many reports of 'windigo psychosis' could not confirm a single case of cannibalistic compulsion (Marano 1982). The term *windigo* is today used among the northern Ojibwa to denote a state of deep depression, without implication of cannibalistic impulses.

4. Syndromes related to Specific Cultural Emphases or Specific Socio-cultural Stress Situations

4.1 Syndromes Related to a Cultural Emphasis on Fertility and Procreation

4.1.1 'Genital shrinking' syndrome. The Malayo-Indonesian term *koro* and the Mandarin Chinese term *suo-yang* (Cantonese *suk-yang*) denote 'shrinking of the penis.' These terms refer to an acute state of panic anxiety prompted by the belief of the affected male person that his penis is shrinking and will disappear, and of the affected female person that her breasts and/or labia are shrinking. The 'genital shrinking' is believed not only to lead to impotence and/or sterility but to death once the organs are completely retracted. This syndrome came to the attention of European psychiatry in the late nineteenth century through reports by colonial physicians working in South East Asia and through the growing interest in traditional Chinese medicine. Chinese traditional medicine interprets *suo-yang* as yin-yang imbalance due to deficiency of the 'warm' male principle yang and excess of the 'cold' female principle yin, so that vitalizing yang remedies are indicated.

For the theorists of psychoanalysis, *koro* served as the concrete example of Oedipal castration anxiety, while some Chinese authors like Yap saw in *suo-yang* the paradigm of a true culture-bound syndrome, assuming that the disorder itself was generated by the suggestive effect of traditional Chinese concepts. However, it has since been ascertained that the typical 'genital shrinking' syndrome also occurs not infrequently among Asian and African populations without Chinese cultural influence. Complaints of genital shrinking are also occasionally verbalized by Western patients but these cases are different from the culturally related 'genital shrinking' syndrome as they are associated with other, usually chronic, neurotic, psychotic, or organic conditions; and the patient's ethnic-cultural group in Western society does not share the belief in the reality of genital disappearance and

ensuing death. *Koro/suo-yang* is the only culturally related syndrome that has occurred in major epidemic outbreaks. Epidemics of 'genital shrinking' have been repeatedly reported in recent decades (Jilek 1986). Outbreaks in Singapore, Thailand, North East India, and South China were precipitated by collective anxieties over perceived threats to the security or even survival of the afflicted population; in Nigeria by fears of magic robbing of the genitals.

4.1.2 'Semen loss' syndrome. Known in the traditional medicine of China as *shen-k'uei*, 'weakness of the kidneys,' in the Ayurvedic medicine of India as *dhat* (from Sanskrit *dhatu*, essential body substance) or *jiryan*, in Sri Lanka as *sukra prameha*, the complaint of 'semen loss' is not uncommon among young men of these countries in which a high premium is placed on reproductive capability and semen is considered a precious elixir of life. The presented symptoms have a hypochondriac quality; they are associated with an anxious and dysphoric mood state and typically attributed to the imagined loss of sperm in urine or to natural nocturnal emissions (Paris 1992). Sperm loss is assumed to cause the symptoms of general weakness, loss of energy, exhaustion, difficulty concentrating, sexual dysfunction, and rather vague somatic complaints. Many of these patients consult practitioners of traditional medicine as well as medical doctors; as immigrants they are also increasingly seen in European and North American clinics.

4.2 Syndromes Related to a Cultural Emphasis on Learnt Dissociation

4.2.1 Latah-type reactions. The peculiar *latah* reactions have been cited by cultural relativists as a paradigm of culturally generated behavior (Kenny 1978), and by biopsychological universalists as cultural elaborations of the neurophysiological startle reflex (Simons 1996). *Latah* reactions were interpreted by Gilles de la Tourette as a variant of his neurological syndrome, and by Kretschmer as a phylogenetic mechanism. The complete *latah* syndrome consists of an initial startle response provoked by a person of certain social status and triggered by a visual, acoustic, or tactile stimulus, the sensitivity to which is both individual and culture-specific. The startle response induces an altered state of consciousness, associated with repeated impulsive utterance of sounds or inarticulate words, often also swearing with sexual or obscene words ('coprolalia'). Characteristic are echopraxia, echomimia, and echolalia, namely the exact imitation of the provoking person's movements, facial and oral expression; even of words and sentences spoken in foreign languages. Automatic

obedience to commands may occur in hypnoid trance and serve the amusement of onlookers. The *latah* syndrome can sometimes culminate in a brief state of cataleptic rigidity. Because of the typical echo symptoms, *latah* reactions are known in French psychiatry as *névroses d'imitation*.

Automatic imitation behavior has also repeatedly been observed in normal indigenous people during first contact with Europeans, as already reported by Charles Darwin from Tierra del Fuego and more recently from remote areas of Melanesia (Gajdusek 1970) and East Africa (Jilek-Aall 1979). The typical *latah* syndrome occurs mostly in females over two geographic zones (Winzeler 1995): the South East Asian zone, encompassing Malaysia, Indonesia (*latah*, 'nervous, ticklish'), Thailand (*bah-tshi*, 'tickle-crazy'), Burma-Myanmar (*yaun*, 'ticklish'), the Philippines (*mali-mali*); the North Eurasian zone, encompassing the Ainu people of Hokkaido and Sakhalin (*imu*, 'startle'), aboriginal peoples in Mongolia and Siberia (Russian, *miryachit*), and the Sami of northernmost Europe ('Lapp panic'). The varied ethnic groups of these two *latah* zones have no culture traits in common other than (a) learnt dissociation which is practiced from early youth on in religious, social, and therapeutic ceremonies, trance rituals, and shamanic seances; (b) learning by imitation and coping by copying the behavior of persons who appear to be more powerful. Sporadic occurrence of *latah* symptoms has been reported among some males in Arabic-Islamic populations of North Africa and Yemen, and among South African Bantu people. While European cases are rarely encountered elsewhere, the endemic and familiar incidence of so-called 'jumping,' a reaction similar to *latah*, among males of French Canadian background in certain rural areas of Maine, New Hampshire, and Quebec, has attracted scientific interest since the 1870s.

4.2.2 Amok-type reactions. The term *amok* is originally derived from the Portuguese-Indian *amuco*, referring to heroic warriors ready to die in battle who are immortalized in Malayan epics, similar to the *berserkr* in ancient Norse sagas. Today, 'running amok'—likewise 'going berserk'—has become a colloquial label for any episode of apparently unprovoked randomly aggressive and homicidal behavior, usually engaged in by attention-craving angry young men in modern Western society. Although such behavior has certain features in common with the *amok* reaction observed among Asian *amok*-runners, it does not represent the specific dissociative syndrome described under this term (Pfeiffer 1994). Typical *amok* reactions are preceded by a dysphoric-tense mood state in the context of perceived or imagined social adversity or slight, loss of prestige or status, interpersonal or socioeconomic problems. A sometimes trivial event then triggers the actual *amok*

reaction. After a phase of meditative brooding an alteration of the state of consciousness ensues in which visual perception changes: the outside world turns into darkness or becomes red, threatening visions may appear, causing feelings of fear or rage. The affected person is suddenly seized by hypermotility and embarks on the *amok* run, a discharge of aggression leading to random destruction and killing, and eventually to suicide or suicide attempt. In case of survival, the attack is terminated by stuporous sleep; afterwards amnesia is claimed for actions committed.

Amok reactions have been presented as specific to the male ethos of Malayo-Indonesian culture. Such reactions also occur among related ethnic-cultural groups in the Philippines and in Laos. However, there are also typical *amok* cases in Papua New Guinea (Burton-Bradley 1975), besides the common non-violent pseudo-*amok*, the psychodramatic 'wild man behavior' of New Guinea highlanders. In historical analysis, *amok* in Southeast Asia appears to have changed from a glorified warrior ethos and means of social protest of the precolonial era, to a dissociative reaction, which in more recent times is mainly found in marginal figures or as an episode during the course of a chronic mental disorder (Murphy 1973).

4.3 Syndromes Related to a Cultural Emphasis on Presenting a Pleasing Physical Appearance: Taijin-Kyôfu Reactions

In contrast to the condition commonly diagnosed in Western psychiatry as social phobia, the Japanese form of anthropophobia, *taijin-kyôfu* ('fear in relation to others'), is not a phobic avoidance of social contacts in order to avoid unpleasant feelings for oneself; rather it is the fear that one's external appearance may be disturbing or offending to the other who as a rule is neither a stranger nor a close relation but a respected acquaintance. Symptoms of *taijin-kyôfu* were already mentioned in the eleventh century Genji saga by Lady Murasaki Shikibu, and detailed clinical descriptions suggest this condition to be typical of Japanese culture (Kimura 1995). However, this type of anthropophobia is also not uncommon in Korea (Lee et al. 1994). The clinical syndrome *taijin-kyôfu* was introduced into psychiatric literature in the 1920s by Shoma Morita as a subtype of the nervous temperament (*shinkeishitsu*) that he considered to be the main indication for his 'Morita Psychotherapy.' The syndrome is not uniform but occurs as one of several phobic anxiety manifestations: as erythrophobia (i.e., fear of blushing in front of others); as eye contact phobia (i.e., fear that others feel bothered when looked at); as body odour phobia (i.e., fear that one's own assumedly offensive body odour will bother others); as dysmorphophobia (i.e., fear of having an extremely unattractive, repulsive face or defective physique); or as fear that one

will grimace or otherwise behave embarrassingly. The sufferers tend to be convinced of their imagined defects to a degree that their phobias appear delusional, and the presence of other psychotic symptoms has to be ruled out in order to delimit *taijin-kyôfu* from a schizophrenic disorder. However, the anthropophobic patient's relation to the human environment is fundamentally different from that seen in chronic schizophrenic psychoses. *Taijin-kyôfu* patients are neither autistic nor paranoid; they suffer from a fear of presenting themselves.

4.4 Syndromes Related to Acculturative Stress

4.4.1 Brain fog. The term 'brain fog,' coined by Nigerian students, refers to a condition first reported by Prince (1960). The brain fog syndrome has since been recognized in a high percentage of Nigerian students at home and abroad, and also in other African countries (Liberia, Ivory Coast, Uganda, Tanzania, Malawi, Swaziland) in students exposed to the acculturative stress of a Western-type education system emphasizing theoretical book knowledge, quite different from the practical know-how and tribal lore acquired through oral traditions by older generations in Africa. It is noteworthy that subnormal intelligence, malnutrition, or physical disease do not account for the symptoms of brain fog which are also seen at educational institutions in Europe and North America among African students in good state of nutrition and general health. The brain fog syndrome is categorically different from the general study stress and examination crises experienced by students from Western or Asian cultures with centuries of literary tradition and education systems already long-based on reading and writing and on memorizing texts for formal examinations. The brain fog syndrome is also clinically different from the common complaints everywhere related to study stress: The mere effort of reading may cause blurred vision and flow of tears. There are also inability to concentrate on reading material and lectures, impairment of retention and memory, daytime fatigue and disturbed night sleep. Characteristic symptoms are the feeling of burning heat on head and body and the sensation of crawling as if caused by insects on, or by worms under, the skin.

4.4.2 Bouffée délirante-type reactions. Clinical findings as well as research data indicate that acute transient psychotic and psychosis-like reactions occurring in African and Afro-Caribbean populations are disorders directly related to culture and culture change, and are encountered with increasing frequency in Africa (Jilek and Jilek-Aall 1970). Such reactions are characterized by intense fear of magical persecution

or retribution and are usually triggered by an event or experience evoking acute anxiety in the context of beliefs in sorcery or witchcraft that persist or even increase under rapid sociocultural changes. *Bouffée délirante*-type reactions are of sudden onset and brief duration, they are associated with paranoid delusions, oneroid (i.e., dream-like) confusion, frequently also visual and auditory hallucinations, and often lead to dramatic and sometimes dangerous acting-out behavior.

Anglophone psychiatrists have described transient psychotic and psychosis-like reactions in Africans under various terms while their francophone colleagues use the diagnostic label *bouffée délirante*, which was introduced into French psychiatry in the 1880s by Magnan and later redefined by French-speaking authors in Africa in accordance with their clinical experience (Collomb 1965). The well-known Nigerian psychiatrist Lambo introduced the English term 'frenzied anxiety' and equated it with *bouffée délirante* (Lambo 1960). As repeatedly stated by Lambo and by other researchers, the main underlying causes for these states are not toxic-organic but sociocultural factors. Among these factors, of paramount importance is the stress exerted by rapid culture change which is leading to the social marginalization of many Africans in the process of 'modernization,' as recently also confirmed in Swaziland (Guinness 1992). Under situations of urbanization and Westernizing acculturative pressures the traditional communalistic society is disintegrating and the supportive kin network is breaking down. The individual then experiences an increasing economic rivalry and social isolation which intensifies the old fears of witchcraft and sorcery, never obliterated by Christianity, while the traditional protective and remedial resources are no longer readily available.

5. Culture-specific Disorders vs. Traditional Ritual Behavior

Culture-specific psychiatric syndromes have to be differentiated from extracurricular but not pathological behavior in the traditional rituals of non-Western cultures. A Western-trained clinician who attaches pathology labels to behaviors and ideas that are considered normal in a non-Western culture, commits a 'eurocentric fallacy.' As a general statement it can be said that the culture-specific disorders are not part of ceremonials in which ritualized altered states of consciousness are induced and practiced for religious or therapeutic purposes. While such institutionalized trance and 'possession' states constitute culture-congenial behavior in certain ceremonials, the culture-specific syndromes described above are considered as abnormality or illness also by the indigenous experts of the culture and are explained in terms of a particular folk etiology which determines traditional therapeutic management.

W. G. Jilek

Psychiatry and Sociology

Sociology and psychiatry have a longstanding relationship which has never been free of tensions and can at least be characterized as ambivalent. On the one hand, psychiatry as a subspecialty of medicine, which has to solve concrete problems in everyday life, has become a subject matter of sociology, which often criticizes psychiatry's concepts and practices. On the other hand, psychiatry has profited from cooperating with sociologists by making use of sociological research methods. The article sets out with describing the relationship between the two disciplines, and then proceeds to discussing the contributions made by sociology towards the understanding of how psychiatry functions ('sociology of psychiatry') before describing the uses of sociology within the field of psychiatry ('sociology in psychiatry').

1. Sociology and Psychiatry—An Uneasy Relationship

Sociology and psychiatry have a common topic: deviant behavior. Sociology, as a scientific discipline which examines the rules by which society functions, must have a genuine interest in phenomena which threaten these rules. Emile Durkheim (1895), one of the founding fathers of sociology, points out in his famous book, *The Rules of the Sociological Method*, that the standards and rules defining what is pathological help to reinforce the norms and values of society. For psychiatry, in turn, a specific form of deviant behavior, called mental illness, is its very 'raison d'être.' In this respect, the relationship between sociology and psychiatry could be regarded as a relationship of equal partners joining their intellectual forces in analyzing a topic of common interest, though using different approaches. However, there is also a different type of relationship between these two disciplines, in so far as one of them, psychiatry as a subspecialty of medicine, has become the subject matter of the other, sociology.

When discussing the relationship between sociology and psychiatry, a profound difference between these two disciplines has to be kept in mind: Psychiatry is not only a scientific discipline—like sociology—but also a practice field, akin to medicine in general, or to education. Sociologists might aim at changing things, but sociology has never been a major player in practical problem-solving, in contrast to psychiatry, which from its very beginning 200 years ago was assigned the societal task of treating the mentally ill or managing (controlling, as sociologists would say) the problem of mental disorders. Van der Geest (1995), in comparing medicine and social sciences (exemplified by cultural anthropology), speaks of two ‘ethnocentrisms,’ i.e., two different cultures, which are dissimilar in three aspects. The culture of medicine is practical and problem-oriented (doctors are supposed to find concrete solutions to concrete problems), whereas the social sciences culture is theoretical; doctors have no time to lose (they have to act promptly before it is ‘too late’), social scientists are not in a hurry to finish their work; finally, doctors measure their success in maintaining and restoring people’s health (they are accountable to people); for social scientists the fulfilment of their task does not lie in an improvement of the lives of the people studied, but in the production of texts about them. The ‘ethnocentrism’ of these two disciplines makes communication difficult and prone to misunderstandings.

Psychiatry’s relationship to sociology is ambivalent. On the one hand the application of sociological research methods to psychiatric problems have undoubtedly contributed to raise psychiatry’s societal visibility and importance—by furthering epidemiological research, which has shown that between one quarter and up to nearly half of the US population suffer from at least one diagnosable mental disorder during a person’s life time (e.g., Robins and Regier 1991, Kessler et al. 1994). On the other hand, sociologists have been, and still are, among the most radical critics of psychiatry, concerning both its concepts and its practice.

One further aspect renders the discussion of the relationship between sociology and psychiatry difficult: Both disciplines are extremely diverse within themselves. Sociology comprises a multitude of different philosophies (e.g., the ‘social constructivist’ and the ‘social realist’ perspectives) and research methods (e.g., the ‘quantitative’ and the ‘qualitative’ approaches). Psychiatry, both as a scientific discipline and a practice of identifying, explaining, and treating behavioral problems, which are deemed to be mental disorders, is even more heterogeneous, since psychological and sociological, as well as biological, approaches live under its roof. There is also a substantial overlap between each of the two disciplines and other fields. Sociology can be broadened to mean social sciences in general, and incorporate social anthropology, social psychology, and other disciplines. Fur-

thermore, fields such as epidemiology, public health, social medicine, health economics, and others, if applied to psychiatric problems, would have to come in. Also, no attempt can be made here to discuss the boundaries of psychotherapy, clinical psychology, and social psychiatry in relation to clinical psychiatry.

For the purpose of this review, which addresses a broad audience, the author—who is a psychiatrist with strong interests in sociology—has found the dichotomy of the relationship between sociology and medicine, proposed by Robert Straus (1957), useful. Following Straus’ distinction between ‘sociology of medicine’ and ‘sociology *in* medicine,’ the ensuing part of the text will be divided into the ‘sociology of psychiatry’ and the ‘sociology *in* psychiatry.’ The first approach discusses sociological contributions toward the understanding of psychiatry as a whole, i.e., of how psychiatry behaves in terms of developing and using concepts and applying them in practice. The second approach deals with the application of sociological methods within the field of psychiatry. While these two approaches are sometimes intertwined, their separation is nevertheless useful for the purpose of orientation. This distinction can, at least implicitly, also be found in two recent reviews of the sociology of mental health and illness, to which the reader of the present review is referred for more detailed discussions of the issues raised here (Pilgrim and Rogers 1999, Busfield 2000). It has to be noted, though, that ‘sociology of mental health and mental illness’ is a broader concept than the two sociologies (*of* and *in* psychiatry) discussed here. In the following two sections these two approaches are illustrated by examples.

2. *Sociology of Psychiatry*

The sociology of deviant behavior is central to sociology. Analyzing how boundaries are drawn between the normal and the abnormal, in other words, how the normal and the abnormal are classified, and analyzing how society reacts to the abnormal is one of the main interests of sociology. Since psychiatry has obtained an important definitional power over the specific type of deviant behavior called mental illness, and since it also has substantial influence on how such behavior is dealt with, it is obvious that psychiatry itself has become a subject matter of sociology. Sociologists have dealt both with psychiatric concepts and with the practice of psychiatry, with a special emphasis on the professional nature of psychiatry, on psychiatric services and the issue of legal vs. medical control of mental disorders.

2.1 *Psychiatric Concepts*

Sociologists have always expressed doubts about the coherence, credibility, and validity of psychiatric

concepts and knowledge. The most profound sociological criticism of psychiatry concerns the concept of mental illness and its classification into discrete diagnostic entities. While such criticism has come forward from many quarters, including the anti-psychiatric and consumer movements as well as scientific psychiatry itself (where some advocates favor dimensional rather than categorical concepts), the specific and original contribution from sociology was the labeling theory in the 1960s (Scheff 1999), a variant of what is called 'social constructivism,' i.e., a theory assuming that reality is a product of human definitions and not something waiting out there to be discovered (Brown 1995). More specifically, using 'symbolic interactionism' as their framework (a theory about how people map out social reality in everyday life), the advocates of 'labeling theory' claimed that the same deviant behavior may either go unnoticed or be labeled as mental illness, depending on the circumstances in which it occurs and is perceived by others. For instance, in a now famous study, Rosenhan (1973) observed that healthy test persons ('Pseudopatients') who presented themselves to psychiatric hospitals and told the doctor that they were hearing voices (saying 'empty,' 'hollow,' and 'thud') were admitted and received a psychiatric diagnosis. Once labeled, so the theory goes, the person's identity and social status is altered significantly. Part of the process is that the labeled person internalizes the new identity ascribed to them and becomes trapped in the new role of a mental patient.

A radical social constructivist perspective creates hostility among doctors, patients, and relatives, since they get the feeling that it denies the reality of suffering connected with mental disorders. While the idea that mental disorders, especially schizophrenia, are caused by labeling is more or less abandoned in recent thinking, labeling is certainly a powerful mechanism when it comes to discussing the role of stigmatization and discrimination (Link et al. 1987). A more moderate form of criticizing psychiatric diagnosis is the notion that through the diagnostic process illnesses are 'socially framed' (Rosenberg 1992). Mirowsky and Ross (1989), while acknowledging that psychological problems are real, criticize that psychiatric diagnosis treats attributes as entities, and that psychiatrists often speak of psychological problems 'as if they are discrete entities, entering the bodies and soul of helpless victims.' They target especially the operationalization of psychiatric diagnosis in modern diagnostic systems, such as the *Diagnostic and Statistical Manual III* (DSM-III) (and onwards) of the American Psychiatric Association (1994). It has to be acknowledged, though, that the construction of DSM-III was partly a reaction to the criticism that psychiatrists were not able to diagnose mental disorders reliably (Rosenhan 1973). However, while operationalization might have increased the reliability of psychiatric diagnosis, the question of validity is still debatable. Brown (1995) has

suggested that instances of medicalization of normal life problems (such as 'late luteal phase dysphoric disorder—LLPDD'; now called 'pre-menstrual dysphoric disorder—PMDD') are mainly a feature of professional 'expansionism.'

2.2 Psychiatry as a Profession

Sociologists have not only dealt with psychiatric concepts but also with the process of professionalization of psychiatry, which is linked closely to both conceptual issues and to the practice of psychiatry. The rise of the psychiatric profession during the nineteenth century has been regarded alternatively as having been due to its functional value for economic order and efficiency under capitalism (Scully 1979), and to its role for maintaining the moral, rather than the economic order (Foucault 1965).

Psychiatrists certainly have difficulties in agreeing with these views, since they have always seen themselves as primarily a helping profession, whose practice is based on scientific advances. There is a different strain of sociological analysis of psychiatry as a profession, going back to the German sociologist Max Weber, who postulated that professionals want to advance their own social status, persuade clients and potential clients about the need for the service they offer, corner the market in that service, and exclude competitors (Freidson 1970, Pilgrim and Rogers 1999). Other sociological approaches to the issue of professionalization include the sociology of deviance (crises in personal lives are reframed as mental illness), symbolic interactionism (regarding the professional power in negotiating the meaning of mental illness), and feminist sociology (men occupy higher-status positions within the more powerful professions).

The concept of power is central to this analysis, and the specific knowledge base of a profession (which can only be obtained by a difficult process of socialization) gives the profession power over its clients, its recruits and related occupational groups. With the emergence of nonpsychiatric mental health professionals, professional power has become a complex issue, since clinical psychologists, community psychiatric nurses, psychotherapists, to name only a few, are also increasingly professionalized and state registered. Also, in the era of managed care, professional autonomy and decision-making power are threatened increasingly by third-party authorization mechanisms.

Finally, those receiving care from professionals start to threaten traditional professional identities. They are themselves becoming more powerful in forming self-help and advocacy groups, and tend to use terms such as 'clients,' 'consumers,' and even 'survivors of psychiatry,' instead of the term 'patients.' These terms have different implications of how the traditional

doctor–patient relationship is redefined. ‘Client,’ unlike ‘patient,’ implies partnership rather than submissivity and passivity. The term ‘consumer’ goes even further in claiming that patients have certain entitlements for service for which they can sue, and the concept of ‘survivor of psychiatry’ denies the right of psychiatry to intervene in a person’s problems. Pilgrim and Rogers (1999) give a detailed account of sociological thinking about these issues, and how the situation has changed since Talcott Parsons (1951) formulated the paradigm of the ‘sick role.’ According to Parsons, the sick role allows people to be exempted temporarily from social responsibilities, but, in exchange, they must accept that they cannot get well on their own, and that they have to look for professional help. Foucault’s (1977) concept of ‘productive power’ provides an interesting sociological framework for the evolving discourse between professionals and the (potential, actual, or ex-) users of their services.

2.3 Psychiatric Practice

The old mental hospital was the mainstay of psychiatry for over 150 years. At the end of this period, in the 1950s, the mental hospital (or the ‘asylum’ as it had been called) became a favorite topic of sociology. There were at least two reasons for this interest. Mental hospitals could be regarded as a ‘small society,’ an experimental situation, so to speak, in order to study sociological phenomena in general (Caudill 1958), and, probably more important, sociologists became critics of the impersonal way in which patients were treated. Goffman (1961), in his famous study based on participant observation, coined the concept of the ‘total institution’ for the mental hospital and similar organizations which disregard the personal needs of their inmates. In a more rigid research design, Wing and Brown (1961, 1970) showed a strong association between the typical poverty of the social environment of the mental hospital and the ‘clinical poverty’ of psychopathological phenomena such as blunted affect and social withdrawal—a view which has been challenged later (Curson et al. 1992). In a different approach, social historians attributed the growth of the asylum during the nineteenth century to more general developments in society, such as the growth of humanitarianism (Jones 1960), of capitalism (Scull 1979), and of surveillance tendencies (Foucault 1977).

Beginning during the 1950s, in countries with large numbers of beds in psychiatric hospitals—such as the USA and the UK—the numbers of psychiatric beds, which had been steadily rising over the first half of the twentieth century, started to fall. While, for instance, in the USA, in the mid-1950s about 600,000 patients were in mental hospitals, this number had come down to below 100,000 some 50 years later. The debate about the reason for this fall is still not resolved.

Psychiatrists attribute it mainly to the introduction of the neuroleptic drugs (which can control delusions and hallucinations). Sociologists have suggested different explanations: That, with the growth of the welfare state, controlling by segregation had become too costly, and that the public’s attitude toward psychiatric patients had changed in the sense of becoming more favorable (for an overview, see Busfield 1986). Furthermore, differences in the extent and kind of implementation of community psychiatry in different countries have been related to different health and social welfare systems (Goodwin 1997).

Forster (2000) examined three sociological theories (political-economy: cost containment; professional dominance: psychiatric ‘expansionism’; and post-structuralism: maintaining order and control) about the process of de-institutionalization, and concludes that none of them explains sufficiently the move away from hospital to community psychiatry. He proposes that the kind and degree of the medicalization of psychiatry has changed profoundly: While mainstream psychiatry is now more medicalized than before, the treatment of less serious mental health problems cannot be monopolized any more by medicine, and is becoming increasingly the practice field of other professions.

Compulsory admission and compulsory treatment are an intrinsic part of psychiatric services. Since the beginning of the twentieth century the legal professions have been involved increasingly in the process of admissions to mental institutions in order to counteract what has been regarded as mismanagement by the medical professions. This has prompted sociologists to analyze the social processes involved. There are basically two sociological positions: Those seeing the legal and the medical systems as two competing institutions (Mechanic 1978), and those who argue that, in practice, they join to become one actor, a ‘treatment-control’ system which ‘takes care’ of residual cases viewed as problematic for society, although the written law distinguishes between treatment and control (Dallaire et al. 2000). In the UK and other countries, a new dimension has been added to this issue with the concept of a ‘community treatment order,’ which would allow compulsory medication for patients living in the community and would let the pendulum swing back to medical control (Pilgrim and Rogers 1999).

Finally, sociologists have also analyzed and criticized specific therapeutic approaches. An example is the classical antipsychotic drugs and the barriers to the professional recognition of their side effects, especially of tardive dyskinesia, as an ‘iatrogenic disease’ (Brown and Funk 1986).

3. Sociology in Psychiatry

Sociologists working within the field of psychiatry are often criticized by their colleagues that they accept

psychiatric concepts naively. Robert Straus (1957) has noted that 'the sociologist *in* medicine risks a good relationship, if he tries to study his colleagues.' Work presented in this section is therefore clearly separated in nature from that discussed in the previous section. In principle, psychiatric diagnosis is taken for granted, or at least not regarded as problematical by these authors.

Typical variables investigated in psychiatric studies using sociological methods include gender, age, social class, and inequality, as well as ethnicity and race (Pilgrim and Rogers 1999). An overlap with the sociology of psychiatry can sometimes not be avoided, especially if questions of disadvantage, stigma, and mental health policy are the topic of a study. Gender is a typical example of such a topic belonging to both sociologies (Busfield 1996).

Sociologists *in* psychiatry have been, and are, active in a large number of fields. They study, or help to study, the distribution of mental disorders in society, and the social factors and processes which may be causal for mental illness or influence its course. They investigate which social factors prevent the early detection, and thus the early treatment, of mental disorders, and which factors influence 'illness behavior' or 'help-seeking behavior' (here conceptual issues such as the professional and lay definition of illness, i.e., aspects of the sociology of psychiatry, are involved), and how effective psychiatric treatments are under different institutional and social conditions. They have introduced new outcome measures for psychiatric interventions, which are less 'illness-centered' and more 'life-centered' (such as quality of life, social functioning, disability, social support, burden on the family) and have promoted the use of these measures to assess the 'reality of life' of persons with mental disorders, including the effects of stigma. Finally, in times of increasing restrictions of funds for health services, sociologists apply these concepts to health policy and health economics.

The epidemiology of mental disorders is discussed elsewhere in this volume (see *Mental Illness, Epidemiology of*). It must be noted though that the epidemiological survey methodology cannot only be used to study the influence of *social* factors, but also of *biological* and *genetic* factors. In fact, before the advent of the molecular biological approach, but also still at the time of writing, many conclusions drawn by psychiatric geneticists were based on epidemiological studies on the distribution of specific mental disorders among the relatives of mentally ill persons.

A few important historical examples of 'sociology in psychiatry' are worth mentioning. During the 1930s, the Chicago school of urban sociology studied the distribution of psychiatric disorders, such as schizophrenia, across the city alongside other forms of deviant behavior, and found higher rates in deprived areas (Faris and Dunham 1939). In the 1950s and 1960s, groups of sociologists and psychiatrists carried

out a number of seminal studies: Cumming and Cumming (1957) investigated public attitudes toward mental illness and tested the efficacy of a large intervention program (which turned out not to be successful), Hollingshead and Redlich (1958), and Langner and Michael (1963) found an association between lower social class and mental illness. Srole et al. (1962) demonstrated the astonishingly high prevalence of mental disorders in metropolitan New York. Star (1955) found that public attitudes towards the mentally ill were stereotyped and quite unfavorable. Finally, Brenner (1973), in a time series analysis covering 117 years, demonstrated that in times of economic recession the yearly rates of admissions to mental hospitals in New York increased.

A few more recent studies and topics applying sociological research methods are described here by way of illustration. Brown and Harris (1978) conducted a detailed sociological analysis on the etiology of depression in women and found that, among women who experienced a major life event, only those who had no close confidant, or in whom other social vulnerability factors were present, became depressed. Concerning the presumed dangerousness of psychiatric patients, Steadman et al. (1998) reported that psychiatric patients who did not abuse drugs or alcohol had the same rates of violence as their non-patient neighbors, and that, if violence occurred, it was directed toward family and friends rather than strangers. A longstanding debate concerns the interpretation of the finding of a higher prevalence of mental disorders in the lower social classes and in deprived city areas, where the 'social causation' and the 'social selection/drift' hypotheses rival for explanation (Fox 1990). Recently Löffler and Häfner's (1999) study in Germany supported the social drift theory, while Fox (1990) had concluded earlier that there was very little, if any, empirical support for social selection/drift processes in serious mental illness. The epidemiological approach to suicide using published statistics has been a topic of much controversy since Durkheim's (1897) seminal study. Douglas (1967) has denied the usefulness of this approach, and suggested that the only scientific topic worthwhile studying is the social meaning of suicide, i.e., the motives of those who kill themselves. A recent review on the sociological literature on suicide is provided by Stack (2000).

Typical problems on the microsocial level which have been studied by sociologists (partly in conjunction with psychiatrists) are: Stigma, quality of life and satisfaction, illness behavior, life events, the emotional climate within the family ('expressed emotion') and its relation to relapse in schizophrenia, social support, coping, compliance and the process of caregiving for the chronic mentally ill, homelessness, and the work environment. Phelan et al. (2000) found that people with psychosis are more feared today than they were in the 1950s. Markowitz (1998) studied the effects of

stigma on the psychological well-being and life satisfaction of persons with mental illness, and Link et al. (1987) looked into the effects of stigma on recovery. Rosenfield (1992) found that the single most powerful influence on the improvement of subjective quality of life of the chronic mentally ill was the improvement of the individual's actual power in terms of economic status. Katschnig et al. (1997) have reviewed the concept of quality of life in relation to mental disorders, and Jackson et al. (2001) have summarized research on predictors of patient satisfaction. Mechanic (1995) relates these issues to the concept of illness behavior, arguing that the disability process is specifically relevant to promoting function and maintaining patients' quality of life, especially in primary care settings, where patient motivation should be increased, helpful attitudes encouraged, coping strategies taught, family members and employers educated, and support provided.

Finally, services research as well as studies which evaluate the functioning of psychiatric services in terms of quality control (Scheid and Greenley 1997) and mental health policy papers (Mechanic 1994) are further examples of sociological involvement in psychiatric issues.

4. Conclusion

As this review has shown, there are numerous points of contact between sociology and psychiatry, and each can learn much from the other. This is especially true at a time when the focus of psychiatry is moving further back into the community, and consumer participation and a 'civil dialogue' are becoming more important. Qualitative research methods, which seek to explain quantitative findings, generate hypotheses and ensure that questionnaires are relevant, are an appropriate tool for accompanying this process (Chard et al. 1997). Also, it might be useful to develop a sociology of the relationship between sociology and psychiatry. This review could serve as modest point of departure for such an undertaking.

H. Katschnig

Psychiatry: Anthropological Aspects

Psychiatry—if we think for instance of psychoanalysis and of medical anthropology—has had an essential influence on philosophical anthropology, determining humankind in its world and its being-with-others from the perspective of manifold risks and disturbances. However, this article is concerned with exactly the opposite relationship, namely that of anthropology to psychiatry (see Blankenburg 1980a, Kraus 1999, Lang 1982).

What mental illness is in its various manifestations and which methods of investigation and therapies are appropriate for mentally ill patients from the aspect of their humanity, is also a question of anthropology as a comprehensive framework. A particular anthropology determines object theory to a high degree, that is, how mental illness can become objective, as well as the methodological accessibility of this object in psychiatry. Anthropological assumptions do not only determine norms usually applied in psychiatry to differentiate between mental illness and health but also determine ethics in psychiatry and address the relationship between body and soul and problems of free will and of self-determination. Because psychiatry as a science and therapeutic practice often latently implies an anthropology, by which psychiatry is deeply determined, psychiatry cannot avoid reflecting these premises. Above all, this is valid for the question of the adequacy of its methods for the respective object. A particular anthropology, however, does not only contribute to the development of what in psychiatry can become the object and its methodological accessibility, but it can also even prevent this development. Thus, certain results of research can be enabled, but can also be prevented.

As yet, it has not been sufficiently realized that psychiatry can be restricted in its scientific and therapeutic possibilities by its anthropology and can even be endangered by dogmatic and overgeneralized

basic assumptions. Problems of reductionism, however, of nothing-but theories, of the methodological preconditions of experience, are increasingly acknowledged. What Jaspers (1965) said about philosophy is also valid for anthropology. Stressing its significance for psychiatry, it does not only free the inner space for new possibilities of knowledge, but can also open horizons more adequate to a better understanding of the patient. A switching between anthropological and empirical research (Mundt and Spitzer 1999) has decisive significance for innovation and thus for the development of psychopathology as well as of psychiatry in its therapeutic and rehabilitative practice.

Ever since the separation of natural and cultural sciences we have differentiated between anthropology in the sense of natural science and philosophical and cultural anthropology. Whereas scientific or biological anthropology, identical with physical anthropology or human biology, is concerned with the biological nature of humankind, philosophical anthropology makes statements about our personal or spiritual essence. Cultural anthropology, mostly interchangeable with ethnology, is concerned with the question of which information is given by cultural statements about what is variable and constant in human beings. To what extent is it possible to start with a previously given essence of human beings and in which way does the human being as the 'nondetermined animal' (Gehlen 1966) determine what he or she is. This question became one of the main topics of existential philosophy, where this human self-determination became the most important feature of a person's essence.

Immanuel Kant ([1798] 1978) already differentiated between a physical and a pragmatic anthropology. Whereas the first is concerned with what humans are by nature, the second, identical with philosophical anthropology, asks what they can make of themselves. Kant's philosophy became important for psychiatry not only because he developed interesting ideas about mental illness, seeing its general features in a loss of communal sense (*sensus communis*), that is, the loss of the ability of a person to be corrected by others (§ 53, p. 117), but especially because he has influenced psychiatry with respect to his methodology. Showing the dependency of experience on *a priori* ideas and thus overcoming the traditional splitting of subject and object, Kant's philosophy ([1781/87] 1965) stood for an opposition of idealism to realism which maintains the independence of the recognizing subject from the object. This opposition has had a constant effect not only on many philosophical schools of thought but also on psychiatry. With his concept of the transcendental subject he paved the way for Husserl's phenomenology and for existential approaches of philosophy. These new concepts and methods on their part made possible approaches like *Daseinsanalyse* (existential analysis), existential psychiatry, and cognitive approaches. Because above all in psychoses the

comprehension of the world by the experiencing subject has changed, these psychiatric approaches claim a better understanding of the cognitive processes in these patients.

The following authors of a philosophical anthropology have become important for psychiatry: J. G. Herder (1744–1803), emphasizing the human as a being gifted with language; G. W. F. Hegel (1770–1831) with his historical philosophical critique of anthropology; M. Scheler (1874–1928), the founder of modern anthropology in his work *The Place of Man in the Universe*; H. Plessner (1892–1985), who speaks of the eccentric position of human beings, who have only to make out of themselves what they are; and A. Gehlen (1904–67) with his determination of humans as deficient beings because of lack of adjustment to their surroundings and reduction of instinct. At the same time an openness to the world corresponds to this lack. For a psychiatry which calls itself anthropological, the following philosophers were above all influential: S. Kierkegaard (1813–55) who initiated the development of existential philosophy; E. Husserl (1859–1938), the main founder of the phenomenological approach in philosophy; M. Heidegger (1889–1976) with his *Daseins* analytic; J. P. Sartre (1905–80) with existential psychoanalysis; and M. Merleau-Ponty (1908–61) with his phenomenology of the body. But on the other hand there has been an influence of medicine, especially of psychiatry, on philosophical anthropology: here we could mention Heinroth (1773–1843), V. von Weizsäcker (1886–1957), and M. Binswanger (1881–1966).

Multiple influences on psychiatry also arose from biological anthropology (including paleoanthropology, human genetics, research on human bodily constitution), from social anthropology and cultural anthropology, from cognitive and evolutionary anthropology. Social anthropology and role theory (see Kraus 1980) had a strong impact on the development of social psychiatry and antipsychiatry followed by many psychopathological concepts and therapeutic measures.

Cultural anthropology examining the cultural variation of the human being as well as human constants independent of culture and epoch shows very clearly the double significance of the concept of anthropology already mentioned above. Showing the variability of the actual being and behavior of human beings, at the same time it marks the boundaries of anthropology as a universally valid theory of the essence of humankind. Cultural anthropology has cultivated a special approach of a transcultural or cultural psychiatry which investigates the variability and frequency of symptoms of disturbance entities, nowadays defined in glossaries, as well as of these entities themselves in different cultures. It has also led to the question of whether regarding the classical entities of disturbances like schizophrenia and manic-depressive illness we are actually dealing with entities of natural diseases or if

these are entities only coming from concepts of understanding. Transcultural or cross-cultural psychiatry is thus fundamentally involved in the contemporary crisis of nosology in psychiatry.

With the notion of a cognitive anthropology, Emrich (1999) sums up different approaches of a psychological, physiological (Singer 1994, Roth 1994), and philosophical constructivism. In cognitive anthropology the leading idea is the general quality of constructivity ascribed to systems generating consciousness (Roth 1994). The progress of modern evolutionary biology in the future could enable a phylogenetic and ontological understanding of mental disturbances.

Heinroth can be looked at as the founder of an anthropological medicine in its true sense in the context of psychiatry, not to be confused with a medical anthropology. Many anthropological approaches in general medicine, especially those of Weizsäcker and Wyss, have also had effects on psychiatry.

Janzarik (1988) has presented an approach of his own to anthropological psychiatry. In his structural-dynamic concept he sees psychopathological phenomena in their neurobiological (dynamic) foundation as coherently connected with biographical structurally bound significances.

Under the heading of a phenomenological-anthropological psychiatry, different approaches can be summarized which have a phenomenological method as well as an anthropological orientation in common. These psychiatric approaches of an eidetic phenomenology of essence and a constitution-phenomenology as well as of *Dasein* and existence analysis relate to different authors of philosophical anthropology in its broader sense such as E. Husserl, M. Heidegger, J. P. Sartre, and M. Merleau-Ponty.

Even if the understanding of phenomenology and phenomenological in these different approaches is not always the same, the notion of phenomenon aims at that 'which-shows-itself-in-itself' and as such is different from the notion of the symptom which points to something which does not just show itself directly, namely to the illness underlying it. An approach strongly oriented to the phenomenon enables us to describe the original individual subjective experience as well as the respective lifeworld of the patient more adequately and differentiated than otherwise possible.

'Anthropological' signifies on one hand what is common to all people and on the other hand what in contrast to the animal is specifically human. In the context of anthropological psychiatry with this term the relationship of psychiatric disturbances to basic human structures is meant, as for instance consciousness and subjectivity, intersubjectivity and individuality, history and temporality, freedom, corporality and so on. These approaches not only take into consideration human essence because of ethical or humanistic reasons, but above all of methodological

reasons. The aim is to understand psychiatric disturbances as regular variations of these basic structures, that means of human essence itself. This is done not so much to investigate the factual conditions for the development of psychopathological phenomena but to investigate the conditions originating from human essence which made them possible. For instance hallucination can be understood out of the normal act of perception as an uncoupling of spontaneous imaginative acts from a normal interaction with receptivity (Blankenburg 1980a, 1980b).

Binswanger's (1955) approach with 'anthropological proportion' has turned out to be especially fertile in psychiatry. The partly oppositional dimensions of height and breadth in human existence, of self-realization and world-realization, of individuation and relationship to community, of need for continuity and openness to innovation, of tolerance and intolerance of ambiguity, of overidentification and underidentification normally stand in a certain proportion to each other. These proportions are shifted in psychiatric disturbances. Relating to this alteration of the respective proportions some pictures of illness are oppositional. Thus an overidentification with their respective being in melancholics can be opposed to an underidentification in hysterics (Kraus 1996a). Overidentification with social role for example, with environment, etc., can understandably precipitate a melancholic phase in the case of their loss. One speaks of an empty-nest depression if a parent becomes depressed when children leave home. Other examples are a depression in the situation of retirement or of moving house. Hysterics, on the contrary, tend rather not to identify with their respective being or their actual feelings. They are striving for being more and something different than they actually are or to show feelings they have not. The abnormal as well as the normal can in this way be located in a polar field which is structured through ideal norms which oppose one another in a field in which 'deviations' from at least two sides are possible, as Blankenburg (1980a) put it. The pathological element can in this way be traced back to healthiness. On the other hand healthiness shows itself as something which always holds the possibility of becoming pathological by an alteration of proportions.

Such a concept of mental disturbances offers a special possibility of identification with the patient in the therapeutic process. Beyond a purely descriptive psychopathology in the sense of Jaspers (1965) it is thus possible to develop a dynamic phenomenology of psychiatric disturbances which has a dialectic character. Jaspers in his subjective psychopathology emphasized the special experience of the patient as opposed to a mere behavioral description in the sense of an objective psychopathology.

An eidetic essence-oriented phenomenology described above goes a step further in trying to grasp the essence of altered experiences and behaviors in a so-

called eidetic reduction in the sense of Husserl. In a process of free imaginative variation here one tries to get from a fact to the essence of a fact, from a sensual to a categorical presentation. Categorical presentation means for instance to recognize a particular species of tree in an actual tree, or in different kinds of behavior and experiences of hysterics the element of under-identification, of the pretence of being instead of actual being. Such an eidetic reduction can also be carried out in relation to Heidegger's notion of '*In-der-Welt-sein*' or Merleau-Ponty's '*Etre-au-monde*' showing the special relationship of patients to themselves and to the world which is expressed in their experiences and behaviors. A constitutive or transcendental phenomenology in the sense of Husserl is to be differentiated from an eidetic phenomenology. Instead of going from the fact to the essence of a fact as in eidetic phenomenology, constitutive phenomenology examines the constitutive achievements of consciousness, which let us perceive the concrete as it appears to us.

This approach of a constitutive phenomenology and the following philosophy of existence became important for psychiatry because in the perception of psychotic patients—but not only for them—the world and its significances constitute themselves in another way than in healthy people. In psychiatry this has resulted not only in making the experience of objects, for instance classical symptoms, into research topic, but also the preobjective experience, that is, the constitutive processes out of which self and world develop.

The preobjective experience is especially important in the intuitive diagnostics, for instance in the so-called precox feeling. Such preobjective experiences are for instance, the spatialization, temporalization, intersubjectivity, and corporality of a patient. Classical symptoms such as delusion, hallucination, phobic anxieties, and obsessive-compulsive symptoms assessed by a psychopathology oriented to the object, turned out to be constructed on such preobjective experiences.

Phenomenology of constitution, as Husserl put it, recently entered into a manifold relationship with cognitive theory and cognitive neuroscience (Wiggins and Spitzer 1997, Gallagher 1997). Varela (1996) even proposed a neurophenomenology. Several authors of the phenomenological-anthropological approach showed how in the contents of delusion and hallucination vs. the psychotic tendency of dissolution of their world, patients try again to give sense to their new world, even if a distorted one (Feldmann and Schmidt-Degenhardt 1997, Müller-Suur 1980, Kraus 1994a).

Husserl's concept of an intersubjectively constituted lifeworld became of increasing significance for psychiatry, above all for the understanding of schizophrenic modes of existence (Callieri and Castellani 1981, Blankenburg 1979). People with schizophrenia are characterized by a damaged rootedness in the

lifeworld, connections of significances and relevancies becoming confused, which shows itself in extravagance and oddity but also in the delusions of these patients. Blankenburg (1971) speaks of a lack of natural self-evidence in schizophrenics. Whereas schizophrenics often lack an inner standard which would allow them a behavior appropriate to the social norms, melancholics being too adapted to these norms are too strongly fixed to the common sense and to their lifeworld (Blankenburg 1979, Stanghellini 1997, Kraus 1996b). This is already shown premorbidly by their hypernormic behavior which is characterized by a lack of distance to normative expectations (Kraus 1996b). This is also shown by the fact that they find their identity above all in their social roles. For this reason they are especially in danger of becoming depressed in the case of the loss of a social role (Kraus 1996b).

Binswanger has developed his existential analysis above all under the influence of Heidegger's *Dasein* analytic in *Being and Time* (Heidegger 1927), which, against the ontologic intention of the author, Binswanger understood as an anthropology. With existential analysis we are concerned with a hermeneutic of the inner life history which is asked for its underlying individual concept of world which determines the concrete experience and behavior of a person.

Sartre's (1962) existential psychoanalysis has also contributed to the better understanding of certain pathological modes of existence, such as those of hysterics, melancholics, and patients with anxiety and obsessive-compulsive disorders. In this way we can establish certain existential types which can have an impact on the classification of these disorders (Kraus 1994b).

The phenomenological-anthropological orientation in psychiatry has promoted a series of therapeutic measures, for instance the anthropological-integrative psychotherapy of Wyss (1982) and existential analysis in the sense of Boss (1951) and Condrau (1963). But it has also influenced other therapies.

Summing up we can say that all anthropological approaches in psychiatry have as their aim to bring psychiatric disturbances in contact with the whole of human reality to achieve better understanding of those disturbances in a way that is appropriate to the essence of humankind. Considering anthropological prepositions in this way allows us to reflect the fundamentals of psychiatry in research as well as in therapy by which the phenomenological-anthropological approaches contribute to further development.

Psychiatry, Evidence-based

No country can afford health services to meet all the possible needs of the population, so it is advisable to establish criteria for which services to provide. Two basic criteria are the size of the burden caused by a particular disease, injury or risk factor, and the cost-effectiveness of interventions to deal with it (Bobadilla et al. 1994).

Health services are rationed. Access in most countries is controlled by money, waiting lists, and by the clinician's decision about what should be done. Health services are concerned to avoid the explicit rationing that would follow if they adopted the position outlined above and so they have become concerned with maximizing efficiency. They have done this by limiting

the input of funds, and by using scarcity to encourage improvements to the process of care. They keep asking 'can science inform practice?' an issue beset by many questions and too few answers. Yet it does seem relatively simple. Research is concerned with discovering the right thing to do; clinical audit with ensuring that the right things are done. The link that can close the gap is said to be evidence-based medicine: 'the conscientious, explicit, and judicious use of current best evidence in making decisions about the care of individual patients' (Sackett et al. 1996).

The evidence-based medicine movement seems to have originated from Archibald Cochrane's set of essays 'Effectiveness and Efficiency: Random Reflections on Health Services,' (Cochrane 1998) first published in 1971 and reprinted by BMJ Books in 1998. He argued that no new treatments should be introduced unless they had been shown in randomized controlled trials to be more effective than existing treatments, or equally effective and cheaper; and that one should evaluate all existing therapies, slowly excluding those shown to be ineffective or too dangerous. Cochrane actually meant efficacy when he wrote effectiveness (he acknowledged hating the word efficacy) but it is now usual to distinguish the three terms: efficacy, does the treatment work; effectiveness, does it work in practice; and efficiency, is it a wise expenditure of funds? The popular press is preoccupied with efficacy (can the doctors cure disease X?), not with effectiveness (do they?) or with efficiency (can we afford the cost?). Evidence-based medicine is concerned with identifying the efficacy of treatments and encouraging their implementation. The goal is increased effectiveness and efficiency (Andrews 1999).

Efficacy: 'Does the treatment work?' means does it produce benefit reliably over and above that to be expected from just being in treatment? Randomized placebo-controlled trials are valuable because they control for the uplifting effect of being in treatment (the true placebo effect). They also control for changes in symptoms and disability attributable to spontaneous remission, including the remission that occurs because people with chronic and fluctuating disorders commonly delay consulting until their disorder is particularly severe and can be expected to improve whatever happens. In some disorders the extent of this overall 'placebo response' is very large. In depression, it is two to three times as large as the change related to the present specific therapies, be they drugs or psychotherapy (see the discussion in Enserink 1999, pp. 238–40). That is, people given a sugar tablet will improve, not because of the tablet, but because of these other processes. People taking the active antidepressant tablet will improve more, but only one third of the overall change will be due to the antidepressant. It is for this reason that changes in symptoms with a specific treatment are suspect, unless they are shown to exceed the changes expected from a nonspecific placebo treatment.

With a few significant exceptions, most randomized controlled trials in psychiatry, even multicentre trials, have relatively small numbers of subjects. It is therefore usual to defer judgment until a number of trials have been done in different centers. If they agree that a certain treatment is better than placebo, then it probably is, but as most use different measures of outcome it has been necessary to develop a method for estimating the average degree of improvement with this treatment. Meta-analysis employs standard data analysis techniques to compare the results of studies by converting, if necessary, the results onto a standard metric, called an effect size. Even so, the wide range of outcome measures in use makes comparison difficult, and it is not always adjusted by expressing change in effect size terms. For example, while trials in depression almost always use the Hamilton scale so that results can simply be averaged, a meta-analysis of panic disorder found over 300 different measures in 58 studies, which has to be evidence of social irresponsibility in science. While each investigator will need to use a disorder-specific measure of symptoms, there is some real advantage in all using a generic measure of disability such as the short forms from the RAND medical outcomes study.

Structured systematic reviews are now common. In memory of Cochrane, a center at Oxford has been established to encourage and disseminate systematic reviews of the medical literature. These reviews abide by strict methodological guidelines and identify the level of confidence that the reader can place on any finding. In mental health, the dominant US publication is a book by Nathan and Gorman (1998). Any clinician, asked by a client what other treatments there are, would be obliged ethically to mention the treatments listed in that book as supported by type 1 evidence before offering advice about the treatment to be preferred. The self-help version of that book should be in every mental health clinician's waiting room (Nathan et al. 1999).

Effectiveness: Does the treatment work in practice when applied by the average clinician to the average client? There is a paucity of such data. Such data as there are show that effectiveness is reduced as one moves from experimental practice to routine clinical practice. Too often treatment as usual seems almost ineffective. Thus the problem is not so much defining the treatments that work as overcoming the degradation of benefit that occurs in practice. There are four issues that undermine the potential effectiveness of a treatment: deficits in coverage, deficits in compliance, deficits in clinical competence, and treatment integrity. Epidemiological studies in the USA, Canada, the UK, and Australia show consistently that only a fifth to a half of people who meet criteria for a mental disorder get help for their disorder (Andrews and Henderson 2000). Coverage is therefore low, variably limited by access to services and by the expectation that there is little point in attending. Poor

coverage when access is limited is understandable, but why should there be poor coverage when a national health service provides access? The Australian national mental health survey asked why the burden of depression persisted when access to care was free. Half the people who identified depression as their main complaint (and were disabled as a result) did not consult because they 'had no need for treatment.' There are data on the mental health literacy of Australians that show that the majority of the population think that relaxation and tonics are good for depression, and that medication is not. It is clear why they do not consult their doctors.

Deficits in compliance and treatment integrity are difficult to estimate, simply because auditing of either will produce a temporary change in behavior. There is evidence that asking people if they have taken all their medication is a valid measure of compliance; at least those who say they haven't can be counseled. One advantage of providing patient treatment manuals for psychological treatments is that the manuals contain explicit sheets on which the homework can be recorded and reviewed. Like homework at elementary school, if the clinician doesn't ask, the client doesn't do. The patient treatment manual also serves to ensure treatment integrity. After all, the manual is the curriculum for the treatment program and clinicians have little opportunity but to follow the framework, personalizing it for each patient, and following the sequence in every case. All psychological therapies should be manualized, because psychotherapy is about learning, and most learning programs have text books.

Coverage and compliance concern the system and the consumer. Clinical competence and treatment integrity concern the physician. How do you make sure the physician knows what to do, and then does what should be done. The evidence-based medicine movement has clear ideas about how clinicians should practice. Ideally, clinicians should constantly be asking 'what is the evidence about treatment for this type of patient with this type of disorder?' Searching the Internet they should source systematic reviews, such as those from the Cochrane Collaboration, before deciding which treatment is appropriate. There are three problems. The first is time; busy practitioners, especially those in private practice, have no opportunity to consult sources in this way. The neediness of patients simply consumes the day. The second is that systematic reviews are about people who satisfied the inclusion and exclusion criteria for RCTs, and who are unlike the pregnant woman, for whom information is needed. The third issue is that the methodological formalism required for such reviews may remove the very data or comments that would be helpful. Systematic reviews are essential, but they may need to be supplemented with more clinically relevant material.

Review journals are flourishing. For example, the aim of the British Medical Association's journal *Evidence Based Mental Health* was to print one-page

summaries of research that had met rigorous standards. Clinicians, with no time to do their own literature searches, could rely on the summaries to guide practice. To a large part this happens, but methodological formalism may be limiting the scope and obscuring meaning. In January 2000, the journal's website had a summary of an RCT in which three sessions of CBT and three sessions of psychodynamic therapy were equally effective in relieving sub-syndromal depression. The take-home message for the busy practitioner was unclear. Psychotherapy that requires transference can be completed in three meetings? CBT that teaches how to change thoughts and behaviors can be achieved in three sessions? That it is important to treat mild symptoms that do not constitute a disorder? Which is strange in a country like the UK, in which 70 percent of people with major depression do not see a doctor and most who do are treated inadequately. The review journals are important, but the editors need to think about the burden of the disease and the implications for practice, as well as about the probity of research designs. Complex problems are unlikely to have simple one-page answers.

Clinical practice guidelines are the traditional avenue used to put research findings into practice. Properly written they can combine a continuum of information from good research to good clinical wisdom, differentiating between statements supported by research, and statements, no less valuable, supported by opinion. The steps in preparing clinical practice guidelines are illustrated in Fig. 1. In summary: when there is a clinical issue and there are no existing guidelines, a panel of all stakeholders should be convened to identify the desired health outcome. They should proceed by preparing a systematic review of efficacy of interventions in relation to this outcome, differentiating clearly between interventions supported by the differing levels of the weight of evidence (level 1a: meta-analysis of randomized controlled trials; level 1b: at least one RCT; level 2: at least one controlled or quasi-experimental study; level 3: non-experimental descriptive studies; level 4: expert committee reports or opinions). Each statement in the guideline is qualified traditionally in accord with the quality of the supporting research evidence. Increasingly, the principal recommendations of guidelines require support from level 1a evidence, lower levels of evidence being valuable to fine-tune that principal recommendation for special groups of patients, or atypical clinical situations.

Most clinicians have access to at least half a dozen such guidelines, and many doctors in primary care have mountains of guidelines, so many that their ability to use any is questionable. While most originators claim that regular revisions will be issued, this has not proven to be the case. The problem is that guidelines have largely been written by advocates keen to support a position and, understandably, they are

Clinical Practice Guidelines Flow Chart

Figure 1
Clinical practice guidelines flow chart

not keen to update the data in terms of new developments. The Royal Australian and New Zealand College of Psychiatrists produced guidelines for 1981–91 (Quality Assurance Project 1983), and in 2001 they at last began working on a revision of some of these. The American Psychiatric Association and the UK Royal College of Psychiatrists have also produced

guidelines for their members. An attempt to produce mental health consensus guidelines that incorporated the views of all stakeholders—the various providers, the consumers and carers, and the public and private funders—appears to have run out of support: who wants to be fair when there is so much to be gained by being partisan? Moreover, when guidelines are prod-

used by independent bodies such as the Agency for Health Care Policy and Research they can run foul of vested interests so that the impact is nullified (cf. breast cancer screening, spinal fusion) (Deyo et al. 1997). Clinical practice guidelines should be a flowering of the scientific method—find out what works and implement it—but too often they are political acts that represent the interests of an advocacy group.

Leaving aside the problem of the accuracy of the information, how is it possible to introduce guidelines that busy practitioners will follow. The Australian National Health and Medical Research Council recently convened a meeting to learn how 14 studies in medicine, surgery, and psychiatry fared as they sought to implement their guidelines. None fared well. Simply publishing the guidelines had no effect at all. The key elements seemed to be to produce guidelines that were simple, short, accurate, and current. Short meant on two sides of a plastic card, even if backed by a source book that contained the science. The content should be sponsored by a respected professional organization and the guidelines should represent a collaboration between all the stakeholders likely to use them, or be affected by them. They gain credence by being published in a reputable journal.

The rules for successful implementation of clinical practice guidelines are not at all clear, but look like a combination of hard work and marketing, done at a local hospital or regional professional organization level. *Getting Research Findings into Practice* (Haines and Donald 1998) is an excellent source book. The process is as follows: involve the key stakeholders and the clinical and management opinion leaders, have an accurate idea of what one wants to change, and a clear idea of the changes to organizational procedures, medical equipment, and clinical skills that will be necessary if implementation is to occur. Provide academic detailing to the clinicians so that all will have a chance to discuss and question the guidelines before implementation starts. Involve the consumers in the preparation of the guidelines and then in their implementation. Put the guidelines on the hospital or group's homepage, and 10 percent of consumers will consult these before attending. Use clinical audit to show that change is occurring and to show improved clinical outcomes. If the change does not improve clinical outcomes, ask whether further implementation is wise. Sustain the whole process by showing an improved cost effectiveness profile and arrange that some of the savings benefit the clinicians who brought this about. Expect that the implementation procedure will cost a considerable amount in staff time; the time costs for staff to attend meetings to produce a simple change to the way acute asthma was managed in one hospital exceeded \$50,000. The costs of implementation were perceived as inordinate even though that money was quickly recouped from the savings that accrued from the improved outcomes once the guidelines were implemented. If originators of the guide-

lines are not prepared to do all this work then they should simply enjoy the process of producing them, for the guidelines will not influence practice. This is not to deny that identifying empirically supported treatments carried out by a profession does not have important professional and political advantages for the profession. Funders, providers, and consumers all like to pretend that efficacy is the same as effectiveness, and lists of empirically supported treatments feed this delusion.

Efficiency: Efficiency or cost effectiveness is about the wise expenditure of scarce health resources. Costing studies are now common; the problem is that most are based on efficacy calculations in which coverage, compliance, and treatment integrity are all believed to be perfect. As effectiveness is much, much less than efficacy, the true costs per unit of benefit are much, much more than those identified in the costing studies. Australia was the first country to require costing data to be submitted when pharmaceutical companies sought to have a new drug placed on the list of subsidized medications. It has rightly been praised for this. Enquiries as to whether the data submitted are cost effective data or cost efficacy data are met with the assurance that the former is the case. As the data are 'commercial—in confidence' they are not amenable to 'freedom of information' enquiries. None are published and one might suspect that most are estimates of cost effectiveness under ideal conditions in which effectiveness is presumed to equal efficacy. As psychological therapies are not subsidized they are not subject to regulation, and randomized controlled trials about efficacy and cost are not required by any country. If we are to be anything more than a medicated society we do need such data.

League tables of the 'cost effectiveness' of medical interventions are beginning to appear. Few include mental health interventions. The median medical intervention cost in a study of 500 life-saving interventions was estimated as \$19,000 per life year saved. In mental disorders, the principal burden comes from the years lived with a disability, not from the years of life lost. Nevertheless, shadow prices under \$30,000 per disability-adjusted life year averted or quality-adjusted life year gained are said to be of interest to health planners. In specialized clinics, where costs and outcomes are known, it appears that drug and psychological therapies for the common anxiety and depressive disorders can be provided at little more than \$5,000 per life year gained. These figures are competitive and it might prove more advantageous if accurately costed league tables of empirically supported therapies in mental disorders were to be prepared by an organization of high repute. I cannot think of a greater stimulus to the implementation of evidence-based psychiatry than some appreciation of the good bargains available. After all, treatment as usual that produces little benefit is very costly to both funder and consumer. The providers benefit in the

short term, making the majority of their income from people who do not get better, but in the long term they become disillusioned by their lack of effectiveness. Evidence-based psychiatry can close the gap between research and practice, but it is not a trivial task. It can improve effectiveness to resemble efficacy and so result in better outcomes for patients, and that is not a trivial achievement. Isn't that what mental health services are for?

Psychiatry, History of

Attempts to heal madness go back in Western medicine at least to Hippocrates. However psychiatry as a medical specialty—that is, a gainful form of medical practice that occupied its practitioners full-time and to the exclusion of other branches of healing—and, hence, as a self-conscious scientific project, was the invention of the late eighteenth century. It had, at the level of ideas, two major prerequisites: a new technique for treating madness, called the moral treatment, believed to effect cure more reliably than anything that had preceded it; and a new institution, the asylum, conceptualized both as the appropriate setting for the cure of madness and as itself an active instrument of cure. While the name eventually given to the specialty in most countries was of German coinage (*Psychiatrie*, first used in 1808 by Johann Christian Reil), the practical initiatives critical in establishing psychiatry came from England and France.

1. Moral Treatment

Psychiatry's founding therapeutic strategy was of combined Anglo-French provenance and as such became the subject of a muted, international priority dispute. cursorily defined, the moral treatment for the cure of insanity meant the use of methods that engaged or operated on the intellect and emotions, as opposed to the traditional methods of bleedings, purges, and emetics applied directly to the lunatic's body. By all accounts, the British cleric and physician Francis Willis had employed moral methods when in 1788–9 he assumed the weighty responsibility of treating the madness of King George III. His contemporary, the French physician Philippe Pinel, duly credited Willis and others with having inspired his own efforts. But when codifying the moral treatment in his *Traité médico-philosophique sur l'aliénation mentale* (1801), Pinel also accused his British colleagues of willfully failing to spell out the method they so enthusiastically recommended. For their part, British reviewers of Pinel's *Traité* dismissed the Frenchman's supposed innovations as pale imitations of British practice.

Wherever priority lay, the moral treatment proved notoriously resistant to precise definition. Contrary to his avowed intention, Pinel never provided an explicit definition in his *Traité*. He instead presented a series of case histories of his own use of the treatment, leaving to his readers the task of inferring its central features. These included:

(a) A preference for 'gentleness' as a therapeutic technique. This choice was rooted in an optimistic Enlightenment belief that insanity never involved a complete annihilation of reason, reducing the mad person to animality, but that a glimmer of 'humanity'

always remained and could be appealed to and reinforced.

(b) The use of 'repression' only as a last resort and then without anger or cruelty. When acting in a repressive capacity, the healer of the insane was expected to exude authority through his physical presence—Willis, for example, was known for his ability to command the obedience of the mad by his piercing gaze.

(c) The grounding of the treatment in an etiology of insanity based on the sensationalist psychology of John Locke and the abbé de Condillac. Regarded as a set of erroneous ideas that had become implanted firmly in the mind, insanity could be cured by a jolting experience that dislodged those ideas and enabled their replacement by sound ones. Hence the theatrical aspects of Pinel's moral treatment: vivid scenes were staged deliberately to impress on mad persons the falsity of their pathological beliefs (Goldstein 1987, Porter 1987).

Clearly, such a therapeutic strategy stamped psychiatry as a humanitarian endeavor and a product of the Enlightenment faith in science. In France, these affiliations were strengthened further by the link between psychiatry and the French Revolution. The Revolutionary government put Pinel in control of the Paris institutions for the insane, and according to a myth that took shape over the course of the nineteenth century, and has only recently been debunked by historians, he inaugurated the moral treatment by literally unchaining the inmates of Bicêtre, an emancipatory gesture that cured them instantaneously. In the USA, the chief proponent of the moral treatment, Benjamin Rush, was so ardent a supporter of the American Revolution that he even figured among the signatories of the Declaration of Independence (Binger 1966). In Britain, ratification of the moral treatment took place in the context of parliamentary investigations into the civil liberties violations entailed in the maltreatment of incarcerated lunatics (Scull 1975).

But if the moral treatment had strong associations with Enlightenment and political liberty, it also lent psychiatry an unscientific taint that proved difficult to eradicate. For, as its proponents liked to point out, it had originated among healers without official educational credentials. Pinel was a bona fide physician but, in keeping with the hostility of the French Revolution toward all privileged corporations, he proudly announced that neither he nor any other member of a medical faculty had devised the moral treatment, that it was the work of a humble layman who served as hands-on caretaker of the insane at Bicêtre. His own contribution was, he said, to have rendered the caretaker's version of the treatment scientific, translating it into the language of sensationalist psychology and demonstrating its efficacy with the new mathematical tool of statistics. Reliance on the moral treatment left Pinel's successors vulnerable to competition from traditional Catholic healers of the

insane, who argued persuasively that medical men had no special skills in administering a noncorporeal remedy. Indeed in France the dispute between alienists and clerics for control of the treatment of insane continued until the end of the nineteenth century, when the anticlerical policies of the Third Republic decided conclusively in favor of the former (Goldstein 1987).

In Britain, it was a layman, the tea merchant William Tuke, who instituted the moral treatment at the York Retreat, the influential Quaker facility for the insane. Tuke was highly vocal about his distrust of medical practitioners pretending to treat insanity with Physick. After a long period of uneasy debate between the models of medical and moral therapy, the official line of British psychiatry became in the 1840s that a judicious combination of both had greater efficacy than the sole use of either. In adopting this position, British psychiatrists shrewdly obviated the protest that clergymen were better equipped than physicians to handle insanity (Scull 1975).

2. The Asylum

The insane asylum is one of a group of institutions, which, in the 1960s, the American sociologist Erving Goffman (1961) labeled 'total' and, in the 1970s, the French philosopher Michel Foucault (1975) described as 'panoptic.' For Goffman, such institutions are characterized by locating the ordinarily compartmentalized activities of sleep, play, and work under a single roof and a single authority and by erecting barriers, both legal and architectural, to social intercourse with the outside world. For Foucault, they are characterized by the incessant visibility of the inmates to the authorities, a visibility redounding to the power of the latter. Both theorists stressed the tight schedule of activities enforced in such institutions. Both noted their proliferation in the West during the late eighteenth and early nineteenth centuries, the period that saw the birth of prison and poorhouse as well as insane asylum.

In itself, the incarceration of deviant populations was no novelty. At least since the 'Great Confinement' of the mid-seventeenth century, western European governments, especially the absolutist monarchies of the continent, had made a concerted effort to establish good order by removing troublemakers from social circulation. The novelty lay rather in an unprecedented confidence in the rehabilitative power of certain forms of incarceration and in a fresh taxonomic sensibility that led to the division and strict segregation of deviants according to type. By contrast, the French *hôpital général* of the age of Louis XIV and its counterparts, the British workhouse and the German *Zuchthaus*, had entertained no therapeutic ambitions and had lumped together madness, idleness, and

debauchery as fully comparable species of unreason (Foucault 1961).

The classical scientific rationale for the asylum was provided in 1819 by Pinel's student J. E. D. Esquirol, who also appropriated the old term 'asylum' (*asile*), meaning a place of refuge, to underscore the benevolent ethos of the new institution. The asylum could cure insanity, said Esquirol, because it temporarily removed mad persons from their habitual surroundings. By dint of this 'isolation,' as he called it, the institution operated as an instance of the moral treatment: the psychic jolt of sensory stimuli arising from a radically altered physical and interpersonal environment dislodged the patient's erroneous ideas, which could then be replaced by rational ones through the expert interventions of the psychiatric doctor. The latter's therapeutic authority was enhanced by the fact that, in the artificial, self-contained world of the asylum, he ruled absolutely (Goldstein 1987).

Like the embrace of the moral treatment, so, too, the wedding of psychiatry to the institutional form of the asylum imposed special professionalization problems on the emergent specialty. In order to survive collectively, psychiatrists needed the support of a governmental or private agency willing to make large capital investments in the construction of asylums and motivated to place the psychiatrist at the top of the asylum's hierarchy of personnel. These goals were first achieved in France, where Esquirol and his disciples joined with moderate liberal politicians to secure passage of the Law of 1838. The Law mandated the establishment of a nation-wide network of asylums headed by psychiatrists, who thereby became salaried functionaries of the French state. In the less centralized British state, psychiatric victory came more gradually. An Act of 1808 providing for the construction of asylums financed by the county rate made no provision for the inclusion of a medical man on the staff. Only with the passage of the Lunatics Act of 1845, which placed institutions for the insane under a permanent national inspectorate composed of lay, legal, and medical commissioners, did the British introduce even an implicit force for the medicalization of the asylum (Jones 1955, Scull 1975).

A combined impulse toward rational state-building and enlightened humanitarianism led the disunited German lands of the first half of the nineteenth century to a spate of new-style, public asylum foundings as well as the medical restructuring of old-style, multi-functional absolutist institutions of incarceration (Goldberg 1999). In the USA, the asylum-building vogue of the same period occurred in two phases: first, emulation of European models in new, privately funded eastern-seaboard institutions; then, goaded by the Jacksonian-era critique that the frenetic competition for wealth and power in democratic America actively bred insanity, the establishment of public asylums by most state legislatures. American asylums were run by medical superintendents—the early name

for psychiatrists in the USA—and were so plentiful that an Association for Medical Superintendents was formed in 1844 (Rothman 1971).

3. Late Nineteenth-century Reconfigurations

The second half of the nineteenth century saw important changes in the institutional and intellectual models that had launched psychiatry. Most dramatically, the prevailing optimism about the therapeutic effect of the asylum gave way to deep pessimism as asylum populations swelled with chronic patients demonstrably impervious to moral treatment (Lantéri-Laura 1972, Scull 1979, Rothman 1971). At about the same time, psychiatrists abandoned their earlier conception of insanity as a curable psychological or psychosomatic disorder and theorized it as an irreversible brain condition and often as a product of 'degeneration.' This degeneration was defined as a pathological departure from the norm initially caused by a noxious environment, poor nutrition, or alcoholism, and subsequently transmitted in the Lamarckian manner through heredity, becoming more severe with each generation. Every European nation had its *fin-de-siècle* theorists of degeneration: Bénédict-Augustin Morel and Valentin Magnan in France, Cesare Lombroso in Italy, Henry Maudsley in Britain, Richard von Krafft-Ebing and Max Nordau in Austria (Pick 1989).

The shift to an organicist conception of insanity was coupled with a shift in psychiatry's international center of gravity from France to Germany. By the mid-nineteenth century, German physicians had thoroughly repudiated an earlier affinity for Romantic, holistic *Naturphilosophie*. Their new taste for positivism was epitomized in psychiatry by Wilhelm Griesinger's textbook, *Pathologie und Therapie der psychischen Krankheiten* (1845) that equated psychiatry with the study of cerebral lesions. Griesinger also epitomized the era's new psychiatric career pattern: he was not an asylum doctor but a university psychiatrist, having been appointed in 1865 to the recently created Chair of Psychiatry and Neurology at the University of Berlin (Decker 1977). Later adopted in other countries, the university psychiatry model increased the attractiveness of the psychiatric career, offering the practitioner a less reclusive lifestyle than was afforded by residence in an asylum. It also changed the intellectual content of the career: psychiatric knowledge was now assumed to be generated less from clinical contact with the insane than from neuroanatomical research in a university laboratory.

A second late nineteenth-century reconfiguration likewise encompassed both psychiatry's scientific theory and its career structure. Asylum psychiatry had worked with a simple binary opposition between sanity and insanity. After 1850, however, psychiatrists began to speak of a large intermediate zone occupied by the *demi-fous*, or half-mad. This conceptual move

eventually led to the articulation of two categories fundamental to the enterprise of twentieth-century psychiatry: the 'psychotic,' whose contact with reality is severely ruptured, and the 'neurotic,' whose minimal maladaptations do not preclude getting on in ordinary society. The former, requiring institutionalization, fit the older model of asylum psychiatry. The latter, who could safely remain in the outside world but would benefit from scheduled visits to the doctor's office, made possible the practice of outpatient psychiatry.

A rough international division of labor governed research on the neuroses and psychoses. The Parisian Jean-Martin Charcot and his many students dominated the study of the less severe forms of mental illness, especially hysteria. Munich-based Emil Kraepelin and his school continued German psychiatric preeminence through their domination of the study of the psychoses. Kraepelin made a psychiatric staple of the diagnostic category, *dementia praecox*, a state of emotional detachment and vacuousness that declared itself in adolescence and carried an invariably bleak prognosis. (The Swiss psychiatrist Eugen Bleuler would in 1911 rename the condition schizophrenia and insist that it might have a favorable outcome.) The Kraepelinian approach held sway in many countries, including the USA, through the first quarter of the twentieth century.

4. *Twentieth-century Trends*

In broad outline, three trends distinguished psychiatry in the twentieth century: the emergence of Freudian psychoanalysis; the discovery and use of psychotropic drugs; and the antipsychiatry movement.

Created by the Viennese neurologist Sigmund Freud as an outpatient treatment for neurotic disorders, psychoanalysis was initially distant from institutional psychiatry. Indeed, Freud's professional overtures to Bleuler and Carl Jung, Bleuler's assistant at the Burghölzli asylum in Zurich, can be read as efforts to obtain a psychiatric imprimatur for the new discipline of psychoanalysis (Freud 1914). Freud never fulfilled this ambition in Europe, but in the less tradition-bound scientific environment of the USA, many professors and medical superintendents welcomed his ideas. Eventually, American psychiatry fully incorporated psychoanalysis. In 1924, when William Alanson White, who had introduced psychoanalytic psychotherapy for schizophrenic patients at St. Elizabeth's Hospital, became president of the American Psychiatric Association, that organization and the American Psychoanalytic Association began holding their annual meetings together. This arrangement lasted until 1974, by which time the Freudian ardor of American psychiatrists had cooled (Barton 1987).

Waning interest in psychoanalysis on the part of American psychiatrists coincided with rising expectations for psychopharmacology on the part of the international psychiatric community. The first psycho-

tropic drug, lithium, was used successfully to manage manic-depression in Australia in 1949. A variety of antipsychotic and antidepressant compounds, most notably the phenothiazines and imipramine, were developed in France and Switzerland in the early 1950s (Baldessarini 1977). The fluoxetine family of antidepressants, whose first member went under the brand name Prozac, was introduced in the USA in the late 1980s and became among the most widely prescribed drugs in the world. Psychopharmacology brought a new wave of self-confidence and therapeutic optimism to psychiatry, promising a relatively safe, speedy, and cost-effective method of alleviating mental illness. It also revived psychiatry's identity as a 'hard' and exact science, the identity cultivated in the second half of the nineteenth century.

Somewhat ironically, then, the reliance on psychotropic drugs was one of the causes of the antipsychiatry movement of the 1960s. Since the beginning of the specialty, psychiatry's incarcerative practices had given rise to sporadic criticism, and some psychiatric abuses, notably the 'euthanasia' program mounted by the Nazi regime during World War II, have only been fully uncovered after the fact (Burleigh 1994). But the antipsychiatry movement of the 1960s, centered on the London-based psychiatrist R. D. Laing, questioned the specialty even more radically and globally. It charged that madness was neither an objective biochemical nor behavioral condition, but a context-dependent label; that Western rationalism was predicated on a denial of its value; and that psychopharmacology robbed patients of the potentially enriching and self-healing experience of full-blown psychosis. Laing's views were supported by the psychiatrist Thomas Szasz in the USA and to some degree by the philosopher Michel Foucault in France. Antipsychiatry gave impetus to the deinstitutionalization of the insane, which occurred in the late 1970s and the 1980s. A less controversial outcome of the movement was the recognition of the patient's right to refuse antipsychotic drugs and electroshock therapy (Sedgwick 1982).

The antipsychiatry movement has now largely spent its force. But as the twenty-first century begins, psychiatry, while among the oldest of the medical specialties, lacks the stability that age might seem to confer. It remains hostage to the mind-body problem, buffeted between psychological and physical definitions of its object and its methods.

Psychiatry: Informed Consent and Care

Informed consent is a philosophical and legal doctrine that has come to serve as the cornerstone of ethically sound clinical care in Western society. This doctrine requires that individuals truly understand and freely

make decisions regarding their treatment. Informed consent is an ideal that emphasizes respect for the individual and places primacy on autonomous decision-making. Furthermore, it is inherently relational, that is, it occurs in the context of a professional relationship in which the fundamental values of the medical profession find expression. Fulfilling the ideal of informed consent in practice is an elusive aim, however. As suggested by intuition, clinical phenomenology, and empirical evidence, it is particularly challenging when consent is sought from individuals who suffer from mental illness. For this reason, it is important to consider the specific issues arising in informed consent in the context of mental health care. This chapter provides a clinically-oriented overview of informed consent in mental illness by: (a) characterizing the core conceptual elements of informed consent; (b) applying informed consent concepts in mental health clinical practice; and (c) giving a brief overview of key empirical data related to mental illness in clinical consent decisions.

1. Elements of Informed Consent

Informed consent does not occur in isolation or in a moment, nor is it reducible to a signature on a legal document. It is a shared, significant process between people—one of whom faces a series of evolving choices critical to his or her mental and physical health, the other of whom is a professional person entrusted with helping to define these choices astutely and present them truthfully, respectfully, and compassionately. In clinical care, promoting the health and alleviating the suffering of the individual patient will be the basis of any treatment considered in the consent process. Consent in this situation focuses on the patient's personal values, is based on the overall goals for care, and hinges on trust in the clinician–patient relationship.

1.1 Information

The sharing of appropriate information is the first of three core elements of informed consent. The patient should be provided with accurate and balanced information in understandable language. This information should include the anticipated risks and benefits of a given treatment, the procedures involved, and its alternatives and their expected outcomes. Alternatives may include implementation of another treatment or additional treatment, or it may involve no intervention upon the course of illness at all. While every minute detail cannot be reviewed in this discussion, rare but serious risks should be characterized in a manner that conveys their relevance and reality. Furthermore, the omission of information in the disclosure process should not be intended to deceive or mislead the person undertaking the decision.

Ideally information related to a matter requiring consent will be disclosed in a manner that fosters dialogue, allows for clarification of complex issues and the identification of misunderstandings, and keeps opportunities open for subsequent discussion as new issues emerge. In obtaining informed consent for treatment of mild depression, for instance, the clinician should discuss the variable course of depressive illnesses, including the potential for symptom resolution in the absence of treatment and the chance of recurrence without intervention. The clinician should review the rationale for a proposed antidepressant agent given the symptoms of the patient and the patient's attitudes and values. The discussion should cover the medication's known possible side effects, potential adverse effects, and their relative likelihood. The clinician should explicitly anticipate the choices that will be faced by the patient in the future in light of the therapeutic alternatives discussed and the nature of the illness. This discussion should be documented by the clinician as an important element of the care process.

Consent forms that accurately and completely describe a treatment and outline patient rights represent an important tool in the consent process. Consequently, consent forms should be developed carefully in terms of their understandability (e.g., simple but precise language), readability (e.g., size of font), content (e.g., purpose, risks and benefits, rights, responsibilities of the clinician/researcher), and related issues. Consent forms, furthermore, signify the importance of a new decision for the patient, and they give specific focus to the dialogue between the professional and the patient. Even general consent forms such as those for hospitalization or for initiating medication—which may or may not confer legal protection when a medico-legal conflict occurs—have this value. From a legal perspective, notes written by the clinician reflecting the disclosure dialogue with the patient may be far more salient and can carry greater weight.

1.2 Decisional Capacity

Decisional capacity, the second element of informed consent, represents a sophisticated clinical assessment of an individual's global and specific cognitive abilities within a particular context and in relation to a particular choice. It is distinct from 'competence' which is a legal determination, i.e., a formal assessment by a judge or other officer of the court regarding a person's ability to function within a general domain of one's life such as financial or medical decisions (Appelbaum and Gutheil 1991). The presence of a serious symptom (e.g., delusions, memory loss, suicidal ideation, diminished cognitive functioning) or of a serious diagnosis (e.g., schizophrenia, dementia, major depression, developmental disability) does not

mean that an individual lacks decisional capacity. Similarly, being a young adolescent or a very elderly person does not, *a priori*, preclude one from being decisionally capable. In the context of mental illness, decisional capacity assessment may be subtle, complex clinical work that entails constructing a cohesive sense of the individual's strengths and deficits in light of a number of factors. The type of decision to be made, the nature, time course, and severity of the person's symptoms, the patient's situation, and past experiences, personal values, psychological defenses or coping 'style,' and other factors should all be considered.

Decisional capacity itself has four principal components, each of which should be viewed on a continuum and not as 'all or none' phenomena (Appelbaum and Grisso 1988). The first component is the individual's ability to express a preference (i.e., capacity for expression or communication). On the extreme end of the continuum will be severely ill psychiatric patients who are mute or catatonic, or who manifest complete language and thought disorganization, and therefore may be intermittently 'incapable' of communication. In the medical context, a patient who is comatose due to metabolic disturbances, aphasic secondary to a stroke, delirious, or unconscious after a head injury will also lack this most fundamental ability. There are times when this component of decisional capacity is very difficult to assess, such as in the spinal cord injured patient who communicates only through eye blinks, or the dysphoric person with Broca's aphasia who is frustrated by the process of generating words but has the capacity to understand and indicate choices. For these reasons, while the ability to communicate is often obvious, this assessment in many situations will require careful interactions with patients and astute observational and listening skills on the part of the clinician.

The second component of decisional capacity is the individual's ability to understand relevant information (i.e., capacity for comprehension). In talking with the clinician, the patient with this ability will be able to take in factual information regarding the nature of the illness, the need for intervention, the kinds of treatments under consideration, their relative risks and benefits, and the possible consequences of not intervening. Comprehension is influenced by intelligence, educational level, and prior experience. In assessing this dimension, it is critical that the patient state his or her understanding of the situation and the choices at hand in their own words. Otherwise it is difficult to know if the patient is using terms and phrases of the clinicians without truly knowing their meaning.

Third is the individual's ability to think through the decision in a way that is 'rational' and deliberate (i.e., capacity for reasoning or rational thinking). This component of decisional capacity relates to the person's analytical abilities given a specific set of facts or data and, like comprehension, is affected by

intelligence and educational level. For instance, the 'rational' person, all other factors being equal, will consistently choose a medication that has a 75 percent likelihood of treating the illness effectively over one that has a 50 percent chance. Similarly, the 'rational' person will consistently choose a medication that poses fewer risks and promises fewer adverse side effects than another medication. In essence, this dimension of decisional capacity has to do with the ability to use objective information.

Fourth, and often most important, is the person's ability to make meaning of the decision and its consequences within the context of his or her personal history, values, emotions, and life situation (i.e., capacity for appreciation). Deeply dependent upon psychological insight, this is the most sophisticated component of decisional capacity. It can be very difficult to assess clinically. In some individuals with early dementia, for instance, a person's social graces and cognitive skills may be only superficially affected and yet these individuals may be unable to think through the meaning of an important treatment decision and its repercussions. In some patients suffering from either anxiety or affective disorders, the negative cognitive distortions inherent to their illnesses may interfere with their abilities to interpret information within a personal context, although other components of decisional capacity may be intact. Importantly, in people with severe mental illnesses such as schizophrenia, the simple presence of psychotic symptoms such as hallucinations or delusions may *not* interfere with the individual's overall decisional capacity, but the cognitive and insight deficits associated with the illness may interfere with their capacity for appreciation of the situation at hand. Alternatively, even the most gravely ill individuals may have difficulty expressing themselves and an incomplete sense of the factual information but may truly appreciate the severity of the situation and possess a deep and consistent sense of who they would like to make decisions for them.

Decisional capacity is therefore a rich construction, not simply reducible to an individual choosing a predetermined 'right answer' when making a decision of importance. It is the person's ability to gather, assimilate, and use information, to truly see the reasons for and against a given option, and to develop a meaningful decision in the larger context of one's life. The seriousness and complexity of any specific decision will govern how rigorously these criteria are applied. In the context of serious mental illness, a person may be fully capable of deciding whether or not to begin a new psychotropic medication but, on a given day, may be incapable of deciding whether to enroll in a clinical protocol involving a medication-free interval and potential randomization to placebo. The standard for decisional capacity is also robust when a very ill patient refuses treatment that is highly recommended because of the benefit it is likely to bring

to him (see discussion in Sect. 2). This is not to say that patients cannot refuse treatment; when the risks of refusal are great, however, there is a greater responsibility on the caregiver to assure that the patient is genuinely capable of this decision and to manage its consequences.

1.3 Voluntarism

Beyond information disclosure and decisional capacity, the final element of informed consent is voluntarism or autonomy. Autonomy represents the expression of the authentic preferences of the individual in the absence of coercive pressures. Voluntary preferences may be tempered by the realities of the situation such as the presence of a serious diagnosis and the lack of 'curative' treatments for many mental illnesses, but should reflect the person's sustained and genuine wishes as evidenced in their expressed values and prior life decisions. Autonomous wishes may be deeply influenced by social and cultural expectations and psychological history. For instance, a patient who has been in the military may be oriented to hierarchical power relationships and may view a clinician's recommendation as an 'order' to be obeyed. Similarly, a seriously mentally ill person who has been institutionalized involuntarily in the past may see themselves as no longer possessing the right to their own choices. Illness processes may also affect patient preferences as well as the ability to express autonomous wishes. A person who suffers deeply either psychologically or physically may feel desperate and desolate, phenomena that can generate inherent internal coercive pressures. A person who has been the victim of violence may see themselves as relatively powerless. Finally, clinical syndromes that involve apathy, alexithymia, amotivation, or cognitive slowing may render ill individuals less able to identify and express their true wishes.

2. Clinical Application of Informed Consent Concepts

Translation of informed consent concepts to clinical practice is affected by the clinical status and situation of the patient. In emergencies, for instance, there may be little time for information-sharing and mutual decision-making and the standard for consent is less rigorous than in other contexts. Acting beneficently, i.e., to save the life or preserve the health of the patient in an acute situation, is the clinician's duty in such circumstances. This is held to be critical ethically and justifiable legally; it is presumed that in such emergency situations the patient wishes to be helped and that the clinician has permission to act with the patient's well-being and best interests at heart. Often the patient, if alert and conscious, will explicitly assent to treatment in these circumstances, i.e., voluntarily accept the choice proffered by the clinician at the time. If the patient is unconscious or is unable to com-

municate at all, the clinician acts with the 'implied consent' of the patient.

When the patient refuses treatment in an emergent situation, however, a very rigorous standard for consent must be applied because of the likelihood of an adverse outcome and because there are many clinical factors that may be adversely affecting the judgment of the patient. Undiagnosed illness, delusional thinking, severe physical pain, emotional distress, and interpersonal pressure all may undermine the ability of the patient to make a fully informed, autonomous choice in an acute situation. Evaluation, hospitalization, and treatment, even against the apparent wishes of the patient, may be essential in such circumstances. Consider two illustrative patient cases:

Case Example 1. A man diagnosed with a serious mental illness characterized by psychotic and mood symptoms was brought to a psychiatric crisis unit after being found wandering on the street near his home. It was discovered that he had superglued his eyelids shut, and it was imperative that he receive medical attention immediately. He was outwardly calm, did not speak, answered questions through nodding, writing, and hand gestures, but actively refused to get into an ambulance to be taken to the medical emergency room. The clinician on duty that evening knew the patient well and was able to deduce that the patient's peculiar behavior was linked to a recurrent delusion he had when entering a manic period. In this case, the patient's ability to make a fully informed decision was impaired by his delusional belief that if he looked directly at people, they would be instantly destroyed by powerful lasers that had been implanted in his eyes. Once the clinician initiated a conversation about these beliefs with the patient, it was possible to clarify that the patient wanted help and that he was willing to accept treatment, but was terrified that he would hurt people or himself be killed. The patient thus had some decisional ability and could offer assent for emergency care. The clinical team opted to pursue a legal process that would allow involvement of a time-limited treatment guardian due to concerns over the patient's compromised insight and judgment and the severity of his delusions.

Case Example 2. An agitated man demanded discharge from a surgical unit two days after an emergency appendectomy. He had elevated heart rate, blood pressure, and temperature, had signs of abdominal infection, and yet was insistent that he leave the hospital. The medical team was conflicted about granting the patient an 'AMA discharge' ('Against Medical Advice')—the nurses and residents believed this to be the patient's 'right to refuse treatment' but the attending clinician did not agree. On initial psychiatric evaluation, the patient showed irritability and very subtle indications of diminished attention, was oriented except to day of the week, and had no other apparent abnormalities on an abbreviated mental status examination. He was noted to be tremulous.

He was placed on involuntary 'hold' status. Within an hour, the patient was agitated, disoriented, and expressed disorganized thoughts. Additional history was then obtained that the patient drank one to two pints of vodka daily prior to admission. Post-surgical infection in combination with alcohol withdrawal had triggered a significant delirium, an early indication of which, ironically, was his treatment refusal and discharge demand. His most distressing symptoms and disorientation resolved rapidly with treatment, and he withdrew his request to leave the hospital.

When a patient refuses treatment there may be a significant clinical issue that requires close attention, and involuntary treatment may be imperative. Clarification of underlying clinical considerations in such circumstances is the caregiver's primary responsibility—a duty grounded in the bioethics principles of respect for persons, clinical standards of care, fidelity, and beneficence. Careful evaluation of the patient's true strengths and abilities is important so that he or she may exercise choice in every area possible. The intent is not to undermine the patient's autonomy. Rather, it is to empower the clinician only insofar as to help advance the health and well-being of the patient and to assure that the patient is optimally able to express his or her true wishes to accept or decline a given therapeutic approach. In sum, in situations where clinical decisions may have very serious or irreversible health consequences, including death, informed refusal of treatment must fulfill the most stringent standards.

The goal of informed, voluntary decision-making may be more clearly fulfilled in the context of care for chronic illness. Over the course of time, the clinician may come to know the patient—their symptoms, their values and concerns, their responsiveness to treatment interventions, and their personal supports. In turn, the patient may have a greater sense of trust, express themselves with greater openness, and gather more complete information about the illness and potential therapeutic interventions. The patient with a chronic illness also lives out the consequences of side effects, adverse reactions, and benefits of treatments in a manner different from the patient with a time-limited health problem. In this context, the patient may better appreciate how their illness and treatment affect other aspects of their life, and it is possible to come to know their preferences and concerns with greater certainty. Expressing autonomous wishes and deciding upon specific treatment approaches and the overall goals of therapy through mutual understanding and dialogue are more intrinsically possible in the context of chronic illness. The standard for consent in chronic illness, thus, is very rigorous in terms of the patient's level of information, opportunities to enhance decision-making, and creating a circumstance in which patients may indicate their wishes and hopes.

In clinical practice, psychiatric advance directives may be valuable in translating concepts of informed

consent to patient care decisions. Advance directives articulate patient preferences for future care. Advance directives are often formal written papers created and signed by the patient; they may also consist of a body of documentation developed by the patient, family members, and clinicians regarding his or her wishes and values concerning personal health care. Advance directives are helpful in that they serve as a reference for the clinician if the patient becomes decisionally incapable or compromised. For example, knowing that they had a pattern of developing compromised judgment during periods of mania, a patient with bipolar disorder completed an advance directive requesting that treatment be instituted despite their (anticipated) protests. Advance directives also provide evidence of the patient's past personal healthcare preferences that may result in controversial clinical decisions, e.g., when patients refuse treatment based on deeply and consistently held personal convictions such as the refusal of blood transfusions by a patient who is a Jehovah's Witness. Ideally, these issues will not be addressed for the first time in a moment of great crisis. They should be anticipated, discussed, and documented carefully beforehand. Advance directives do not, under any circumstances, replace the wishes expressed by a patient who is currently decisionally capable. Moreover, there should be opportunities to adapt, or even reverse, earlier decisions as one cannot always tell prospectively how one will respond in a crisis situation. For these reasons, advance directives may guide but can never supplant prudent, reflective clinical decision-making.

In surrogate decision-making, healthcare choices are made for the decisionally impaired patient by another person. This person may be a spouse, sibling, adult child, friend, or a court-appointed guardian. The surrogate decision-maker has the responsibility of serving the best interests and well-being of the patient while seeking to make decisions that are faithful to the personal values and prior wishes of the patient. This can be difficult. In some situations, the patient's wishes are not known. In other situations, the patient is too young or too cognitively compromised to have demonstrated their personal values. In yet other situations, these values and wishes are known and appear to conflict with accepted standards of clinical care. Consequently, in working with surrogate decision-makers, it is important for clinicians to clarify the goals and value system governing the choices made on behalf of the patient. It is also crucial that the patient's decisional capacity be assessed accurately and, in most circumstances, the patient's symptoms be treated aggressively so that they can contribute to the choices made to whatever extent possible.

3. Empirical Studies on Consent in Clinical Care

Nearly 400 studies performed since 1970 suggest that informed consent is an ideal that is often difficult to

achieve in clinical and research practice involving people with physical and mental illness (Sugarman et al. 1999). These data indicate, however, that issues faced in clinical care for mental illness are not radically different in degree or kind from those encountered in the treatment of physical illness (Stanley et al. 1988). Moreover, an extensive body of evidence on consent consistently demonstrates the poor readability, understandability, and ineffectiveness of formal consent documents in clinical care (Grossman et al. 1994). An important recent advance in the informed consent field has been the development of the MacArthur Competence Assessment Tool for Treatment (MacCAT-T) (Grisso et al. 1997). This is a structured interview designed to assess patients' clinical care decision-making abilities based on empirical work conducted over ten years by Appelbaum and Grisso. While this instrument is best utilized as a tool for approaching decisional capacity evaluation, not as a definitive 'test' of competence, it will introduce greater consistency of consent standards to both scientific and clinical arenas.

Evidence on consent in the care of mental illness reveals many key challenges for clinicians (Roth et al. 1982). Studies of psychotic, affective, and dementia disorders, for instance, have shown that symptoms of mental illness may adversely impact information-based or more strictly cognitive aspects of consent (Roberts 1998). In the 1995 MacArthur Treatment Competence Study (Appelbaum and Grisso 1995), the decisional abilities of patients with schizophrenia or major depression, patients with ischemic heart disease, and non-patient community volunteers (total $n = 498$) were assessed. When acutely ill, the psychiatric patients in this study had greater difficulties with decision-making on several formal cognitive measures than did the medically ill patients and community participants. The problems were more severe for individuals with psychotic symptoms than for depressed individuals. Clinical treatment led to significant improvement of these deficits, resulting in closer resemblance across the three groups.

Smaller studies echo these findings. An early study by Schachter et al. (1994) involving 38 schizophrenia patients revealed that the presence of conceptual disorganization, delusions, and hallucinations was associated with patients' poor performance on the information elements of consent. Appelbaum et al. (1981) assessed 50 people admitted to a mental health inpatient unit and found that most were unable to consent to hospitalization. Later this team evaluated 100 voluntarily hospitalized psychiatric patients, finding that a significant minority did not understand information presented to them on the purpose of hospitalization and discharge (Appelbaum et al. 1998). Beck (1988) evaluated the capacities of 56 psychiatric patients on antipsychotic medications, revealing that they had limited understanding and appreciation of their treatment. Stanley et al. (1988) compared the

reasoning ability of elderly individuals suffering from major depression ($n = 45$) and dementia ($n = 38$) with elderly control subjects ($n = 20$). The cognitively impaired dementia patients and, to a lesser extent, the depressed patients had significant deficits on a number of decision-making items. Similarly, Marson et al. (1995) used a clinical vignette-based instrument to measure the level of competence exhibited in medical treatment decisions by individuals with dementia and healthy comparison subjects. Not unexpectedly, this work revealed that the severity of cognitive impairment in dementia correlated with lack of ability to formulate logical reasons for treatment choice, i.e., addressing the 'rational reasons' dimension of decisional capacity. Interestingly, global measures of dementia severity such as the Mini-Mental Status Exam were not predictive of clinical decision-making capacity.

Studies of advance directives and surrogate decision-making also have important implications for mental health care. Several survey and interview studies have revealed that advance directives are underutilized (Bradley et al. 1998) and that patient preferences are rarely identified prospectively (Seckler et al. 1991). In terms of surrogate decision-making, several studies have shown that most elderly patients would prefer that a family member such as a spouse or adult child serve as an alternative decision-maker (High 1989). Studies of hypothetical decision-making by proxies suggest that they may not assess patients' wishes accurately, however Sachs et al. (1994) studied 42 decisionally capable dementia patients, 64 proxy decision-makers, and 60 well elderly individuals and found that the decision-makers' predictions of patient preferences were overall discordant with the patients' own stated wishes. Similarly, Warren et al. (1986) studied participation choices made by proxy decision-makers and 168 decisionally capable nursing home patients with respect to hypothetical, minimal risk research projects. The results demonstrated that the surrogate decision-makers used criteria other than the patient's predicted preferences in making these choices.

Clear evidence is also emerging that the barriers to consent may be amenable to intervention, offering significant hope (Roberts et al. 2000). Interventions in which information is presented verbally and in writing, using clear and understandable language, have been shown to improve patients' understanding of consent decisions (Carpenter et al. 2000). The timing of consent information and the provision of information in a relaxed manner or on repeated occasions is important to patients' abilities to integrate and apply this data (Roberts 1998). Treatment of symptoms, ranging from hallucinations to physical pain, has been observed to improve the quality of patients' decision-making. Finally, clinician behaviors that reflect how the consent process is valued, e.g., by giving time to the consent dialogue, have been found to be valued by

patients and surrogate decision-makers (Roberts and Roberts 1999). The observation that educational efforts, symptom treatment, and attitudinal obstacles can be addressed suggests a number of constructive approaches to consent in the context of clinical care for the mentally ill.

L. W. Roberts

Psychoanalysis: Adolescence (Clinical–Developmental Approach)

Until relatively recently, the study of adolescence was synonymous with the theory and practice of psychoanalysis. The major contributors to adolescent development came from eminent clinicians and theorists, such as Anna Freud (1936), Peter Blos (1962), Erik Erikson (1950). The adolescent crisis, psychosexual maturation, identity formation, and the second separation–individuation phase are all psychoanalytic concepts that have remained alive ever since they were first introduced during the twentieth century. Since

then, the fields of adolescent development and adolescent psychopathology have differentiated greatly, and a myriad of theories and models, many developed in antagonism to psychoanalysis, have evolved. Grand theories and clinical observations have far less currency at the start of the twenty-first century than do systematic cross-sectional and longitudinal studies.

The discovery of adolescence by psychoanalysts became the entry point of the study of development across the life cycle. If an essential new set of tasks develops in adolescence, such as the creation of identity, then there was reason also to explore similarly significant transformations in adulthood. The important initial point was to overcome the singular psychoanalytic focus on early childhood, especially the oedipal years. In this vein, Erikson and others discovered stages of adulthood that reach well into old age. Thus adolescent development has to be viewed in the context of a shifting conception of psychoanalytic developmental psychology which views early childhood as only one important period of development.

But there is certainly no consensus on the issue of development in psychoanalytic circles: Even now, most psychoanalysts believe that the formative periods in life are the early attachment years, and the oedipal period between the ages of 5 and 7. If there was a shift, it was less to explore the later stages of life and more to understand the earliest, pre-oedipal stage of development. It is this fundamental notion of early childhood that has denied the life cycle theorists, with all their creativity, a very significant role in psychoanalytic practice.

However, adolescence, as the intermediary space between childhood and adulthood, has become a significant aspect of most psychoanalysts' thinking about development and psychopathology. This phase of life represents a theoretical compromise, a recognition that new transformations occur beyond the oedipal years, without needing to give up the primacy of early childhood for personality development and symptom formation.

With the majority of innovations about adolescence and the life cycle coming from outside psychoanalysis, it would be easy to dismiss the analytic approach. But many modern adolescent clinicians and researchers recognize that psychoanalysis has changed greatly, and that, when applied carefully, it continues to be an important interpretive method in the social and behavioral sciences. But such modern versions of psychoanalytic theory and research must include the many innovations of adjacent fields (e.g., Smelser 1999), especially the cognitive sciences, psychiatric epidemiology, anthropology, and academic developmental psychology.

The approach taken in this article is to integrate psychoanalytic concepts in an integrative framework called clinical-developmental psychology. This approach represents a synthesis of psychoanalytic concepts, especially Eriksonian identity theory, object

relations psychoanalysis as well as cognitive-developmental theory. Thus, the integrated theoretical, clinical, and research perspective does not represent psychoanalysis proper, nor does it represent traditional cognitive psychology in the tradition of Jean Piaget. It is, instead, a working out of the contradictions of two significant paradigms of human development that have formed the building blocks of a new synthesis. This new approach forms a dynamic and transformational theory of adolescent development and the lifespan, within a research paradigm and a differentiated treatment approach.

In general, psychoanalysis has become far more open to these kinds of syntheses than ever before. Bowlby's contribution (1969), for example, represents an integration of psychoanalytic and ethological thinking. The result is neither psychoanalysis nor ethology, but a theory of attachment that is one of the most significant advances of psychoanalytic thought. Modern psychoanalysis has become far more open, because of the rapid developments in academic developmental psychology and other fields and an increasing openness to integrate these approaches.

1. Psychoanalysis

The popular notion is that Freud's theory was about unconscious motivation, sexuality, aggressive drives, and the three structures, id, ego, and superego. Freud is, furthermore, credited with having created a comprehensive theory of human emotions. These general conceptions about Freud's contributions are not incorrect, but they are incomplete. Freud was equally dedicated to cognition and logic. He was convinced that psychiatric symptoms and psychological conflicts could be deciphered following a logical, hermeneutic strategy of interpretation. He also described in the 'Introductory Lectures' (Freud 1933), as well as in 'Mourning and Melancholia,' a theory of human relationship, one that was to become the dominant modern psychoanalytic perspective called 'object relations theory.'

These two Freudian approaches, cognitive and relational, have expanded over the decades and were joined by a major third psychoanalytic perspective, the life cycle approach. Interestingly, the cognitive branch of psychoanalysis came to overshadowed by the far more elegant and researchable cognitive contributions of academic developmental psychology, especially the work of cognitive and social cognitive psychologists. The life cycle approach, building primarily on Erikson's work (e.g., Erikson 1950) was acknowledged in psychoanalytic circles but never really shaped central psychoanalytic theory and practice. However, as mentioned above, it did help to extend the traditional focus on the early oedipal and pre-oedipal years at least into adolescence, as a second period of separation.

The life cycle approach in psychoanalysis changed into a research paradigm primarily through the work of George Vaillant (1977). Vaillant introduced a hierarchy of defenses in the tradition of Anna Freud, extended their development beyond adolescence into adulthood, and defined 'families of defenses,' defined not only in negative terms but also as adaptive styles. Vaillant showed, for example, how projection, with its pathological preoccupation with others, is related to a higher level adaptive defense which he calls 'empathy.' Vaillant applied this hierarchy of defenses to a fascinating set of longitudinal studies, especially the so-called Grant Study of Harvard men selected for their health. These men have now reached their eighties, and the research on them has demonstrated that a set of psychoanalytic constructs that were widely viewed as unresearchable, such as defense mechanisms, can be studied rigorously, have a developmental core, and are one way to trace the evolution of development in adulthood.

The psychoanalytic approach to adolescent development and the lifespan requires us to address C. G. Jung as well. His insights have been impressive and continue to garner a larger readership interested in development, meaning, and spirituality. Jung was really the first psychoanalytic thinker to dedicate significant effort to understand the transformations a person goes through during life. He was also fascinated by the collective symbols and unconscious processes of development and transformation in human development. While Jung had some interest in adolescents, his central developmental contribution was about mid-life, what he viewed as a typical shift from the external world to an inner and spiritual life. It is not difficult to create a bridge between these ideas to a theory of adolescent development. Many of Jung's ideas apply to adolescent themes of creating a sense of collective belonging to a generation, to a preoccupation with 'making it in the world,' and a preoccupation with being unique.

But it is the so called object relations strand of psychoanalysis of Fairbairn (1952) and Winnicott (1965) and others that has become the organizer of modern psychoanalysis, in the form of Kohut's self-psychology, as relational psychoanalysis, and as a research paradigm in the form of attachment theory. These relational approaches have reshaped the psychological and psychoanalytic understanding of adolescence. In the earlier version, the adolescent crisis was viewed as stemming from the need to separate, to overcome childhood identifications, and to create autonomy. For that reason, Blos called this phase the second separation-individuation phase (the first one being the one that Margaret Mahler described for the toddler). In the modern relational version of the adolescent, separation is far less important than are new relational capacities, and new forms of interconnections between the adolescent, the family, and society. The psychoanalytic adolescent of the twenty-

first century is far less of a rebel who pushes the parents away than a person yearning for support and closeness, and wishing to find a new balance between family relationships and new intimate relationships. It is impossible to disaggregate what represents a new reality for families, what is a new adolescent ethos, and what is a reframing of psychoanalytic theory. All forces are at play, and while there is no single psychoanalytic scholar who is developing a new theory of adolescence, many clinicians and researchers are contributing to this relational shift.

Erikson's contribution, while having had limited resonance in psychoanalysis, continues to exert considerable influence in developmental psychology, despite the fact that he did not use traditional empirical methods of sampling and proof. He showed that understanding adolescence means to go deeper, to understand the cognitive and emotional dimensions of meaning-making. At the time of writing, no one has yet been able to combine these kinds of keen observations and theoretical synthesis when studying adolescent life. Erikson's conceptualization of adolescent identity formation, and the processes it includes (crisis, diffusion, foreclosure, moratorium), remain the standard by which subsequent contributions are measured, even if those contributions might be far more precise and valid empirically.

Since Erikson introduced his work, much has changed in the world of adolescents. Given the social dimension of the construct, one would expect cultural and historic changes (what Erikson (1968) called 'the historic moment') to influence the very nature of the adolescent experience. But also, new theories and research evidence have reshaped our understanding of how meaning-making and identity formation develop in the second decade of life. It is these cultural changes of adolescence, and the new developments inside and outside psychoanalysis, that gave impetus to a clinical-developmental synthesis of adolescent theory, research, and practice (see *Developmental Sciences, History of*).

2. Clinical-developmental Assumptions of Adolescence and the Life Cycle

2.1 Development of Representations of Self and Other

Clinical-developmental psychology of adolescence has a foundation in a relational and interactionist perspective. Such a psychoanalytic and cognitive perspective views interpersonal relationships and their internalizations as essential dimension of human development, symptomatology, and more recently, psychological treatment. Some of the pioneers of cognitive-developmental psychology (e.g., Piaget 1926) took the interactionist idea and applied it to an

abstract, epistemic, logical subject of self in relation to an equally cognitive and abstract general 'other.'

Evidence has accumulated since then, that significant relationships with less abstract 'others,' such as parents, teachers, siblings, and friends are constructed actively and interpreted by the self, and that one result is an internal set of self and object representations. The concept that relationships and experiences with important others become represented internally is common, despite many conceptual differences, to a number of theories of psychology and psychoanalysis. These theories include classical psychoanalysis and branches of the modern psychoanalytic schools, such as self-psychology, object relations theory, and attachment theory. They also include the developmental theories built on the ideas of Vygotsky, Piaget, Mead, and Baldwin.

Although psychoanalysts and attachment theorists all share the view that the weaving of various significant relationships creates the inner fabric of the self, the clinical-developmental psychologist examines the *typical transformations* of relationships over the course of the lifespan (Noam and Fischer 1996). There is now evidence from a number of cross-sectional and longitudinal studies for the clinical-developmental view that internal representations of the self and others change over time in childhood, adolescence and even adulthood (e.g., Broughton 1978, Noam et al. 1995).

This view owes much to Piaget and Kohlberg, whose early work on the moral judgment of the child (Kohlberg 1969, Piaget 1932) revealed that children's constructions of social rules and relationships change systematically as they grow. Piaget and Kohlberg's ideas have been refined; new cognitive-developmental perspectives on the child's relationship to the social world in general, and to important others, now exist throughout the developmental literature.

While clinical-developmental psychology is built on an understanding of normative cognitive development, significant theoretical and clinical extensions of the traditional cognitive models have occurred. The psychoanalytic frame plays a very important role in these theoretical extensions. For example, there is greater awareness that representations of significant relationships can be quite resistant to change, despite their potential for transformation. Even an adult tends to represent the parents as relatively powerful figures, at times continuing to view them from the perspective of a child. But although the inner representational life is conservative in nature, most people are capable of changing their perspectives on significant relationships, and are able to do what attachment theorist have called 'updating the working model.'

Clinical-developmental psychology recognizes the fluctuations between progress and regress in development, the resistance to changing one's early representations, and the evolution and progression that often take place simultaneously. These fluctuations are especially strong during the adolescent years, when

close relationships with the family have to be brought into a new balance with peer influences and identity development.

2.2 Normative Development

In order to understand the developmental dimensions inherent in adolescent psychopathology, it is essential to understand what occurs typically in ‘normal development.’ How else can we know which challenges arise naturally during this phase, and which represent the beginnings of serious deviation and maladaptation? For example, anxieties in early childhood are common (e.g., fears of separation, monsters, darkness, etc.) and are not necessarily a cause for clinical concern. But severe separation anxiety in middle childhood and adolescence is not typical, and such anxiety often requires clinical attention. Another example is presented by Offer and colleague who have argued against Erikson’s notion of serious adolescent crisis as a part of normal development. They present evidence that ‘normal’ adolescence is far less conflictual and risky than thought previously.

While theory development and clinical observation, the traditional psychoanalytic tools, can help us to understand what is developmentally normal and what is not, it is only through empirical studies with community samples that these distinctions can properly be made. Such studies can also help us to determine what the prevalence of anxiety, aggression, depression, suicidality, etc., is in the child and adolescent population. How do they vary by socioeconomic class, geographical location, ethnic group, and gender? And how do these problems change over time? Answers to some of these questions have already come from large-scale longitudinal epidemiological studies (for a review, see Costello and Angold 1995).

These findings give us the tools to apply, in a meaningful way, the concepts of delay and aberrant pathways that have proved to be so useful to studies of mental retardation, delinquency, and psychosis. We can, for example, trace a delinquent’s moral development, allowing us to see that it is delayed in comparison to that of his nondelinquent peers (e.g., Gibbs et al. 1984). Findings such as these give us a developmental focus; they allow us to see that it is not only behavior or brain functioning that distinguishes delinquents from nondelinquents, but also level of adolescent socio-moral maturity. More importantly, once we understand the moral delay, we can, among other interventions, begin to focus our interventions on supporting the process of maturation of the cognitive system that guides moral development.

Clinical-developmental psychology, however, is not just an application of the study of normal development to the realm of psychological dysfunction. It is also a reformulation of a number of traditionally held assumptions of normative theory. Key among these

reformulations is the view that adolescent symptoms may be expressed differently depending on the individual’s level of development (e.g., Noam 1988). Typically, in early phases of development, impulsive, action-oriented symptoms are more frequent, while later in development, internalizing symptoms such as depression arise with greater frequency. Therefore, the idea that higher stages of development are necessarily more adaptive, as is suggested by many developmental theories, requires serious reconsideration. The clinical-developmental psychologist does not view development as progressing simply from egocentric, oral, unsocialized, or impulsive stages to those defined by the ability to take another person’s perspective and show tolerance, empathy, and ‘phallic’ strength. Developmental theories have assumed this view for too long.

But we now know that a similar developmental course that leads to increased self-knowledge and strengths in some people leads to alienation, self-deception, and self-destructive behavior in others (e.g., Noam et al. 1995). Reaching Piagetian formal operations, for example, can throw the adolescent into a dangerous identity crisis, providing the adolescent with so many potential ‘selves’ that no choice seems possible (e.g., Perry 1970). Chandler (1973) referred to this cognitive crisis of adolescence as the ‘epistemological loneliness of formal operations’ (p. 381).

2.3 Age Chronology

The clinical-developmental approach is far less focused on chronological age than are most research approaches to development and psychopathology. Unfortunately, it has become quite common to label a model or study as being an example of research in ‘developmental psychopathology’ if age is introduced as a significant variable. But chronological age is a very crude indicator of the underlying processes of biological maturation, cognitive capacity, peer and family relationships, and one’s understanding of one’s self. Age does, of course, play a role in development in most of these domains, but there is frequently a significant variation in maturity in each of these areas within a single age group.

There are, of course, also age trends in some forms of psychopathology. For example, suicide rates rise dramatically in adolescence, as do other disorders such as depression, and conduct problems. Schizophrenia is typically an illness that begins in late adolescence or young adulthood. Age, therefore, can serve as a simple way to organize an understanding of many underlying pathogenic processes. However, the simplicity of this approach is deceptive (see Rutter 1989).

In psychopathological development, as in normal development, we often find that chronological age is

by no means a guarantor that basic cognitive and social-cognitive processes have occurred. For example, despite textbook claims to the contrary, many adolescents and adults never achieve formal-operational thought (i.e., tables in a typical psychology textbook list adolescence next to formal operations, as if all adolescents function at that cognitive stage). While many adolescents have achieved a formal operational level of thinking, others continue to function at the level of concrete operations, and indeed may remain at this level for the rest of their lives.

Consequently, if we use chronological age as the principle developmental marker, then the important variations that occur in every group of normally-developing individuals will receive insufficient attention. For the clinical-developmental psychologist, this suggests that chronological age needs to be supplemented with a domain-specific understanding of a person's capacities in different areas of development.

But, although capacities are often measured in terms of chronological age, the more sophisticated measurements of development that we have as we enter the twenty-first century call on us to subsume the idea of chronological age into our understanding of progressive adaptation and skill acquisition. In so doing, our research finds significant links between development and psychopathology in adolescents, where chronological age plays only a minor role. Level of social cognitive functioning and the shape of the internal self and object representations, rather than age, are often associated with specific disorders.

2.4 Lifelong Development and Recovery

Significant developmental changes can, and regularly do, occur long after childhood and adolescence. The lifelong process of development has been described eloquently by Erikson (1950), Vaillant (1977), Baltes (1997), and others. But despite a great deal of progress in understanding the achievement of salient life tasks, meaning making, and cognition, little progress has been made in applying this understanding to psychological treatment and recovery. Indeed, little is known even now about typical problems and psychological dysfunctions that arise with development throughout life.

Critical to clinical-development is the understanding that at each point in life, fundamental shifts in cognitive, emotional, social, and interpersonal development are possible, and that these shifts follow a certain logic and organization. For example, adults who identify strongly with work, authority, and control, can become disappointed when others do not live up to their expectations. These inclinations to disappointment, perfectionism, and excessive control might be long-standing, stemming from compulsive character traits that were formed in childhood. But

they might also stem from the way people, as adults, define their basic categories of self, their world, and their relationships. Perhaps the categories most central to them are responsibility, predictability, and accountability. These categories and their salience can change over time into a greater acceptance of human frailty and of the limitations of control and predictability. As complex ways of understanding and experiencing change, past rigidities are also revisited. Each new chapter in a person's life typically rewrites earlier chapters. Understanding the ways in which people can transform their representational world allows the developmental therapist and developmentally-oriented psychoanalyst to help the patient revisit old relationships, overcome old vulnerabilities, work through past traumas, and help to prevent new ones from occurring. But the clinical-developmental perspective puts a great deal of emphasis on the self-righting and healing potential that is triggered under the right therapeutic conditions.

3. Extending the Psychoanalytic Paradigm: Differential Therapy with Adolescents

The next brief section will deal with using clinical-developmental principles to differentiate adolescent functioning and briefly introduce differential treatment implications. For a more detailed discussion see (Noam 1988), where four different levels of adolescent functioning and intervention strategies are described. Because of space considerations only two adolescent positions will be differentiated here. This section will show that there is no single treatment approach for adolescents, even youth who share the exact same age, but that the approach will differ fundamentally, not only by diagnosis, but also by developmental organization of self and relationship representation.

3.1 Reciprocal–Instrumental Self-complexity

Establishing treatments for adolescents who function at the reciprocal–instrumental self-complexity level is difficult. First, these adolescents are viewed by society as delayed developers, and often have many problems adjusting to the demands placed on them. They tend to be oppositional, even delinquent, and have a concrete and instrumental approach to relationships. Adding to these problems is the fact that play therapy is not appropriate at this age, because it seems infantilizing to them. Many intervention specialists take account of the verbal capacities of these adolescents in devising a treatment strategy. Because these adolescents are often quite verbal, therapists expect the youngsters to talk about their problems. But talking therapies generally do not work, nor do treatments that require a great

deal of self-reflection and insight. The therapist who tries such an approach is usually greeted with contempt and hostility, and can expect communication to break down.

And yet, it is these adolescent girls and boys who are at risk of developing problems at school, dropping out, using drugs and alcohol, behaving aggressively, and running away from home. They need a great deal of support and mentoring, in the forms of individual therapy and group interventions, to learn how to negotiate life, and how to develop goals that do not 'get them into trouble.' If adults are conducting the intervention, it is important they orient the work toward joint goals, giving the adolescent a great deal of room to decide what should happen. It is very important that therapists do not get caught up with questions such as 'what kind of therapy am I pursuing,' but instead that they remain extremely flexible, leaving the office when it is appropriate, to play, eat, or walk. It is not by chance that coaches and child-care workers are often successful with these adolescents; they are often perceived as nonthreatening and available when the adolescent needs them.

It is also essential to create contexts of peer learning and therapy for these adolescents. These environments can help the adolescents to learn how to overcome their difficulties in empathizing with others. A combination of developing group intimacy and confronting problem behavior by peers is powerful in helping the adolescent overcome an over-reliance on self-protection and move toward a more mature developmental understanding of the self and the world.

3.2 Mutual-Inclusive Self-complexity

At this point, talking therapy has a real potential for making the adolescent feel understood and supported. Sharing one's inner life with adults and peers, and framing it in psychological terms, becomes a powerful motivation toward intimacy and recovery. Group conformity is at its height, and so is the constant fear of losing the 'relationship base,' of abandonment by parents, teachers, and friends. It is this fear of losing those who define the self, and of not fitting in, that is a core feature of this adolescent's adolescence.

The ability of these youngsters to frame experiences in psychological terms, to describe feeling states and interactions with important others, encourages most therapists to explore patterns and motivations, autonomous self-observation and critical judgment about self and relationships. These explorations usually lead to surprisingly superficial descriptions, which frustrate both therapist and client. Surprised by this 'lack of self,' the therapist may interpret this state as an early, and primitive, manifestation of a separation-individuation problem. The clients, consequently, feel

incompetent, sensing that they are not living up to expectations. Feeling inadequate leads to feeling hopeless, and clients are thereby silenced. The silence, in turn, makes the therapist and client often feel quite uncomfortable, increasing the potential for low self-esteem and depression.

There is no therapeutic model that clearly fits this stage of adolescence, which is surprising in light of the fact that so many adolescents who enter therapy function at this level. One reason might be that we did not know about this developmental gestalt before the emergence of social cognition. Existing therapy methods that use supportive strategies run the risk of under-challenging the patient. The relationship can easily become stale as the adolescent waits for some challenge or some guidance in framing the problems in new ways.

Insight-oriented therapy, on the other hand, requires an observation of systematic patterns of the self which is not available to adolescents at this developmental stage. Following a set of goals that is experienced as self-chosen, questioning existing conventions, and creating new ones, requires a differentiation between the part of the self steeped in prescribed pathways and conventions, and the part that is reflecting, doubting, and questioning. Therapists can be sure that they have an ally in the patient, who can contain cognitively, at least under supportive conditions, both sides of the self. For that reason, more traditional psychodynamic therapy can be applied, which becomes even more viable as the person grows into full adulthood.

4. Conclusion

The psychoanalytic perspective continues to provide important impulses for the study and treatment of adolescents and their families. Erikson provided significant theoretical tools, and Bowlby introduced a research paradigm that has been amazingly productive. But further integrations of perspectives, especially pertaining to the cognitive dimensions of adolescent thought, have proven necessary. The clinical-developmental approach not only expands the theoretical tools for the study of adolescent development and adolescent risk: It also introduces a developmental typology of intervention and prevention strategies. Intervention advances with adolescents have been slow, despite the introduction of many strategies. It is possible that progress has been slow in part because the emphasis has been primarily on differentiating disorders, rather than on understanding these disorders in the context of adolescent development.

Psychoanalysis: Current Status

1. Freud's Theory of the Mental Apparatus

Freud's (1953a) starting point was his study of hysterical patients and the discovery that, when he found a way to help these patients piece together a coherent account of the antecedents of their conversion symptoms, dissociative phenomena, and pathological affective dispositions, all these psychopathological phenomena could be traced to traumatic experiences in their past that had become unconscious. In the course of a few years Freud abandoned his early efforts to recover repressed material by means of hypnosis, and replaced hypnosis with the technique of 'free association,' an essential aspect of psychoanalytic technique until the present time.

Practicing this method led Freud to several lines of discovery: to begin, he conceptualized unconscious mechanisms of defense that opposed the recovery of memories by free association. He described these mechanisms, namely repression, negation, isolation, projection, introjection, transformation into the opposite, rationalization, intellectualization, and most important, reaction formation. The latter involves overt, chronic patterns of thought and behavior that serve to disguise and disavow opposite tendencies linked to unconscious traumatic events and the intrapsychic conflicts derived from them. The discovery of reaction formations led Freud to the psychoanalytic study of character pathology and normal character formation, and still constitutes an important aspect of the contemporary psychoanalytic understanding and treatment of personality disorders (for practical purposes, character pathology and personality disorders are synonymous concepts).

A related line of development in Freud's theories was the discovery of the differential characteristics of conscious and unconscious thinking. Freud differentiated conscious thinking, the 'secondary process,' invested by 'attention cathexis' and dominated by

sensory perception and ordinary logic in relating to the psycho-social environment, from the 'primary process' of the 'dynamic unconscious.' That part of the unconscious mind he referred to as 'dynamic' exerted constant pressure or influence on conscious processes, against the active barrier constituted by the various defensive operations, particularly repression. The dynamic unconscious, Freud proposed, presented a general mobility of affective investments, and was ruled by the 'pleasure principle' in contrast to the 'reality principle' of consciousness. The 'primary process' thinking of the dynamic unconscious was characterized by the absence of the principle of contradiction and of ordinary logical thinking, the absence of negation and of the ordinary sense of time and space, the treatment of a part as if it were equivalent to the whole, and a general tendency toward condensation of thoughts and the displacement of affective investments from one to another mental content.

Finally, Freud proposed a 'preconscious,' an intermediate zone between the dynamic unconscious and consciousness. It represented the storehouse for retrievable memories and knowledge and for affective investments in general, and it was the seat of day-dreaming, in which the reality principle of consciousness was loosened, and derivatives of the dynamic unconscious might emerge. Free association, in fact, primarily tapped the preconscious as well as the layer of unconscious defensive operations opposing the emergence of material from the dynamic unconscious.

This model of the mind as a 'place' with unconscious, preconscious, and conscious 'regions' constituted Freud's 'topographic theory.' He eventually replaced it with the 'structural theory' namely, the concept of three interacting psychic structures, the ego, the superego and the id (Freud 1961).

1.1 The Id

The id is the mental structure that contains the mental representatives of the 'drives,' that is, the ultimate intrapsychic motivations that Freud (1955) described in his final, 'dual drive theory' of libido and aggression, or metaphorically, the sexual or life drive and the destruction or death drive. In exploring unconscious mental processes, what at first appeared to be specific traumatic life experiences turned out to reflect surprisingly consistent, repetitive, intrapsychic experiences of a sexual and aggressive nature.

Freud (1953a) was particularly impressed by the regularity with which his patients reported the emergence of childhood memories reflecting seductive and traumatic sexual experiences on the one hand, and intense sexual desires and related guilt feelings, on the other. He discovered a continuity between the earliest wishes for dependency and being taken care of (the psychology, as he saw it, of the baby at the mother's

breast) during what he described as the 'oral phase' of development; the pleasure in exercising control and struggles around autonomy in the subsequent 'anal phase' of development, (the psychology of toilet training); and, particularly, the sexual desire toward the parent of the opposite gender and the ambivalent rivalry for that parent's exclusive love with the parent of the same gender. He described this latter state as characteristic of the 'infantile genital stage' (from the third or fourth to the sixth year of life) and called its characteristic constellation of wishes and conflicts the positive Oedipus complex. He differentiated it from the negative Oedipus complex, that is, the love for the parent of the same gender, and the corresponding ambivalent rivalry with the parent of the other gender. Freud proposed that oedipal wishes came to dominate the infantile hierarchy of oral and anal wishes, becoming the fundamental unconscious realm of desire.

Powerful fears motivated the repression of awareness of infantile desire: the fear of loss of the object, and later of the loss of the object's love was the basic fear of the oral phase, directed against libidinal wishes to possess the breast; the fear of destructive control and annihilation of the self or the object was the dominant fear of the anal phase directed against libidinal wishes of anal expulsion and retentiveness, and the fear of castration, 'castration anxiety,' the dominant fear of the oedipal phase of development, directed against libidinal desire of the oedipal object. Unconscious guilt was a dominant later fear, originating in the superego and generally directed against drive gratification (see Sect. 1.3). Unconscious guilt over sexual impulses unconsciously equated with oedipal desires constitutes a major source of many types of pathology, such as sexual inhibition and related character pathology.

Freud described the oral phase as essentially coinciding with the infantile stage of breast feeding, the anal phase as coinciding with struggles around sphincter control, and the oedipal stage as developing gradually during the second and through the fourth years, and culminating in the fourth and the fifth years of life. This latter phase would then be followed by more general repressive processes under the dominance of the installation of the superego, leading to a 'latency phase' roughly corresponding to the school years, and finally, to a transitory reactivation of all unconscious childhood conflicts under the dominance of oedipal issues during puberty and early adolescence.

The drives represent for human behavior what the instincts constitute for the animal kingdom, that is, the ultimate biological motivational system. The drives are constant, highly individualized, developmentally shaped motivational systems. Under the dominance of the drives and guided by the primary process, the id exerts an on-going pressure toward gratification, operating in accordance with the pleasure principle. Freud initially equated the drives with primitive

affects. After discarding various other models of unconscious motivation, he ended up with the dual drive theory of libido and aggression.

He described the libido or the sexual drive as having an 'origin' in the erotogenic nature of the leading oral, anal, and genital bodily zones; an 'impulse' expressing the quantitative intensity of the drive by the intensity of the corresponding affects; an 'aim' reflected in the particular act of concrete gratification of the drive; and an 'object' consisting of displacements from the dominant parental objects of desire.

The introduction of the idea of an aggressive or 'death' drive, arrived at later in Freud's writing, stemmed from his observations of the profound self destructive urges particularly manifest in the psychopathology of major depression and suicide, and of the 'repetition compulsion' of impulse driven behavior that frequently seemed to run counter to the pleasure principle that supposedly governed unconscious drives. He never spelled out the details of the aggressive drive as to its origins. Freud described drives as intermediate between the body and the mind; the only thing we knew about them, Freud (1957a) suggested, were 'representations and affects.'

1.2 The Ego

While the id is the seat of the unconscious drives, and functions according to the 'primary process' of the dynamic unconscious, the ego, Freud (1961) proposed, is the seat of consciousness as well as of unconscious defense mechanisms that, in the psychoanalytic treatment, appear as 'resistance' to free association. The ego functions according to the logical and reality based principles of 'secondary process,' negotiating the relations between internal and external reality. Guided by the reality principle, it exerts control over perception and motility; it draws on preconscious material, controls 'attention cathexes,' and permits motor delay as well as selection of imagery and perception. The ego is also the seat of basic affects, particularly anxiety, as an alarm signal against the danger of emergence of unconscious, repressed impulses. This alarm signal may turn into a disorganized state of panic when the ego is flooded with external perceptions that activate unconscious desire and conflicts, or with overwhelming, traumatic experiences in reality that resonate with such repressed unconscious conflicts, and overwhelm the particularly sensitized ego in the process.

Freud originally equated the 'I,' that is, the categorical self of the philosophers, with consciousness. Later, once he established the theory of the ego as an organization of both conscious and unconscious functions, he at times treated the ego as if it were the subjective self, and at other times, as an impersonal

organization of functions. Out of this ambiguity evolved the contemporary concept of the self within modern ego psychology as well as in British and American object relations and cultural psychoanalytic contributions (Kernberg 1984). An alternative theory of the self was proposed by Kohut (1971), the originator of the self-psychology approach within contemporary psychoanalysis.

Nowadays, an integrated concept of the self as the seat of subjectivity is considered an essential structure of the ego, and the concept of 'ego identity' refers to the integration of the concept of the self. Because developmental processes in early infancy and childhood are now better understood, an integrated self concept usually goes hand in hand with the capacity for an integrated concept of significant others. An unconscious tendency toward primitive dissociation or 'splitting' of the self-concept and of the concepts of significant objects runs counter to such integration.

Character, from a psychoanalytic perspective, may be defined as constituting the behavioral aspects of ego identity (the self-concept) and the internal relations with significant others, (the internalized world of 'object relations'). The sense of personal identity and of an internal world of object relations in turn reflects the subjective side of character. It was particularly the ego psychological approach—one of the dominant contemporary psychoanalytic schools—that developed the analysis of defensive operations of the ego, and of pathological character formation as a stable defensive organization that needed to be explored and resolved in the psychoanalytic treatment. In the process, ego psychology importantly contributed to the psychoanalytic treatment of personality disorders.

Freud (1957c) conceptualized narcissism as the libidinal investment of the ego or self, in contrast to the libidinal investment of significant others ('objects'). In proposing the possibility of a withdrawal of libidinal investment from others with an excessive investment in the self as the basic feature of narcissistic pathology, he pointed to a broad spectrum of psychopathology, and thus first stimulated the contribution of Abraham (1919), and later those of Grunberger (1979), Jacobson (1964), Kernberg (1975), Klein (1957), Kohut (1971), and Rosenfeld (1964). Thus crystallized the description of the narcissistic personality as a disorder derived from a pathological integration of a grandiose self as a defense against unbearable aggressive conflicts, particularly around primitive envy.

1.3 The Superego

In his analysis of unconscious intrapsychic conflicts between drive and defense, Freud regularly encountered unconscious feelings of guilt in his patients, reflecting an extremely strict, unconscious infantile

morality which he called the superego. This unconscious morality could lead to severe self-blame and self-attacks, and particularly to abnormal depressive reactions, which he came to regard as expressing the superego's attacks on the ego. It was particularly in studying normal and pathological mourning, that Freud (1957c) arrived at the idea of excessive mourning and depression as reflecting the unconscious internalization of the representation of an ambivalently loved and hated lost object. In unconsciously identifying the self with that object introjected into the ego, the individual now attacked his own self in replacement of the previous unconscious hatred of the object; and the internalization of aspects of that object into the superego reinforced the strictness of the individual's preexisting unconscious infantile morality.

Freud traced the origins of the superego to the overcoming of the Oedipus complex via unconscious identification with the parent of the same gender: in internalizing the oedipal parent's prohibition against the rivalry with him or her and the unconscious death wishes regularly connected with such a rivalry, and against the incestuous desire for the parent of the other gender, this internalization crystallized an unconscious infantile morality. The superego, thus based upon prohibitions against incest and parricide, and a demand for submission to, and identification with the oedipal rival, became the guarantor of the capacity for identification with moral and ethical values in general.

Freud also described the internalization of the idealized representations of both parents into the superego in the form of the 'ego ideal.' He suggested that the earliest sources of self esteem, derived from mother's love, gradually fixated by the baby's and small child's internalizations of the representations of the loving mother into the ego ideal, led to the parental demands also becoming internalized. In other words, normally self-esteem is maintained both by living up to the expectations of the internalized idealized parental objects, and by submitting to their internalized prohibitions. This consideration of self-esteem regulation leads to the clinical concept of narcissism as normal or pathological self-esteem regulation, in contrast to the theoretical concept of narcissism as the libidinal investment of the self.

2. Psychoanalytic Treatment

2.1 The Psychoanalytic Theory of Psychopathology

This theory proposes that the clinical manifestations of the symptomatic neuroses, character pathology, perversions, sexual inhibitions, and selected types of psychosomatic and psychotic illness reflect unconscious intrapsychic conflicts between drive derivatives following the pleasure principle, defensive operations

reflecting the reality principle, and the unconscious motivations of the superego. Unconscious conflicts between impulse and defense are expressed in the form of structured conflicts between the agencies of the tripartite structure. There are ego defenses against impulses of the id; the superego motivates inhibitions and restrictions in the ego; at times the repetitive, dissociated expression of id impulses ('repetition compulsion') constitutes an effective id defense against superego pressures. The resolution of unconscious conflicts implies the analysis of all these intersystemic conflicts.

All these conflicts are clinically expressed by three types of phenomena: (a) inhibitions of normal ego functions regarding sexuality, intimacy, social relations, and affect activation; (b) compromise formations between repressed impulses and the defenses directed against them; and (c) dissociative expression of impulse and defense. This latter category implies a dominance of the splitting mechanisms referred to before. These have acquired central importance in the understanding of severe character pathology as reflected in contemporary psychoanalytic thinking.

2.2 The Structural Formulation of the Psychoanalytic Method

Psychoanalytic treatment consists, in essence, in facilitating the reactivation of the pathogenic unconscious conflicts in the treatment situation by means of a systematic analysis of the defensive operations directed against them. This leads to the gradual emergence of repressed impulses, with the possibility of elaborating them in relation to the analyst, and their eventual adaptive integration into the adult ego. Freud (1953c) had described the concept of 'sublimation' as an adaptive transformation of unconscious drives: drive derivatives, converted into a consciously tolerable form, are permitted gratification in a symbolic way while their origin remains unconscious. The result of this process is an adaptive, non-defensive compromise formation between impulse and defense. In analysis, the gradual integration into the patient's conscious ego of unconscious wishes and desires from the past and the understanding of the phantasied threats and dangers connected with them facilitates their gradual elaboration and sublimatory expression both in the consulting room and in everyday life.

2.3 The Object Relations Theory Formulation of Psychoanalytic Treatment

In the light of contemporary object relations theory, the formulation based upon the structural theory (resolution of unconscious conflicts between impulse and defense) has changed, in the sense that all

unconscious conflicts are considered to be imbedded in unconscious internalized object relations. Such internalized object relations determine both the nature of the defensive operations and of the impulses against which they are directed. These internalized object relations constitute, at the same time, the 'building blocks' of the tripartite structure of id, ego, and superego. Object relations theory proposes that the gradual analysis of intersystemic conflicts between impulse and defense (structured into conflicts between ego, superego, and id, decomposes the tripartite structure into the constituent conflicting internalized object relations. These object relations are reactivated in the treatment situation in the form of an unconscious relation between self and significant others replicated in the relation between patient and analyst, that is, the 'transference.'

The transference is the unconscious repetition in the 'here and now' of unconscious, conflicting pathogenic relationships from the past. The transference reflects the reactivation of the past conflict not in the form of a memory, but in the form of a repetition. This repetition provides essential information about the past, but constitutes at the same time, a defense in the sense that the patient repeats instead of remembering. Therefore, transference has important informative features that need to be facilitated in their development, and defensive features that need to be therapeutically resolved once their nature has been clarified. Transference analysis is the fundamental ingredient of the psychoanalytic treatment.

2.4 The Psychoanalytic Treatment Process

Gill (1954) in a classical definition that is still relevant today, proposed the definition of psychoanalysis as a treatment that facilitates the development of a 'regressive transference neurosis' and its resolution by means of interpretation alone, carried out by the analyst from a position of technical neutrality.

The concept of a regressive transference neurosis refers to the gradual gathering into the relationship with the analyst of the patient's most important past pathogenic experiences and unconscious conflicts. The concept of a regressive transference neurosis has been largely abandoned in practice because, particularly in patients with severe character pathology, transference regression occurs so early and consistently that the gradual development of a regressive transference neurosis is no longer a useful concept.

Gill's proposal that the resolution of the transference be achieved 'by interpretation alone,' refers to 'interpretation' as a set of the psychoanalyst's interventions that starts with 'clarification' of the patient's subjective experiences communicated by means of free association, expands with the tactful 'confrontation' of aspects of the patient's patterns of behavior that are expressed in a dissociated or split off manner from his

subjective awareness, and thus complements the total expression of his intrapsychic life in the treatment situation, and finally evolves into 'interpretation per se.' Interpretation per se implies the formulation of hypotheses regarding the unconscious meanings in the 'here and now' of the patient's material, and the relation of these unconscious meanings with the 'there and then' of the patient's unconscious, past pathogenic experiences.

The concept of 'technical neutrality' refers to the analyst's impartiality regarding both impulse and defense, with a concerned objectivity that provides a helpful collaboration with the patient's efforts to come to grips with his intrapsychic conflicts.

This definition of the nature of psychoanalytic treatment needs to be complemented with the contemporary concepts of 'transference,' 'countertransference,' 'acting out' and 'working through.'

2.5 An Object Relations Theory Model of the Transference and Countertransference

Modern object relations theory proposes that, in the case of any particular conflict around sexual or aggressive impulses, the conflict is imbedded in an internalized object relation, that is, in a repressed or dissociated representation of the self ('self representation') linked with a particular representation of another who is a significant object of desire or hatred ('object representation'). Such units of self-representation, object representation and the dominant sexual, dependent or aggressive affect linking them are the basic 'dyadic units,' whose consolidation will give rise to the tripartite structure. Internalized dyadic relations dominated by sexual and aggressive impulses will constitute the id; internalized dyadic relations of an idealized or prohibitive nature the superego, and those related to developing psychosocial functioning and the preconscious and conscious experience, together with their unconscious, defensive organization against unconscious impulses, the ego. These internalized object relations are activated in the transference with an alternating role distribution, that is, the patient enacts a self representation while projecting the corresponding object representation onto the analyst at times, while at other times projecting his self representation onto the analyst and identifying with the corresponding object representation. The impulse or drive derivative is reflected by a dominant, usually primitive affect disposition linking a particular dyadic object relation; the associated defensive operation is also represented unconsciously by a corresponding dyadic relation between a self representation and an object representation under the dominance of a certain affect state.

The concept of countertransference, originally coined by Freud as the unresolved, reactivated transference dispositions of the analyst is currently defined

as the total affective disposition of the analyst in response to the patient and his/her transference, shifting from moment to moment, and providing important data of information to the analyst. The countertransference, thus defined, may be partially derived from unresolved problems of the analyst, but stems as well from the impact of the dominant transference reactions of the patient, from reality aspects of the patient's life, and sometimes from aspects of the analyst's life situation, that are emotionally activated in the context of the transference developments. In general, the stronger the transference regression, the more the transference determines the countertransference; thus the countertransference becomes an important diagnostic tool. The countertransference includes both the analyst's empathic identification with a patient's central subjective experience ('concordant identification') and the analyst's identification with the reciprocal object or self representation ('complementary identification') unconsciously activated in the patient as part of a certain dyadic unit, and projected onto the analyst (Racker 1957). In other words, the analyst's countertransference implies identification with what the patient cannot tolerate in himself/herself, and must dissociate, project or repress.

At this point, it is important to refer to certain primitive defensive operations that were described by Klein (1952) and her school in the context of the analysis of severe character pathology. Primitive defensive operations are characteristic of patients with severe personality disorders, and emerge in other cases during periods of regression. They include splitting, projective identification, denial, omnipotence, omnipotent control, primitive idealization, and devaluation (contempt). All these primitive defenses center on splitting, i.e., an active dissociation of contradictory ego (or self) experiences as a defense against unconscious intrapsychic conflict. They represent regression to the phase of development (the first two to three years of life) before repression and its related mechanisms mentioned are established.

Primitive defensive operations present important behavioral components that tend to induce behaviors or emotional reactions in the analyst, which, if the analyst manages to 'contain' them, permit him to diagnose in himself projected aspects of the patient's experience. Particularly 'projective identification' is a process in which: (a) the patient unconsciously projects an intolerable aspect of self experience onto (or 'into') the analyst; (b) the analyst unconsciously enacts the corresponding experience ('complementary identification'); (c) the patient tries to control the analyst, who now is under the effect of this projected behavior; and (d) the patient meanwhile maintains empathy with what is projected. Such complementary identification in the countertransference permits the analyst to identify himself through his own experience with the aspects of the patient's experience communicated by

means of projective identification. This information complements what the analyst has discovered about the patient by means of clarification and confrontation, and permits the analyst to integrate all this information in the form of a 'selected fact' that constitutes the object of interpretation. Interpretation is thus a complex technique that is very much concerned with the systematic analysis of both transference and countertransference.

2.6 Contemporary Trends of the Psychoanalytic Method

Contemporary psychoanalytic technique can be seen as having evolved from a 'one person psychology' into a 'two person psychology' and then into a 'three person psychology.' The concept of 'one person psychology' refers to Freud's original analysis of the patient's unconscious intrapsychic conflicts by analyzing the intrapsychic defensive operations that oppose free association. The 'two persons psychology' refers to the central focus on the analysis of transference and countertransference. In the views of the contemporary intersubjective, interpersonal and self psychology psychoanalytic schools, the relationship between transference and countertransference is mutual, in the sense that the transference is at least in part a reaction to reality aspects of the analyst, who therefore must be acutely mindful of his contribution to the activation of the transference. The so-called 'constructivist' position regarding transference analysis assumes that it is impossible for the analyst to achieve a totally objective position outside the transference/countertransference bind.

In contrast, the contemporary 'objectivist' position, represented by the 'three person psychology' approaches of the Kleinian school, the French psychoanalytic mainstream, and significant segments of contemporary ego psychology proposes that the analyst has to divide himself between one part influenced by transference and countertransference developments, and another part that, by means of self reflection, maintains himself/herself outside this process, as an 'excluded third party,' who, symbolically, provides an early triangulation to the dyadic regression that dominates transference developments. This triangulation in the treatment situation becomes particularly important in the treatment of severe personality disorders.

The 'repetition compulsion' as a resistance of the id is very likely a form of acting out as a defense against emotional containment of an extremely painful or traumatic set of experiences. 'Working through' refers to the repeated elaboration of an unconscious conflict in the psychoanalytic situation. It is a major task for the analyst, who has to be alert to the subtle variation in meanings and implications of what on the surface

may be appear to be an endless repetition of the same conflict in the transference. The patient elaboration of the conflict that presents itself with these repetitive characteristics also implies the function of 'holding' originally described by Winnicott (1965). It consists of the analyst's capacity to withstand the onslaught of primitive transferences without retaliation, abandonment of the patient, or a self devaluing giving up, and the maintenance of a working relationship (or 'therapeutic alliance') that addresses itself consistently to the healthy part of the patient, even when the latter is under the control of his most conflicting behaviors. Bion's (1967) concept of 'containing' is complementary to 'holding,' in the sense that holding deals mostly with the affective disposition of the analyst, and containing with his cognitive capacity to maintain a concerned objectivity and focus on the 'selected fact,' permitting the integration in the analyst's mind what the patient can only express in violently dispersed or split off behavior patterns.

'Dream analysis' developed in the context of the method of free association, and constituted, in Freud's (1953b) view, a 'royal road to the unconscious.' Freud's discovery of primary process thinking derived from his method of dream analysis. By now, psychoanalytic thinking has evolved into the view that there are many 'royal roads' to the unconscious. The analysis of character defenses, for example, or of particular transference complications, may be equally important avenues of entry into the patient's unconscious mind.

The technique of dream analysis consists, in essence, in asking the patient to free associate to elements of the 'manifest content' of the dream, in order to arrive at its 'latent' content, the unconscious wish defended against and distorted by the unconscious defensive mechanisms that constitute the 'dream work,' and have transformed the latent content into the manifest dream. The latent content is revealed with the help of the simultaneous analysis of the way in which the dream is being communicated to the analyst, the 'day residuals' that may have triggered the dream, the unconscious conflicts revealed in it, and the dominant transference dispositions in the context of which the dream evolved. Dreams also provide some residual, universal symbolic meanings that may facilitate the total understanding of the latent content.

'The analysis of character' may be the single most important element of the psychoanalytic method in bringing about fundamental characterological change. Character analysis is facilitated by the patient's use of reaction formations, that is, his defensively motivated character traits, as transference resistances. Thus, the activation of defensive behaviors in the transference, reflecting the patient's characterological patterns in all interpersonal interactions, facilitates both the analysis of the underlying unconscious conflicts, and in the process, the resolution of pathological character patterns. The result is an increase in the

patient's autonomy, flexibility, and capacity for adaptation.

The overall objective of psychoanalytic treatment is not only the resolution of symptoms and pathological behavior patterns or characteristics, but fundamental, structural change, that is, the expansion and enrichment of ego functions as the consequence of resolution of unconscious conflict and the integration of previously repressed and dynamically active id and superego pressures into ego potentialities. Such change is reflected in the increasing capacity for both adaptation to, and autonomy from, psychosocial demands and expectations, and an increased capacity for gratifying and successful functioning in love and work.

3. Treatment Results: Research on Outcome

The Menninger Psychotherapy Research Project, a naturalistic study comparing psychoanalysis, psychoanalytic psychotherapy, and supportive psychotherapy, showed psychoanalysis to be the most effective of these approaches with patients presenting relatively good ego strength, while patients with severe ego weakness—what nowadays would be described as presenting severe personality disorders or borderline personality organization—improved most with psychoanalytic psychotherapy (Kernberg et al. 1972). That research also showed how important supportive elements were throughout all modalities of treatment (Wallerstein 1986). A comprehensive review of outcome studies on psychoanalytic psychotherapy and psychoanalysis by Bachrach and collaborators (Bachrach et al. 1985) concluded that the improvement rates are in the 60–90 percent range, but it also pointed to limitations and problems in the methodology utilized.

Recently, studies regarding the treatment process and outcome of psychoanalysis and psychoanalytic psychotherapy have become more precise in defining the specific treatment variables of psychotherapeutic and psychoanalytic treatments, and several systematic studies on psychoanalytic psychotherapies and psychoanalysis are in progress (Fonagy 1998). A recent study by the Stockholm Outcome of Psychoanalysis and Psychotherapy Project (STOPPP) has found, on the basis of a relatively large patient population, that psychoanalytic treatment, in comparison with psychoanalytic psychotherapy, obtained a significantly higher degree long range symptomatic improvement (Sandell et al. 1997).

Psychoanalysis, History of

With the centenary of the birth of psychoanalysis, historians have begun to perceive that the biography of Sigmund Freud (1856–1939) and the interpretation of psychoanalysis constitutes an important chapter in twentieth-century cultural and intellectual history both as a body of theory and as cultural practice. An ongoing attempt to determine the meaning of Freud and psychoanalysis has led to the publication of hundreds of volumes, and the historiography of psychoanalysis has found its own place within the history of science. Historical literature about psychoanalysis ranges from the self-representations and autobiographical works of Freud to the first official biography, from moderate revisionism and contextualized approaches to the harsh, and at times hostile, clinical, feminist, epistemological, hermeneutical, and psychobiographical critiques of today. Each culture has absorbed Freud and psychoanalysis differently; but, a general history of psychoanalysis as a single science can be catalogued in three ways: (a) as a history of the psychoanalytic theories from Freud to the present; (b) as a history of the psychoanalytic movement, its institutions and practices; (c) as a self-reflection on the historiography of psychoanalysis itself.

1. A History of the Psychoanalytic Theories from Freud to the Present

The development of Freud's theory of the unconscious and his psychotherapeutic method can be understood on the basis of his professional development in the context of a process of differentiation and specialization of the sciences, in particular medicine and philosophy, in the late nineteenth century. Historical works of the kind, for example studies of the scientific and social context and the institutional structure of the discipline, have created a methodologically sophisticated and broad view of the psychoanalytic discipline, including empirical research and epistemological interpretation.

Various types of hermeneutical studies of psychoanalysis itself, that is, visions of it as a system of

symbols and as a method for culture-decoding rather than as a type of natural science, have broadened the view of the history of psychoanalysis. Jean Laplanche and Jean-Baptiste Pontalis's *Vocabulaire de la Psychanalyse* (1967), the first conceptual dictionary of psychoanalysis, is based on the techniques of the history of philosophy and the French tradition of the epistemology of the sciences. As the basic concepts of the psychoanalytic theory have undergone changes that reflect the development of the sociopolitical climate, the authors have incorporated the later concepts of Freud and his followers as well as critics who created new schools and theories of psychoanalysis (e.g., Melanie Klein, Jacques Lacan). Their attempts have stimulated a whole universe of separate hermeneutical and epistemological studies.

Freud's psychoanalysis with its keywords *subjectivity* and the *scientific empirical method* has been interpreted as a characteristic product of Viennese modernity, and has been seen as a parallel to phenomena like Zionism and Austromarxism. Bourgeois society and European modernity experienced significant crises in Vienna of the *fin de siècle*, where psychoanalysis was founded in the last decades of the Austro-Hungarian Monarchy. On a sociopolitical level, the multinational state tended to search for a renewal that included different forms of living. During the period between 1890 and 1910, extraordinary achievements were made in the areas of music, literature, art, and science. These were fundamentally influential for new developments in observation and thought in the twentieth century, and the psychoanalytic theory enjoyed its first heyday in the years before World War I. The following factors were generative forces behind the *fin de siècle* creativity: the rise of new cultural founding figures of the liberal bourgeoisie, the influence of the Jewish intelligentsia, and the upward mobility of immigrants from the Austro-Hungarian Empire; the resistance against the political dirigism, bureaucracy and the repression of the Church and censorship; the cultural networks established with European centers and circles abroad; the import of foreign ideas; and the intellectual exchange between the submetropolises of the countries of the monarchy (Nautz and Vahrenkamp 1993).

From 1859 until 1938, Sigmund Freud lived and worked in Vienna, and the significance of Vienna as the site of psychoanalysis' foundation and development is evident. Socio-politico-cultural studies have dealt with Freud's *fin de siècle* (see Schorske 1981, McGrath 1986), viewing psychoanalysis within Viennese culture, for example at the juncture of a specific time and place. Special interest has focused on Freud's Jewish identity and the relationship between Judaism and psychoanalytic theory, ranging from minimalistic to maximalistic explanations.

Psychoanalytic theory and Freud's biography were and in many ways still are intertwined in a unique way. Therefore, the historian is in the position of having to

treat psychoanalytic concepts as both strictly personal documents and as data governed by the architecture of the theoretical system. In Freud's early texts, the evolution of psychoanalytic theory is presented linearly, as though it were fundamentally the same as any other scientific field, but there are serious historiographic difficulties entailed in approaching psychoanalysis in this fashion. Freud's self-analysis, his autobiographical writings, and self-created image of psychoanalysis as a science and various theoretical concepts of psychoanalysis (e.g., seduction theory, dream interpretation, Oedipal conflict, resistance, repression, transference, and countertransference) have become prominent in the field of psychoanalytic historiography, including Freud's own changes of theory throughout his life, as well as post-Freudian developments (e.g., drive-psychology, ego-psychology, the development from defense to adaptation, from instinctual to motivational diversity).

2. A History of Freud's Biography, the Psychoanalytic Movement, and its Institutions and Practices

In the historiography of psychoanalysis, the genre of Freud studies has been differentiated from the historical examination of the psychoanalytic movement in its local national centers and within specific cultures. Biographical studies dominate over sociohistorical works, and the focus has been on the struggle over legacy and legitimacy rather than on a social history of the profession.

2.1 Freud Biographies

Three groups of historical literature about Freud have been described: (a) publications of primary sources, for example Freud's correspondences; (b) publications of historical materials concerning case studies and theoretical works of Freud; and (c) critical-academic studies about psychoanalysis. The history of Freud biography and the psychoanalytic movement began with Freud's autobiographical works *On the History of the Psychoanalytic Movement* (1914) and *An Autobiographical Study* (1925), and in his own historical papers, Freud—in his one-sided but coherent story—suggests that the history of psychoanalysis is basically the history of refusals, resistances, and the necessary regroupings of the orthodoxies (ideas, institutions and people/practitioners themselves). His story of psychoanalysis appears to be synonymous with the history of its splits, schisms, and dissidents. But, just as the proliferation of schools and the consequent battles among and splittings within psychoanalytic institutes stimulated abundant polemics, these upheavals also stimulated reworkings of almost every important item in the history of Freud biography.

Dreams from *The Interpretation of Dreams*, patients from *The Studies on Hysteria* and later case studies have been analyzed and reanalyzed from new perspectives; all the schisms and quarrels in the history of psychoanalysis were rediagnosed by the latter-day schismatics and schism-haters. Based on newly accessed archival material and historical information, early speculations and widely differing interpretations have been reconsidered. Freud biographies have addressed almost every aspect of Freud's life (profession, social status, political views, culture, religion, affection-emotion), sometimes in a general fashion, sometimes in a very specific manner, and reflecting the time and the standpoint of their authors. To forestall future falsifications in popular biographies and early attempts at studying Freud's biography by his pupils and followers, Freud's daughter Anna Freud felt prompted to authorize Ernest Jones to write a first full-scale biography (Young-Bruehl 1998). Freud studies proper began with the pioneering research of Siegfried Bernfeld; his scholarship was invaluable to Ernest Jones when putting together his trilogy *The Life and Work of Sigmund Freud* (1953–57), yet, at least some of Bernfeld's findings were suppressed in Jones'. As a member of the first generation of loyal followers, Jones' monumental work became the precipitant for a third type of historical accounts: critiques of Jones's biography, or what might be called second-order biographies.

For a long time, Freud's prominence nurtured the illusion of an isolated, ahistoric development of psychoanalysis. A cultural-historical approach to Freud became more intense as the 1960s unfolded, as biography was in general too role-model-oriented. With Henri Ellenberger's *The Discovery of the Unconscious* (1970), a mode of Freud biography contextualizing Freud began to flourish, taking the precursors of Freud's ideas more into account than Jones did.

2.2 The Psychoanalytic Movement

Interest in supporters, students, and contributors of Freud has long been marginal or limited to only the most well-known representatives. With the publication of *The Minutes of the Vienna Psychoanalytic Society* (Nunberg and Federn 1962–75), a new focus was put on the institutional framework, the form in which these individuals cooperated scientifically, and how they organized their exchanges with other social structures. Works on Freud's friendships and professional relationships include the dynamical and sociological aspects of the formation of groups, the production of scientific knowledge, the structure of mastery and slavery (often basic to the formation of psychoanalytic institutions), as well as more contextually embedded accounts of specific psychoanalytic cultures. Further, *Freud and his Followers* (Roazen 1975) stimulated studies of the family networks and

subnetworks; as a consequence, biographies of early pupils and later analysts have emerged. Their adherent or schismatic relations to Freud figured largely in these accounts. A special body of historical literature has focused on the role and influence of female patients and analysts. The founding of new psychoanalytic schools has created a new intellectual-historical approach, including the professionalization and institutionalization of the discipline in different cultures and at different times. From the early days of psychoanalysis, the internationalization of psychoanalysis had its own motor and effect on theory and practice (e.g., Kutter 1992, 1995). Taking geographical and temporal particularities into account, a Western (European and North American) perspective has been criticized.

Economic and political circumstances, as well as cultural and sociohistorical connections, have all influenced the theoretical, practical, and organizational developments of psychoanalysis as a discipline and are part of the production of psychoanalysis as a corpus of knowledge. Fenichel (1998) has observed the impacts of outside reality on the production of theory and practice during the years when Central European Jewish psychoanalysts, candidates in training and their families were forced to flee National Socialist Germany and Austria and the occupied countries in Europe. The production of scientific findings and the transformation and transfer of knowledge as social processes in which internal and external factors are in a constant exchange does not minimize the role of the founder of the science of the unconscious in its beginning, but it destroys the illusion of a single isolated discovery. The shifts in the history of psychoanalysis can be seen and interpreted as a complex, dialogical, multi-author enterprise and depend on the studies of the special scientific tradition and the study of psychoanalytic microcultures (see Hale 1995, Lockot 1985, Roudinesco 1982).

3. A Self-reflection on the Historiography of Psychoanalysis Itself, and the Problems of Methodology

The history of psychoanalysis over the past generation has been a rapidly growing, controversy-ridden, and attention-attracting area. Over the past 30 years, each of the historical visions has inspired and/or provoked a revision, and each revision a counter-revision. The history of psychoanalysis has to take into account the peculiar, complex, and powerful interplay among psychoanalysis, historiography, and social, cultural, and political ideology; because this has not been recognized, many widely disparate accounts of psychoanalytic history have been proffered. Neighboring fields, such as the history of medicine, philosophy, psychology and science, women's studies, the history of law, crime, and deviance, the history of

professions, the history of sexuality, the history of the body, and cultural studies, literature, queer/gay/gender studies, have had their impacts on the historiography of psychoanalysis as well.

Studies in the area of Freud biography and the pre- and early history of psychoanalysis have received more attention. Because connections with later periods seem less powerful and convincing, the fixation on Freud himself and, even more particularly, on the originary decade of Freud's discoveries have meant that later developments during and especially since Freud's lifetime are receding in prominence.

The various schools of psychoanalysis have fashioned for themselves idealized genealogies, lines of intellectual filiation between the great minds of the past and contemporary practitioners, tracing a suitable line of evolution, and have been selective of their usable past. They may also assist in sharpening contested interdisciplinary or intradisciplinary boundaries in which 'positive' episodes are memorialized, taken as characteristic of the essence, while 'negative' ones are omitted, serving to legitimate particular theories and methodologies and delegitimizing others. Historical accounts of psychoanalytic theory and practice have to include thoughts and speculations about the special acquisition and transmission of psychoanalytic knowledge.

A 'coherent' picture of Freud and the psychoanalytic movement has undergone a profound change. In the historiography of psychoanalysis, at least two different schools of thought have been described: the 'official' history of Freud, which has been largely though not exclusively produced and consumed by practicing psychoanalysts, and a 'revisionist' approach that has emerged in the last three decades and has been mainly produced by people working outside of institutional psychoanalysis (e.g. historians, psychologists, philosophers, sociologists, political scientists). For a long time, the two groups have debated separately—with a trend to specialization and fragmentation thereby repeating the fragmentation of the object they are analyzing—and have tried to avoid other findings. But lately, a dialogue between historians and clinicians—both interested in history—concerning the history of psychoanalysis has arisen, and there have been attempts to overcome prejudices. One outcome of this dialogue has been the formation of local and international organizations and discussion groups and the establishment of special journals and periodicals. Still, the issues of language, including the problems of translation and the questions concerning authorship and audience remain central, as in other scientific disciplines. Language questions have been correlated with speculative histories on Freud and the psychoanalytic movement.

After the historical optimism of the mid-century period, the height of the professional prestige of psychoanalysis, when there was remarkably little criticism from historians of psychiatry, a revisionist

historiography of psychoanalysis was stimulated; traditional biography and the general longitudinal narrative were followed by the study of institutions introducing the ideal of objective, systematic, and quantitative analysis, having in mind methodologically sophisticated, empirically substantial, and sociologically-oriented scholarship. On the other hand, as scholars have argued, the demystifications of hagiographical idealizations have often only generated 'heroic' neo-marxist and Foucauldian remystifications. Revisionist and hagiographical literature have been diagnosed by contemporary scholars as both reductionistic and lacking self-reflection.

Psychoanalysis as a theory and a profession emphasizes the value and virtue of self-awareness and in its therapeutical practices often employs a developmental mode of inquiry; nevertheless, with a few exceptions, it has remained resolutely unintrospective about the methodological and ideological conditions under which it writes the narrative of its own past. That is all the more peculiar in light of the past decade's extensive and sophisticated discussion concerning different conceptual, methodological, and epistemological strategies for writing the history of science generally. Two approaches have been observed, the internalist approach, stressing cognitive development, and the externalist approach, focusing on the social, economic, political, and professional determinants of scientific theory and practice. All history writing has been diagnosed perspectively as the expression of a particular historical environment, culture, background, and self-consciousness among cultural-critics. LaCapra (1988) emphasizes the Freudian point that any historian's relationship with the past, and through that with the present, is a transference relationship, and that, in this transference, repetition and denial come more easily than working through and mourning (Smith and Morris 1992).

Jones' idealization of Freud has been rejected, and, particularly in the medium of psychobiography, a much more contextualized, conflicted, and complicated founder of psychoanalysis has emerged in the historical literature. Jones did not interpret blanks in his documentation as secrets or resistances, but nowadays psychologically informed biographers consider the fact that many of the most important things in people's lives are never recorded.

Contrary to the sophisticated histories of Freud's unfolding discoveries, historians have lamented the difficulties of psychobiography, and some of the key methodological problems concerning childhood experiences, the workings of the mind, and the character of thought, have been widely recognized—although such recognition has not yet informed a major historiographical work on psychoanalytic biography and history writing.

Despite the progressive de-Freudianization of psychiatry and psychology in general, Freud's place as one of the supreme minds of the twentieth century

remains secure for most historians. Psychoanalysts have altered psychoanalytic theory over the course of time, their theoretical and methodological findings depending on their analysands, their social context, and the historico-political changes in general. Historiography has altered accordingly, considering and tolerating the complexity instead of simplistic and popular versions of psychoanalysis.

Psychoanalysis in Clinical Psychology

1. Historical Background to Psychoanalysis

As is well known, Freud's discovery of the talking cure was really that of an intelligent patient (Anna O) and her physician (Breuer). The patient found out for herself that certain symptoms disappeared when she

succeeded in linking up fragments of what she said and did in an altered state of consciousness (which we would now call dissociative) with forgotten impressions from her waking life. Breuer's remarkable contribution was that he had faith in the reality of the memories which emerged and did not dismiss the patient's associations as products of a deranged mind. Breuer, of course, left the therapeutic battlefield as soon as his patient's speech and behaviors started to go beyond the boundaries marked out by turn-of-the-century Viennese society.

Psychotherapy had to wait for a more powerful intellect who would not take fright at the instinctual elements in the psychological world of so-called civilized man. At first Freud sought to unearth the traumas which he believed lay at the origins of the neuroses. Later, when confronted by evidently incorrect statements, he modified his theory assuming consistency between recollection and childhood psychic reality rather than physical reality. The issue of accuracy of memories of childhood sexual trauma remains controversial, although its relevance to psychoanalytic technique is at best tangential. Freud's technique, however, was dramatically modified by his discoveries. The intense emotional relationship between patient and physician, which had its roots in catharsis following hypnotic suggestion, had gradually subsided into what was principally an intellectual exercise to reconstruct the repressed causes of psychiatric disturbance from the fragments of material derived from the patient's associations. It was a highly mechanistic approach reminiscent of a complex crossword puzzle. In the light of therapeutic failures, however, Freud once more restored the emotional charge into the patient-physician relationship. However, in place of hypnosis and suggestion, he used the patient's emotional reactions to the therapist. He thought that these reactions were explicable as transferences of the patients' feelings about their past relationships on to the current analytic relationship. Instead of seeing the patient's intense emotional reaction to the therapist as an interference, Freud came to recognize the importance of transference as a representation of earlier relationship experiences which could make the reconstruction of those experiences in analysis highly meaningful to that individual (see *Therapist-Patient Relationship*). Freud's early clinical work lacked some of the rigor which came to characterize classical psychoanalysis. His occasional encouragement to his patients to join him on holiday might now be considered boundary violations. What is perhaps less well known is that Freud remained somewhat skeptical about the effectiveness of psychoanalysis as a method of treatment. Indeed, autobiographies of some of his patients testify to his great flexibility as a clinician and use of nonpsychoanalytic techniques, including behavioral methods. Nor was Freud the only clinician to use psychoanalytic ideas flexibly. The Hungarian analyst Sandor Ferenczi was

one of the first to discover the treatment of phobic disorders by relaxation and exposure, although his discovery had little impact on subsequent clinical practice.

The technique of psychoanalysis after Freud's death came to be codified with those (such as Alexander and French, and Frieda Fromm-Reichmann) who attempted to revive or retain Freud's original clinical flexibility being subjected to powerful intellectual rebuttals. In reality, psychoanalysts probably continued to vary in the extent to which they observed the ideals of therapeutic neutrality, abstinence, and a primarily interpretive stance, but these deviations could no longer be exposed to public scrutiny for fear of colleagues' forceful condemnation. Personal accounts of analyses with leading figures yield fascinating insights into variations in technique, principally in terms of the extent to which the analyst made use of personal relationship. There has been an ongoing dialectic throughout the history of psychodynamic approaches between those who emphasize interpretation and insight and those who stress the unique emotional relationship between patient and therapist as the primary vehicle of change. The controversy dates back to disputes concerning the work of Ferenczi and Rank but re-emerged with the first papers of Balint and Winnicott in London opposing a Freudian and Kleinian tradition, and somewhat later in the United States with Kohut opposing classical ego psychology.

Since the early 1990s, the pluralistic approach of modern psychoanalysis has brought out into the open many important dimensions along which psychoanalysts' techniques may vary. In particular, the recent trend to consider analyst and patient as equal partners engaged in a mutual exploration of meaning has directly challenged many of the classical constructs. This controversy is too fresh to permit a conclusive assessment. It is evident, however, that fairly fundamental reconsideration of the aims and techniques of psychoanalytic therapy is currently underway.

2. The Basic Assumptions of Psychoanalysis

Notwithstanding the theoretical heterogeneity of psychoanalytically based therapeutic approaches, there is probably a core set of assumptions to which all psychodynamic therapists would, to a greater or lesser extent, subscribe. These can be basically summarized as follows: (a) intrapsychic conflict is an all-pervasive aspect of human experience; (b) the mind is organized to avoid displeasure arising out of conflict and maximize the subjective sense of safety; (c) defensive strategies are adopted to manipulate ideas and experience in order to minimize displeasure; (d) psychological disturbance arises developmentally, so an adaptation that was rational and reasonable at an earlier developmental phase may leave residues that

cause maladjustment in adulthood; (e) social experience is organized into relationship representations; self and other are depicted in specific interactions charged by powerful emotional content; (f) these relationship representations inevitably re-emerge in the course of psychoanalytic treatment.

2.1 Technique—Principal Features

2.1.1 Neutrality and abstinence. Based on the classical framework of libidinal theory, Freud explicitly enjoined against the analyst giving in to the temptation of gratifying the patient's sexual desire. Obviously, this is primarily an ethical issue. However, within the psychoanalytic context it also justifies the analyst's stance of resisting the patient's curiosity or using the therapeutic relationship in any way that consciously or unconsciously could be seen as motivated by the need to gratify their own hidden desires. Within this classical frame of reference, the patient must also agree to forgo significant life changes where these could be seen as relevant to current psychotherapeutic work. In practice, such abstinence on the part of the patient is rare. Yet long-term psychodynamic treatment may founder if the emotional experiences of the therapy are obscured by the upheavals of significant life events.

Abstinence primarily ensures the neutrality of the therapist. The therapist must resist the temptation to direct the patient's associations and must remain neutral irrespective of the subject matter of the patient's experiences or fantasies. It is perhaps this aspect of the psychoanalyst's therapeutic stance that makes psychoanalysts most vulnerable to ridicule, but it is probably genuinely critical for the therapist to retain emotional distance from the patient to a degree which enables the latter to bring fantasies and fears of which they feel uncertain. Nevertheless, neutrality at its worst denies the possibility of sensitivity; recent literature on the process and outcome of psychotherapy makes it clear that the therapist's genuine concern for the patient must be manifest if significant therapeutic change is to be achieved.

2.1.2 Mechanisms of defense. Classical psychoanalytical theory and its modern equivalent (ego psychology) see conflict at the core of mental functioning. They see defenses as adaptations to intrapsychic conflict. Within object relations theories, defenses are seen as helpful to the individual to maintain an authentic or 'true' self representation or a nuclear self (see *Defense Mechanisms*). Attachment theory understands defenses as assisting in the maintenance of desirable relationships. The Klein-Bion model makes limited use of the notion of defense mechanisms but uses the term in the context of more complex hypo-

thetical structures called defensive organizations. The term underscores the relative inflexibility of some defensive structures which are thus best conceived of as personality types. For example, narcissistic personality disorder combines idealization and destructiveness; genuine love and truth are devalued. Such a personality type may have been protective to the individual at an earlier developmental stage, and has now acquired a stability or autonomy which must be rooted in the emotional gratification which such a self-limiting form of adaptation provides.

Irrespective of the theoretical frame of reference, from a therapeutic viewpoint clinicians tend to differentiate between so-called primitive and mature defenses based on the cognitive complexity entailed in their functioning. In clinical work, primitive defenses are often noted together in the same individual. For example, individuals loosely considered 'borderline' tend to idealize and then derogate the therapist. They maintain their self-esteem by using splitting (clear separation of good from bad self-perception) and then projection. Projective identification is an elaboration of the process of projection. An individual may ascribe an undesirable mental state to the other through projection but when the other can be unconsciously forced to accept the projection and experience its impact, the defense becomes far more powerful and stable. The analyst's experience of a fragment of the patient's self state has in recent years been considered an essential part of therapeutic understanding.

Through projective identification the patient can experience a primitive mode of control over the therapist, whether in fantasy or in actualized form. Bion argued that when the self is experienced as being within another person (the therapist), the patient frequently attempts to exert total control over the recipient of the projection as part of an attempt to control split-off aspects of the self. Bion also argued that not all such externalizations were of 'bad' parts of the self. Desirable aspects of the self may also be projected, and thus projective identification can be seen as a primitive mode of communication in infancy. There are other aspects of projective identification which we commonly encounter clinically. These include the acquisition of the object's attributes in fantasy, the protection of a valued aspect of the self from internal persecution through its evacuation into the object, and the avoidance or denial of separateness. It is thus a fundamental aspect of interpersonal relationships focused on unconscious fantasy and its appreciation is critical for the adequate practice of long-term psychotherapy.

Some mechanisms of defense are thought to be more characteristic of the less severe psychological disorders (e.g., depression, anxiety, obsessive-compulsive disorders, etc.). It is beyond the scope of this article to consider the various defense mechanisms in detail. Since Anna Freud's classical work, these defense mechanisms have become fairly generally

accepted, if only as terms of mild rebuke between mental health professionals. Thus we generally accept that motivated repression may be associated with momentary forgetting of conflictual contents, that denial may be invoked by individuals wishing to disavow the emotional significance of an experience, that reaction formation is helpful in turning terror into aggression, and that identification with the aggressor may be the only solution available to a maltreated child who becomes an abuser in adolescence.

The diagnostic significance of defense mechanisms is controversial. Some researchers have claimed that an individual's habitual mode of defense has predictive value beyond that of psychiatric diagnosis. Given the theoretical ambiguity that surrounds the concept, it is unlikely that its use as part of a diagnostic formulation is justified. It does, however, assist the psychoanalytic clinician in conceptualizing the patient's reactions. In particular, these defenses are likely to be encountered in the course of psychoanalytic treatment at moments of intense emotional resistance. For example, it is common to observe patients experiencing considerable difficulty in recalling the contents of treatment sessions, yet their memory for other less central aspects of their lives appears to be exceptional. Being alert to the presence of defenses is important, not because it provides an opportunity for confrontation with ideas which the patient seems reluctant to acknowledge, but rather because it alerts the analyst to the presence of underlying anxieties which need to be tackled if resistance to the therapy is to be overcome.

2.1.3 Modes of therapeutic action. The primary mode of the therapeutic action of psychoanalytic psychotherapy is considered to be *insight*. Insight may be defined as the conscious recognition of the role of unconscious factors in current experience and behavior. Unconscious factors encompass unconscious feelings, experiences, and fantasies. Insight is more than mere intellectual knowledge. Thomä and Kächele (1987) consider insight to be equidistant from emotional experience and intellect. Etchegoyen (1991) distinguished descriptive insights from demonstrated (ostensive) insights which represent a more direct form of knowing, implying emotional contact with an event one has experienced previously.

Although specific formulations of the effect of insight depend on the theoretical framework in which explanations are couched, there is general agreement that insight's therapeutic effect is to integrate mental structures in some way (Thomä and Kächele 1987). Kleinian theorists see the healing of defensively created splits in the patient's representation of self and others as crucial. One may be more specific by specifying split or part-objects as isolated representations of intentional beings whose motivation is insufficiently well understood for these to be seen as coherent beings. In this case insight could be seen as a

development of the capacity to understand internal and external objects in mental state terms, thus lending them coherence and consistency. The same phenomenon may be described as an increasing willingness on the part of the patient to see the interpersonal world from a third-person perspective.

A simple demonstration to the patient of such an integrated picture of self or others is not thought to be sufficient. The patient needs to work through a newly arrived at integration. Working through is a process of both unlearning and learning: actively discarding prior misconceptions and assimilating learning to work with new constructions. The technique of working through is not well described in the literature, yet it represents the critical advantage of long-term over short-term therapy. Working through should be systematic and much of the advantage of long-term treatment may be lost if the therapist does not follow through insights in a relatively consistent and coherent manner.

In contrast to the emphasis on insight and working through are those clinicians who, as we have seen, emphasize the relationship aspect of psychoanalytic therapy (Balint, Winnicott, Loewald, Mitchell, and many others). This aspect of psychoanalytic therapy was perhaps most eloquently described by Loewald when he wrote about the process of change as: 'set in motion, not simply by the technical skill of the analyst but by the fact that the analyst makes himself available for the development of a new "object-relationship" between the patient and the analyst ...' (Loewald 1960 pp. 224–5). Sandler and Dreher (1996) have recently observed 'while insight is aimed for, it is no longer regarded as an absolutely necessary requirement without which the analysis cannot proceed.' There is general agreement that the past polarization of interpretation and insight on the one hand and bringing about change by presenting the patient with a new relationship on the other was unhelpful. It seems that patients require both and both may be required for either to be effective.

It has been suggested that change in analysis will always be individualized according to the characteristics of the patient or the analyst. For example, Blatt (1992) suggested that patients who were 'introjective' (preoccupied with establishing and maintaining a viable self-concept rather than establishing intimacy) were more responsive to interpretation and insight. By contrast, anaclitic patients (more concerned with issues of relatedness than of self-development) were more likely to benefit from the quality of the therapeutic relationship than from interpretation.

2.2 Psychoanalysis in Clinical Psychology

While intensive long-term psychoanalysis is relatively rarely offered nowadays as a therapy except to those engaged in psychotherapeutic training, long-term psychoanalytic psychotherapy, using the same principles but with session frequency at once or twice a week is

perhaps the most common long-term treatment offered for personality and emotional problems by clinical psychologists. Clinical psychology is increasingly concerned with the evidence base of the treatments that psychological therapists engage in. What hope is there in this era of empirically validated treatments, which prizes brief structured interventions, for a therapeutic approach which defines itself by freedom from constraint and preconception, and counts treatment length not in terms of number of sessions but in terms of years? Can psychoanalysis ever demonstrate its effectiveness, let alone cost-effectiveness?

There can be no excuse for the thin evidence base of psychoanalytic treatment. In the same breath that psychoanalysts often claim to be at the intellectual origin of other talking cures (e.g., systemic therapy, cognitive behavior therapy), they also seek shelter behind the relative immaturity of the discipline to explain the absence of evidence for its efficacy. Yet the evidence base of these 'derivatives' of psychoanalytic therapy has been far more firmly established than evidence for psychoanalysis itself. Of course, there are reasons given for this—reasons such as the long-term nature of the therapy, the complexity of its procedures, the elusiveness of its self-declared outcome goals, and the incompatibility of direct observation with the need for absolute confidentiality. None of these reasons stands up to careful scrutiny, however.

What is surprising, given this unpropitious backdrop is that there is in fact some suggestive evidence for the effectiveness of psychoanalysis as a treatment for psychological disorder.

2.2.1 The evidence base of psychoanalytic treatment. Psychoanalysts have been encouraged by the body of research which supports brief dynamic psychotherapy (see *Psychological Treatment, Effectiveness of*). A meta-analysis of 26 such studies has yielded effect sizes comparable to other approaches (Anderson and Lambert 1995). It may even be slightly superior to some other therapies if long-term follow-up is included in the design. One of the best-designed Randomized Controlled Trials (RCTs), the Sheffield Psychotherapy Project (Shapiro et al. 1995), found evidence for the effectiveness of a 16-session psychodynamic treatment based on Hobson's (1985) model in the treatment of major depression. There is evidence for the effectiveness of psychodynamic therapy as an adjunct to drug dependence programs (Woody et al. 1995). There is ongoing work on a brief psychodynamic treatment for panic disorder (Milrod et al. 1997). There is evidence for the use of brief psychodynamic approaches in work with older people (Thompson et al. 1987). There are some excellent studies confirming the cost-effectiveness of psychoanalytic brief therapy in a naturalistic clinical setting.

There are psychotherapy process studies which offer qualified support for the psychoanalytic case. For example, psychoanalytic interpretations given to clients which are judged to be accurate are reportedly associated with relatively good outcome (Crits-Christoph et al. 1988). There is even tentative evidence from the reanalysis of therapy tapes from the NIMH (National Institutes of Mental Health) Treatment of Depression Collaborative Research Program that the more the process of a brief therapy (CBT, cognitive behavior therapy, IPT, Interpersonal therapy) resembles that of a psychodynamic approach, the more likely it is to be effective.

Evidence is available to support therapeutic interventions which are clear derivatives of psychoanalysis. However, most analysts would consider that the aims and methods of short-term, once-a-week psychotherapy are not comparable to 'full analysis.' What do we know about the value of intensive and long-term psychodynamic treatment? Here the evidence base becomes somewhat patchy.

The Boston Psychotherapy Study (Stanton et al. 1984) compared long-term psychoanalytic therapy (two or more times a week) with supportive therapy for clients with schizophrenia in a randomized controlled design. There were some treatment-specific outcomes, but on the whole clients who received psychoanalytic therapy fared no better than those who received supportive treatment. In a more recent randomized controlled study (Bateman and Fonagy 1999), individuals with a diagnosis of borderline personality disorder (BPD) were assigned to a psychoanalytically oriented day hospital treatment or treatment as usual. The psychoanalytic arm of the treatment included therapy groups three times a week as well as individual therapy once or twice a week over an 18-month period. There were considerable gains in this group relative to the controls and these differences were not only maintained in the 18 months following discharge but increased, even though the day hospital group received less treatment than the control group. A further controlled trial of intensive psychoanalytic treatment of children with chronically poorly controlled diabetes reported significant gains in diabetic control in the treated group which was maintained at one-year follow-up (Moran et al. 1991). Experimental single case studies carried out with the same population supported the causal relationship between interpretive work and improvement in diabetic control and physical growth (Fonagy and Moran 1991). The work of Chris Heinicke also suggests that four- or five-times-weekly sessions may generate more marked improvements in children with specific learning difficulties than a less intensive psychoanalytic intervention (Heinicke and Ramsey-Klee 1986).

One of the most interesting studies to emerge recently was the Stockholm Outcome of Psychotherapy and Psychoanalysis Project (Sandell 1999). The study followed 756 persons who received national

insurance funded treatment for up to three years in psychoanalysis or in psychoanalytic psychotherapy. The groups were matched on many clinical variables. Four- or five-times-weekly analysis had similar outcomes at termination when compared with one to two sessions per week psychotherapy. However, in measurements of symptomatic outcome using the SCL-90, improvement on three-year follow-up was substantially greater for individuals who received psychoanalysis than those in psychoanalytic psychotherapy. In fact, during the follow-up period, psychotherapy patients did not change but those who had had psychoanalysis continued to improve, almost to a point where their scores were indistinguishable from those obtained from a nonclinical Swedish sample.

Another large pre-post study of psychoanalytic treatments has examined the clinical records of 763 children who were evaluated and treated at the Anna Freud Centre, under the close supervision of Freud's daughter (Fonagy and Target 1996). Children with certain disorders (e.g., depression, autism, conduct disorder) appeared to benefit only marginally from psychoanalysis or psychoanalytic psychotherapy. Interestingly, children with severe emotional disorders (three or more axis I diagnoses) did surprisingly well in psychoanalysis, although they did poorly in once or twice a week psychoanalytic psychotherapy. Younger children derived greatest benefit from intensive treatment. Adolescents appeared not to benefit from the increased frequency of sessions. The importance of the study is perhaps less in demonstrating that psychoanalysis is effective, although some of the effects on very severely disturbed children were quite remarkable, but more in identifying groups for whom the additional effort involved in intensive treatment appeared not to be warranted.

The Research Committee of the International Psychoanalytic Association has recently prepared a comprehensive review of North American and European outcome studies of psychoanalytic treatment (Fonagy et al. 1999; also see <http://www.ipa.org.uk>). The committee concluded that existing studies failed to unequivocally demonstrate that psychoanalysis is efficacious relative to either an alternative treatment or an active placebo, and identified a range of methodological and design problems in the 50 or so studies described in the report. Nevertheless, the report is encouraging to psychoanalysts. A number of studies testing psychoanalysis with 'state of the art' methodology are ongoing and are likely to produce more compelling evidence over the next years. Despite the limitations of the completed studies, evidence across a significant number of pre-post investigations suggests that psychoanalysis appears to be consistently helpful to patients with milder (neurotic) disorders and somewhat less consistently so for other, more severe groups. Across a range of uncontrolled or poorly controlled cohort studies, mostly carried out in Europe, longer

intensive treatments tended to have better outcomes than shorter, nonintensive treatments. The impact of psychoanalysis was apparent beyond symptomatology, in measures of work functioning and reductions in health care costs.

3. Conclusions

Psychoanalytic notions are no longer considered 'outlandish' from the point of view of empirical psychology. New discoveries from the experimental human sciences have yielded much data consistent with psychoanalytic ideas. None of these studies can 'prove' psychodynamic ideas as the two pertain to independent realms of human functioning: the laboratory and the consulting room. However, taken as a whole, they point to the existence of underlying psychological processes posited by psychodynamic theoreticians when offering their model of human development and the pathological outcomes that may arise from it. Psychodynamic theory is unlikely ever to be comprehensively validated in empirical studies. All that we can hope for is that the general model of a person, painstakingly assembled on the basis of neuropsychological, social, and cognitive-psychological investigations, will not be too dissimilar from the vision of human functioning which has emerged from the clinical endeavors of psychodynamically oriented practitioners.

Psychoanalysis in Sociology

Psychoanalysis, as developed by Sigmund Freud and his followers, has had a major impact upon sociological theory and modern sociology. Freud's central

discoveries—the unconscious, sexual repression, the Oedipus complex, and the like—have been deployed by sociologists to interpret and discuss the self and human subjectivity, gender and sexuality, the family and socialization, language and ideology, as well as the formation of cultural identities and forms of political domination. Notwithstanding this impact, sociology as a discipline has long had a difficult, and indeed fraught, relationship with psychoanalysis. Sociologists have criticized psychoanalytical theory on the grounds of its methodology, epistemology, and ontology. Despite these criticisms, many contemporary sociologists remain engaged with, and some strongly committed to, the psychoanalytic tradition in order to conceptualize the relation between the individual and society, especially the complex, contradictory ways that human subjects acquire and reshape the ideas, values, symbols, beliefs, and emotional dispositions of the wider society. This has been particularly evident over recent decades, in which Freudian themes and psychoanalytic motifs have been used to analyze sexual politics, issues of identity and lifestyle, as well as the debate over modernity and postmodernism.

1. Freud and the Sociological Imagination

Freudian psychoanalysis shares with sociology a primary preoccupation with the fate of the individual or self in the context of social relationships and the wider cultural process. While Freud's own writings were primarily derived from his clinical work with patients, and to that degree are at variance with the core methodologies of mainstream social science, his characterization of human personality and self-identity has clear parallels with, say, Thomas Hobbes' theory of human nature or Karl Marx's account of the self-seeking individual in organized capitalist society. Yet whereas both Hobbes and Marx stress the impact of social forms in the constitution of the self, Freud's methodological starting point is the individual psyche, principally the instinctual impulses and libidinal longings that shape the human imagination. The self for Freud is radically fractured or divided, split between consciousness of identity and the repressed unconscious. The biographical trajectory of the self, according to Freud, is carried on against the backdrop of this radical otherness of the unconscious, a domain of the psyche that infuses three agencies of the psyche: id, ego, and superego. The id, lying at the root of unconscious desire, is that which cannot be symbolized yet constantly strives for expression in our daily lives, manifesting itself in dreams, day-dreams, slips of the tongue, and the like. It is a hidden area of the self which knows no reality, logic, or contradiction; the unconscious is at the root, says Freud, of how people for example can simultaneously love and hate their

parents. The superego, as internal anchoring of cultural prohibition, is founded in this id. Desire, according to Freud, infiltrates all human intentions, ideals, and imperatives. Similarly, Freud sees parts of the ego as interwoven with the force of the id, the self arising as a product of the unconscious.

While Freud's writings on human personality and the constitution of the self have proven of interest to sociologists, it is his account of the relations between self and society—primarily his late writings on civilization—that has most influenced the development of modern sociology. In his late writings, Freud comes to see human beings living under the destructive force of a terrifying death drive, as well as strict cultural prohibitions on sexual desire and enjoyment. These themes are set out in his magisterial books *Beyond the Pleasure Principle* (1920) and *Civilization and its Discontents* (1930). Civilization, writes Freud, is repressive. Society imposes severe psychic demands upon individuals to achieve cultural conformity, demands that produce intense personal misery and neurotic suffering. Some sociologists have interpreted this aspect of Freud's sociology as at one with the conservative social thought of Hobbes, likening it to the theorem that cultural reproduction demands the overcoming of chaotic passion. But it is clear that this involves a radical misunderstanding of Freud's position. The dualisms that Freud uses to analyze modern civilization (consciousness/unconscious, desire/repression, the pleasure principle/the reality principle, Eros/Thanatos) suggests a disjunction between self and world. According to Freud, ambivalence is at the core of the individual's relation to the self, to others, and to society.

Freud's writings on the fate of the self in contemporary culture have strongly influenced sociological debates—from Herbert Marcuse to Michel Foucault. Too much repression, Freud says, leads to intense unconscious anguish, hostility, and rage. At such a point, the intensification of unconscious desire can release the 'mental dams' of sexual repression in a far-reaching way. The issue of the subjective seeds of social and political transformation are thus at the heart of Freud's theoretical contribution to sociology and social theory.

2. The Integration of Psychoanalysis and Sociology

With regard to social analysis and sociological theory, Freudian ideas have loomed large in the sociological conceptualization of human subjectivity and interpersonal relationships, sexuality and modern culture, as well as the mix of reason and irrationality in politics and history. There have been three key sociological developments in this connection: first there has been several early and influential articulations of psycho-

analysis and sociology developed in Europe (particularly as represented in the work of the Frankfurt school of sociology) and North America (especially in the writings of Talcott Parsons); second, structuralist and poststructuralist appropriations of psychoanalysis as refracted in sociological debate; and finally, feminist and postmodern social theory has been significantly shaped by psychoanalysis.

2.1 Early Disciplinary Articulations

In Europe, Herbert Marcuse and Theodor Adorno—leading members of the Frankfurt school of critical theory—turned to Freud in order to reconceptualize the relation between self and society. The political motivation prompting this turn to Freud had its roots in Marcuse's and Adorno's attempts to conceptualize the rise of fascism, Nazism, and also the spread of bureaucratic capitalism. From Freud's theory of the Oedipus complex, and particularly his theorem concerning the repression of infantile sexuality, Marcuse and Adorno developed the notion of 'the authoritarian personality.' Driven by a desire for conformity and clear rules, the authoritarian personality was viewed by Marcuse and Adorno as a character type strongly prevalent in the German middle classes, a character type who hungered for strong leadership, social order, and regulation. Not only in Nazi Germany, however, was this personality type to be found; in the advanced liberal societies of the West, tendencies towards authoritarianism and conformism are increasingly evident. Marcuse thus spoke of the emergence of 'one-dimensional man.'

Marcuse's radical Freudianism, in particular, won a wide audience in the 1960s—not only in social science circles, but among student activists and sexual liberationists. Arguing that the so-called 'sexual revolution of the 1960s' did not seriously threaten power structures of the established social order, Marcuse sought to show how demands for freedom were routinely rechanneled for commercial interests. The core of his analysis rested upon the distinction he drew between basic and surplus repression. Basic repression he defined as the minimum level of psychological renunciation demanded by the social structure and cultural order. Repression that is surplus, by contrast, refers to the intensification of self-restraint demanded by asymmetrical relations of power. Marcuse describes the 'monogamic-patriarchal' family, for example, as a site of surplus repression. Interestingly, while Marcuse saw signs of surplus repression increasingly everywhere in late capitalist society, he remained remarkably optimistic about the possibilities for social and cultural change.

On the other side of the Atlantic, a different approach to the integration of psychoanalysis and sociology was fashioned. The core thematic of this

approach concerned social order, socialization, and the reproduction of the social system. The grand theorist of American sociology, Talcott Parsons, employed Freudian ideas to understand how basic symbols and values are internalized by human subjects throughout the socialization process. According to Parsons's appropriation of Freud for social theory, the structure of human personality is an outcome of an internalization of desired objects, role relationships, and ethico-cultural values that make up the broader social network. In this approach, it is the linkage of personality structure, the social system, and the cultural system that is stressed. Unlike Marcuse's and Adorno's emphasis on the social manipulation of the unconscious, Parsons finds a kind of pre-established harmony between the individual and society.

2.2 *Structuralist and Poststructuralist Psychoanalytic Sociology*

For many years the integration of psychoanalysis and social analysis developed by the Frankfurt school was commonly regarded as the most sophisticated and important work in this subfield of modern sociology. From the late 1960s onwards, however, the impact of French theory, particularly structuralist and post-structuralist philosophy, became increasingly influential in terms of theorizing the social dimensions of psychoanalysis. The key figure in this connection was Freud's French interpreter, Jacques Lacan. Seeking to rework the core concepts of psychoanalysis in the light of modern linguistics, Lacan argued that the unconscious exemplifies key features of language; as Lacan famously argues, 'the unconscious is structured like a language.' The subject or 'I,' according to Lacan, is not self-transparent, but is rather located in a system of signification from which identity is fashioned. For Lacan, intersubjectivity is at the center of psychological functioning and its disturbances; distortions or pathologies at the level of the self are, says Lacan, located in 'the discourse of the other.'

It is perhaps Lacan's essay 'The mirror stage as formative of the function of the I' (1949) that has come to exert most influence on contemporary sociological theory. In the essay, Lacan conceptualizes the small infant's initial recognition of itself in a mirror or reflecting surface, and of how this generates a sense of identity. Through the mirror, says Lacan, the infant makes an imaginary identification with its reflected image, an identification which the infant reacts to with a sense of jubilation and exhilaration. But the mirror image of the self for Lacan is, in fact, a distortion; the mirror lies. The mirror stage is radically 'imaginary,' in Lacan's theorization, since the consolingly unified image of selfhood which it generates is diametrically opposed to the bodily fragmentation and lack of coordination of the child. These imaginary traps and distortions are a universal and timeless feature of self-organization, and Lacan sees such illusions as directly

feeding into and shaping pathologies of the self in contemporary culture.

Lacan was not especially interested in the social applications of psychoanalysis; it was one of his followers, the French Marxist political philosopher Louis Althusser, who brought Lacanian theory into the center of key debates in sociology. In his important essay '*Ideology and Ideological State Apparatuses*' (1971), Althusser analyzed ideology in terms of the process by which individuals come to understand and relate to themselves in a manner which supports dominant class relations. According to Althusser, ideology provides an imaginary identity, an imagined map for locating oneself in the wider social network. Echoing Lacan, Althusser uses the notion of the mirror stage to deconstruct ideology. There is a duplicate mirror-structure at the heart of ideology says Althusser, a structure that grants to the self an ideological mirror in which it can recognize itself and other people. Althusser calls this process 'interpellation'—the capturing of the individual within the net of received social meanings.

The Lacanian/Althusserian account of the de-centering of the subject has been highly influential in recent sociological theory, and has impacted upon debates concerning agency, structure, class, social fragmentation, and cultural order. The social-theoretical work of Paul Hirst, Barry Hindess, Stuart Hall, Etienne Bailbar, Pierre Machery, Fredric Jameson, and Slavoj Žižek is, in differing ways, indebted to the Lacanian/Althusserian theory of the subject and its ideological subjection.

2.3 *Feminism, Postmodernism, and Psychoanalytic Sociology*

It is not only in studying politics and social change that psychoanalysis has become an important theoretical tool for sociology, but also in debates concerning gender and sexual politics. Freudian ideas have been incorporated into social theory. In the sociology of sexuality, the sociology of the family, and especially the social theory of gender transformation, Freudian psychoanalysis has played a vital role in expanding sociologists' understanding of the subjective and affective components of human social relationships.

The psychoanalytic perspective made a forceful entry into contemporary feminist sociological theory in Juliet Mitchell's pioneering book, *Psychoanalysis and Feminism* (1974). Mitchell deployed Freudian and Lacanian psychoanalytic ideas as a means of connecting a discussion of gender power with an Althusserian/Marxist theory of late capitalist society. Against this theoretical backdrop, she asserted that definitions of masculinity and femininity are framed through linguistic and historical structures—with man as a self-determining, autonomous agent, and woman as a lacking other. Such gender dualism, according to Mitchell, is highly conducive to capitalist social

regulation—the split between private and public, the pathologies of the familial life, and the like. Mitchell's ideas, while criticized in some feminist sociological circles, had a lasting impact on psychoanalytically-oriented feminist sociology. Especially in terms of Lacanian feminist approaches, the writings of authors such as Julia Kristeva, Luce Irigaray, Jacequeline Rose, and Judith Butler have significantly influenced sociological debate in recent years.

In the United States, the feminist theories of Nancy Chodorow, Jessica Benjamin, and Jane Flax have been influential in contemporary sociology. These feminist authors draw from the psychoanalytic perspective, but rather than turn to Lacan and French psychoanalysis their work selectively incorporates the insights of Freudian and post-Freudian (especially object-relational) theory. In Chodorow's work, it is part of an attempt to understand the psychic components of female and male socialization, especially in terms of the unconscious forces that shape gender roles. In Benjamin's work, psychoanalysis is deployed to rethink the dynamics of domination and submission within the wider frame of gender, society, and history. In Flax's discussion of psychoanalysis, feminism, and postmodernism, it is primarily a set of philosophical observations about the development of gender relations and the sociology of sexuality and intimacy.

Related to the intertwining of psychoanalysis and feminism, postmodernist appropriations of psychoanalysis have also been influential in recent sociological interventions. This has been especially true for the contested modernity/postmodernity debate, in which sociologists as diverse as Anthony Giddens, Alain Touraine, and Zygmunt Bauman have drawn from Freud to analyze anew the self and self-identity. In the writings of Michel Foucault, Jean-François Lyotard, and Jacques Derrida, which have also had a strong influence on sociological theory, there has been much debate about the fate of the individual or 'death of the subject' in postmodernist culture. In all of these discussions, psychoanalysis has provided sociology with conceptual tools for questioning and deconstructing the enlightenment and rationality of progress.

Psychoanalysis: Overview

By psychoanalysis is generally understood, in the first instance, the psychological theory and corresponding clinical practice developed by Sigmund Freud in the first four decades of the twentieth century, and in most usage the term refers also to at least some of the developments that proceed directly from Freud, such as Jungian, Kleinian, and Lacanian theory, though the proper boundaries of psychoanalysis are hard to mark and subject to dispute. This article will, after a brief sketch of Freud's development, survey the principal theoretical issues raised by psychoanalytic theory, the main developments in psychoanalysis after Freud, and the relation of psychoanalysis to other fields of human enquiry.

1. Freud's Life and Writings

Freud was born of a Jewish family in Freiberg (now in the Czech republic) in 1856. He qualified as a physician at the University of Vienna, becoming early involved in neurological research under the tutelage of the physiologist Ernst Brücke, a positivist and Darwinian. After three years of medical practice at the General Hospital in Vienna, Freud received an appointment as lecturer in neuropathology. A period spent at the Salpêtrière in Paris exposed Freud to the French neurologist Jean Charcot's use of hypnotherapy to treat mental disorder. In 1886 Freud set up in private practice in Vienna, applying Charcot's methods, and in 1893 he published with the Viennese physician Josef Breuer *Studien über Hysterie* [*Studies on Hysteria*], an account of the use of hypnosis to effect the cathartic recall of forgotten traumatic experience, underpinned by a schematic theory of mental dissociation. This led Freud to attempt to formulate a general theory of mental functioning in strict neurological terms, his

'Project for a scientific psychology' of 1895, which he abandoned without completing. Thereafter, Freud concentrated on the analysis of clinical material provided by his patients and undertook a self-analysis. The explorations of these years led to the publication in 1900 of *Die Traumdeutung* [*The Interpretation of Dreams*], Freud's first full statement of psychoanalytic ideas. Here Freud defended the substitution of free association for hypnosis as a clinical method. Over the following decade Freud published *Zur Psychopathologie des Alltagslebens* [*The Psychopathology of Everyday Life*] (1904) and *Drei Abhandlungen zur Sexualtheorie* [*Three Contributions to the Theory of Sexuality*] (1905), and began to acquire a following, leading to the founding in 1910 of the International Psychoanalytic Association. The spread of psychoanalysis in Europe and the United States was accompanied by internal disagreement and the formation of alternative schools, most notably those of Alfred Adler and Carl Jung. Freud's later writings focused on theoretical questions and the application of psychoanalysis to cultural issues. Forced by the Anschluss to flee Austria, Freud died in London in 1939. (Jones 1953–7 and Gay 1988 are classic intellectual biographies of Freud. Decker 1977 analyses Freud's intellectual historical context.)

2. Fundamental Conceptual Issues in Psychoanalytic Theory

Though subject to fierce criticism from many quarters, Freud's theories achieved over the course of the twentieth century a massive degree of influence in all of the humanities and human sciences, and contemporary publication suggests that their power to stimulate is by no means exhausted. The theoretical dissemination of psychoanalytic ideas far exceeds the prevalence of psychoanalysis as a clinical practice: though institutes of psychoanalysis are established and thrive in most Western countries, psychoanalytic therapy has been consistently repudiated by the medical establishment and accorded no recognized place in psychiatric treatment. The greater clinical influence of psychoanalysis has been achieved through dilution, its transmutation into less demanding and theoretically committed forms of treatment: psychotherapy in its myriad contemporary forms, though it most often represents itself as wholly distinct from psychoanalysis, is barely conceivable without its historical relation to Freud.

Both the influence exerted by psychoanalysis and the chronic controversy surrounding it are closely connected to the highly ambiguous, indeterminate status of psychoanalytic theory, reflected in the host of epistemological, methodological, and conceptual problems which it sets. Freud presented his theories, which he revised constantly, in terms that display very

clearly the importance for his development of diverse strands in nineteenth-century thought, including philosophy and a number of the natural sciences (Darwinian biology, sexology, evolutionary anthropology, brain anatomy, associationist psychology; see Sulloway 1979 and Kitcher 1992). Furthermore, the range of phenomena that Freud regarded psychoanalysis as subsuming grew continuously, from specific forms of individual pathology (hysteria, neurosis) and abnormal psychological explananda (dreams, parapraxes) to mental functioning in general, and thence to morality, religion, art, and the social order. These factors—the continual development and interdisciplinary scope of Freud's theories, and the heterogeneity of the theoretical sources on which Freud drew—help to account for the paradoxical appearance that psychoanalysis gives of being at once an attempt to extend naturalistic, mechanistic, and reductionist modes of explanation to the human sphere, and a hermeneutical enterprise fundamentally more akin to literary criticism and philosophical reflection than to biology.

The conceptual indeterminacy of psychoanalytic theory may be analyzed under three headings.

2.1 The Structure of Psychoanalytic Theory

Though Freud appealed increasingly to the application of psychoanalytic ideas to social and cultural phenomena as a source of corroboration, and some post-Freudian developments have sought to shift the emphasis in this direction, psychoanalytic theory is primarily a theory of individual mental functioning. There is, therefore, a basic distinction to be drawn between the trans-individual applications of psychoanalysis and the psychoanalytic theory of the individual mind, which has logical priority in all contexts of psychoanalytic explanation.

The psychoanalytic theory of the individual mind may be divided for analytical purposes into three levels: the clinical level at which interpretations of individuals are formulated and case histories composed; low-level hypotheses concerning particular kinds of psychological configuration, such as Freud's theories of psychosomatic hysterical disorders, obsessional neurosis, psychosis, mourning and melancholia, disturbances of memory, sexual orientation, formation of male and female identity, and character types; and the highest, unifying level of psychoanalytic theory, called by Freud 'metapsychology,' consisting of abstract, semiphilosophical assumptions about the nature and general form of the mind.

At the center of the metapsychology is Freud's concept of the dynamic unconscious. The notion of the unconscious had an important place in nineteenth-century thought (Ellenberger 1970, Whyte 1979), versions of the concept being discoverable in philos-

ophers such as Arthur Schopenhauer, Friedrich Nietzsche, and Eduard von Hartmann, and in the nascent empirical psychology of Friedrich Herbart, Gustav Fechner, Hermann von Helmholtz, and Wilhelm Wundt. Occurrences of the concept of the unconscious in nineteenth-century writings tended, however, to be either theoretically undeveloped (as in Schopenhauer), or to play a merely ancillary role in metaphysical speculation (as in Hartmann), or to be qualified by uncertainty regarding the reference and explanatory value of the concept (as in the empirical psychologists). Freud may be said to have given the concept a fully scientific character, insofar as he both brought the philosophical conception of the unconscious into close relation with problems of psychological explanation and gave the concept a theoretical and empirical determinacy which it lacked previously.

Freud conceived the unconscious as an instinctually grounded source of motivation which is directly responsible for the ubiquity of conflict in normal mental life and substantially independent from cognition in its mode of operation. The nature of unconscious mental activity is explicated through Freud's theories of wish-fulfillment, of primary (as opposed to secondary) process thinking, and of the pleasure (as opposed to the reality) principle, these theories being closely associated with a developmental story. Though Freud asserted the autonomy of psychological characterizations of the unconscious from neurological speculation in *The Interpretation of Dreams*, and always claimed that the unconscious is composed of 'ideas' rather than somatic states, i.e., that it has an intentional character, at all periods of his development Freud regarded 'economic' descriptions of mental life—descriptions in terms of quantities of neural energy—as also essential to the metapsychology. Psychoanalytic theory thus incorporates suggestions of both dualism and physicalist reductionism.

Within this framework, the metapsychology underwent continual modification, the most important development being Freud's move from an account that ties the existence of the dynamic unconscious directly to repression—the first topographical model of *Ucs.*, *Pcs.*, and *Cs.*, articulated in Freud's metapsychological papers of 1915—to the structural model of ego, id, and superego presented in *Das Ich und das Es* [*The Ego and the Id*] (1923), according to which the unconscious is aboriginal, and distributed across the major portion of the ego as well as the id. Whereas the first model implies that unconscious mentality is created only through aberrations in conscious mental life, which remains the core of subjectivity, the second model implies that consciousness requires a special 'making conscious' of mental states and that human subjectivity by its nature extends beyond consciousness. The structural model may thus be argued to impact in a quasi-philosophical manner on the traditional and commonsensical conception of the self or

person. (For scholarly expositions of Freud's metapsychological concepts, see Laplanche and Pontalis 1967.)

Though Freud's own writings stress the interdependence of the three levels, there is some vacillation in Freud between regarding the metapsychology as the crowning and defining achievement of psychoanalysis, and reducing it to a mere superstructure that might be radically overhauled and is replaceable, in principle if not in practice, by neurological science. Questions may thus be raised concerning the relations of the three levels, and in this context various possibilities present themselves. Psychoanalysis may be identified with either a theoretical edifice offering a general, philosophically significant model of the mind; or a cluster of lower-level theories aiming at the formulation of psychological laws in specific subdomains of psychology; or an accumulated body of case studies of individuals serving primarily to specify a therapeutic technique. These options—in numerous variations and combinations—have been defended and explored by theorists in close connection with different views of the epistemological foundations of psychoanalysis.

2.2 Epistemological and Methodological Issues

Because of the physicalist–reductionist strain in psychoanalysis, and the positivistic character of the conception of knowledge appealed to by Freud in his claims for the scientificity of psychoanalysis, there has been a natural (and, in the English-speaking world, dominant) tendency to consider the question of the empirical warrant for psychoanalytic theory in the context of scientific methodology. This mode of approach to psychoanalysis is associated with a negative estimate of the objectivity and cognitive value of psychoanalysis.

Two major writings in this sphere are Karl Popper (1963, Chap. 1) and Adolf Grünbaum (1984). Popper conducted an enormously influential attack on psychoanalysis in the course of defending falsifiability as the key to scientific method. According to Popper, psychoanalysis does not open itself to refutation, and so fails to satisfy the condition of falsifiability which, in his account, provides the necessary and sufficient condition for determining the scientific standing and candidacy for rational acceptability of a theory. In view of its immunity to counterevidence, Popper holds, psychoanalysis must be classified (alongside Marxism) as a 'pseudo-science.' Grünbaum, operating with a different conception of scientific method, maintains in opposition to Popper that psychoanalysis does meet the conditions for evaluation as a scientific theory, but proceeds to offer a detailed critique of what he takes to be Freud's inductive reasoning. Freudian theory reposes, Grünbaum argues, on the claims that only psychoanalysis can give correct

insight into the cause of neurosis, and that such insight is causally necessary for a durable cure. Grünbaum then emphasizes the empirical weakness of psychoanalysis' claim to causal efficacy, and presses the frequently voiced objection that the therapeutic effects of psychoanalysis may be due—for all that Freud is able to demonstrate to the contrary—to suggestion. Grünbaum argues further that, even if the clinical data could be taken at face value, the inferences that Freud draws are unwarranted.

Different conceptions of science carry different implications for the epistemological status of psychoanalysis, and a sufficiently anti-rationalistic conception of science, such as Paul Feyerabend's, may succeed in eliminating the epistemological discrepancy between psychoanalysis and the natural sciences; but this strategy carries obvious costs. It is generally agreed that, without repudiating altogether the concept of a distinctive scientific method in the manner of Feyerabend, the prospect of defending the epistemological credentials of psychoanalysis in the terms supplied by the philosophy of natural science is poor. Attempts to test psychoanalytic hypotheses experimentally in controlled, extraclinical contexts have been inconclusive (see Eysenck and Wilson 1973). The comparison with cognitive science, which has successfully claimed for itself empirical support, may appear to aggravate the epistemological situation of psychoanalysis. (For discussion of psychoanalysis' scientificity, see Hook 1964 and Edelson 1984.)

An alternative approach to the epistemological issue is to abandon the assumption that psychoanalysis must be shown to conform to the model of explanation of the natural sciences in order for it to be held to have cognitive value. This involves breaking with Freud's own understanding of psychoanalysis, but it may draw support from the fact that Freud also on numerous occasions emphasizes the alignment of psychoanalysis with, and its dependence on, commonsense principles of reasoning: the everyday assumptions about the mind that are embedded in commonsense ('folk') psychology.

A diversity of approaches falls under this heading, but they share agreement that the right way to understand psychoanalysis is to regard it as reworking the routes of psychological understanding laid down in our ordinary, everyday grasp of ourselves, and validated independently from scientific methodology.

Some philosophers, encouraged by Ludwig Wittgenstein's writings on the philosophy of psychology and remarks on Freud (Wittgenstein 1978), explored the notion that psychoanalytic explanation trades off the concept of a *reason* rather than that of a cause, and tried to suggest that psychoanalytic interpretation is directly continuous with the practice of explaining agents' actions by citing their reasons. Though psychoanalysis is thereby freed from the burden of having to appeal to strict causal laws, the epistemological grounds of which prove so problematic, an evident

difficulty faces this approach, arising from the tension between the assumption of the agent's rationality which is presupposed by the very application of the concept of a reason, and the nonrational or irrational character of the mental connections postulated in psychoanalytic explanation. The resulting concept of 'neurotic rationality' employed by some philosophers reflects this discomfort.

However, more satisfactory solutions along these lines can be developed by making the relation of psychoanalysis to commonsense psychology less direct. One such approach regards psychoanalysis as a *theoretical extension* of commonsense psychology. It is argued that the familiar schema of practical reason explanation, formalized in the practical syllogism, is in psychoanalytic explanation fundamentally modified by the substitution of the concepts of wish and fantasy for those of belief and desire, and by the replacement of a direct, intrapsychic relation between desire and mental representation for the syllogistic relation between practical reasoning and action. The basis for assigning content and explanatory role to wishes and fantasies—thematic linkages, relations of meaning—remains, however, the same. Melanie Klein's development of Freud's theories, which attributes enormous importance to the role of fantasy in mental life, is standardly appealed to by proponents of this approach. In this view, the overarching epistemological ground for psychoanalysis lies in its capacity to offer a unified explanation for phenomena—dream, psychopathology, mental conflict, sexuality, and so on—that commonsense psychology is unable or poorly equipped to explain (see *Irrationality: Philosophical Aspects*), while exploiting the same interpretative methodology as commonsense psychology and complementing commonsense psychological explanations. (See Wollheim 1974, 1991, Wollheim and Hopkins 1982, Hopkins 1992, Neu 1991, Cavell 1993, Levine 1999.)

An alternative epistemological route from commonsense psychology to psychoanalysis is to proceed by way of *philosophical theory*: given an independently elaborated philosophical theory of psychoanalytically relevant aspects of human subjectivity, intersubjectivity, and representation, it becomes possible to interpret psychoanalysis in the terms provided by this theory and thereby extend to psychoanalysis whatever cognitive authority the theory possesses. Proponents of this approach typically draw on different philosophical traditions from the commonsense-extension theorists, whose philosophical allegiances characteristically reflect a mixture of empiricism and Wittgenstein. (The two approaches are, however, not necessarily incompatible.)

Jürgen Habermas and Jacques Lacan provide two clear examples of this mode of approach. Habermas' (1968, Chaps. 10–11) hermeneutic account asserts a complete separation of psychoanalysis from the natural sciences, this association being attributed to a

naturalistic and scientific misconception of psychoanalysis on Freud's part, and seeks instead to integrate psychoanalysis with communication theory and to set it in the context of a nontraditional conception of rationality and cognitive interest. The unconscious and its symbolism are understood by Habermas in terms of specific forms of distortion of communication and interruptions to self-communication; psychoanalytic interpretation and treatment are understood correspondingly as directed to retrieving elements that have suffered exclusion from the field of public communication, and to engendering a form of self-reflection that will undo self-alienation and thereby emancipate. (Ricoeur 1965 offers an alternative hermeneutic approach.)

Lacan's reading of Freud (see Evans 1996) evinces a similar methodological structure: a general theory of subjectivity and representation, in Lacan's case deriving from multiple sources including Ferdinand de Saussure and G. W. F. Hegel, is employed to elucidate psychoanalytic concepts. The concept of the unconscious is explicated by Lacan in terms of paradoxes arising necessarily from the attempt to represent the self and its objects, and constraints put on interpersonal desire by its symbolic mediation, while Freud's theories of the nature of unconscious mental processing are recast in terms borrowed from structural linguistics.

2.3 Further Theoretical Issues

An issue that has plagued psychoanalysis since its inception concerns the conceptual possibility of mental phenomena being unconscious. Nineteenth-century philosophy of psychology raises frequently the question whether the posit of unconscious mental phenomena is warranted or even intelligible, Franz Brentano for example devoting to it a chapter of his *Psychologie vom empirischen Standpunkte* [*Psychology from an Empirical Standpoint*] (1874). Freud's own response was to emphasize the dogmatism of those who reject the notion of unconscious mental phenomena in advance of considering what explanatory gains may be made by employing it, these being of course, in Freud's view, decisively favorable. It is fair to say that beyond this point little progress has been made with the problem, which to that extent remains without a satisfactory solution. This does not, however, constitute a serious embarrassment for psychoanalysis, since the identity of mental phenomena with consciousness maintained by opponents of psychoanalysis is as hard to supply with a philosophical proof as the concept of unconscious mental phenomena is hard to make intuitively acceptable. The issue has in any case been largely overtaken, or at any rate moved down the contemporary philosophical agenda, by the confident

positing of unconscious mental processing witnessed by Noam Chomsky and cognitive psychology.

In its place a new question has emerged concerning what it may mean to speak of mental content which is prelinguistic, unconceptualized, or nonpropositional. Psychoanalytic theory, most markedly in its Kleinian development but also in Freud, appears to require the existence of such content, in view of what it claims about the mental life of infants and primary process thinking. The opposition here is between those who wish to take such talk at face value, as referring to mental states with no less reality than the beliefs and desires attributed in commonsense psychology, and those who regard it as violating *a priori* conditions on the possession of mental states, and are consequently obliged to either reject or offer nonrealistic readings of psychoanalytic accounts of the infant's mind and primary process (Cavell 1993). The prominence of this issue in contemporary discussion of psychoanalysis reflects the continuing shift in twentieth-century philosophy, also evidenced in Habermas's and Lacan's reconstructions of psychoanalysis, away from Cartesianism towards a consideration of mental states in terms of their conditions of attribution and thus in relation to language.

A further set of questions regarding the nature of psychoanalysis is raised by the recent ascent of cognitive science (see *Cognitive Science: Philosophical Aspects*). Freud's unpublished *Project* allows itself to be recast in contemporary, computational terms, and it has been argued that the same sort of reconstruction should be applied to Freud's properly psychoanalytic theories. This would open up the possibility of integrating psychoanalytic theory with the models and hypotheses of present-day cognitive psychology, and further theoretical integration with evolutionary psychology may also be envisaged.

This raises the conceptual question whether psychoanalysis is essentially a subpersonal psychological theory, or whether it is as much a theory of the fully personal level as commonsense psychology. The former is necessary if there is to be direct theoretical integration of psychoanalysis with cognitive psychology; if psychoanalysis is a personal-level psychology, then its relation to cognitive psychology will prove as problematic as that of commonsense psychology. Examination of Freud's writings shows that the question is hard to answer. On the one hand, a move in the direction of subpersonality would appear to be implied in the explanatory shift away from consciousness, and to be required if psychoanalysis is to succeed in offering explanations where commonsense psychology gives out. On the other hand, to regard unconscious motivation and content as on a par with involuntary bodily processes, and as no more intrinsically tied to the self or subjectivity than a neural event, would appear to reflect a deep misunderstanding of the nature and purpose of psychoanalytic explanation. Plausibly, psychoanalysis needs

to be read as containing both personal and sub-personal elements, but to say this is, of course, still to leave the matter unclear.

Questions of possible theoretical integration aside, cognitive psychology poses an epistemological challenge to psychoanalysis. If cognitive psychology should prove capable of explaining the same set of explananda as psychoanalysis, and if its explanations are not isomorphic with those of psychoanalysis, then psychoanalytic theory would lose its claim to explanatory value: Freudian theory would simply have been supplanted, and the commonsense-extension theorist's defense of psychoanalysis would collapse. In such circumstances the only prospect of legitimating psychoanalytic theory would lie in allying the theory with some anti-naturalistic philosophical outlook. Critics of psychoanalysis who share Popper's misgivings about psychoanalysis' scientificity, and those who believe that Freud remained too close to commonsense psychology and failed to carry through a sufficiently strict program of scientific naturalism in psychology, regard this *dénouement* as the most likely.

As this section has shown, discussion of psychoanalysis is inseparable from a multitude of broad philosophical issues: it cannot be maintained that psychoanalysis is unproblematically grounded on experience, nor that there is any one self-evidently correct reading of the conceptual structure of psychoanalytic theory. No other major psychological theory finds itself in the same position. Consequently, even if it is agreed that psychoanalysis should be removed from the context of the philosophy of science, no determinate account of the nature or epistemology of psychoanalytic theory can be arrived at without importing general philosophical commitments. The inevitable result is that the estimation of psychoanalytic theory is embroiled with a number of fundamental philosophical antinomies, above all the conflict between scientific naturalism and anti-naturalism in philosophy and the human sciences.

3. Post-Freudian Developments in Psychoanalytic Theory

The vast range of developments of Freud's ideas may be roughly distinguished into those that attempt an explicit synthesis of psychoanalysis with some other body of theory in the human sciences and those that seek to remain within the terms of Freud's specifically psychological program, aiming either to carry forward Freud's own theories, or to formulate rival, non-Freudian forms of psychoanalysis.

The former will be surveyed in the next section. Post-Freudian developments of the latter kind (see Eagle 1984, Frosh 1987) have in some cases been driven by purely theoretical considerations, reflecting particular views of the relation of the clinical to the theoretical components in psychoanalysis, of the

relation of psychoanalytic theory to the natural sciences, and of the epistemology of psychoanalysis. Instances include the attempts of American theorists such as Merton Gill, Karl Pribram, Emmanuel Peterfreund, David Rapaport, and B. B. Rubinstein to reconstruct Freud's metapsychology in the terms of the natural sciences or to discard it altogether; and, at the opposite end of the spectrum, the endeavors of Jean-Paul Sartre and Ludwig Binswanger to re-express what they take to be Freud's central insights in a philosophical idiom wholly purified of naturalistic elements, 'existential psychoanalysis.'

The more fruitful and influential post-Freudian developments in psychoanalytic theory, however, have taken place in close association with clinical work, and thus engage with Freud's empirically significant, low-level hypotheses, as much as with his metapsychology. The earliest instances are provided by Freud's dissenting contemporaries (see Brown 1961). Jung's 'analytical psychology' disputes Freud's view of the importance of sexuality, and more fundamentally asserts the direct and determining participation in psychic life of unconscious mental contents with a wholly impersonal content and origin, psychological 'archetypes' composing a 'collective unconscious' (see Nagy 1991). Again, Adler's monistic interpretation of human behavior in terms of responses to feelings of inferiority, and Otto Rank's theory of the trauma of birth as the source of mental disorder compete directly with Freud's view of the determinants of mental life.

Only Jung succeeded in founding a school of psychoanalysis that is fully independent of Freud; the ideas of Adler, Rank, and other early figures in the psychoanalytic movement, such as Sandor Ferenczi, were instead either discarded or incorporated into later developments in Freudian theory. The most presently active traditions in psychoanalytic thought are those of Lacan, Klein, and the school of ego psychology which descends from Anna Freud. These schools are geographically anchored in, respectively, France, Britain, and the United States.

As indicated above, the tendency in Lacan's reading of Freud is to raise psychoanalysis to the level of a philosophical discourse, an approach which—encouraged also by the work of Jacques Derrida—has been endorsed by many French philosophers (see, e.g., Henry 1985) and literary theorists who have made use of Lacanian ideas. While some elements in Lacan, such as his claim that the unconscious is structured like a language, may be regarded as reconstructive, other parts of Lacanian theory, such as his account of the infant as acquiring its ego through imaginary identification with a mirror image, offer novel extensions to Freudian theory. Other theses of Lacan's, such as his conception of psychoanalytic treatment as directed towards the acceptance of a fluid self-identity rather than firmly integrated ego, and his view of human discontent as deriving from the metaphysics of

subjectivity rather than the hedonic costs of renouncing instinctual gratification, seem indisputably revisionary.

The Kleinian development of Freud, referred to also as the British school of object-relations, rests on an innovation in clinical practice. The psychoanalysis of children undertaken by Klein greatly expanded the body of data available to psychoanalytic theory. On the basis of the new evidence concerning the mental life of very young children afforded by her employment of the play technique, Klein hypothesized that relations to external objects are standardly—in childhood and throughout adult life—facilitated and mediated by representations of objects in fantasy. On that basis Klein developed a synchronic and diachronic model of the mind as incorporating a fantasized ‘inner world’ composed of ‘internal figures’ and exhibiting certain key structures (called by Klein the ‘depressive’ and ‘paranoid-schizoid positions’) and patterns of activity (splitting, projective identification) determining crucial aspects of the subject’s relation to objects in reality (see Segal 1989, Hinshelwood 1990, and *Object Recognition: Theories*). Some aspects of Kleinian theory remain highly controversial—particularly Klein’s affirmation of Freud’s concept of the death instinct, and the richness of the mental life that her account attributes to the child in its first few months of life—but it has been vigorously extended in the post-Kleinian work of Wilfred Bion, Donald Winnicott, Hannah Segal, and others, especially with reference to psychosis (an area largely neglected by Freud) and symbolism (see Anderson 1992).

Ego psychology developed out of work by Anna Freud, whose *Das Ich und die Abwehrmechanismen* [*The Ego and the Mechanisms of Defence*] (1936) sought to shift the emphasis of psychoanalytic interpretation away from the contents of the id toward the modes of operation employed by the ego in its task of mediating the relations of drives to external reality on the grounds that only in this way can the specificity of an individual’s psychology be grasped and addressed therapeutically. (Anna Freud and her followers clashed with Kleinian members in the course of schismatic ‘Controversial Discussions’ held at the London Institute for Psycho-Analysis in the 1940s.) This theoretical reorientation became more pronounced in the work of Heinz Hartmann in the United States, who produced a systematic account of the ego as comprising a sphere of autonomy and as serving the function of adaptation. Later developments stemming from Hartmann include Margaret Mahler’s work on the infant–mother relation and Heinz Kohut’s ‘self-psychology.’

The diversity of post-Freudian schools is frequently cited as an argument against the cognitive value of psychoanalysis. Whether this implies a lack of convergence of the kind that may properly be taken to impugn the objectivity of a theory is, however, a moot point. Plausibly, the diversity of psychoanalytic theory

derives in large part from their adjustment to different therapeutic techniques—entailing different explanatory foci—and at least some of the disagreement that appears to remain may be attributed to differences of formulation rather than of substance (implicit versions of Kleinian ideas, for example, can be detected readily in Lacan and ego psychology). The degree to which different psychoanalytic theories are intertranslatable, and to which consilience may be discovered among the clinical interpretations of differently schooled analysts, has, however, yet to be determined.

4. *The Relation of Psychoanalytic Theory to other Human Sciences*

Wherever the human sciences conceive their object in intentional or semantic terms—that is, in all but the most austere reductionist contexts—the possibility of establishing a continuity with psychoanalytic theory exists and has been explored to some degree; in most of the social sciences, a variety of interfaces with psychoanalysis have been formulated. Freud’s own writings on culture, religion, and social theory—*Totem und Tabu* [*Totem and Taboo*] (1913), *Massenpsychologie und Ich-Analyse* [*Group Psychology and the Analysis of the Ego*] (1921), *Die Zukunft einer Illusion* [*The Future of an Illusion*] (1927), *Das Unbehagen in der Kultur* [*Civilization and its Discontents*] (1930), *Der Mann Moses und die monoththeistische Religion* [*Moses and Monotheism*] (1939)—provide models for the trans-individual application of psychoanalysis but have not been adopted in mainstream social and cultural thinking (similarly Jung, whose exploration of cultural anthropology was more intensive than Freud’s); probably the element in Freud to have most influenced these spheres has been, closer to the psychology of the individual, his theory of moral development (Deigh 1996).

The most extensive applications and developments of psychoanalytic ideas beyond the psychology of the individual have taken place in contexts where psychoanalysis has promised to fill an explanatory lacuna in some other body of theory and vice versa; here the possibility of a genuine synthesis is created.

Marxism found itself in just such a situation, and elicited highly original developments in the critical theory of the Frankfurt school. A basic consonance of Marxism (regarding its theory of ideology, alienation, and the social superstructure) with psychoanalysis is established by their shared concern with the analysis of forces conditioning and limiting rationality and freedom. The theoretical need of Marxism for psychoanalysis derives from the absence from classical Marxist theory of any account of the subjective process whereby ideology is instantiated and rendered effective at the level of the individual. The corresponding need of psychoanalysis consists in its failure to take account of or make conceptual provision for the culturally

variable mediation of human desire and the permeation of sociohistorical conditions to unconscious mental functioning (Freud's insensitivity to the role of cultural variables was asserted early on by psychoanalytic theorists such as Karen Horney).

In this light, the social holism of Marx and the methodological individualism of Freud could be regarded as complementary rather than opposed, and capable of yielding in conjunction a form of social psychology which would unify the instinctual and cultural, and individual and social, dimensions of human existence. Theories that sought such a unification—specifically, a comprehensive theory of capitalism and of features of modernity such as mass culture and fascism—were advanced by Erich Fromm, Wilhelm Reich, Herbert Marcuse, Max Horkheimer, T. W. Adorno, and others (see Held 1980, Chap. 4). Habermas's reading of Freud also belongs to this tradition.

The project of critical theory has been partially recapitulated in the intense preoccupation of feminist theory with psychoanalysis over recent decades (Mitchell 1975 and Chodorow 1978 are early, seminal works). Here the theoretical alliance has been more ambivalent, however. On the one hand psychoanalysis has seemed to offer feminist theorists a unique and necessary theoretical route to a deep understanding of women's subjectivity; no other psychological theory appears to carry a similar promise of allowing a unified understanding of sexuality, gender, and power relations. On the other hand, psychoanalysis has appeared to be antithetical to the purposes of feminism, on account of its reflections of Freud's own patriarchy and conservatism, and the putative biological determinism and essentialism of Freudian theory, whereby existing social relations and identities are universalized. Resolutions to this dilemma have typically taken the form of a partial historicization of Freudian theory (sometimes appealing to the work of Michel Foucault) and an exploration of post-Freudian (especially Lacanian) theory, aimed at constructing a form of psychoanalysis adequately oriented towards the cognitive-emancipatory interests of women.

S. Gardner

Psychobiology of Stress and Early Child Development

Stressors that threaten well-being activate physiological systems that, while fostering immediate survival, can interfere with repair of the body, defense against illness, and development. Two systems play major roles in stress: the sympathetic adrenomedullary (SAM) system that produces adrenaline and other catecholamines, and the limbic-hypothalamic-pituitary-adrenocortical (LHPA) system that produces the steroid hormone cortisol in humans. Of these two systems, the LHPA system exerts slower, more persistent actions, and is often the focus of research on stress physiology. A growing literature indicates that conditions associated with stress, maltreatment and neglect during fetal and early development alter regulation of the LHPA system in ways that could heighten vulnerability later to stress-related disorders. During early life, individual differences in temperament interact with qualities of the caregiving environment to predict cortisol responses to psychosocial stressors. Combined, these growing literatures on normal and atypical development promise to explicate mechanisms through which early experiences affect physical and psychological health.

1. Psychobiology of the LHPA System

Animal studies constitute the bulk of research on this system. Determining their implications for human development is a major challenge. Current perspectives drawn from the animal research will be presented in this section.

Cortisol is the end product of a cascade of events that begins with stimulation of cells in an area of the brain called the hypothalamus. These cells secrete

peptide hormones (CRH and AVP) that, in turn, cause cells in the pituitary gland (once thought of as the master endocrine gland) to produce yet another biochemical, ACTH. ACTH is secreted into the bloodstream where it is picked up by receptors on the cortex of the adrenal glands, stimulating the adrenal to secrete cortisol (Johnson et al. 1992). Humans produce cortisol even when they are not stressed. Nonstressed or basal cortisol production follows a daily rhythm. Like a thermostat, basal levels are maintained through negative feedback loops; the primary feedback sites are located in two areas of the brain, called the hypothalamus and hippocampus. Through multiple pathways in the brain, internal and external threats to well-being cause increased activity in this LHPA system that raise cortisol levels over baseline (de Kloet 1991). Responses to psychological stressors operate through pathways involving an area of the brain called the amygdala that also plays important roles in organizing behavioral reactions to threat. CRH, the peptide that begins the cascade of events that stimulates cortisol production, is produced in many brain areas, including sites such as the amygdala, where it is believed to play a major role in regulating threat reactive behavior and in stimulating both the LHPA and the SAM systems to react to psychological stressors. One major theory relating stress to depression focuses on repeated stressors and the orchestrating role of extra-hypothalamic CRH (Nemeroff 1996). The cumulative impact of stressors on health has been described as allostatic load, or the health-impairing costs of survival-facilitating activity of the LHPA system (McEwen 1998).

Understanding how the LHPA system promotes both health and disease is a core problem in stress research. Both hypo- and hyper-responsivity of the LHPA system are associated with disorder (de Kloet et al. 1998). Disorders of hypo-responsivity include those related to failure to contain immune inflammatory responses and to maintain the responsivity of areas of the brain involved in emotions and information processing; hyper-responsivity disorders include those related to immune suppression, cardiovascular disease, and affective psychopathology. One line of reasoning traces these contrasting impacts through the two types of receptors for cortisol that mediate two modes of the hormone's effects (de Kloet et al. 1998). The first, a 'proactive' or 'permissive' mode, maintains basal activity of the system, regulates the threshold of the system's response to stressors, promotes coordination of the daily rhythm in the hormone, and helps maintain the viability of brain systems involved in selective attention, sensory integration, and response selection. Low levels of circulating cortisol affect this mode through stimulating MR or Type I receptors in the central nervous system. The second, a 'reactive' or 'suppressive' mode, operates through GR or Type II receptors that mediate highly catabolic events promoting increases in energy availability, modulation

of the immune system, and threat-related learning. GRs are occupied increasingly as cortisol rises above basal levels into stress ranges. Both proactive and reactive modes support health and survival. However, the reactive mode, if sustained, threatens health. In the hypothalamus and hippocampus, occupation of GR or Type II receptors also terminates the stress response, serving as a brake on the duration of the reactive/suppressive stress mode. In animals, early experiences appear to alter the balance of MRs/GRs, lowering the level of hormone at which the system shifts from proactive to reactive functioning and allowing the reactive, suppressive mode to continue for longer periods before cortisol returns to basal levels.

A recent line of developmentally relevant research focuses on mechanisms relating the LHPA system to systems involved in growth and development of the brain and body. Of particular note are studies examining the interaction of glucocorticoids, MR/GR balance and serotonin (5-HT) receptor activity in the hippocampus (López et al. 1998), and studies examining the interaction of glucocorticoids, growth hormone, and insulin growth factors (e.g., IGF-1) (Johnson et al. 1992). In animals, conditions that elevate glucocorticoids chronically also increase basal glucocorticoid levels, affect MR/GR ratios, and lower serotonin activity in the hippocampus. These conditions include stress during pre- and postnatal development. These changes are associated with heightened vulnerability to stressors later in life, as well as problems with behavior regulation, response inhibition, and sensitivity to self-administration of drugs of abuse (de Kloet et al. 1998). Critically, again in animals, conditions associated with responsive caregiving during postnatal development reduce the impact of prenatal stress and buffer the impact of postnatal stressors (Caldji et al. 1998, Levine 1994).

2. Studies in Infants and Young Children

2.1 Measurement Issues

Research in children has been stimulated by the development of cortisol assays that use samples of free-flowing saliva (Kirschbaum and Hellhammer 1994). Unfortunately, salivary sampling does not allow the assessment of activity higher in the system (i.e., at the pituitary and brain levels). Blood sampling is needed to assess ACTH concentrations, and a spinal tap is typically needed to measure CRH. Particular drugs are usually given to probe the physiology of the LHPA system in ways that bypass individual differences in how the person perceives and interprets events. Because of their invasiveness, none of these techniques is used typically with normally developing children.

In addition, the researcher who studies the LHPA system must attend to many confounding variables that constrain how studies can be conducted. Because of the daily rhythm in the hormones, all samples must be conducted at the same time of day. Careful attention needs to be given to the child's health, what he or she has eaten and drunk recently, and the familiarity of the context (Kirschbaum and Hellhammer 1994). These constraints have limited the study of this system in children. Despite this, a literature is developing which promises to inform our understanding of early risks for later physical and emotional pathology.

2.2 Developmental Changes in Responsivity

Prenatally, the LHPA system produces cortisol by the beginning of the second trimester. In animals, the mother's cortisol affects the fetus, resulting in the development of fewer MRs and larger LHPA responses to stressors (Barbazanges et al. 1996). In humans, fetal vulnerability (low birthweight, prematurity) increases with increased maternal psychosocial stress and LHPA activity (Sandman et al. 1997).

The full-term neonate exhibits robust, graded elevations in cortisol that sensitize to repeated pain-eliciting events (e.g., heel lances) and habituates to repeated handling stressors (e.g., physical examinations) (Gunnar 1992). Responsiveness to handling stressors appears to decrease at around 3 months of age, after which stressors such as physical examinations fail to provoke elevations in cortisol for most infants. Another marked decrease in cortisol responsivity is observed between 6 and 12 months of age, after which during infancy it becomes difficult to provoke elevations in cortisol, on average, to many mild stressors (Gunnar 2000).

2.3 Relationships as Regulators of the HPA system

By 6–12 months, social interactions with caregivers mediate cortisol responses. Thus, brief maternal separations fail to elevate cortisol if substitute caregivers are sensitive and responsive, while elevations are noted when substitute caregivers are not (Gunnar 2000). Similarly, the availability of the parent in secure attachment relationships buffers elevations in cortisol to events that elicit wariness and behavioral distress, while elevations are noted for toddlers exhibiting similar wariness/distress if the attachment relationship is insecure (Spangler and Schieche 1998). Elevations in cortisol have also been noted for toddlers with the type of disorganized/disoriented attachment more typically noted among infants of depressed and/or abusive parents. Higher home baseline levels of cortisol have also been reported among 3-year-olds whose

mothers were clinically depressed during the child's first year of life. These data are consistent with the literature in animals cited above relating maternal care to stress reactivity and regulation.

Social relations with peers are potent stimuli of the LHPA system in human adults and animals (Kirschbaum and Hellhammer 1994). For children, this appears true at least as early as the preschool years. For toddlers and preschoolers, childcare involving long hours of interaction with like-aged playmates produces elevations in cortisol for many children (Dettling et al. 1999). Even short periods of interaction in half-day preschool programs may elevate cortisol for some children. Children who show activation of the LHPA system in peer settings are those with problematic peer relations; peer rejection, low dominance status, and social withdrawal tend to characterize these children. Problematic styles of interacting (e.g., anger, aggression, and poor self-control) that foster peer rejection also correlate with higher and more responsive patterns of cortisol production in preschool peer groups (Gunnar et al. 1997).

3. Temperament

Both extreme shyness and problems in effortful control have been associated with LHPA system activity in young children. Extreme shyness has been hypothesized to reflect altered thresholds for activation of stress physiology involving central fear circuits in the brain (i.e., amygdala-bed nucleus pathways). Thus, increased responsiveness of the LHPA system has long been hypothesized for extremely shy, socially anxious children (Kagan et al. 1987). Strong evidence for this hypothesis is largely lacking when children are assessed under conditions of social challenge (Gunnar et al. 1997); however, shyness, whether measured by teacher report or direct observation, has been found to correlate positively with cortisol sampled at home (de Haan et al. 1998). It is not clear why cortisol correlates more readily with shyness when home hormone concentrations are examined. It may be that under conditions of challenge, moderating factors such as coping strategies and social support need to be taken into account, while home levels are more reflective of tonic influences.

Rothbart has identified effortful control as a higher-order dimension of temperament that emerges from factor analyses of temperament questionnaires during the preschool years. Attention focusing and the capacity to inhibit prepotent responses form the core of this dimension, which Posner and Rothbart (1994) argue reflects the development of an attentional network involving the anterior cingulate gyrus which in animals also plays a role in containing the cortisol stress response (Diorio et al. 1993). In children, effortful control modifies relations between negative emotionality and behavior (Eisenberg et al. 1994). In

preschool-aged children, parent and teacher reports of effortful control tend to be negatively correlated with cortisol levels and measures of cortisol responsivity in classroom settings (Gunnar et al. 1997). Whether these correlations reflect mechanisms linking the LHPA system to the neurobiology of effortful control or the impact of effortful control on the behaviors that create stressful social encounters has not been determined.

4. Neglect, Maltreatment, and Trauma

Based on the animal research, early neglect and abuse should alter the activity of the developing LHPA system. So far, there is only a small literature on this in humans. Because of the multiple genetic and experiential risk factors typically noted in children with maltreating backgrounds, isolating the impact of adverse early experiences on the human LHPA system promises to be difficult. A full discussion of this emerging literature is beyond the scope of this article. Two findings related to physical and sexual abuse seem consistent enough to mention. First, during periods of active abuse young children do exhibit elevated cortisol levels and heightened responsivity to CRH challenge suggestive of a hyper-responsive LHPA system. Once the child's life circumstances are stabilized, however, for most children this hyper-responsiveness diminishes. The exceptions may be (a) depressed maltreated children who show a flattening of the daily rhythm in cortisol production (Hart et al. 1996), and (b) maltreated children with chronic post-traumatic stress disorder (PTSD) and who have higher baseline cortisol and catecholamine levels that are correlated with the duration of abuse (De Bellis et al. 1999).

In addition, the relations between growth failure, maltreatment, and LHPA system bear comment. Physical abuse and neglect sometimes produce significant growth delays due to reduced pituitary production of growth hormone (GH), cell insensitivity to GH, and blunted GH responses to provocative challenges, alterations that all revert to normal when the child is removed from the maltreating circumstances (Alanese et al. 1994). Theoretically, the LHPA system may be involved in the etiology of this syndrome, called variously psychosocial short stature or psychosocial dwarfism (Johnson et al. 1992). Children adopted from deprived, orphanage conditions exhibit growth failure, and six years after adoption have elevated baseline cortisol levels that were correlated with length of orphanage experience (Gunnar 2000).

5. Future of Research

Psychobiological studies of stress in young children have burgeoned since the development of techniques to measure cortisol noninvasively in saliva. Com-

munity studies of children negotiating the normative stressors of childhood are beginning to make connection with studies of children from highly stressful, adverse life circumstances and those with clinical disorders. As in studies of adults and animals, individual differences in response to stressors are common and related to the child's social circumstances and temperament. The challenge for the future is to determine the relation between LHPA function in early development and child outcomes and to explicate the relevant molecular processes.

Psychohistory

1. Its Meaning

The term *psychohistory* (originally written *psychohistory*) emerged in America in the 1950s to designate historical writings utilizing psychology, for the most part depth psychology, as their primary frame of

reference or mode of explanation. Two of its tenets in particular distinguish psychohistory sharply from other systematic approaches to the human past. The first of the two, which is rarely spelled out even in methodological writings, is that the facts of human history consist entirely of what people did whether spontaneously or under pressure of circumstances. To the psychohistorian, an intellectual revolution thus signifies thinkers changing their minds; a decline in fertility translates as women bearing fewer children; urbanization conveys people living increasingly in cities. Other historians may agree that even such seemingly impersonal historic developments all come down to human doings, yet whenever other historians narrate or explain developments of the sort they tend in the first instance to see belief systems or birth rates or urban:rural ratios changing rather than people thinking or acting differently. The other highly distinctive tenet of psychohistory is, by contrast, fully and even emphatically explicit in the psychohistorical literature: that the determinants of human conduct, whether individual or collective, are largely unconscious. Historians of other schools will often freely acknowledge deeply subjective causation of historic human behavior only to shy away from it in their own research as too dauntingly difficult to reconstruct, let alone demonstrate. To the psychohistorian, however, whatever the difficulties involved, there is simply no other way for history to be understood (see *History: Theories and Methods*).

2. Its Development

Psychohistory originated as applied psychoanalysis, with Freud and his disciples drawing on their clinical findings now and again to illuminate historical facts (see *Psychoanalysis: Overview*). At first, those clinical findings bore heavily on the patterns and pitfalls of individual emotional development, with a strong emphasis on pregenital sexuality as it emerges in childhood bit by bit and then undergoes repression even while continuing to inform emotional life. Accordingly, the earliest applications of psychoanalysis to history—including those by Freud himself, who long set the standard for his followers—were biographic and focused on the infantile concerns latent in the words and deeds of eminent or paradigmatic historic figures (see *Biography: Historical*). A landmark work in this category was psychoanalyst Erik H. Erikson's *Young Man Luther* of 1958, which argued that Luther's bold quest for spiritual autonomy was that of his whole age writ large (see *Erikson, Erik Homburger (1902–94)*). Unlike biography in relation to historiography as a whole, psychobiography remains to this day the basic as well as the leading form of psychohistory. At the same time, it was as quick as psychoanalysis itself to move beyond its initial Freudian orthodoxy (see *Freud, Sigmund (1856–1939)*).

Post-Freudian concepts utilized in psychobiography when this is practiced as applied psychoanalysis have notably included C. G. Jung's 'individuation,' Alfred Adler's 'inferiority complex,' Erik H. Erikson's 'identity crisis,' Heinz Kohut's 'narcissistic rage,' and Jacques Lacan's 'language of the id.'

Psychohistory long continued to show its derivation from psychoanalysis even where it broadened its scope beyond psychobiography. As late as the 1970s psychohistorians who explored social groups, whole cultures, or long-range collective developments, did so as a rule only in terms of the individual psychodynamics thought to have determined them, tracing their salient characteristics to formative experiences widely shared by the individuals involved, and most often to pathogenic childrearing practices on the order of abrupt weaning or intrusive parenting. Correspondingly, the preferred subjects under the head of group behavior were instances of social pathology such as witchcraft, or of political pathology such as Nazism. The most systematic psychohistorical approach to group behavior to emerge on these individualistic premises is prosopography duly slanted: the profiling of the likes of saints or witches or Nazis in terms of variables of psychoanalytical significance in their individual family histories—ages of parents and siblings, for instance, or again early parent or sibling losses (see *Prosopography (Collective Biography)*).

A prominent early alternative to the individual personality as the basic unit even of large-scale, broad-gauged psychohistorical accounts or analyses was the study of a mass leader whose following interacted with him like a single composite being. Freud himself pioneered this departure from the classic individualistic model that underlay his own science of psychoanalysis. In his *Group Psychology and the Analysis of the Ego (Massenpsychologie und Ichanalyse)* of 1922 he treated mass phenomena for the most part as simultaneous, parallel regression by individuals, but in a couple of highly suggestive passages he speculated on human consciousness as originally shared by a Darwinian primal horde from which a leader eventually emerged with a mind and will of his own; such shared group consciousness, he considered, might revive at critical historic junctures under the spell of a charismatic leader who threw back to that aboriginal tribal chief. Freud (1939) worked this speculative construction into a highly imaginative reading of the Moses story, with Moses reincarnating the tribal father supposedly slain and later exalted by his sons acting in concert. Given the very nature of this concept of group consciousness as a reversion to a tribal leader and following, subsequent psychohistorical treatments of leader and led have mostly dealt with political collectivities such as Lincoln's or Nixon's America, or again William II's and especially Hitler's Germany.

On the Freudian model of group process, then, group identity constitutes a regressive throwback to an original shared consciousness in the face of a strong

leader. But a rival conception of shared mental life, one that makes it out as permanent and leaderless, came into psychohistory independently. Its *locus classicus* lies outside of psychohistory: in the 'collective consciousness' (*conscience collective*) that Emile Durkheim in his *Suicide* of 1897 inferred from the patterned regularity of suicide rates over and beyond the particular subjective causation of each individual suicide. An early specimen of such a leaderless group model in psychohistory was Caroline E. Playne's *The Neuroses of the Nations* of 1925, which owed nothing to psychoanalysis and indeed wholly ignored it. When William L. Langer, in a resounding presidential address to the American Historical Association in 1957, called the mastery and use of depth psychology the historian's 'next assignment,' he expressly meant its application to leaderless group phenomena, which he exemplified by the epidemic of religious and cultural pathology that followed in the wake of the Black Death of 1348. (Oddly, Langer made no reference to a pioneering work in this mold just then published by his Harvard University colleague Walter Abell (1957) about how the waxing and waning insecurities of medieval European life were projected into Europe's public art of the time.) By the 1970s the dynamics of 'group process,' as it came to be called, topped the psychohistorical agenda, with collective fantasy as its privileged medium of analysis. An exemplary early product of this approach to group process was Paul Monaco's (1976) work, which teased the deep-lying national anxieties of France and Germany in the 1920s out of the recurrent motifs and techniques of each country's most popular movies of those years. Another choice area, still under exploited, for ferreting out the unconscious underpinnings of group activity is historical demography (see *Historical Demography*), especially the adjustments of aggregate birth rates to the felt needs of a population with regard to its overall numbers.

As the term 'group process' itself implies, explanation in psychohistory gradually has shifted from unconscious motives and meanings to unconscious mechanisms governing thought and conduct, while conscious purposes have been even more marginalized in the process. This shift reflects the continuing self-distancing of psychohistory from its parent discipline of psychoanalysis, focused as the latter is on latent impulses originating in childhood. Nowhere is this shift more evident than in the concept of traumatic reliving, which matured within psychohistory well before it was taken up in psychoanalysis. Psychoanalysis had first confronted adult psychic trauma during World War One in the form of battle shock for which, as for other emotional ailments, it sought a childhood referent that in this case was not forthcoming. Comparative psychobiography established two patterned, alternative reactions to emotional trauma: either a continual recall accompanied by the full, tormenting original affect, or a repression of the

traumatic affect, and sometimes even of the traumatic memory itself, followed by a contrived, controlled, disguised reexperience or reliving of the trauma to the apparent end, never attained, of mastering the attendant affect that could not be mastered at the time of the experience itself. These same mechanisms have subsequently been shown to operate as well on the collective level in instances of group trauma, and to operate independently of the widely varying reactions of the individuals composing the traumatized group. Precursively, William L. Langer in handing out his 'next assignment' conceived of the after effects of the Black Death, notably its morbid reenactments such as the Dance of Death, as just such a case of group traumatic reliving.

3. *Its Problematic*

Psychohistorical research is uniquely demanding of its practitioners because of its concern with subjective phenomena that are rarely if ever directly recorded. To understand a piece of the human past psychohistorically, researchers must first master the relevant facts at least as thoroughly as the practitioners of any other mode of inquiry. But much more, they must become immersed in those facts, make them vicariously their own, and feel out their inner determinants by dint of this imaginative identification with their original experience. The method is strikingly like the one promoted by Henri Bergson under the name of 'intuition': to study a subject intellectually from the outside until one enters into it subjectively through a core insight around which everything known about it will then fall into place. Such intimate, personal self-projection into a historic subject is treble problematic. For one thing, it presupposes a basic equivalence of mental and emotional constitution as between researchers and their human subjects, however remote those subjects may be from them historically, and even if they are groups rather than individuals like themselves. For another, researchers' identification with their subject must be thoroughgoing, yet unless they can also sustain some critical awareness outside of that identification the insights gained through it will be lost. And for a third, pieces of the researchers' own mental underworld may slip unnoticed into their reading of a subject. This danger, often called 'countertransference' by loose analogy with psychoanalysts projecting into their patients, is the risk most cautioned against by psychohistorians themselves. Actually, an affinity in researchers for their subject's inner experience can, on the positive side, sensitize or alert them to connections and meanings they might otherwise miss. Besides, a purely projective finding will not stand up in any case inasmuch as it will fail to fit all the evidence, let alone satisfy anyone apart from the researchers themselves.

Researchers will feel the rightness of their inner

grasp of a subject when it not only pulls together all the relevant facts at their disposal, but points the way to unsuspected additional corroborative evidence. Yet the discovery of such new evidence, however suggestive, is in itself no proof that their inner grasp of their subject is universally valid. Because of the very nature of psychohistorical explanation, to validate a psychohistorical thesis takes more than just a wealth of corroborative material, even if the thesis itself is what turned up key pieces of that material. To pass muster, a psychohistorical thesis must also carry subjective conviction, beyond the researchers themselves, with others willing and able to put themselves in the subject's place in their turn and see whether the proposed unconscious source of the thought or action at issue checks out subjectively with them too.

This second, subjective criterion of verification means in brief that a psychohistorical thesis must be emotionally as well as intellectually compelling. Consequently it can rely on no pre-given theory for support. Yet however direct its appeal, its need for subjective on top of objective verification demands too much effort, not to add goodwill, of critics accustomed instead to merely material and logical criteria of validation. As a substitute test of validity I therefore propose that, in psychohistory as in any science, a thesis is confirmed if, first of all, the known evidence all runs its way, if moreover it could potentially be refuted by new evidence, and if finally any piece of what it purports to explain cannot very well be explained otherwise. To take a simple example of this last stipulation from my own thesis that Hitler was traumatized by his mother's iodoform poisoning during her terminal cancer treatment: why else did he put it to his generals in late 1944 that his Ardennes offensive had caught the Allies off guard because they believed he was dead already 'or at all odds am down with cancer somewhere and can't live any more or drink any more' except that deadly iodoform poisoning induces a burning thirst together with an inability to drink? (Binion 1976, p. 143).

4. *Its Crisis Years*

As a historical school in its own right, psychohistory flourished above all in the US during the 1960s and 1970s. Even then, like all new departures, it was highly controversial, especially within the historical professions, because of its constitutive tendency to undercut all other modes of historical explanation. It has since suffered considerably from the decline of psychoanalysis, with which it is rightly associated in that the two still share at least the premise of unconscious motives and meanings. Experimental graduate programs in the field have all folded, while course offerings on college campuses have dwindled to the vanishing point. The ranks of researchers in the field are fast

thinning even as the stringent standards of verification invoked for it by critics and adepts alike are discouraging prospective practitioners. Fewer psychohistorical books and articles are appearing year by year. Of the two major specialized journals, *The Psychohistory Review* ceased publication in 1998 while *The Journal of Psychohistory* has lost most of its initial circulation. Perhaps worst of all for the discipline, the consensus of outsiders is that its scholarly output is falling off qualitatively as well.

On the other hand, psychohistory has left its impress on most other kinds of historical inquiry, especially those that emerged or developed later than psychohistory itself. Biographies and even general histories now routinely incorporate psychohistorical materials and interpretations. The study of mentalities often verges on psychohistory. So does that of historic memory, especially in the concern with memory gaps or distortions that has dominated the field. Gender history and gay history, as well as the history of emotions, lean heavily on psychohistorical concepts and findings. Many a term launched in psychohistory, such as Erikson's 'identity crisis,' has become common coinage elsewhere, while the mechanism of traumatic reliving by individuals and groups alike has found its way into a broad variety of scholarly contexts, including even a quantitative history of testation in late medieval Tuscany (Cohn 1992) (see *Identity in Childhood and Adolescence*).

The fact that psychohistory has lost much of its vitality of the 1960s and 1970s, or again that it is being put to subordinate uses by historians of other orientations, does not affect its constitutive claim to provide a privileged access to causality in history. Given this inherently persuasive claim, neither the recent loss of momentum by psychohistory as a method in its own right nor its present auxiliary status in historical research can very well be regarded as permanent.

Psycholinguistics: Overview

1. Introduction

Psycholinguistics is a field that combines methods and theories from psychology and linguistics to derive a fuller understanding of human language. From psychology, it inherits experimental methodology and a body of knowledge about processes in perception, memory, attention, learning, and problem-solving. From linguistics, it derives detailed descriptions of specific languages, rigorous accounts of the shape of grammar, and ideas about the nature of human language (Osgood and Sebeok 1967).

The basic issue that motivated the establishment of psycholinguistics as a separate field of study was the problem of the 'psychological reality' of linguistic concepts. For example, speakers of English can form the plurals of nouns by adding the suffix *-s*. This process allows us to form the plural *chandeliers* from *chandelier*. But do we actually use a productive rule to produce this plural or do we simply retrieve the plural *chandeliers* from our long-term memory as a unit? Psycholinguistic research shows that, in fact, both rote and rule are operative at various times in language production (Pinker 1999).

This issue of psychological reality applies to all levels of language structure and usage, including articulatory phonetics, auditory phonetics, phonology, morphology, lexicon, syntax, semantics, and pragmatics. It applies to all of the constructs of linguistics, including rules, grammars, paradigms, trees, segments, words, and morphemes. When we hear words, do we break them up into their component phonemes and distinctive features (see *Phonology*), or do we recognize them as wholes? When we listen to sentences, do we actually construct tree-like representations of the types proposed by linguists or do we somehow extract meaning without building up formal structures? If we do use formal grammars to listen and speak, what is the exact shape of the grammars that we use?

Exploration of the psychological reality of linguistic structures immediately leads us to two related fields of study. The first is developmental psycholinguistics, or the study of child language acquisition (Fletcher and MacWhinney 1995). If we believe that adults form the plurals of nouns by adding *-s*, we need to consider how young children can learn to apply this rule to produce 'cats' and not 'foots' or 'tooths.' If we argue that they simply learn each form by rote, how can we account for the fact that they make errors like 'feets' and the fact that they can produce the plural for a new word like 'wug' even without having been given that form explicitly?

An even more difficult issue involves how rules of grammar might be processed in the brain. Addressing this question has led psycholinguists to explore issues in neurolinguistics (Stemmer and Whitaker 1998) and cognitive neuroscience (Gazzaniga 1997). When the field of psycholinguistics first developed in the 1950s, psychologists knew little about the detailed functioning of the human brain and were forced to treat it as a 'black box.' However, as our understanding of the functioning of the human brain grew during the 1980s and 1990s, it became clear that a precise understanding of the functioning of human language would have to make reference to neural mechanisms. The interactive approach to cognition (McClelland and Rumelhart 1986) used artificial neural networks to model the processing of human language. Directly opposed to connectionism was Fodor's (1983) modular approach to cognition that emphasized the independence of separate cognitive modules for each level of linguistic structure. Researchers have attempted to test the contrasting predictions of the interactive and modular approaches using standard experimental methodology. However, this work has indicated that neither of the strong positions can be maintained (Simpson 1994). To better understand the mechanisms involved, psycholinguists are now trying to link experimental methodology to methods for the imaging of the human brain during language processing. On this level, it appears that processing works in terms of interactive modules.

This article will examine research in six core areas of psycholinguistics: spoken word recognition, sentence comprehension, sentence production, message construction, memory limitations, and cross-linguistic comparisons. In addition to these core areas, psycholinguists are involved in the study of reading, conversational interaction, figurative language, text comprehension, aphasia, child language disorders, gesture, prosody, neurolinguistic imaging, animal communication, and language evolution. However, our analysis here will focus on these six core areas.

2. Word Recognition

When we listen to speech, we perceive words as following each other in clear temporal succession, like the beads on a string or the boxcars on a railway train. However, these perceptions underestimate the extent to which words are actually being blurred together by coarticulation and assimilation. Extreme examples of this blurring occur in forms such as *'supchu'* for 'What's up with you?' However, even nonphrasal sequences such as 'I owe you a yo-yo' show similar blurring. Even without blurring, the job of segmenting sentences into words would be a tough one. Consider a phrase such as 'my catalog value for Mark's piece.' Within this phrase, there are fragments that match a variety of other possible words, such as 'mike,' 'eye,' 'I,' 'cat,' 'at,' 'cattle,' 'log,' 'you,' 'Val,' 'ark,' 'arks,' 'are,' and 'form.' The reason why we tend not to hear these alternative forms is fairly simple. If we decided to commit ourselves to having heard the word 'mike,' we would end up with the nonsensical segmentation of 'mike at a log value for Mark's piece.' At each point during sentence perception, many of these alternative words are partially active in a short list of competitors. Competitors that recognize larger segments such as 'catalog' are preferred over those that recognize smaller strings or which break up larger strings into pieces, such as 'cat a log.' If a competitor leaves an unrecognized fragment, then its own recognition is weakened. These constraints work together to guarantee a maximally satisfactory segmentation. Although segmentation is primarily driven by the competition of words for matches, it is also facilitated by stress patterns, pauses, and other prosodic patterns (Norris 1994).

Segmentation relies on word recognition, but this process is also highly dynamic. Words do not have clear and invariant forms. Consonants leave no clear and invariant imprint on the auditory stream, since they are heavily blended into vowels. Because of differences in their vocal tracts, men and women produce vowels in radically different ways. Dialect differences and variations in speech level and further variability to word forms. Again, the solution to this problem involves lexical competition. For example, in the NAM model (Goldinger et al. 1989), the sound

corresponding to a word like 'deep' will activate a neighborhood of similar words, such as 'deal,' 'dear,' 'peep,' or 'keep.' Within this domain of rhyming forms, competition is particularly keen between words that share the same initial segments, such as 'deep,' 'deal,' 'dear,' and 'deed.' The ability of a word to dominate in this competition is a function of the strength of its match to the features of the input.

These competitive models can be given a specific neuronal instantiation in terms of a neural network model based on self-organizing feature maps (Mäkkiläinen 1993). In these models, an unorganized, but interconnected, flat sheet of simulated neural tissue is trained to recognize a set of input words. As learning progresses, words that share features move to adjacent areas in the feature map. In our example, the words 'deep,' 'deal,' 'dear,' and 'deed' would occupy a small neighborhood on the larger map. The network operates in a winner-take-all fashion so that, when 'deep' starts to receive the highest level of activation, it will inhibit the activation of the competitors through a series of lateral connections. Maps of this type mimic actual cortical tissue in their use of position to represent featural structure and their reliance on lateral inhibition to sharpen the outcome of a competition.

The study of the precise mechanics of word recognition has relied on studies of word reading rather than listening. The advantage of studying visual word recognition is that experimenters can use the laboratory computer to control tightly the display of words on the computer screen. The tasks most commonly used in this area are naming and lexical decision. Both tasks are sensitive to frequency, neighborhood effects, grammatical relations, and priming effects. For example, the word 'doctor' will prime a subject's naming of the word 'nurse' and the word 'govern' will prime naming of the words 'government' and 'governing,' but not 'misgovern.' This means that the time to read the word 'nurse' out loud will be less when it follows 'doctor,' than when it follows a control word like 'house.' The details of these various priming effects provide psycholinguists with a powerful method for mapping out the shape of the mental lexicon or dictionary (Balota 1994).

3. Sentence Comprehension

At one time, psycholinguists thought that the process of word recognition preceded the process of sentence comprehension. The idea was that we must first identify all the words in a sentence before we can feed these words to a comprehension mechanism that decides what it all means. In the late 1970s, Marslen-Wilson (1975) and others showed that sentence processing is not blocked out in this way. Instead, processing keeps up with word recognition in a fully

incremental, or online fashion. Both word recognition and sentence comprehension attempt to keep up with speech exactly as it comes in, although sometimes there is a slight lag, particularly for sentence comprehension. You might notice this lag if you find that you are trying to read a newspaper or watch a television program while someone is talking to you. You hear their words, but you may not be processing exactly what they say. They may then stop and ask you whether you have been listening. Somewhat dishonestly, you reply that you have and to prove this you repeat the last seven or eight words they have said. In fact, you were not really understanding the message in any very deep way. Rather, you were squirreling away the words in a superficial form in your short-term memory, hoping not to have to actually do the work of fully comprehending the message.

3.1 Incrementalism

The previous example is interesting, because it illustrates the exception to the general rule of incrementalism. Generally speaking, we process incoming material incrementally, both lexically and conceptually. Take as an example the sentence, 'The boy chased the baboon into the bedroom.' As soon as we hear 'the' and 'boy,' we immediately begin to relate them to each other. We then relate this unit to the following verb 'chased.' Milliseconds after hearing 'chased,' we begin to construct an interpretation of the activity in which there is a boy doing some chasing. By the time we hear 'baboon,' we can begin to sketch out the figure that the boy is chasing. We do not need to wait until we have heard all the words in the sentence to begin to extract these meanings. In this sense, sentence processing is both interactive and incremental—we tend to make decisions about material as soon as it comes in, hoping that the decisions that we make will not be reversed. Although processing is incremental, it only builds as much structure as it needs in order to keep words related. The real job of comprehension is delayed until more of the message is heard.

3.2 Garden-pathing

There are times when the initial decisions that we have made take us down the garden path. A classic example of garden-path processing occurs with sentences such as 'The communist farmers hated died.' It often takes the listener awhile to realize that it was the 'communist' that died and that it was the 'farmers' who hated the 'communist.' Inclusion of a relativizer to produce the form, 'The communist that farmers hated died' might have helped the listener sort this out. A somewhat different example is the sentence, 'The horse raced past

the barn fell.' Here, we need to understand 'raced past the barn' as a reduced relative clause with the meaning 'The horse who was raced past the barn.' If we do this, the appearance of the final verb 'fell' after 'barn' no longer comes as a surprise.

Garden paths arise when a word or suffix has two meanings, one of which is very common and one of which is comparatively rare (MacDonald et al. 1994). In a sentence like 'The horse raced past the barn fell' the use of the verb 'raced' as a standard transitive verb is much more common than its use as the past participle in a reduced passive. In such cases, the strong meaning quickly dominates over the weak meaning. By the time we realize our mistake, the weak meaning is fully suppressed by the strong meaning and we have to try to comprehend the sentence from scratch. A classic garden-path example from Lashley (1951) is the sentence 'Rapid righting with his uninjured left hand saved from destruction the contents of the capsized canoe.' When this sentence is read aloud, listeners find it extremely difficult to understand the second word as 'righting' rather than 'writing.'

3.3 Lexical Effects

Current models of sentence processing emphasize the extent to which lexical and syntactic ambiguities of individual words trigger competing syntactic structures (Trueswell and Tanenhaus 1994). For example, there are two readings of the sentence 'Flying planes can be dangerous.' The planes can be either dangerous to their pilots and passengers or dangerous to on-lookers down on the tarmac. Both interpretations of the participle 'flying' are fairly strong. Because the two readings are of similar strength, they can compete with each other and no garden-pathing arises. Another example of this type is 'He bought her pancakes' in which 'her' can be either the possessor of the pancakes or the recipient of the pancakes. Both meanings are strong and can compete with each other during sentence processing, yielding a clear ambiguity.

Sometimes lexically based expectations can be fairly complex. Consider these sentences in which the verbs 'criticize' and 'apologize' set up contrasting expectations:

John criticized Mary, because she hadn't delivered the paper on time.

John apologized to Mary, because he hadn't delivered the paper on time.

John criticized Mary, because he hadn't delivered the paper on time.

John apologized to Mary, because she hadn't delivered the paper on time.

Processing of the first two sentences is quick and easy, because the gender of the pronoun matches that of the expected agent. However, the processing of the second pair is more problematic, because the gender of

the pronoun forces the selection of an unexpected cause or of the criticism or the apology (McDonald and MacWhinney 1995).

3.4 Modularity

Although processing on individual linguistic levels is highly incremental, the interaction between levels is not immediate. During the first 300 milliseconds after hearing a word, we attend primarily to its auditory shape, rather than to the degree to which it fits into some grammatical context. Take as an example the sentence 'The sailors took the port at night.' Here the word 'port' could refer to either the wine or the harbor. We can ask subjects to listen to sentences like this while watching a computer screen. Directly after subjects hear the word 'port' we can present one of these three words on the computer screen: 'wine,' 'harbor,' and some control word such as 'shirt.' If we do this, we will find that the recognition of both 'wine' and 'harbor' is facilitated in comparison to the control word 'shirt.' If we change the sentence to something like 'The sailors drank the port at night,' we might expect that the context would bias the subject to respond more quickly to 'wine' than to 'harbor,' because one is not likely to drink a harbor. However, there is evidence that both 'wine' and 'harbor' are facilitated in comparison to the control word 'shirt,' even when the context tends to bias the 'wine' reading of 'port.' This facilitation is fairly short-lived and the contextually appropriate reading soon becomes dominant.

This type of result indicates that, in the first fraction of a second after hearing a word, we rely most strongly on auditory cues to guide our processing. This is not to say that context is not present or not being used as a cue. However, during the first fraction of a second, we need to focus on the actual auditory form in order to avoid any 'hallucinatory' effects of paying too much attention to context too soon in processing.

4. Sentence Production

There are many similarities between sentence comprehension and sentence production. In both activities, we rely heavily on the words in our lexicon to control syntactic structures. Both activities make use of the same patterns for determining grammatical structures. The most important difference is that, during sentence production, we are in full control of the meanings we wish to express. In comprehension, on the other hand, we are not in control and have to follow the ideas of others.

The production of sentences involves at least four processes (Levelt 1989). The first process is message construction. This process takes our goals and intentions and builds up a thread of ideas to be

articulated. The process of lexical access then converts these ideas in word form. The third process uses positional patterning to order words into phrases and clauses. The fourth process activates a series of verbal gestures through articulatory planning. As in the case of comprehension, these four stages are conducted not in serial order, but in parallel. Even before we have finished the complete construction of the message underlying a sentence, we begin the process of articulating the utterance. Sometimes we find out in the middle of an utterance that we have either forgotten what we want to say or do not know how to say it. It is this interleaved, incremental, online quality of speech production that gives rise to the various speech errors, pauses, and disfluencies that we often detect in our own speech and that of others.

Speech errors come in many different forms. Some involve simple slurring of a sound or retracing of a group of words. Others provide more dramatic evidence of the nature of the language planning process. Some of the most entertaining speech errors are spoonerisms, which owe their name to an English clergyman by the name of William Spooner. Instead of 'dear old queen,' Spooner produced 'queer old dean.' Instead of 'ye noble sons of toil,' he produced 'ye noble tons of soil.' Instead of 'I saw you light a fire in the back quad, in fact you wasted the whole term,' he said 'I saw you fight a liar in the back quad, in fact you tasted the whole worm.' These errors typically involve the transpositions of letters between words. Crucially, the resulting sound forms are themselves real words, such as 'liar,' 'queer,' and 'worm.' The tendency of these errors to produce real words is known as the 'lexical bias' in speech errors and indicates the extent to which the lexicon itself acts as a filter or checker on the articulatory process.

Another illuminating group of errors is named after a character named Mrs. Malaprop in the play *The Rivals* by Sheridan. Some examples of malapropisms include 'Judas Asparagus' for 'Judas Iscariot,' 'epitaphs' for 'epithets,' or 'croutons' for 'coupons.' Some malapropisms arise when uneducated speakers attempt to produce unfamiliar words, but many of these errors are true slips of the tongue. In a malapropism, the two words have a similar sound but a very different meaning. The fact that speakers end up producing words with quite the wrong meaning suggests that, at a certain point during speech planning, the output processor handles words more in terms of their phonological form than the meaning they express. It is at this point that malapropisms can occur.

When two words end up competing directly for a single slot in the output articulatory plan, the result is a lexical blend. For example, a speaker may want to describe both the flavor and the taste of some food and end up talking about its 'flaste.' Or we might want to talk about someone's 'spatial performance' and end up talking about their 'perfacial performance.' These

errors show the extent to which words are competing for placement into particular slots. When two words are targeting the same slot, one will usually win, but if there is no clear winner there can be a blend.

Another remarkable property of speech errors is the way in which grammatical markers seem to operate independently of the nouns and verbs to which they attach. Consider an exchange error such as 'the floods were roaded' for 'the roads were flooded.' In this error, the plural marker *-s* and the past tense marker *-ed* go to their correct positions in the output, but it is the noun and the verb that are transposed. This independent behavior of stems and their suffixes indicates that words are being composed from their grammatical pieces during sentence production and that grammatical markers contain clear specifications for their syntactic positions.

Some of the earliest thinking on the subject of speech errors was done by Sigmund Freud at the beginning of the century. Freud believed that slips of the tongue could provide evidence for underlying anxieties, hostilities, and worries. From this theory, arose the notion of a 'Freudian slip.' We now know that the majority of speech errors are not of this type, but it still appears that at least some could be viewed in this way. For example, if a speaker is discussing some activities surrounding a local barber, he might say 'He made hairlines' instead of 'He made headlines.' These errors indicate contextual influences from competing plans. However, even rare examples of this type of contextual influence seldom reveal underlying hostilities or neuroses.

5. Message Construction and Perspective

The basic goal of both sentence comprehension and sentence production is the linking of spoken forms to underlying conceptual meanings. In the 1970s, psycholinguists thought of these conceptual structures in terms of links between simple sentences or propositions. These propositions represented relations that had no clear relation to the actual physical perspective of the speaker. More recently, work in philosophy, robotics, psychology, and cognitive linguistics has recast this view of meaning structures in terms of dynamic activities that are linked to the embodied perspective of the speaker.

Consider what occurs when a speaker relates a fable, such as the story of 'the Tortoise and the Hare.' In this story, there are basically three perspectives: one for the tortoise, one for the hare, and one for the narrator. The narrator says 'the hare decided to rest.' At this point, the narrator is taking the perspective of the hare and describing the hare's actions from that perspective. Next, the narrator shifts to the perspective of the tortoise and describes how he passes the sleeping hare. These various shifts and blends of perspective

are important aspects of all narrative structures. However, we can see their impact everywhere in language. For example, if we want to point out that there is a dent in the side of the refrigerator, we may use the impersonal construction, 'someone knocked a dent in the refrigerator' or we may use the pseudo-passive, 'the refrigerator got a dent knocked into it.' In the impersonal we are forced to point a finger at an unspecified perpetrator of the deed. In the pseudo-passive, we background or de-emphasize the doer of the activity, focusing instead on the result. These choices all reflect variations in perspective.

Another choice we make is between alternative perspectives on a single action. For example, we could describe a picture by saying, 'the girl gave a flower to the boy.' In this case, we are taking the viewpoint or perspective of the girl and describing the activity of giving from her perspective. Alternatively, we could say, 'the boy got a flower from the girl.' In this alternative form, we view the action from the perspective of the recipient. Depending on whether we choose to view the action from the viewpoint of the giver or the receiver, we will use either the verb 'give' or the verb 'get' Language is full of choices of this type, and sentence production can be viewed as involving a continual competition between choices for perspectives. The selection of pronouns is determined by the need to link up referents to earlier perspectives. Shifts from the present tense to the past also reflect movements in perspective to various points in time.

6. Cognitive Resources

Our ability to process language is shaped by our basic cognitive capacities. Even people with severe mental retardation acquire a basic control over spoken language. On the other hand, normal speakers vary in the degree to which they can remember long strings of words. The notion of a verbal working memory (Gathercole and Baddeley 1993) has figured heavily in attempts to derive the psychological reality of linguistic rules. For example, a sentence with multiple center embeddings, such as 'the man the dog the cat scratched bit smiled' are impossible for most people to understand. Psycholinguists believe that the problem here lies not in the violation of a linguistic rule, but in the fact that this structure places unrealistic demands on memory. Variations in memory span or capacity have also been related to differences in ability to learn words in a new language (Gupta and MacWhinney 1997), process complex sentences (Just and Carpenter 1992), and acquire reading skills in school.

Capacity limitations also shape the ways in which we form long-term memories from language. In general, the exact surface form of sentences often fades within seconds after we hear them (Potter and Lombardi 1990). This is particularly true of the

commonplace, predictable material that is used in textbooks or in experiments on sentence processing. However, if one examines memory for more lively, charged, interpersonal communications, a very different picture emerges. For this type of discourse, memory for the specific wording of jokes, compliments, insults, and threats can be extremely accurate, extending even over several days (Keenan et al. 1977). Often we are careful to note the exact phrasing of language spoken by our close associates, since we assume that this phrasing contains important clues regarding aspects of our interpersonal relations. For material that contains no such interpersonal content, we focus only on underlying meaning, quickly discarding surface phrasings.

7. Cross-linguistic Comparisons

All languages have sound segments, syllables, words, phrases, and sentences. In all languages, processing is online, incremental, and interactive. However, languages differ markedly in the particular grammatical contrasts they choose to mark and the devices that they use to mark them. In languages such as Warlpiri or Hungarian, word order is remarkably flexible. In languages such as Navajo or Eskimo, a single complex word may express what English does in a seven-word sentence.

Psycholinguistic comparisons of processing in different languages (MacWhinney and Bates 1989) use a simple common task to examine the effects of radically different structures. In one type of experiment, subjects listen to a sentence such as 'The eraser is pushed by the cat' and have to point to a picture that shows who is the actor. Consider a comparison of these sentences from English and Spanish:

The lion kisses the cow.

El león besa la vaca. (The lion kisses the cow).

A major difference between these two languages revolves around the use of variable word orders. In Spanish, it is possible to invert the word order and produce *la vaca besa el león*, while still meaning that the lion is kissing the cow. This inversion is even clearer if the particle *a* is added to mark the direct object, as in these variant orderings in which the two nouns are moved into different places around the verb *besa*.

El león besa a la vaca.

A la vaca besa el león.

Besa el león a la vaca.

Besa a la vaca el león.

These differences between English and Spanish can be traced to the relative cue validities of word order and object marking in the two languages. In English, it is virtually always the case that the noun that appears before the verb is the subject of the sentence. If the verb is an active verb, the preverbal noun is almost

always the actor. This means that the cue of preverbal positioning is an extremely reliable guide in English to assignment of the actor role. In Spanish, there is no such simple rule. Instead, the best cue to assignment of the actor role is the presence of the object marker particle *a*. If one of the nouns in a two-noun sentence is marked by *a*, then we know that the other noun is the agent or subject.

Other languages have still other configurations of the basic cues to sentence interpretation. For example, Hungarian makes reliable use of a single case marking suffix on the direct object. German uses the definite article to mark case and number. The Australian language Warlpiri marks the subject with a variety of complex case markings. Navajo places nouns in front of the verb in terms of their relative animacy in the Navajo 'Great Chain of Being' and then uses verbal prefixes to pick out the subject. These languages and others also often rely on number agreement between the verb and the noun as a cue to the subject. English also requires subject-verb agreement, but this cue is often missing or neutralized. In languages such as Italian or Arabic, subject-verb agreement marking is extremely clear and reliable.

When a monolingual speaker comes to learning a second language, they need to fundamentally retune their sentence-processing mechanism. First, they need to acquire a new set of grammatical devices and markings. Second, they need to associate these new devices with the correct cue validities. Third, they need to reorganize their expectations for particular sequences of cues and forms. Initially, the learner simply transfers the cues, cue validities, and habits from the first language to processing of the second language. Over time, the cue validities change smoothly, until they eventually match that of the native monolingual (de Groot and Kroll 1997).

8. Summary

In this article we have examined six core issues being addressed by psycholinguists. These areas are central to the study of psycholinguistics, because they allow us to evaluate the psychological reality of linguistic formalisms. The interaction between psycholinguistics and linguistic theory has been intense, reciprocal, and dynamic. We have learned that language processing is interactive and incremental in regard to word recognition, sentence comprehension, sentence production, and message construction. We know that cross-linguistic differences in processing are closely related to differing levels of reliability for the cues involved and the ways in which structures impose demands on verbal memory capacity. Some versions of linguistic theory have moved to adapt to some of these findings from psycholinguistics (Pollard and Sag 1994). However, a satisfactory resolution of the core

issue of the psychological reality of linguistic structures has not yet been obtained.

B. J. MacWhinney

Psychological Anthropology

Psychological anthropology considers connections between the individual and sociocultural milieu, including cultural influences on personality and psychological foundations of society and culture. The field comprises studies of child rearing, self-representation, emotion, motives, moral reasoning, cognition, dreaming, mental disorder, gender relations, violence, racism, and cultural symbolism, among other things. Theoretical and methodological perspectives include cultural psychology, ethnopsychology, psychoanalytic anthropology, cross-cultural studies of child development, evolutionary psychological anthropology, and cognitive anthropology (see *Cognitive Anthropology*).

Although it shares concerns with several related fields (i.e., social psychology, cultural psychology (in psychology), cross-cultural psychology, and ‘applied’ psychoanalysis), psychological anthropology differs from these enterprises in being strongly committed to ethnographic fieldwork in diverse cultures. This engagement with culture (and cultures) leads psychological anthropologists to put two demanding questions to theories of mind and personality: they ask if such theories adequately consider cultural influences on the individual, and whether they can in any way illuminate cultures, particularly the symbolic content of expressive culture and the logic of local knowledge. Whereas the first question poses doubts about the universal validity of Western psychology, the second, pointing in the opposite direction, encourages interest in psychoanalysis and cognitive science, psychoanalysis because it addresses content and cognitive science because it addresses logic.

Some cultural determinists or culturalists define their work as ‘cultural psychology.’ In their view,

'psychological anthropology' implies universalism and reductionism and, correlatively, too little concern with local cultures. Concurring with this appraisal, still others narrow their concerns to 'ethnopsychology,' to local cultural ideas about the mind or person. Yet for many others 'psychological anthropology' remains a comprehensive enterprise that allows for both cultural influences on subjectivity and for psychological interpretations of society and culture. It may also include evolutionary perspectives on human nature and attention to precultural social environment in child development.

1. Culture and Personality

Franz Boas, the founder of modern American anthropology, was interested in general psychology or human nature as well as 'folk psychology,' the way in which the 'genius of peoples' is shaped by local history and culture (Stocking 1992). Many of his students, however, were more influenced by his interest in this second, cultural psychology than by his interest in general psychology. Margaret Mead argued for the plasticity of sexuality and gender relations, and she rebutted Piaget and others effectively who were asserting similarity between the thinking of 'primitives' and children. Ruth Benedict contended that cultures inculcate radically different worldviews and, therefore, that subjectivity varies substantially from one culture to another. In yet another version of this cultural determinism, the neo-Freudian psychoanalyst Abram Kardiner, working with several anthropologists, suggested that the 'primary institutions' of a culture (i.e., family organization, child-rearing practices) produce a distinctive 'basic personality structure.' This shared personality core, in turn, informs 'secondary institutions' (e.g., art, myth, ritual, politics) through projection. The model guided attempts to measure basic personality structure with projective personality tests and to document the effects of child rearing with cross-cultural studies, such as those carried out by John W. M. Whiting and his many students.

The principal tenets of this 'culture and personality' theorizing and research were congruity between personality and culture, and reproduction of shared personality and culture through child-rearing practices. By the late 1960s, these tenets were in doubt. Life histories and projective personality testing had demonstrated shared psychological traits in communities, but they had also revealed much individual variation. The assumption that child-rearing practices have robust consequences for personality and culture also seemed less certain. Edward Sapir, Boas's most brilliant student, expressed reservations about culture and personality well before these empirical results. In his view, personality and culture are interrelated, partly because they have a common nexus in symbolic communication and social interaction, but he also emphasized that individual personality is not simply a

passive effect of social environment. Observing that cultural knowledge and practices are unevenly distributed in groups and that the same cultural practices can have diverse meanings and emotional entailments for individuals, Sapir inferred that the individual is the creative locus and foundation of culture. Although he had misgivings about it, Sapir concluded that psychoanalysis was the best available language for describing individual psychology.

More in keeping with Sapir's thinking, some psychoanalytically oriented anthropologists focused on expressions of human nature and individual personality in cultural beliefs and practices (e.g., Géza Róheim, George Devereux, Weston La Barre, and Melford E. Spiro). Róheim, the first of these psychoanalytic anthropologists, was especially critical of culture and personality for ignoring human nature and for underestimating cultural and psychological diversity within societies and communities.

2. Social Anthropology and Psychoanalysis

In the early twentieth century British anthropologists turned their attention from social evolution to actual social life, including questions about social actors. Accordingly, they were interested in the newly emerging fields of social psychology and psychoanalysis. Both C. G. Seligman and W. H. R. Rivers read Freud. Bronislaw Malinowski especially was intrigued by the conflict between sexual impulses and social norms in psychoanalytic theorizing. A pragmatic empiricist, Malinowski nonetheless had difficulty grasping hidden structures and processes, whether social or psychological. Assuming that intrapsychic complexes were evident in observable social relations, he argued that the Oedipus complex takes a quite different form in the matrilineal Trobriands. When the response among psychoanalysts to this intervention was less than positive, Malinowski's already ambivalent interest in psychoanalysis waned considerably (Stocking 1986).

Various expressions and degrees of ambivalence about psychoanalysis were in fact common in British social anthropology. While social anthropologists sought to understand culture in terms of social relations, it was apparent that the drama of social life involves motivated social actors with personal histories. They could not help but notice, moreover, that expressive culture often includes oedipal themes and bodily imagery (e.g., Meyer Fortes, Edmund Leach, and Victor Turner but especially John Layard, Kathleen Gough, T. O. Beidelman, and L. R. Hiatt).

3. Psychological Anthropology

As the basic tenets of culture and personality became more questionable, the field began in the 1960s to reinvent itself under the heading of 'psychological anthropology.' There was less interest in typifying

entire cultures and more concerted efforts to explore specific issues. Tensions between culturalist and psychoanalytic or otherwise psychological approaches have persisted, however. Recently, the theoretical scene has been further complicated by the emergence of evolutionary psychological anthropology, a perspective that competes with psychoanalytic anthropology in some respects and complements it in others.

3.1 Human Nature

Culturalists contend that human nature lacks content, except perhaps for a capacity for learning language and culture. Many psychoanalytically oriented anthropologists are convinced, however, that human beings are desiring, emotional, and moral creatures as well as creatures capable of learning language and culture (Ingham 1996). For their part, evolutionary psychological anthropologists argue that human beings come equipped with inclinations and capabilities oriented toward ensuring inclusive fitness. The evolutionary and psychoanalytic perspectives converge in some respects, particularly in their attention to deception and sexuality. Proposals by evolutionary psychological anthropologists and evolutionary psychologists that childhood experience may shape reproductive strategies also converge in interesting ways with thinking in psychoanalytic anthropology. The ethnographic evidence for these varying views of human nature is ambiguous. While cultural diversity argues against an essential human nature, recurrent themes in the ethnographic data appear to have just the opposite implication. In support of a common human nature, it is noticed, for example, that oedipal themes and culture heroes and mischievous tricksters are nearly everywhere present in myth and folklore (Johnson and Price-Williams 1996).

3.2 Incest Aversion

Although there are attempts to explain incest aversion in cultural terms, the most lively discussions involve psychoanalytic and evolutionary, neo-Westermarckian perspectives. Wolf's work in particular evokes debate, partly because it purports to have devastating consequences for psychoanalysis. Wolf adduced data on Chinese *simpua* marriage (a son marries an adopted daughter with whom he has a 'sisterlike' relationship) to argue that familiarity in childhood inhibits sexual desire (the *simpua* marriages result in higher rates of infertility and divorce). Spain (1987) responded that both Freud and Westermarck predict no incestuous behavior as a result of normal child development. Subsequently, Wolf (1995), again dismissing Freud, drew on attachment theory to argue that the familiarity effect begins as early as the second year of life,

presumably before the oedipal period. Nonetheless, a further response to Wolf seems likely. Wolf did not investigate mother-child relationships or childhood sexuality, and he does not consider that attachment theory is a branch of psychoanalysis and that there is clinical literature that implicates early attachment in the development and resolution of childhood oedipality.

3.3 Embodiment and Desire

It has become increasingly common to assert that the body and desire are socially or culturally constructed. 'Embodiment' in this thinking refers not to the bodily grounding of the self or mind but to the way in which culture or discourse shapes ideas about the body and bodily experience. The experience of embodiment is then expressed in 'narratives' about the body.

A different approach to embodiment assumes a more active, motivated subject in which motivation and body image reflect unconscious object relations and internalized moral values as well as the more immediate effects of social discourse. In a study of a recovered anorexic woman, for example, Banks (1998) shows that the woman's changing personal narratives about eating had more to do with her emotional experiences, personal relationships, and religious convictions than dominant cultural discourses about beauty and thinness. A fantasy story about a cookie jar, written in a diary at 11 years of age, implies that the woman's anorexia during adolescence was a way of organizing memories of maternal neglect in early life and religiously inflected anxieties about the dangers of sexuality. The temptation of the cookies and the decision to forego them in the story anticipated the way in which anorexia would become a defense against sexuality during adolescence. Far from being a passive self, the woman was an active subject who responded to discourses about the body in terms of her personal experience and deeply internalized religious convictions.

Culturalists and discourse theorists say that sexual desire and romantic love are 'socially constructed' or 'invented' along with the body, and, to be sure, they provide ample ethnographic material in support of this contention. It is not clear, however, how discourse fashions motivation or affect in desire and love. Cognitive and culturalist anthropologists theorize that motives are represented in the mind as cultural schemas (D'Andrade and Strauss 1992). A case has been made for this approach but, again, it is uncertain how schemas 'stick' in the mind or how they acquire affective force. As Banks's study suggests, cultural schemas may take hold in intrapsychic object relations, that is, in unconscious representations of emotionally significant relationships, especially with parents. If this is so, it does not suffice to say that the

body or desire is socially constructed. Developmental studies of individuals challenge simplified versions of social constructionism but so, too, does the evidence for cultural universals. One of these challenges is the finding that more or less durable passionate attachment is virtually universal in human societies (Jankowiak 1995).

3.4 Attachment, Oedipus Complex, Socialization

Observations in various cultures suggest that warm, nurturing parenting and paternal presence in early life lay an emotional basis for sociability and positive self-regard. They also suggest that secure early attachment postpones and reduces sexual activity in adolescence and lays an emotional foundation for durable love relationships and warm, empathic parenting. An evolutionary argument relates these findings to reproductive strategy, that is, it is theorized that during the course of human evolution secure attachment in childhood promoted durable passionate attachment and high-quality parenting in adulthood, whereas insecure attachment promoted increased sexual activity and multiple relationships. The first pattern supposedly favored reproductive success where supportive environments resulted in lower death rates, whereas the second pattern was more likely to lead to reproductive success where adverse material conditions resulted in higher mortality (Chisholm 1992). Another formulation finds the Oedipus complex in these scenarios. In this argument, secure attachment results in early onset and resolution of oedipal attachments and, eventually, in an emotional capacity for enduring passionate attachment, whereas insecure attachment promotes more persistent and sexualized forms of oedipal attachment and, consequently, promiscuity and other forms of sexualizing and objectifying sexual partners. Accordingly, the secure form of the Oedipus complex supported the transition to pair-bonding and increased paternal investment in offspring during early human evolution (Ingham 1999).

Attachment is probably everywhere part of early child development, but this need not imply that secure attachment is everywhere produced in the same way. On the contrary, evidence suggests that diverse parenting styles and family arrangements can promote secure attachment. Whether it can be added that attachment and the Oedipus complex vary greatly from society to society continues to be a subject for debate, however. Some writers think they do (Spain 1992), while others find the evidence less than persuasive (Spiro 1992). Attachment and oedipality aside, there is no doubt that children are socialized into their cultures. Many studies show that children learn their cultures from an early age, and that this learning informs perception, emotional expression, and moral reasoning as well as social attitudes and worldview. Many such studies contest assumptions about what

constitutes 'normal' development. Shweder (1991), for example, argues that theories of moral development may say more about Western concerns with individual rights than anything about the universal course of moral development.

3.5 Self and Emotion

Culturalists and postmodernists argue that the self and emotion, like embodiment and desire, are culturally determined or socially constructed, and, consequently, that they too vary greatly from one culture to another. One often-repeated idea is that the self is more individualistic or 'egocentric' in modern societies and more communal or 'sociocentric' in traditional societies. Implicit in these arguments is an assumption that what people think about themselves and how and what they feel are heavily constrained by words and idioms. It is argued, for example, that Russians are more expressive emotionally than Americans. In support of this contention, it is noted that Russians have a richer store of words and phrases for describing emotion and more linguistically marked emotional bodily expression than Americans (Wierzbicka 1998).

It can be objected, however, that linguistic constructionism risks typifying whole peoples and underestimating psychological complexities. Although self-descriptions may differ somewhat from culture to culture in how much they refer to social ties, studies in various cultures show that individuals are often better described as having both individualistic and communal inclinations, and, moreover, that this is so even in cultures that would seem to be highly communal (see, e.g., McHugh 1989). Research in the US suggests that the common assertion that Americans are unusually individualistic may be doubly simplistic, not only because Americans are communal as well as individualistic but also because their individualism assumes different forms depending on social class and neighborhood.

What is proving more interesting for many researchers than local lexicons is the way in which self-representation and emotional expression are organized through the stories people tell about themselves and to themselves. Research is being done, for instance, on how individuals use self-narratives to reconstruct and negotiate social identities in diasporic communities. Interest in self-narratives is part of a broader trend toward methodologically rigorous discourse-centered ethnography in psychological anthropology. Speech productions are tape-recorded, transcribed with technical notation, and examined for narrative style and speech style. They are then further examined for what they express about the self and culture. Since discourse is inherently dialogical—interlocutors are both speakers and listeners—attention to discourse translates the abstract relation

between self and society, psyche and culture, into a more concrete mutual relation between interlocutors. In studies of personal narratives about religious conversion, Stromberg (1991) shows how conversion makes culture personally meaningful by transforming referential symbols into constitutive symbols. In the conversion process, symbols that refer to the external world become part of self-identity. At the same time, they may become a personal language for managing intrapsychic conflict, say between desire and moral duty. In one of his studies a man feels powerless and insufficiently masculine. Speech style, body posturing, and cultural symbolism imply that this self-organization involves wishes for masculine power, memories of a brutal father, and feelings of having been overpowered by women, especially his mother and motherlike wife. His dreams represent a masculine power as phallic, flying horses, and the mother figure as a vaginallike tornado. Recommitment to Christian faith occurs after the man identifies in his dreams with a potent, athletic Christ (Stromberg 1991).

Another set of issues concerns how universal emotions or common emotional predicaments are organized in particular cultures. One example is grieving, arguably a universal experience. In some cultures mortuary rituals involve multiple burials and reburials or cremations and re-cremations in which the deceased is figuratively and literally deconstructed and reconstructed. Beliefs associated with such practices sometimes link the mother with the deceased, and the rituals themselves may involve eating the flesh of the deceased and giving the flesh of the deceased or its symbolic equivalent to relatives. In a comparative study of these practices, Stephen (1998) draws on Melanie Klein's object-relations psychoanalysis to theorize that many emotional losses resonate with separation from the mother at some level and may, therefore, activate unconscious traces of child rage and guilt and related needs to make reparation.

3.6 *Unconscious Meaning and Motivation in Myth and Ritual*

Because it seems to speak to symbolic content in this way, efforts to understand the unconscious meaning and motivation of expressive culture draw more on psychoanalysis than any other psychology. Psychoanalytically oriented anthropologists have often argued that relations with supernatural figures recreate or repair imaginary relations with parents (see Obeyesekere 1981). Various studies suggest that puberty rites and adolescent initiation rites may be oriented toward resolving oedipal ties to parents and orienting young people toward marriage. Ancient Greek myths can be read as implying that adolescent transition rites function in this way. Perhaps the exception that proves the rule, the story of Oedipus may be a deviant form of more common myths in which the hero marries and becomes king after passing

through an initiatory trial with a monster (see Goux 1993). Other elements in Western culture may have similar socializing functions. In a rigorously close reading of the text and its midrashic commentaries, Paul (1996) shows that mythic patricide and incestuous desire are recurrent though disguised themes in the five books of Moses. The reading suggests the Torah activates unconscious oedipal fantasies and related guilt feelings but that it also represents both paternal prohibitions and a substitute for the maternal object. In effect, the Torah may serve the growing boy or girl in the Hebrew community as a model for normative displacement and transformation of childhood attachments.

Culturalists frequently complain that psychoanalytic interpretations of cultural symbolism are simplistically universalistic and reductionistic. This may be a fair criticism in some cases—there are examples of overly mechanical and insensitive uses of psychoanalytic interpretation in the anthropological literature—but it seems unfair in many others, including those cited here. Psychoanalytic anthropologists are usually careful to consider ethnographic details and conscious personal and cultural meanings. Indeed, they contend that the evidence for unconscious meanings and motives lies precisely in such ethnographic details and conscious meanings.

4. *Basic Dilemma, Contemporary Perspectives*

As in the past, psychological anthropologists are struggling with an empirical and theoretical bind involving cultural particularism and psychological universalism, the influence of the sociocultural milieu on the individual, on the one hand, and the motivated agency of psychological subjects, on the other. Advocates of cultural psychology and ethnopsychology try to resolve the dilemma on the side of culture. They sometimes say their viewpoint allows for an active self—this is the point of their replacing the language of cultural determinism with that of social and cultural constructionism—but it is often difficult to see how their self is more than a passive product of culture. While their culturalist approach opens productive questions about how individuals are shaped or constrained by their sociocultural milieus, usually it leaves motivation and the perplexing, enigmatic features of those milieus in question. Universalistic psychoanalytic and evolutionary approaches have a reverse set of strengths and weaknesses. They offer theories and hypotheses about motivation but they are less well equipped to deal with social context and cultural influence.

Cognizant of both horns of the dilemma, many psychological anthropologists are exploring ways of conceptualizing the interplay between self and other, personality and culture. On the culturalist/constructionist side of the discussion, the growing interest in discourse-centered ethnography is arguably the most

noteworthy development (Besnier 1994). While it may sidestep motive and volition, it encourages attention to symbolic expression; it takes the culturalist approach beyond reified notions like individualism and sociocentrism to more detailed understanding of the complexities of subjectivity and culture; and, finally, because speech is inherently dialogical, it conduces toward a view in which the subject is not only the locus of cultural influence but also an active, speaking agent in the production and reproduction of culture. On the psychoanalytic side, there is effort to renew the encounter between psychoanalysis and social anthropology (Augé 1999, Heald and Deluz 1994). In this approach, culture mediates social relations and is not reducible to individual psychology but may tap into unconscious fantasy and emotion. In a dialogical version of this approach, individuals and groups influence each other through pragmatic discourse. More particularly, their rhetorical practices exert social and political effects by suppressing, mobilizing, and redirecting common sense, moral reasoning, and unconscious motivation, especially around issues of attachment, sexuality, aggression, and love. Finally, attention is given to the ways in which individuals resist these tactics or accede to them according to their social positions and psychological dispositions (Ingham 1996). In an attempt to integrate discourse theory with culturalist, cognitive, and psychoanalytic approaches, Nuckolls (1996) argues that cultural knowledge everywhere emerges in conversation and that it is always a paradoxical, dialectical mixture of diverse desires, goals, and rationalizations. At the same time, the dissonance in cultural knowledge engenders desires for coherence and synthesis. Unity and agreement remain elusive, however, and when achieved soon give way to further dialogue and disagreement. What is true of cultural knowledge in these respects is evidently true of psychological anthropology, itself an ongoing conversation. However appealing synthesis may be, it seems that psychological anthropology is entrapped in paradox and dialectic no less than its subject matter.

Psychological Climate in the Work Setting

Psychological climate is defined as 'employees' perceptions of their work environment' and has been the focus of considerable research in organizational psychology. Measures of psychological climate are intended to assess work environments as they are perceived and interpreted by employees (James et al. 1990). Examples of psychological climate dimensions include, but are not limited to, role clarity, job importance, leader support, and workgroup cooperation.

Research has linked psychological climate variables to work-related outcomes such as job satisfaction, job involvement, and job performance. Furthermore, research has attempted to determine whether there is a hierarchical model to psychological climate. That is, do the individual climate variables all represent assessments of the degree to which organizational events can contribute to desired ends (as described by one's personal values) and reflect an underlying higher order construct?

The next sections will examine the development of psychological climate research from its conception to its current state of affairs and probable future research directions.

1. The Origins of Psychological Climate Research

Beginning with Lewin et al.'s (1939) discussion of 'social climates' in the workplace, assessing employee climate perceptions became increasingly interesting to organizational researchers. However, the idea of psychological climate, as it is studied now, was not first comprehensively discussed until the late 1960s. Litwin and Stringer (1968) presented a model of the determinants of motivated behavior in organizations that included the concept of organizational climate. It should be pointed out that in the early stages of psychological climate research it was referred to as organizational climate, though that term is now used to describe shared perceptions of organizational policies and practices, rather than individual employees' perceptions of characteristics of the workplace. According to Litwin and Stringer (1968), the organization is seen as generating an organizational climate, which in turn either positively or negatively affects particular motivational patterns of employees. They theorized that climate could provide managers with the link between an organization's procedures/prac-

tices and the concerns and needs of individual employees. This link would help managers determine what practices would stimulate employee motivation. Litwin and Stringer (1968) defined several important dimensions of organizational climate, including structure (perception of formality and constraint in the organization), challenge (perception of challenge, demand for work, and opportunity for sense of achievement), reward and support (emphasis on positive reinforcement rather than punishment), and social inclusion (sociability, belonging, and group membership). Finally, Litwin and Stringer (1968) tested their hypotheses in an experiment that simulated eight days of actual organizational life in three companies with very different organizational climates. The organizations differed in terms of the amount of structure (strict procedures vs. more flexible procedures), responsibility given to employees (e.g., low vs. high), reward and punishment (e.g., only punishment vs. a combination of both punishment and rewards), warmth and support (isolated employees vs. friendly workgroups), cooperation and conflict (e.g., cooperation is praised or not), and risk and involvement (e.g., organization stressing conservatism vs. stressing challenge). Litwin and Stringer's (1968) results indicated that type of organizational climate was related to employee satisfaction and employee performance. Overall, they found that what they called an achieving climate (e.g., high employee responsibility, cooperation among employees is stressed, tolerate conflict and support risk taking) led to the best outcomes for the employees (i.e., high satisfaction) and the organization (i.e., high performance).

Litwin and Stringer's (1968) work provided the impetus for increased research on psychological climate in work settings. This subsequent research identified several problems that confounded much of the original psychological climate research. The most important of these was a 'level of analysis' problem.

1.1 Distinction between Psychological Climate and Organizational Climate

James and Jones (1974) conducted a review of the climate literature and commented that, while organizational climate research had received a considerable amount of attention, the 'conceptual and operational definition, measurement techniques, and ensuing results' (James and Jones 1974 p. 1096) were highly diverse and contradictory. These problems were causing organizational climate to be viewed as a somewhat nebulous construct. James and Jones (1974) argued that previous climate research could be organized into three different, but not mutually exclusive, approaches to defining and measuring organizational climate. They designated these approaches as: (a) the multiple-measurement-organizational attribute approach,

which views climate as a set of organizational attributes measured by a variety of methods; (b) the perceptual measurement-organizational attribute approach, which uses only perceptual tools to measure climate but still sees climate as an organizational level variable; and (c) the perceptual measurement-individual attribute approach, which views climate as perceptual and an individual level phenomenon. James and Jones (1974) believed that researchers needed to differentiate between climate measured at the organizational level and at the individual level. They proposed that psychological climate was an individual attribute, whereas organizational climate was a situational attribute of the organization. Furthermore, by establishing these new definitions, researchers would be able to focus on either psychological climate or organizational climate which would, in turn, lead to research that would better be able to define both constructs and how they both related to other variables.

Later studies helped shape the boundaries between psychological climate and organizational climate (Schneider 1975). Psychological climate was defined as individual descriptions of organizational practices and procedures, which are useful in understanding the influence of the organizational environment on individual performance and satisfaction. Organizational climate, on the other hand, refers to a collective description of the organizational environment, and is thought to relate to organizational level outcomes. This distinction allowed psychological climate researchers to focus squarely on individual level issues, such as the relationship between psychological climate and various outcome variables (e.g., individual job performance). However, as the definition of psychological climate became somewhat solidified, researchers began to debate whether there was a distinction between psychological climate and job satisfaction. This debate was settled when researchers reached the consensus, through theoretical arguments (James and Jones 1974) as well as empirical research (Schneider and Snyder 1975), that psychological climate reflected descriptions of the work environment whereas job satisfaction reflected an affective evaluation of the work environment.

1.2 Hierarchical Model of Psychological Climate

As the definition of psychological climate became generally accepted, researchers began to expand the list of perceptual variables they used to measure individuals' descriptions of their work environment. However, research on the measurement properties of psychological climate also began to indicate that these psychological climate variables often clustered within four higher order factors: role, job, leadership, and workgroup (James and James 1992). While the exact

number and specific names of psychological climate variables clustered under these higher order factors changes depending on the scale used, the following examples should provide a general illustration of these higher order factors. The 'role' higher order factor is often made up of role ambiguity, role conflict, and role overload. The 'job' higher order factor often comprises job challenge, job autonomy, and job importance. The 'leader' higher order factor is most often made up of leader trust and support, leader goal facilitation, and leader hierarchical influence. Finally, the workgroup higher order factor often comprises work group cooperation, work group friendliness, and workgroup pride. Furthermore, this early research viewed these four psychological climate factors as 'distinct cognitive organizing principles for perceptual variables' (James and James 1989 p. 93).

However, James and James (1989) argued that there is a further hierarchical relationship among psychological climate dimensions. Specifically, they suggested that the judgment process of appraising organizational events in relation to one's personal values is common to each climate dimension. These value-based appraisals represent assessments of the degree to which organizational events can contribute to desired personal ends. Moreover, these judgments were hypothesized to reflect an underlying general factor (PCg), which represents an overall evaluation of whether the work environment is personally beneficial or detrimental to one's well-being. Research by James and James (1989) as well as others (e.g., Brown and Leigh 1996) has shown support for the idea of PCg. The PCg model, because it presents climate as one overarching construct, subsequently made examining the relationship between psychological climate and other variables much simpler.

2. Current Research

Current research falls into two categories: research that focuses on the relationship between psychological climate variables and other constructs (e.g., job performance); and research that focuses on the hierarchical structure of psychological climate.

2.1 Psychological Climate and Work-related Outcome Variables

Research has demonstrated that psychological climate perceptions provide an important mediating link between organizational characteristics and consequential work outcomes such as employee attitudes, motivation, psychological well-being, and performance. A recent meta-analysis (Parker et al. 1998) examined the relationships between individual-level higher order climate perceptions (e.g., role, job,

workgroup, leader) and work outcomes such as employee work attitudes, psychological well-being, motivation, and performance. It was found that individuals' climate perceptions had significant relationships with their job satisfaction, work attitudes, psychological well-being, motivation, and performance. Furthermore, each of the climate categories exhibited a somewhat different pattern of relationships with the various outcomes. For example, employees' job (e.g., importance, autonomy) and role (e.g., overload, clarity) perceptions appeared to have the weakest relationships with all of the outcome variables. Interestingly, the leader (e.g., goal emphasis, support) and work group (e.g., cooperation, warmth) constructs were most predictive of employees' work attitudes. A similar pattern was evident for the relationships of the various psychological climate dimensions with employee motivation and performance. For psychological well-being, however, job and leader perceptions provided the strongest relationships. Overall, it appears that employees' climate perceptions have stronger relationships with their work attitudes than with their motivation and performance. This pattern of relationships indicates that the effects of climate on motivation and performance may be mediated by employees' work attitudes. This hypothesis was tested in the study and supported. Thus, the relationship between employees' motivational and behavioral reactions to perceptions of their work environment and their motivation and performance does seem to be mediated by their overall evaluations of these perceptions.

Most studies that have considered the relationship between psychological climate variables and work-related outcome variables have assumed a linear relationship. Current research is investigating whether this is the case.

2.2 Nonlinear Relationships Between Psychological Climate and Outcome Variables

Researchers have debated over whether the relationships between certain climate dimensions (e.g., job autonomy) and outcome variables (e.g., job satisfaction) are linear or nonlinear in nature. For example, job autonomy is assumed by some researchers to follow an inverted U shape. That is, while medium levels of job autonomy are thought to be more desirable than low levels, very high levels of job autonomy are potentially harmful since it implies difficulty in decision making and high responsibility on the job. Other researchers, however, have assumed a linear relationship between job autonomy and job satisfaction: the more autonomy workers experience, the more satisfied they are with the job.

Previous studies examining psychological climate variables have shown support for both the linear and

nonlinear points of view. However, the nonlinear relationships found in prior research have been somewhat weak, often explaining only a small amount of additional variance (1–2 percent) over the linear model. In summary, the evidence is inconclusive as to which type of relationship exists.

However, research examining methodological problems associated with using a common response format may provide an explanation for these weak curvilinear findings. The use of a common response format has been shown to introduce shared item variance (i.e., common methods variance, or CMV) and elevate relationships among job perceptions (Glick et al. 1986). However, one can measure constructs using a multimethod approach. By measuring constructs with more than a single method one should be able to address the common response format problem mentioned above. A recent study (Baltes et al. 1999b) used both multitrait-multimethod (MTMM) data and monomethod data to test the relationships between climate dimensions that have been hypothesized to have nonlinear relationships with job satisfaction. Strikingly different results were found between the monomethod and MTMM data. Whereas the monomethod results mirrored earlier inconclusive findings, the MTMM data indicated that nonlinear equations explained significantly more of the relationship between all three climate dimensions and job satisfaction. These results suggest the following. First, the use of MTMM data allows one to test for nonlinear effects more effectively. Second, nonlinear quadratic effects better model the relationship between role clarity, role overload, job autonomy, and the outcome variable job satisfaction. These results, of course, have implications for both measurement and interpretation of psychological climate variables and work-related outcomes.

2.3 Hierarchical Structure of Psychological Climate

As mentioned earlier, recent climate research has used the James and James PCg model to justify collapsing multiple indicators of psychological climate into one overarching appraisal of the work environment (Brown and Leigh 1996, James and James 1992). However, it may be premature for psychological climate researchers to accept the construct validity of PCg because the James and James (1989) study relied on a single response format (i.e., traditional Likert scale). As mentioned earlier, the use of a common response format (i.e., monomethod data) has been shown to introduce shared item variance, which can elevate relationships among constructs. As a result, the intercorrelations among climate dimensions that generate support for PCg may be the result of nonrandom measurement errors caused by common methods variance. The hypothesis that support for

PCg is the result of common methods variance has received some support (Parker 1999). However, research efforts that use multiple measures of psychological climate are required to more appropriately test whether PCg is the result of common methods variance (James and James 1989). A study conducted by Baltes et al. (1999b) used multitrait-multimethod data collection to examine the hierarchical model of psychological climate (PCg). Two different self-report response formats were used to measure 12 psychological climate constructs. The PCg model, when tested with multitrait-multimethod data, did not fit the data. The lack of support for the PCg model appears to be caused by a strong common methods bias, which caused a 35 percent bias (i.e., inflation) in the observed correlations among the constructs. These results do not support the practice of collapsing psychological climate dimensions into an overarching construct. Furthermore, support was also not found for collapsing to the aforementioned four higher order constructs: role, job, leader, and workgroup. This result is perhaps the most troublesome given the extent of prior research that has considered the relationship between these higher order constructs and work-related outcome variables. These results are the product, of course, of one study and need to be replicated before previous research linking higher order psychological climate factors to outcome variables is considered obsolete.

3. Future Research

The results of current and past research will probably lead to three streams of future research. First, with respect to the relationship between psychological climate and various work outcomes, future research needs to test more complicated mediation and/or moderation models that include other work-related variables, such as employee work attitudes and/or other individual difference variables. By testing more complicated models researchers will be better able to discern how psychological climate fits into the workplace environment.

Second, if the relationships between these climate variables and job satisfaction are nonlinear then perhaps the important substantive question to ask employees is not the traditional one of how much they have of, for example, role clarity, but how what they have differs from what they would like. That is, the discrepancy between what they would like and what they have becomes the important question to ask since this discrepancy would indicate where they fall along the nonlinear curve. Knowing where an employee falls on the regression curve would allow one to predict what effect more or less of a climate dimension would have. Just knowing how much an employee has of, for example, job autonomy, would not allow a researcher

to effectively hypothesize what effect more or less job autonomy would have on the job satisfaction of that employee. Future research should not just ask the traditional question of how much an employee has of certain climate dimensions, but focus on the discrepancy between what they have and what they desire to better understand and predict outcome variables such as job satisfaction.

Finally, future research should assess psychological climate dimensions with other methods, such as essays or interviews, and test the PCg model. Whereas some current research, as mentioned earlier, has called into question the existence of a higher order psychological climate factor, more research with multiple measurement methods needs to be completed to address this issue more adequately.

Psychological Development: Ethological and Evolutionary Approaches

1. Introduction: The Science of Animal Motives

Classical ethology, the ‘biology of animal behavior’ (Eibl-Eibesfeldt 1970, Hinde 1982), compares descriptions of how different species act in their natural environment, and in families and societies. Lorenz proposed that genetically determined motor programs or Innate Release Mechanisms (IRMs), triggered by environmental Sign Stimuli, confer ‘dispositions to learn’ that benefit the species. By comparing spontaneous behavior rituals and sequences of display or response between individuals, ethologists seek evidence of innate impulses in different species, and determine the genetic relationships and evolutionary lineage (see *Comparative Method, in Evolutionary Studies*). Ethology developed from zoology and field studies of wild animals. It accepts that animals have motives and awareness that can be understood by accurate description of their behaviors in nature, and how these develop. Darwin’s *Expression of the Emotions in Man and Animals* (1872) inaugurated ethological science (see *Darwin, Charles Robert (1809–82)*). He related human feelings to those one can infer in animals from their expressions.

Tinbergen (1951) identified innate signaling behaviors of communication—in mating, nest building, care of young, territorial defence, hunting or escape from predators, sharing environmental resources, etc. (see *Evolutionary Social Psychology*). He defined four time-scales of behavioral determination: over evolutionary time; in development of the individual; in control of behavioral tendencies over hours, days, or months; and in adaptive functional response to immediate environmental events. He used field experiments to identify that stimuli or behavior signals are ‘releasers’ of innate activities.

Scientists research animal senses, often very different from ours, and the ways animals move to

investigate their environment. Communicative signals are instructive, because they have evolved to be perceived. Rhythmic light flashes, visible movements of body parts, vocal or other sounds, or vibrations, convey effective messages, even in primitive species. How animals react to signal patterns gives further evidence about internal processes that guide attention, movements, and emotions. In humans, innate hearing and vision has been explored by studying the vocal sounds, face expressions, and body movements that infants prefer, and the emotions infants express (Fernald 1992, Papousek and Papousek 1987, Stern 2000, Trehub 1990, Trevarthen 1998, 1999).

As in Darwin’s day, evidence for species-specific motives and feelings in humans comes from comparing spontaneous expressions of people in different cultures, and by observing infants before they have had the chance to learn (Eibl-Eibesfeldt 1989). Newborn infants communicate and imitate, and children show systematic changes in behaviors and interests (Stern 2000, Trevarthen 1998). As children’s motives develop, they change the behavior of caregivers, stimulating ‘intuitive parenting’ and the sharing of meanings (Papousek and Papousek 1987).

2. Learning, Cognition, and Communication

Efforts have been made to relate ethological theory to concepts of experimental psychology and ‘conditioning’ in simplified laboratory situations (Hinde 1982). After decades of rejection by psychologists of ‘mentalist’ interpretations, the idea that animals may share motives, feelings, and conscious experiences comparable to those of human beings has again become scientifically acceptable (see *Human Cognition, Evolution of; Evolution of Cognition: An Adaptationist Perspective*). Psychologists postulate internal ‘representations’ that process perceptual information and control actions of subjects in complex circumstances. More recently, attention has turned to the evolved functions of emotional regulatory systems in the brain, and their role in self-awareness and intelligence (Damasio 1994) (see *Emotions, Evolution of*).

Cognitive psychology acknowledges that human behavior is regulated by conscious states and intentions, and that learning integrates emotions and mental representations. Nevertheless, cognitive science remains individualistic and rational—focused on reality. Complex intelligence is analyzed in terms of perceptual categorizations and hierarchical representational systems. Different modes of intelligence are thought to be formulated anatomically in identifiable brain regions. In particular, social intelligence is considered to pass, in evolution and development, through grades of cognitive representation, and levels of awareness of cognition in other individuals—from immediate, ‘thoughtless’ sensorimotor reactions, to verbalizable, rationally formulated ‘theories of mind’

(see *Evolution of Cognition: An Adaptationist Perspective*). Dynamic Systems Theory, opposed to linear causal explanation, attributes behavior patterns and mental representations to 'emergent properties' thrown up in complex systems comprising large numbers of elements—neural connections, perceptual feature detectors, sensorimotor loops, motoric forces, representations in memory, social transactions, etc. In neither of the dominant contemporary theories of complex mental life and behavioral coordination is evolved anticipatory motivation given a determinant role.

No adaptive behavior of an animal subject is without innate 'constraints' due to prefunctional configuration (morphogenesis) of sensory and motor structures, brain tissue, and nerve connections, which map both the body and its future engagement with the outside world in a coherent, subjective space and time. What is innate is an active neurobiological initiative that investigates the environment, applying specific anticipatory, probing processes of behavior. 'Critical periods,' or ages in which active investigations of experience change, correspond to brain growth periods that are generally more open to learning (see *Lifespan Development: Evolutionary Perspectives*).

3. Behavior from Dyads to Large Social Groups

Subjective motives communicated to other individuals become intersubjective (Bråten 1998). In the more intelligent, behaviorally complex species there is a rich capacity for display of mental impulses—of attention, intention, and emotion. Intersubjective relations assume central importance in reproduction, feeding, establishment of cooperative groups in families or much larger societies. Interspecific collaborations, including predator–prey interactions, control behavior in dyads and larger groups, regulating ecological relations between animals psychologically.

Sociobiology has formulated theories to explain the evolutionary advantages of various forms of conflict and cooperation within and between communities, and special complementary adaptations of individuals in the service of the group, or to propagate a genetic type. Reductive cost-benefit analyses, of energy balance sheets for motor and metabolic investment, or of transmission and survival of genes in populations (reproductive success), have prevailed, which can be explained by an unwillingness of quantitative biologists to attribute self-regulatory motives and emotions to animals as individuals, or members of families and cooperative groups (see *Evolution, Natural and Social: Philosophical Aspects*). They see behaving animals as driven by forces of competition for future success that are indifferent to any aspirations for, or pleasures in, life in the present. The genetic history of humans indicates that there has been rapid adaptation to an

extremely large range of environments, and new adaptability by cooperative learning of behavioral traditions (Cavalli-Sforza and Cavalli-Sforza 1995) (see *Genes and Culture, Coevolution of; Cultural Evolution: Overview*).

The benefits of competition have been exaggerated. Research on the psychopathology of infanticide or mass killing by individuals indicates that direct competition by assault results from a loss of pleasure in the kinds of altruistic and affectionate motives of play that lead to creative invention of new and beneficial motives, ideas, or activities in a group (Bekoff and Byers 1998). Communication between members of a species and between differently adapted species without concern for gain leads to intricate dynamic ecological systems and mutual dependency. Some behaviors of predator and prey in natural ecological equilibrium are cooperative, or mutually supportive. Skilled collective understanding of the environment by intelligent social species depends on positive motives for sharing enjoyment of experience and skilled action, such as are abundantly shown by the young of many species when they play together.

4. Attachment, Companionship, and Parental Support of Early Development

Emotions linked to innate behaviors regulate parent–offspring attachments and caregiving (see *Attachment Theory: Psychological*). In many species, mutual adaptations of motives in parents and young facilitate cooperative encounters that nurture the young, and parenting strategies limit the offspring's dependency. The food, care, and support that nestlings or nurslings receive sustain the developing body and brain. Human infants show attachment to the physiological or bodily benefits from mothering (Schore 1994), the biological importance of which was first demonstrated experimentally in monkeys. Infants also respond to psychological expressions of pleasure and interest carried by the voice, facial expressions, and gestures of the parent, and these lead to 'proto-conversations' and companionship (Trevvarthen 1998, 2001b; Trevvarthen and Aitken 2000). Infants and parents seek contact and affective communication, and deprivation of sympathetic parenting has detrimental effects on both emotional and cognitive development of a child.

Pleasure and pain may be the main emotions or neurochemical systems seeking parental nurturance in mammals, including humans (Panksepp 1998), but more complex emotions, including self–other conscious states and relational emotions such as pride and shame, regulate intersubjective motives and assist the learning of a wide range of socially and culturally important skills in infants (Stern 2000, Draghi-Lorenz

et al. 2001) (see *Self-conscious Emotions, Psychology of*). Infants seek emotional confirmation to develop knowledge and skills (Trevvarthen and Aitken 2000).

5. *Motives and Benefits of Play*

Animal motives are revealed not only in behaviors that immediately benefit the individual, or the propagation and flourishing of the group or species. Their essential creative aspect is vivid in play (Bekoff and Byers 1998). Ethological and psychological theories of play appear confused by a desire to find a function outside motivation itself. However, by its nature, and by any definition, play behavior largely is determined by the anticipatory processes of behavioral control, and not any immediate adaptive consequence. Play behaviors are more apparent in the more social species that have elaborate intersubjective capacities or social awareness. By giving strong and continuous messages of exuberant motives, play invites sympathetic attention and, indeed, participation by others in changing outcomes and risks. Human children, like young of other species, can play alone, practising and shaping perceptuo-motor skills. But behaviors exhibited in self-satisfying play have a potential to be social, and they are responsive to provocative or 'teasing' interactions with other individuals. Play fighting between young in a cooperative family group is affiliative, consolidating relations and training awareness of mutual intentions. Many play behaviors anticipate functions of mature 'innate' behavior patterns. Thus, play expresses motives for behaviors that require exercise of motor and cognitive processes for their maturation. It would seem pointless to attempt a cognitive rationalization of play if play is the prior behavior, adapted to generate intelligence and regulate cognition.

Research with infants confirms that play develops relationships and skills, as well as creating rituals and 'formats' of cooperation. The imaginative or 'symbolic' play of young children foreshadows the creative efforts made by young adult athletes, and the striving of outstanding craftsmen, artists and scientists throughout their lives (Bekoff and Byers 1998). Art, appreciation of beauty in artefacts and ceremony in human communities may be related to universal rhythms and modes of intimate communication between infants and their partners (Dissanayake 2000).

6. *'Communicative Musicality' and the Pulse of Human Thought and Imagination*

Animal communication employs precisely timed rhythms, modulations of expressive activity, and accurate interaction of movements in communicating individuals (Tinbergen 1951). Infants' expressions,

and their refined discrimination of temporal, prosodic, harmonic, and melodic features of vocalization or musical sounds, beginning before birth, indicate that human language communication draws on rich pre-verbal talents for expressive gesture and perception (Trehub 1990). Human sensitivity for the emotive rhythms, qualities, and narrative sequences of expressive song and dance, may be evolved with bipedal standing and walking, which free the erect body, and especially the hands and voice, for flexible poly-rhythmic gestures that can richly express dynamic emotions and their blends and changes in interpersonal engagements (Trevvarthen 1999). Emotions are conveyed in regulated 'contours' or 'melodies' of muscle activity. They are held together by a coherent time-generating process in the brain that creates a hierarchy of acts and succession of perceptual events in one 'mind time' (Pöppel 1994). Infants discriminate the pulse, expressive quality, narrative succession, and contingency of response in adult expressions.

7. *The Biology of Human Imitation, Cultural Learning, and Language*

Monkeys and apes learn in social play, and imitate, but parental support for learning is limited in sub-humans, and the most elaborate monkey play is between peers. Apes play over a wider range of ages, and their play assists development of family and group bonds, and they imitate how adults forage and use transformed objects as 'tools' for getting food. No apes show the intricate intersubjective exchanges of human vocal and gestural play with infants soon after birth, or the constructive and narrative-making fantasy games of toddlers. Donald (1991) argues from comparative cognitive psychology and the fossil record that it is likely that the first bipedal hominids were communicating nonverbally, by gestural mimetic narratives, about nonpresent experiences (see *Cultural Evolution: Theory and Models*). He concludes that grammar of language evolved out of the rhythmic syntax of gestural mimesis (see *Evolution and Language: Overview*). Study of developments towards language of infants and toddlers supports this theory (Locke 1993).

Human beings have unique motives for cultural learning—the acquisition of artificial knowledge and skills. These govern progress from preverbal forms of communication and play (Trevvarthen 1998). Human ethology is necessarily a science concerned with these motives. All cultural cooperation among humans, however artificial, depends on a uniquely productive capacity for 'mirroring' feelings, interest, and purposes of other persons, and for solving cognitive, practical, moral, and artistic problems collaboratively (Bruner 1996). Studies of imitation reveal that a neonate human has a remarkably complete image of move-

ments in the expressive parts of another person's body, an image that is both receptive through the constellation of all senses, and capable of forming a matching movement in communicative interactions (Bråten 1998, Nadel and Butterworth 1999).

Human language learning depends upon joint attention and sympathetic understanding of intentions (Tomasello and Farrar 1986). Toddlers acquire use of words by following convergent interest to grasp meanings in other persons' speech (Locke 1993). Long before verbal communication, an infant is proficient in 'protoconversational' games, and in participation in rhythmic rituals of action games and songs, which parents are highly motivated to share, intuitively matching and complementing the emotions expressed by the infant (Trevvarthen 1998).

8. The Evolutionary Neuroembryology of Motives and Emotions

Discoveries in neurobiology enhance our knowledge of adaptive motive systems and emotions and their role in self awareness and communication (Schoe 1994). Brain mechanisms of emotion in brainstem regions influence the higher functions of imagination, thought, and language (Panksepp 1998) and exercise an influence over the maturation of cortical cognitive systems in both prenatal and postnatal development of mammals, including human beings (Trevvarthen 2001a). Cortical mechanisms for perceiving postural, facial, and vocal expressions, as well as manual gestures, for remembering experiences associated with different expressed emotions, and for generating such expressions as elaborate narratives of internal impulses and feelings, are enlarged greatly in humans as compared to homologous brain areas of other species (Damasio 1994, Trevvarthen 2001a). Play is associated with manifestations of neurochemical well-being or 'happiness' (Panksepp 1998). Often young animals play vigorously with body movements at a particular age, and it has been noted that in this 'sensitive period' the cerebellum of the hind brain is undergoing accelerated growth and acquiring refinements of circuitry necessary for accurate and rapid motor control.

9. Future Directions

Only recently has over two centuries of research on the comparative anatomy of brains and their development been comprehensively integrated with psychological theories of cognition and learning. A focus on the forebrain cortex, and the effects of cortical lesions on human awareness, memory, and motor skills had left the core systems that incorporate motivational and emotional controls out of the picture. Recognition

that acquired skills and knowledge are directed, focused, selected, and integrated by subcortical systems leads to questions about how adaptations of behavior and awareness that anticipate experience and shape learning are generated. Ethological theory directly supports new enterprises in human genetics, neuroethology, and developmental neuroscience, and applied fields, such as education and psychiatry. We anticipate a more balanced natural science of mental life integrating the processing of empirical experience and reason with inherited emotive impulses for both individual experience and cooperative social life. Important questions will arise concerning what determines human affairs and our relation to the natural world.

Psychological Therapies: Emotional Processing

It is now well established that systematic exposure to phobic stimuli markedly reduces associated fear and several theories about the psychological mechanisms underlying the efficacy of exposure therapy have been advanced (Craske 1999). Emotional processing theory (e.g., Foa and Kozak 1986) initially was advanced as one explanation of the effectiveness of exposure therapy in the treatment of anxiety disorders. This article traces the origin of the concept of emotional processing, describes emotional processing theory and how it accounts for the effectiveness of psychological

therapies in treating anxiety disorders, and discusses recent developments in the concept of emotional processing.

1. History of the Emotional Processing Concept

The concept of emotional processing has its origin in Lang's (1977) analyses of fear-relevant imagery in the context of behavior therapy and fear reduction. In studying the procedure of systematic desensitization, Lang et al. (1970) found three predictors of successful treatment: greater initial heart-rate reactivity during fear-relevant imagery, greater concordance between self-reported distress and heart rate elevation during fear-relevant imagery, and systematic decline in heart-rate reactivity with repetition of the imagery. On the basis of these findings, Lang (1977, p. 863) suggested that 'the psychophysiological structure of imagined scenes may be a key to the emotional processing which the therapy is designed to accomplish'. While Lang did not expand on the concept of emotional processing, in subsequent papers he further elaborated on the theory of emotional imagery in behavior therapy (e.g., Lang 1984).

Lang's (1977, 1984) theory holds that a fear image is a cognitive structure containing stimulus, response, and meaning information that serves as a program to avoid or escape from danger. For example (see Fig. 1), the fear structure of a dog phobic includes representations of dogs, representations of physiological and behavioral responses in the presence of dogs (e.g., rapid heart-rate, sweating, running away), and representations of meanings associated with dogs (e.g., 'Dogs are dangerous') and with responses to dogs (e.g., 'Rapid heart rate and sweating mean that I am afraid'). The fear structure is activated by environmental input that matches some of the information stored in the structure. According to Lang (1977, p. 867), 'the aim of therapy could be described as the reorganization of the image unit in a way that modifies the affective character of its response elements.' He further proposed that for image modification to occur, the fear structure must be at least partially activated. Accordingly, it is this aspect of the theory that accounts for the relationship between physiological measures (e.g., elevated heart-rate reactivity) and good outcome in exposure therapy for fear. However, Lang did not specify how activation of the fear structure brings about alterations in the structure.

The concept of emotional processing was subsequently taken up by Rachman (1980, p. 51) who proposed a working definition of emotional processing as 'a process whereby emotional disturbances are absorbed, and decline to the extent that other experiences and behaviors can proceed without disruption.' Accordingly, successful processing would be evidenced by a person's ability to confront a previously distressing event without evidencing signs of emotional distress. By contrast, several clinical phenomena

Figure 1

A schematic diagram of the fear structure of an individual with a dog phobia. The ovals indicate stimulus representations, diamonds indicate response representations, and rectangles indicate meaning representations. Lines indicate associations among representations

such as persistent fears and obsessions, failures to benefit from treatment designed to reduce fears, and the return of fear after apparently ‘successful’ treatment would be evidence of failed or incomplete emotional processing.

Rachman (1980) noted that the majority of people are able successfully to process the upsetting events that occur in their lives and proposed a number of situational, personality, and contextual variables that are likely to produce difficulties in processing an emotionally disturbing event. For example, difficulties in emotional processing are likely to occur in generally anxious and introverted individuals who confront intense, dangerous, unpredictable, and uncontrollable events. Rachman further discussed factors that can facilitate emotional processing, such as prolonged exposures to fear relevant stimuli or images without distraction. Rachman’s analysis does not constitute a theory of emotional processing. Rather, it is an attempt to describe the sort of phenomena for which an adequate theory of emotional processing may provide an explanation. Indeed, as noted by Foa and Kozak (1986), Rachman’s approach to defining and analyzing emotional processing suffers from circular reasoning: the fear reduction that is attributed to successful emotional processing is the same evidence used to infer that successful emotional processing has occurred.

2. *Emotional Processing Theory: Basic Concepts and Mechanisms Underlying Treatment*

2.1 *The Cognitive Structure of Fear*

Building on Lang’s (1977, 1984) theory, Foa and Kozak (1986) conceptualized fear as a memory structure that serves as a blue print for escaping or avoiding danger that contains information about the feared stimuli, fear responses, and the meaning of these stimuli and responses. When a person is faced with a realistically threatening situation (e.g., a car accelerating at you) the fear structure supports adaptive behavior (e.g., swerving away). However, a fear structure becomes pathological when the associations among stimulus, response, and meaning representations do not accurately reflect reality in that harmless stimuli or responses are erroneously interpreted as being dangerous. Furthermore, characteristic differences between different anxiety disorders are thought to reflect the operation of specific pathological fear structures (cf. Foa and Jaycox 1999). For example, the fear structure of individuals with panic disorder with agoraphobia is characterized by fear of physical sensations associated with their panic symptoms (e.g., rapid breathing, heart palpitations) and interpretation of these sensations as meaning that they are having a heart attack or are going crazy. As a result of this

misinterpretation, panic disordered individuals avoid locations they anticipate will give rise to panic attacks or similar bodily sensations, such as physical exertion.

By contrast, the fear structure of individuals with posttraumatic stress disorder (PTSD) involves associations among trauma-related harmful stimuli and similar but non-harmful stimuli, erroneous interpretation of safe stimuli as dangerous (e.g., 'All men are rapists'), and erroneous interpretations of responses to mean self-incompetence (e.g., 'My symptoms mean I can't cope with this'). Accordingly, when encountering a trauma reminder, the PTSD sufferer experiences strong emotional reactions similar to those that occurred during the trauma. Support for these hypotheses comes from a study comparing traumatized individuals with and without PTSD to one another and to nontraumatized individuals using the Posttraumatic Cognitions Inventory (PTCI), a measure of negative cognitions about the self, negative cognitions about the world, and self blame. Individuals with PTSD showed higher scores on all three scales than did the other two groups who did not differ from one another (Foa et al. 1999).

2.2 Emotional Processing as Modification of the Fear Structure

If fear behavior reflects the activation of an underlying cognitive fear structure, then changes in the fear structure will result in corresponding changes in behavior. Foa and Kozak (1986) proposed that psychological interventions known to reduce fear, such as exposure therapy, achieve their effects through modifying the fear structure. They further suggested that, 'The hypothesized changes in the fear structure may be conceptualized as the mechanism for what Rachman (1980) has defined as emotional processing' (Foa and Kozak 1986, p. 22).

2.3 Necessary Conditions for Emotional Processing

According to emotional processing theory (Foa and Kozak 1986), two conditions are necessary for therapeutic fear-reduction to occur. Similar to Lang (1977, 1984), Foa and Kozak suggested the fear structure must be activated in order for it to be available for modification. Activation occurs when a person is exposed to information that matches some of the information stored in the fear structure. But activation by itself is not sufficient. New information that is *incompatible* with the pathological aspects of the fear structure must also be available and incorporated into the existing structure for emotional processing to occur. Indeed, exposure to information that is *consistent* with the existing fear structure would be expected to strengthen existing associations. Although experiences may have the effect of either strengthening

or weakening existing fear structures, the term emotional processing is reserved for modifications that result in fear-reduction.

2.4 Indicators of Emotional Processing and Relation to Treatment Outcome

Fear and emotional processing are theoretical constructs that cannot be observed directly. Rather, they must be inferred through observable variables. Because emotional processing is being offered as an *explanation* of fear reduction, it is important that the indicators of emotional processing be different from the indicators of fear reduction. To avoid circularity, Foa and Kozak (1986) distinguished between measures of emotional processing during the course of exposure therapy and treatment outcome. Specifically, they proposed that emotional processing can be inferred from: (a) self-reports (e.g., 'I'm afraid') and physiological reactivity (e.g., elevated heart rate) that are indicative of fear activation; (b) gradual decreases of these measures during continued exposure to fear-relevant information; and (c) diminished initial fear reactions across successive exposures. In contrast to these indicators, Foa and Kozak viewed treatment outcome as a much broader notion that encompasses variables not specifically targeted in treatment, such as the quality of a person's job performance, personal relationships, and their degree of life satisfaction.

Several studies are consistent with the hypothesized relationship between indicators of emotional processing and treatment outcome. For example, individuals with PTSD experience distressing intrusive thoughts about their traumatic experience; carefully avoid people, places, and activities that remind them of the traumatic event; and experience disruptions in memory, concentration, and sleep. An effective treatment for PTSD is imaginal exposure to memories of the traumatic experience (Shalev et al. 1996). It has been found that individuals who exhibited fear activation during imaginal reliving, followed by decline across sessions achieved better outcome (e.g., fewer intrusive thoughts, less avoidance, and improvements in memory, concentration, and sleep) than individuals who did not exhibit fear activation or who exhibited fear activation with minimal habituation across sessions (cf. Foa 1997). The validity of these predictors of outcome has been demonstrated in other anxiety disorders as well, such as obsessive-compulsive disorder and specific phobias (Foa and Kozak 1986).

2.5 Sources of Corrective Information

It is easy to see how exposure therapy, in which fearful individuals are helped to confront feared images or situations, results in activation of a fear structure. But what kind of information does exposure therapy

provide to correct erroneous associations among the stimulus, response, and meaning representations in the fear structure?

One important source of corrective information is *habituation*, by which repeated exposure to a stimulus that reliably elicits a specific response results in a decline in that response. Foa and Kozak (1986) proposed that habituation of physiological responses within an exposure therapy session, one of the indicators of emotional processing, constitutes an important source of information for modifying aspects of the fear structure. For example, habituation generates new response information about the *absence* of physiological responding in the presence of the phobic stimulus that is incompatible with prior response information. Physiological habituation also counters erroneous meaning representations underlying the cognition that fear will persist until escape occurs. Repeated and prolonged exposure may also provide corrective information as to the realistic likelihood of feared consequences. For example, the fear structure of an individual with obsessive compulsive disorder may include meaning representations with unrealistically high estimations of the probability of contracting a severe illness from touching doorknobs. As a result, doorknobs are carefully avoided thereby preventing the person from learning that touching doorknobs does not pose a serious health risk. Treatment through exposure (e.g., touching dirty doorknobs) and response prevention (e.g., refraining from washing) provides the corrective information that the probability of becoming sick after touching a doorknob is actually extremely low.

3. Recent Advances in Emotional Processing Theory

3.1 Mechanisms Underlying Natural Recovery from Trauma

Studies investigating patterns of reactions to a trauma over time indicate that individuals differ in their ability to successfully process the traumatic event and thus recover naturally with the passage of time. While most trauma victims process the trauma successfully, a substantial minority fails to do so and consequently develops chronic PTSD (Foa 1997). Why do some traumatized individuals recover and others go on to develop chronic disturbances? Foa (1997) suggested that three common mechanisms underlie both natural recovery from trauma and reduction of PTSD severity via treatment. The first mechanism is *emotional engagement* with the trauma memory, which in the context of exposure therapy has been termed fear activation. In relation to natural recovery, emotional engagement refers to fear activation that occurs upon encountering a trauma reminder in the natural en-

vironment. Just as fear activation has been found positively associated with treatment outcome, the absence of emotional engagement has been found to be associated with poor natural recovery following a traumatic event. For example, individuals who *dissociate* during or shortly after experiencing a traumatic event experience greater PTSD symptom severity later on, compared to those who do not dissociate. The dissociation phenomenon connotes the absence of emotional engagement with the trauma memory and hence, according to emotional processing theory, will retard emotional processing. A delay in the peak reaction to a traumatic event may also be conceptualized as the absence of emotional engagement and thus is expected to hinder emotional processing and subsequent recovery. Consistent with this hypothesis, individuals whose peak symptom severity occurred within two weeks of the traumatic event were less symptomatic 14 weeks later than were individuals whose symptoms peaked between 2–6 weeks after the event. A second mechanism hypothesized to underlie both natural recovery and improvement with treatment is the *degree of organization or articulation* of the trauma narratives (Foa 1997). In support of this hypothesis, a higher degree of narrative articulation shortly after the trauma predicted greater recovery (lower PTSD symptom severity) three months later. In the same vein, exposure therapy for PTSD was associated with increased organization and decreased disorganization of the trauma narrative over the course of treatment, and those changes were correlated with symptom improvement.

The third hypothesized mechanism for recovery is a *change in core cognitions* about the world and the self. As discussed earlier, two basic dysfunctional cognitions are thought to underlie PTSD: the world is completely dangerous and the self is totally incompetent. It follows that recovery would be associated with less negative cognitions (Foa and Jaycox 1999). Indeed, in a longitudinal study of crime victims, individuals who retained their PTSD diagnosis three months after their assault exhibited more negative cognitions compared to those who no longer had PTSD. Similarly, cognitions about the world and self were less negative after treatment for PTSD than they had been before treatment (see Foa 1997, for discussion of the preceding two studies).

The ways in which exposure therapy is thought to promote fear activation and modification of erroneous cognitions have been explicated earlier. But how does emotional processing theory account for natural recovery? It is proposed that natural emotional processing and the consequent recovery occurs via repeated activation of the trauma memory in daily life through engagement with trauma-related thoughts and feelings, sharing them with others, and confronting trauma-reminder stimuli. In the absence of repeated traumatization or 'emotional breakdown,' these natural exposures contain information that disconfirms the

common post-trauma cognition that the world is a dangerous place. For example, a rape victim may repeatedly encounter men that are physically similar to the perpetrator, thus activating the trauma memory structure. As these encounters do not lead to additional assaults, the natural initial postrape inclination to view the world as entirely dangerous is not confirmed and thus gradually subsides. In addition, repeated thinking or talking about the traumatic event promotes habitation of negative emotions and the generation of an organized trauma narrative. By contrast, individuals who avoid engaging with the traumatic memories by either suppressing related thoughts and feelings or avoiding trauma-related situations, do not have the opportunity to form an organized narrative or disconfirm the initial post-trauma negative cognitions and thus develop chronic disturbances. Indeed, mothers who lost their babies to Sudden Infant Death Syndrome and were able to share their loss with a supportive social network resolved their grief more satisfactory 18 months after the trauma than did mothers who were not able to share their grief with supportive others (Lepore et al. 1996).

3.2 Emotional Numbing and Emotional Processing in PTSD

In an apparent paradox, individuals with PTSD frequently report experiencing intense negative emotions when reminded about the traumatic (re-experiencing) while also having difficulty experiencing and expressing emotions in situations that call for an emotional response (emotional numbing). To explain this paradox, Litz et al. (2000) hypothesized that the strong emotional reactions cued by trauma reminders among individuals with PTSD temporarily depletes their emotional resources, thereby reducing emotional responsiveness to subsequent events. Consistent with this hypothesis, veterans with PTSD who were first shown a video tape of combat images and then asked to rate a series of slides depicting emotionally positive images (e.g., a baby) were emotionally more reactive to the combat video, but less reactive to the positive slides than veterans without PTSD. In contrast, no differences between groups emerged when the veterans viewed neutral images (e.g., furniture) before rating the positive slides. Thus, veterans with PTSD displayed emotional numbing for the positive slides, but only after first experiencing negative emotional arousal.

The research by Foa and co-workers (see Foa 1997) on the consequences of emotional nonengagement and by Litz et al. (2000) on the relationship between arousal and emotional numbing suggests two ways in which extreme emotional reactivity following a traumatic event may interfere with emotional processing and recovery. According to Foa acute emotional reactivity can lead to extensive avoidance, thereby

preventing exposure to corrective information. Litz and co-workers proposed that chronic emotional reactivity can lead to emotional numbing, thereby reducing emotional engagement with the trauma memory.

3.3 The Effects of Corrective Experiences: Alteration of Existing Cognitive Structures or Development of New Cognitive Structures?

Foa and Kozak (1986) defined emotional processing as a change in the pathological elements of an existing fear structure following exposure to corrective information. A plausible alternative is that exposure to corrective information results in the formation of a *new* memory structure that coexists with the old fear memory rather than replacing it (Bouton 1988). Accordingly, a person's behavior in a given situation will be determined by which of the two structures is activated. From Foa and Kozak's perspective, the return of fear following successful treatment represents a further change in the fear structure. Bouton's theory would view relapse as a reduction in the accessibility of the new nonfearful memory. Support for Bouton's hypothesis comes from research conducted by Craske and co-workers (cf. Craske 1999), demonstrating that certain procedural variations in treatment by exposure therapy produced less between-session fear reduction, but prevented the long-term return of fear at follow-up.

3.4 Worry and Depressive Rumination

Emotional processing concepts have been utilized in the analysis of worry (Borkovec and Lyonfields 1993) and depressive rumination (Teasdale 1999). Although somewhat different analyses have been offered for these two phenomena, both Borkovec and Teasdale suggested that cognitive processing in one channel or at one level of meaning (linguistic/conceptual or propositional) may interfere with processing in another channel or level of meaning (imagery or implicational). Specifically, on the basis of studies showing that verbal articulation of fearful material results in less physiological arousal than imagining the same material (e.g., Vrana et al. 1986), Borkovec and co-workers have proposed that worry serves to inhibit emotional imagery. The short-term consequence of worry is to minimize emotional distress by limiting activation of the fear structure. However, the long-term consequence of avoiding full activation of the fear structure, as discussed above in the context of emotional numbing and emotional nonengagement, is to inhibit emotional processing and thereby maintain the worry.

Although the concept of emotional processing has generally been limited to the field of anxiety, Teasdale and co-workers (cf. Teasdale 1999) have proposed an

emotional processing model of depression. The model distinguishes between two different, but interacting levels of cognitive meaning, and proposes three different configurations of the interactions between these levels of meaning, also referred to as the 'three modes of mind.' One level of meaning is propositional, corresponding to the kind of information that can be conveyed in a single sentence. The other, implicational, represents higher order meaning derived from recurring patterns or themes. In the case of depression, the implicational meaning of experiences such as failing a class or the break-up of an important relationship may be a failure in all aspects of one's life. Importantly, the model posits that emotions are directly generated by the implicational level, while the propositional level of meaning only effects emotional states indirectly through the continual cycling of information between the two levels of meaning. Depressive rumination involves the cycling of depressogenic information between these two levels of meaning, thereby generating and maintaining dysphoria.

Teasdale (1999) further suggested that each meaning level can operate in one of two modes. In the *direct* mode, processing occurs in real time, whereas in the *buffered* mode information is allowed to accumulate before it is processed further. Although both levels of meaning can be operating in direct mode at the same time, only one level can be buffered at a given time. This yields three possible configurations, each one having different consequences for the person's emotional experience. When neither level of meaning is buffered, 'mindless emoting' occurs, in which people identify themselves with their emotional reactions and engage in little self-reflection. When the propositional level of meaning is buffered, individuals are said to be in the 'conceptualization/doing' configuration in which they think about themselves and their emotions as objects and develop goal-oriented strategies to cope with their problems and emotions. For example, depressive rumination frequently involves the person thinking about the nature, causes, and consequences of their depression. The third configuration, called 'mindful experiencing/being,' occurs when the implicational level is buffered and is characterized by 'integrated cognitive-affective inner exploration, use of present feelings and "felt senses" as a guide to problem solution and resolution, and a non-evaluative awareness of present subjective-self-experience' (p. S77).

Within this model of depression, Teasdale (1999) has defined effective emotional processing as 'processing that leads to modification of the affect-related schematic models [i.e. implicational level of meaning] that support processing configurations maintaining dysfunctional emotion' (p. S65). He further hypothesizes that emotional processing will occur only when the implicational system is buffered, thereby allowing the integration of new and old information. Accordingly, two general strategies can be used to promote

changes in implicational meaning. One strategy is to help depressed individuals create and encode in memory new implicational meanings, and many current cognitive therapy techniques (e.g., cognitive restructuring) help in doing so, although such techniques may run the risk of maintaining the conceptualizing/doing configuration. A second strategy, unique to Teasdale's theorizing, is to help people learn to shift from either of the two modes of mind that do not promote emotional processing (mindless emoting and conceptualizing/doing) to the one that does (mindful experiencing/being). This involves exercises in mindfulness, similar to some forms of meditation, in which individuals learn to become aware of, and acknowledge depressogenic thoughts without exclusively focusing on them. Teasdale found that a treatment program combining traditional cognitive therapy interventions with mindfulness exercises was more effective in preventing relapses among individuals with recurrent major depression than was cognitive therapy alone.

4. Concluding Comments

Emotional processing theory was advanced by Foa and Kozak (1986) primarily to account for the effectiveness of exposure therapy in the reduction of anxiety. However, consideration of its historical antecedents (Lang 1977, Rachman 1980) indicates the concept of emotional processing originally was conceived more broadly. Rachman (1980) in particular proposed that the concept should encompass a range of phenomena that includes, but is not limited to, anxiety and the efficacy of exposure therapy. In keeping with this, recent advances in such topic areas as natural recovery following trauma (Foa 1997), PTSD symptom structure (Litz et al. 2000), worry (Borkovec 1993) and relapse following recovery from depression (Teasdale 1999) have extended the domain of emotional processing theory and demonstrate its continued heuristic value.

At the same time, questions remain for future research as to the nature and limits of emotional processing, two of which are briefly noted. First, does exposure to corrective information alter existing cognitive structures, as proposed by Foa and Kozak (1986), or does it result in the acquisition of a new memory (Bouton 1988, Craske 1999)? Resolution of this issue has implications for understanding the process of relapse and development of relapse-prevention strategies. Second, to what extent do procedures that promote emotional processing of fear and anxiety promote the emotional processing of other problematic emotional reactions, such as sadness/depression, anger, or guilt? In exposure therapy, an important source of corrective information is habituation. However, it may be that these other emotions do not habituate (Pitman et al. 1991) and that alternative procedures may be needed to promote their

emotional processing, such as traditional cognitive restructuring techniques and mindfulness strategies (Teasdale 1999). Thus, resolution of this issue has implications for the design of interventions for other problematic (nonfear) emotional reactions.

Psychological Treatment Delivered Nontraditionally

The term ‘psychotherapy’ generally connotes an interactive, face-to-face process in which a trained mental health professional attempts to help a client or group of clients effect personal change. Authority and responsibility for facilitating such change reside with the professional, whose presence and expertise are deemed necessary to guide and control the meetings in accordance with sound clinical and ethical practices.

Since the 1970s an array of interventions for delivering psychological assistance have come into being that deviate significantly from the traditional psychotherapy format. In general these newer formats enjoy widespread popularity among the general public and their use is less directly controlled by a mental health professional. Such alternative psychological interventions include self-help and mutual support groups, radio and TV shows dispensing psychological advice, interactive computer software packages for addressing a wide variety of personal problems, self-help books, self-help audio and video tapes, and most recently a spate of cyberspace offerings. The latter category includes self-help guides, single session e-mail and bulletin board advice, ongoing e-mail counseling, real-time chat groups, and most recently, web telephony and videoconferencing.

A small body of research evaluating effectiveness focuses primarily on paraprofessionals and self-help books, and shows these alternatives to be sometimes as effective as more classic psychotherapy. However, much more research is needed. Added benefits of alternative formats are lower cost, convenience of access and use, and the availability of psychological aid for people who otherwise either would not, or could not, utilize traditional psychotherapy. Examples include the homebound, those in remote areas, people who consider psychotherapy stigmatizing, and individuals with a strong need for privacy and independence when dealing with their psychological problems.

This article first examines some of the social and cultural factors contributing to the development and use of these newer forms of psychological treatment. The treatments themselves are then reviewed along two dimensions. The first dimension is the source of the help: is it professional, paraprofessional, nonpro-

fessional, or some mix? The second dimension is the nature and degree of contact between help giver and help seeker. Finally, the status of research, along with issues about quality, safety, and protection of the public are briefly discussed.

1. Social Climate and the Rise of New Forms of Psychological Treatment

Viewed as a group, the newer models of psychological assistance, as compared with traditional forms of psychotherapy, tend to involve less direct professional contact and control, even when the treatment is designed or delivered by a mental health professional. This shift away from strictly professional delivery of mental health services reflects an intersection of several social developments. Observations about social trends are based on developments in the USA and may differ in applicability to other parts of the world.

At a broad societal level, considerable value has come to be placed on empowering the individual, as opposed to almost total reliance on institutions and professionals for information, support, and assistance. This stems in part from a post-Watergate, post-Vietnam weakening of US public confidence in its major institutions, including the corporate world, government, and the medical establishment. Various activist movements (e.g., those concerning civil rights, women, consumer rights, gays and lesbians), beginning in the 1960s and continuing to the present, also reinforce values about personal entitlement and empowerment. A result of this trend is that people now demand a greater measure of involvement and control over their physical and mental health care.

Technological advances in communications are a further factor in stimulating individual desire for greater control of over personal well-being. Before the 1980s many personal issues such as alcohol and drug abuse, child molestation, family violence, sexual orientation, bulimia and anorexia nervosa, cancer, sexually transmitted diseases, Alzheimer's disease, fetal alcohol syndrome, mental illness, to name but a few, were topics rarely spoken of in public. Early television talk shows played an important role in shining a spotlight on such previously closeted issues. As people became increasingly sophisticated about the relationship between stress and health, and the potential damage that various stressful life events can cause, the public also demonstrated its eagerness for help.

However, scientific surveys of the prevalence and incidence of mental health problems, at least insofar as the US public is concerned, make it clear that we do not now have, and probably never will have, a sufficient number of trained mental health professionals to meet the needs of all those reporting diagnosable psychological problems. Meanwhile, the need for psychological services continues to grow, fed in part by dramatic advances in medical science. More

people with serious chronic medical conditions are surviving, many into old age, putting numerous stresses on both patients and their families.

At the same time, the growth of managed health care, with its focus on cost containment, has resulted in limiting access to care, especially for mental health concerns (see *Managed Care and Psychotherapy in the United States*). This is so despite a growing body of research from the field of psychoneuroimmunology (Hafen et al. 1996), demonstrating that psychological stressors have a negative impact on the immune system, general health, and overall functioning (see *Psychoneuroimmunology*). The same body of research also shows the social support and the opportunity to discuss problems constructively can positively affect health, enhance the quality of life, and even promote longevity. Western medicine, though desirous of promoting health and preventing the occurrence or the worsening of disease, fails fully to capitalize on what is known about the mind-body connection and its impact on health and well-being.

Further, under managed care, doctors and nurses, traditionally an important source of informal psychological assistance, now have less time to spend with their patients than in the past. The ironic result is a public increasingly aware of the connection between stress and physical and psychological illness, but finding affordable psychological services growing more scarce.

To summarize, four factors stand out as particularly influential in promoting nontraditional psychological treatments: (a) the growing public awareness and desire for help at the very time that for many the availability of affordable professional psychotherapy is decreasing; (b) the value placed on personal entitlement and empowerment in today's society; (c) an ongoing revolution in electronic forms of communication, including the very rapid growth and easy accessibility of information and services via the Internet; (d) the rapid dissemination of information by today's highly competitive mass media businesses. Given these forces, it is not surprising that enterprising people have, and no doubt will continue to find, alternative, accessible, less costly (although sometimes financially quite profitable) ways of delivering psychological treatments.

One such example of a break from traditional psychotherapy began in the late 1970s, as the number and type of self-help/mutual support groups multiplied rapidly (Goodman and Jacobs 1994). Such groups had existed for decades, the best known being Alcoholics Anonymous and Recovery, Inc. (see *Alcoholics Anonymous*). But suddenly groups sprang up for almost every conceivable personal problem from substance abuse, to parenting concerns, to being a victim of violence, to life transitions such as divorce, retirement, or bereavement, to lifestyle issues such as sexual orientation, transvestitism, open marriages, as well as groups for almost every disease listed by the

World Health Organization. Millions of people joined them and, although some groups utilize professional leaders or professionally developed ideas, many have little or no professional input. Sociologist Frank Reissman (Gartner and Reissman 1984) terms the heart of the self-help group movement the 'helper-therapy' principle—the idea that when people suffering from a common problem come together for mutual support, they not only receive help from others, particularly from those more experienced in coping with the problem, but also give help, and in so doing are themselves strengthened and empowered. In the 1980s many health professionals held negative views about self-help groups, asserting that lay people left on their own were likely to harm each other by dispensing bad advice. Less openly discussed were their concerns over loss of professional control and income. Over time professionals have become more supportive of self-help groups as both an adjunct to traditional treatment and as a useful, member-governed intervention in its own right. Today many professionals are directly involved with groups in a variety of roles such as consultants, researchers, leaders, co-leaders with group members, and even as participants who share the group's common concern.

More recent alternatives to traditional psychotherapy have been generated as a result of the ongoing technological revolution in electronic communication, which continues to offer new means of interacting to large numbers of people. On the Internet, some formats take advantage of real-time communication to deliver psychological aid, while others necessitate time delays between the posting of messages requesting psychological help and the responses to those messages. One recent review of psychological assistance on the Internet (Barak 1999), listed 10 types of interventions: (a) information resources on psychological concepts and issues; (b) self-help guides; (c) psychological testing and assessment; (d) help in deciding to undergo therapy; (e) information about specific psychological services; (f) single-session psychological advice through e-mail or e-bulletin boards; (g) ongoing personal counseling and therapy through e-mail; (h) real-time counseling through chat, web telephony, and videoconferencing; (i) real-time and delayed-time support groups, discussion groups, and group counseling; (j) psychological and social research. The next section offers a framework for organizing the many and varied nontraditional intervention formats offered to the public.

2. A Framework For Viewing Nontraditional Forms Of Psychological Assistance

Two basic elements in most traditional psychotherapy are (a) live, real-time, face-to-face contact between a help seeker and a help giver and (b) the help giver

Figure 1

Nature and type of psychological treatments

being a trained mental health professional. This section outlines alternative psychological treatments in terms of their departure from these two elements, that is, alternative formats for delivering psychological aid are shown according to two major categorizations.

The first categorization is the nature of the contact between help seeker and the source of the help: is it live and face-to-face? If not, is there some type of two-way communication between the helper and help seeker? If so, is it in real time or delayed time? (Note that in either case, the true identity of either party may not be known.) If not, does the help seeker interact and receive feedback from a packaged program such as those that can be bought and used on personal computers or accessed via the Internet? If not, what is the format for the delivery of the noninteractive aid?

The second categorization refers to the training of the person offering the mental health aid: is the person a trained mental health professional, a paraprofessional, or a nonprofessional? The intention is to provide a framework for categorizing any type of psychological treatment. For the examples listed in Fig. 1, P = professional, PP = paraprofessional, and NP = nonprofessional. The listing is not intended to be exhaustive.

The relatively unregulated nature of the various forms of nontraditional psychological treatment being offered to the lay public has raised concerns about their safety, quality, and effectiveness. Research into the use of paraprofessionals vs. professionals, self-help books vs. therapist-delivered services, and computer-assisted vs. therapist-delivered treatment generally shows these alternatives to be similar in effectiveness to professionally delivered psychotherapy (Christensen and Jacobson 1994). But not only is that body of scientific studies relatively small, some newer

computer-based formats have never been studied. Thus, many important questions remain unanswered. For example, are some nontraditional formats more appropriate for certain types of people, or certain types or levels of severity of problem?

Further, the relatively unregulated nature of the Internet leaves open the possibility of poor quality offerings, untested claims, and even outright charlatanism among those designing and offering psychological assistance. In the interest of assuring quality psychological services for the public, priority needs to be given to research, as well as education for both Internet users and service providers, about appropriate standards.

Psychological Treatment, Effectiveness of

1. Introduction

Despite its relative youth, the field of psychotherapy has faced many challenges, including one that disputed the very purpose it intended to accomplish. In a review of the effectiveness of psychotherapy, Eysenck (1952) concluded that 74 percent of patients, drawn from 24 studies, and diagnosed as neurotic, were found to make progress considered equivalent to a similarly diagnosed group of individuals who received no treatment.

This finding stimulated years of controversy regarding the effectiveness of psychotherapy, as well as a determined and focused effort on the part of researchers to establish empirically the beneficial effects, if any, of psychotherapy. In addition to reporting the findings supporting the efficacy of psychotherapy treatment, the remainder of this discussion will present related findings from this effort: (a) the durable effects of psychological treatment, (b) the factors leading to patient improvement, and (c) the disturbing evidence that suggests that not all patients benefit from treatment. Of related importance to this discussion is the paradoxical outcome that often accompanies many scientific investigations; namely, that as each question is sufficiently answered, more questions take its place.

2. The Definition of Psychotherapy

In general, psychological treatment is a method designed to change a person's thoughts, feelings, or behaviors with the intention of facilitating increased functioning and life adjustment. Approaches to psychotherapy are numerous and diverse including such orientations as cognitive, behavioral, client centered, gestalt, and existential therapies. All of the various approaches involve a confiding relationship with a trained therapist focused on a patient in need of assistance.

3. The Effectiveness of Psychotherapy

As mentioned above, the conclusion made by Eysenck stimulated both the frequency and quality of studies designed to evaluate the outcome of therapy. Researchers pursuing evidence to refute Eysenck's claim have investigated a number of domains that are considered relevant to distinguishing the effects of psychotherapy. Assessments of the benefits of psychotherapy have focused on such domains as an increase in problem-solving skills, reduction in symptoms, improvements in interpersonal and social functioning, and health. The changes noted in patients treated with psychotherapy have been compared to groups of individuals who have not been exposed to therapy. Reviews of this literature have confirmed the beneficial effects of therapy, concluding that treated patients consistently fare better than untreated patients (Lambert and Bergin 1992, 1994).

An often used statistical technique, meta-analysis, has enabled researchers to summarize individual collections of empirical data, comparing the effect sizes of treatment, placebo, and control groups. For example, using meta-analysis, Smith et al. (1980) reported that the average person in treatment is better off at the end of treatment than 80 percent of the untreated

Figure 1

Comparison of placebo and psychotherapy effects in relation to no-treatment control

persons. A graphic representation of the effect sizes (treatment, placebo, and control) found in a number of meta-analytic reviews is presented in Fig. 1.

4. Treatment Duration and Lasting Effects

In contrast to the length of treatment associated with early theories of psychoanalytic psychotherapy, the extant literature suggests that substantial benefits from treatment occur in relatively short durations, and equally important, these gains are maintained. Dose-effect designs, derived from the dosage model introduced by Howard et al. (1986), have confirmed a positive rate of effect as the dose (i.e., number of sessions) increases, with diminishing returns at higher dosage levels. Studies from the dose-effect literature suggest that, for many clinical disorders, a range of 10 to 20 sessions is sufficient for 50 percent of patients to return to normal functioning. Moreover, promising results occur as the dosage level is increased to the extent that 75 percent of patients can be expected to recover substantially after 26 to 50 sessions (Lambert et al. 2001).

Although a majority of patients experience significant benefits from psychotherapy, there is also evidence that different clusters of psychological symptoms respond to treatment at distinct rates of improvement. It appears that symptoms of poor morale respond most quickly, followed by chronic symptoms of distress, with symptoms intrinsic to the character of the patient recovering the slowest. Observed trends in patient improvement have led some researchers to propose a phase model of recovery in which personal welfare, symptom reduction, and interpersonal and social functioning improve in sequence.

In addition to results supporting relatively short recovery periods for a majority of patients, there is evidence that beneficial gains from psychotherapy are

enduring. Although adjustment from psychotherapy treatment does not prevent recurrences of psychological disturbance, it appears that many patients maintain healthy functioning for prolonged periods of time subsequent to treatment. However, exceptions to the notion of lasting treatment gains are noted in the conclusions of a review by Nicholson and Berman (1983), which included patients suffering from symptoms of substance abuse, eating, recurrent depression, and personality disorders.

5. Factors Important to Psychotherapy Outcome

In addition to the research focused on supporting the effectiveness of psychotherapy, considerable emphasis has been placed on the factors attributable to positive patient outcome. Findings from this research fall into three general categories: patient variables, common variables, and specific intervention variables.

5.1 Patient Variables

Although a number of studies have investigated the impact therapists have on psychotherapy outcome, there is surprisingly little evidence that suggests therapists or their techniques are central and essential factors affecting patient outcome. On the contrary, it is in fact the patient that is most likely to determine successful outcome. The literature focusing on the study of patient variables is too voluminous to repeat, and thus only the most important findings are reported here.

Each patient entering treatment brings a diverse array of factors when presenting to the clinician. These include a variety of psychological disorders, historical backgrounds, stresses, and the quality of their social support networks to name just a few. Patient variables found to have relationships with outcome are severity

of disturbance, motivation and expectancy, capacity to relate, strength of ego, psychological mindedness, and ability to recognize relevant problems (Garfield 1994). Therefore, patients suffering from challenging symptoms as well as relative deficits in numerous patient variable categories are likely to experience negligible improvement during treatment. For example, the borderline, alcoholic patient with suicidal tendencies who is forced into treatment, believing that most marital problems are a result of an insensitive spouse, is likely to benefit less from treatment than the depressed patient who voluntarily begins treatment and is determined to make personal changes that will lead to marital harmony.

Although patient variables have been conveniently categorized, the impact each has on the outcome of therapy is not equal. In general, the severity of disturbance is the patient variable that is most related to the outcome of the treatment. Patients with serious mental disorders, such as the schizophrenic, schizoaffective, and bipolar disorders are typically treated primarily with psychopharmacological management, suggesting the challenge these disturbances provide for psychotherapy alone. Personality disturbances also appear immutable to change in the short term use of psychotherapy.

5.2 Common Factors

Because outcome researchers have consistently failed to find sufficient evidence indicating superior effect sizes for particular theoretical modalities, some have concluded that psychotherapy equivalence is a result of factors common to all theories of psychotherapy. Whereas some view these beneficial ingredients as both necessary and sufficient for change, others perceive that these ingredients act in coalition with variables that are unique to particular interventions. It is important to note that regardless of the position held, factors common to all treatments are likely to account for the greatest amount of the improvement in patients undergoing psychotherapy.

In a review of the empirical research, Lambert and Bergin (1994) grouped many of the shared active ingredients of a variety of psychotherapies into three categories: support, learning, and action factors. The factors included in these categories seem to operate most actively during the in-session process of therapy, resulting in a collaborative working relationship that allows clients to confront and cope with reality more effectively. Factors that engender a collaborative relationship include a client's increased sense of trust, security, and safety, along with a reduction in tension, threat, and anxiety that in turn promotes a client's awareness of problems and ultimately new and more healthy perspectives on fears, appropriate risk taking, and motivations for resolving problems in interpersonal relationships.

Factors receiving the most attention in the literature are the common factors considered to be the core of therapy (empathy, warmth, and positive regard). A number of related terms such as acceptance, tolerance, therapeutic alliance, working alliance, and support are also used to describe these ingredients (see *Therapist–Patient Relationship*). In a study designed to explore which of several therapist variables distinguished most consistently between more effective and less effective therapist trainees, Lafferty et al. (1991) concluded that a client's perception of empathy is important to outcome, because less effective therapists, those with patients experiencing more distress as a result of treatment, were found to have lower levels of empathy.

Findings from studies investigating the therapeutic relationship have suggested that a positive working alliance between the patient and therapist is a necessary condition for patient improvement. When asked for factors that were most helpful in their treatment, patients tended to endorse the personal qualities of their therapists, using adjectives such as 'sensitive,' 'honest,' and 'gentle.' The results of similar studies confirm the import that patients place on the characteristics of therapists (Horvath and Greenberg 1994).

Additional evidence supporting the necessity for a strong working relationship is the positive association repeatedly found between scores on measures of early treatment alliance and psychotherapy outcome. In clinical trial studies comparing multiple treatments for particular psychological disorders, patients' positive assessment of the therapeutic alliance is one of the best predictors of psychotherapy outcome (e.g., Krupnick et al. 1996). Although a significant amount of evidence points to common factors as mediators of patient change, the notion of beneficial ingredients unique to specific therapies cannot be ruled out, as occasionally such interventions can be shown to contribute to successful outcomes in patients independent of common factors (see *Psychological Treatments: Randomized Controlled Clinical Trials*).

5.3 Specific Interventions

The drive to empirically validate the efficacy of specific interventions is due, in part, to the field of psychotherapy's commitment to theoretically based approaches, as well as the influence of political and economic forces. Collectively, these factors have led to the use of comparative outcome studies, which generally avoid the ethical and methodological problems associated with no-treatment and placebo controls, while enabling researchers to study the effectiveness of particular techniques or theories by comparison.

5.3.1 Anxiety disorders. Specific behavioral treatments have been found to be effective in treating

patients with anxiety disorders. To date, two treatments, systematic exposure and applied relaxation techniques, have been shown to be efficacious in treating a variety of anxiety disorders. Exposure is a broad term that encompasses both interoceptive and situational exposure interventions. Interoceptive procedures attempt to reliably produce panic-type sensations, with the intent of severing or weakening the patient's associations between certain bodily cues and their respective reactions to panic. The technique of situational exposure, also known as *in vivo* exposure, refers to the patient's repeated intentional encounters with a feared stimulus. Given the focus placed on the catalyst of fear, it is not surprising that clearly identifying the stimulus that induces the patient's reactions is crucial for the success of these procedures.

Evidence suggests that the most effective treatment strategy includes identification of feared stimuli, confrontative periods of exposure sufficient in length to reduce the patient's level of anxiety, and a focus on thoughts providing self-efficacy or performance accomplishment. A general strategy employing the use of exposure techniques appears to be the only efficacious intervention for agoraphobia (DeRubeis and Crits-Christoph 1998). Similar techniques have been shown to be successful for social phobic, panic, and post-traumatic stress disorder patients as well.

The results of a form of relaxation, referred to as applied relaxation, appear to show promise in treating specific anxiety disorders. Applied relaxation entails instructing patients in the skill of progressive muscle relaxation. Patients are generally taught how to progressively relax specific muscle groups. Whereas the evidence supporting the use of applied relaxation techniques alone is mixed in the panic disorder literature, it appears there is support for treating generalized anxiety disorder with relaxation training.

Additional evidence suggests that the treatment of specific disorders is most successful when particular interventions are combined with specific theory-based therapies. For instance, panic disorder is treated most effectively when a cognitive-behavioral theory of therapy is used in tandem with behavioral techniques. Barlow et al. (1989) compared relaxation training (RT), imaginal exposure plus cognitive restructuring (E+C), and a combination of these two interventions (RT+E+C). Outcome was determined by the percentage of patients experiencing panic attacks. Results indicated that 36 percent of the WL (wait-list control) patients, 60 percent of the RT patients, 85 percent of the E+C patients, and 87 percent of the RT+E+C patients were free of panic attacks at the end of treatment.

5.3.2 Depression. Like anxiety-based disorders, there is some evidence supporting the use of specific behavioral techniques in the treatment of depression;

however, in the case of depression, these procedures are no more effective than cognitive, interpersonal, and psychodynamic-interpersonal therapies. For example, behavioral activation alone, which refers to a patient scheduling activities that promote mastery as well as pleasure experiences, has been found to be as effective as cognitive therapy. Whereas behavioral activation is a procedure that makes concerted efforts to involve patients in constructive and pleasurable activities, cognitive therapy emphasizes the modification of maladaptive thoughts, beliefs, attitudes, and behaviors of individuals. Although some researchers predicted the superiority of cognitive therapy's ability to successfully treat depressive patients (Hollon and Beck 1986), the results of large well-controlled studies suggest that interpersonal and psychodynamic-interpersonal therapies are efficacious as well. In contrast to the focus that cognitive therapy places on maladaptive thoughts, beliefs, and behaviors, the interpersonal theory perceives depression as the consequence of problems in the interpersonal history of the patient.

5.3.3 Eating disorders. As eating disorders are generally characterized by harmful cognitions surrounding weight and physical image, cognitive and behavioral interventions have been the most extensively researched treatments. In particular, cognitive behavior therapy has been the focus of much research in the treatment of bulimia nervosa, showing promising results. However, it appears that interpersonal therapy provides generally equivalent results when long term follow-up findings are considered (Fairburn et al. 1993).

5.3.4 Substance abuse disorders. Reviews of the treatment of substance abuse disorders suggest that various therapy modalities have been found effective in treating patients. Therapies that provide generally equivalent results are cognitive, cognitive behavior, and psychodynamic derived therapies. Whereas patients abusing alcohol have been treated, with similar success, using psychodynamic, cognitive behavior, and psychoeducational treatment modalities, opiate dependent patients have been treated with cognitive and supportive-expressive psychodynamic therapies with generally equivalent results.

Some caution should be applied when interpreting the above findings, however, as the results mentioned are typically based on randomized clinical trials. To date, there is little evidence suggesting that these findings generalize to the clinical setting. The question of whether one technique is comparatively unique and more effective than another is a consistent topic in the literature of psychotherapy. There is currently little

evidence supporting superiority of particular interventions, although future research may note unique contributions. For instance, there is a growing body of evidence suggesting that the use of therapy manuals allow for the detection of discernable differences in the behavior of therapists, while at the same time enhancing the effects of specific therapy procedures. Perhaps these contributions will allow for more accurate comparisons in outcome studies. The search for specific techniques and common factors that distinguish successful treatment has proved to be difficult because of the myriad factors that likely exist in the interactions between therapists and clients.

6. The Negative Effects of Psychotherapy

Findings from the study of the progress and outcome of patients undergoing psychotherapy have resulted in both expected and unexpected conclusions. Most patients receiving treatment improve, a minority of patients remain unchanged, and contrary to the intent of psychotherapy, some patients actually worsen as a result of treatment. Independent reviews of the literature suggest that there are patients who fail to achieve beneficial gains from treatment. Although accurate estimates of patient worsening are difficult to make because the results of such incidents are not often the focus of psychotherapy outcome studies, estimates of patient worsening vary between 0 and 15 percent (Lambert and Bergin 1992). Similar to patient improvement, it appears that the phenomenon of deterioration is equivalent across theoretical orientations. In addition, treatment failures are reported in all client populations, treatment interventions, and group and family therapies.

Despite what appears to be an equitable distribution of treatment failures, specific factors have been associated with deterioration. Consistent with the influence that patient variables often have in treatment success, patient characteristics appear closely linked to treatment failure. Severity of mental illness alone is predictive of unsuccessful outcome, and severe levels of mental illness in combination with specific interventions designed to breach, challenge, and undermine entrenched coping strategies and defense mechanisms are more likely to result in treatment failure. Consequently, psychotic, borderline, schizophrenic, and bipolar patients are those patients most frequently experiencing deterioration during the course of treatment. Similar findings have been reported in the psychoanalytic literature, as patients lacking quality interpersonal relationships, low anxiety tolerance at the inception of treatment, and low motivation were more likely to worsen when treated with psychoanalysis and purely supportive therapies, whereas patients treated with supportive-expressive psychotherapy enjoyed better outcomes. Deterioration is not unique to individual therapy, however. Reviews of

group psychotherapy outcome have reported a positive correlation between treatment failure and patient variables such as low participation, poor self-esteem, poor self-concept, and more significant needs for fulfillment. Additional personal characteristics associated with patient deterioration include hostility, interpersonal dysfunction, and negative expectations of treatment.

The above findings suggest that it is important to consider the type of intervention most appropriate for a particular client; however, harm is not the fault of patient and intervention alone. The results of studies investigating therapists' contributions to the phenomenon of deterioration have suggested that specific therapists' behaviors can lead to treatment failure. For instance, the results of a study investigating the relationship between therapist's emotional adjustment, empathy, directiveness, support, and credibility, and patient outcome found that a therapist's empathic abilities were the most predictive of patient outcome (Lafferty et al. 1991). Additional findings of the study suggested that effective therapists were also likely to provide more direction and support than ineffective therapists. These researchers were also interested in the similarity in values held by the therapists and patients, and found that less-effective therapists emphasized values, such as the importance placed on a life of comfort and excitement, whereas effective therapists considered intellectual values, such as reflection, as more important.

Another study suggested that patient deterioration is related to therapist countertransference reflecting disappointment, hostility, or irritation (Mohr 1995). In addition, there was some indication that client deterioration is more prevalent when clinicians underestimate their client's illness or overestimate their client's progress in treatment. Research exploring the importance of leadership styles in group therapists suggests that confrontational and aggressive group therapists tended to have more treatment failures in their groups. These therapists were observed to be more likely to insist upon immediate client disclosure, emotional expression, and change in attitude.

7. Conclusion

Years of clinical research have produced compelling evidence for the value of psychotherapy. Contrary to Eysenck's controversial publication regarding the efficacy of psychotherapy, outcome studies have confirmed that patients benefit in a variety of domains from treatment. According to the dose-effect literature, benefits derived from therapy transpire in relatively brief periods of time. For many clinical disorders, generally one-half of all patients return to normal functioning in 10 to 20 sessions. An additional 25 percent of patients experience substantial improvement when dosage levels are increased to 30 to 50 sessions. The benefits from treatment appear to be

durable, as the results of follow-up studies suggest that the effects of treatment endure for at least one to two years subsequent to treatment.

Not all patients experience the beneficial effects of treatment, and this finding has inspired the investigation of factors facilitating both positive and negative change. The results of such studies have indicated that a patient's level of disturbance is most predictive of outcome; however, desire to change, interpersonal skills, ego strength, psychological mindedness, and awareness of relevant problems have all been found to be related to outcome. In addition to patient variables predictive of successful outcome, there are characteristics of a therapeutic relationship that facilitate a patient's sense of trust, safety, and security. According to patients' reports, therapist empathy and a strong therapeutic alliance are most predictive of treatment outcomes.

Although the use of specific interventions has showed promising results in the case of particular disorders, in general the search for superior treatment strategies has been disappointing, and according to some researchers unnecessary, given the complexity of potential interactions between therapists, clients, and modes of therapy. Regretfully, not all patients improve from treatment, indeed, some actually worsen. Knowledge of this phenomenon is somewhat limited; however, there is evidence that suggests that treatment failure is best predicted by severity of mental illness. Furthermore, factors inhibiting the development of a strong therapeutic alliance also predict negative outcome.

Although researchers have contributed empirical evidence supporting the effectiveness of psychotherapy, they are just learning to understand why patients tend to improve. In time, it is likely that focused and determined research will eventually lead to greater insights into this important question.

M. J. Lambert and E. J. Hawkins

Psychological Treatments, Empirically Supported

Changes in the US healthcare system, set in full motion during the past decade and continuing to evolve, are likely to have a profound impact on the way psychotherapy is practiced. Two primary forces are driving the changes: (a) the increasing penetration of managed care and other types of cost-conscious medical plans, and (b) the development and proliferation of clinical practice guidelines (see *Psychotherapy*:

Clinical Practice Guidelines). The most notable impact of these trends has been the requirement for greater accountability on behalf of service providers. Essentially, managed care and practice guidelines ask the question: does a treatment work and, if so, is it cost effective? Although these forces are influencing every area of healthcare, the current paper will discuss their specific impact on the practice of psychotherapy, and explore why the identification, promotion, and dissemination of empirically supported treatments (ESTs; i.e., those with controlled research data supporting their efficacy, see below for the specific criteria used to make this determination) is essential to the survival of psychological interventions as a first-line treatment for emotional disorders.

1. Managed Care

More than any previous event, managed care organizations (or any other system monitoring the utilization and cost of service such as health maintenance organizations, capitated contracts with providers, etc.) are reshaping the practice of psychotherapy (see *Managed Care and Psychotherapy in the United States*). In the traditional fee-for-service model, decisions about the cost and length of treatment were primarily a function of choices made by the doctor and patient. The allocation of resources (i.e., cost of psychotherapy) was of little concern to the clinician. In fact, the fee-for-service model encourages the provision of service, as more service creates more income. However, in response to the increased costs of psychotherapy, and in particular to the perceived 'endless' nature of psychotherapy, managed care organizations are pressuring clinicians to allocate decreasing (less than usual) amounts of service.

While to date, the focus of managed care organizations cost cutting has been almost entirely on limiting the number of sessions a patient receives, ultimately, in order to compete, managed care organizations will have to focus on the quality and efficacy of the psychotherapeutic interventions as well. Managed care organizations are clearly motivated to cut costs. However, they must also satisfy the consumer (i.e., patient), and payor (e.g., employer providing health benefits) and therefore have to balance cost cutting with patient outcome. Simply reducing the length of care will not accomplish this goal, because many, and perhaps the majority, of psychotherapists are trained in 'long-term' therapeutic interventions which by nature require more sessions than managed care organizations are willing to allocate. Simply reducing the length of therapies devised to take place over a longer period of time is likely to result in ineffective outcomes, leading both to consumer dissatisfaction and increased costs down the road as the severity of the disorder may increase, becoming less responsive to treatment. Thus, concern for the effectiveness of an intervention will eventually temper the managed care

organizations focus on economics. Ultimately, managed care organizations will be interested in clinicians providing the 'optimal intervention...the least extensive, intensive, intrusive and costly intervention capable of successfully addressing the presenting problem' (Bennett 1992, p. 203).

2. Practice Guidelines

A second force that will have a significant impact on the practice of psychotherapy is the establishment of clinical practice guidelines and treatment consensus statements. As noted by Smith and Hamilton (1994), 'Guidelines are now being developed because there is a perception that inappropriate medical care is sometimes provided and that such inappropriate care has both health and economic consequences' (p. 42). It is well known that in all medical fields there is significant variability in treatments delivered to patients with various illnesses. Patients are not necessarily receiving the most effective treatment. Consequently, in order to ensure that patients uniformly receive the optimal intervention—whether it be a type of medication, surgical procedure, or psychotherapeutic intervention—clinical practice guidelines are being developed. For the most part, the development of practice guidelines relies on systematically evaluating scientific and clinical input.

One organization developing practice guidelines is the federal Agency for Healthcare Policy and Research (AHCPR). In order to create impeccable guidelines, only treatments with documented efficacy from randomized controlled trials are considered. Therefore, for an intervention to be included as a first-line treatment, research evidence attesting to its efficacy must be available. Without this evidence, one cannot conclude if a treatment is effective or ineffective, or make judgments about its relative efficacy compared with other available treatments.

The recommendations of the clinical practice guidelines are quite clear. Consider the wording from the AHCPR guideline for Depression (Depression Guideline Panel 1993). When psychotherapy is going to be selected as the sole treatment, the guideline states 'Psychotherapy should generally be time-limited, focused on current problems, and aimed at symptom resolution rather than personality change as the initial target. Since it has not been established that all forms of psychotherapy are equally effective in major depressive disorder, if one is chosen as the sole treatment, it should have been studied in randomized controlled trials' (Depression Guideline Panel 1993, p. 84). In addition to endorsing specific treatments for depression that had sufficient empirical evidence (e.g., cognitive, behavioral, interpersonal), the report goes on to state 'Long-term therapies are not currently indicated as first-line acute phase treatments' (p. 84).

Along the same line as treatment guidelines, consensus statements are likely to carry a significant

amount of weight in determining what treatments have been shown to be effective as well. For example, in 1991 a Consensus Development Conference on the Treatment of Panic Disorder was held, sponsored by the National Institute of Mental Health. As was true in the process of developing the AHCPR treatment guidelines, the merit of various treatments was determined by the available scientific evidence. The format of the conference was to let 'each camp put its best data forward' and the panelists would evaluate and weigh the evidence to formulate a consensus statement (Wolfe and Maser 1994). As in the case of treatment guidelines, specific treatments were judged to be effective for panic disorder: Several pharmacological compounds and cognitive behavioral psychotherapy (cf. Panic Consensus Statement published in Wolfe and Maser 1994). Once again, as is true of treatment guidelines, the wording of the Panic Consensus Statement as to the use of treatments not supported by empirical evidence, whether they be psychological or pharmacological, is quite clear, 'One risk of maintaining individuals in nonvalidated treatments of panic disorder is that misplaced confidence in the therapy's potential effectiveness may preclude application of more effective treatment.' The statement spells out a specific concern about the use of psychotherapies without demonstrated effectiveness for panic disorder, 'The nature of the therapeutic relationship makes it difficult for the patient to seek additional or alternate treatment.'

As one can imagine, as clinical guidelines and treatment consensus statements continue to emerge for a wide array of emotional disorders, they will have a significant impact on the way clinicians practice psychotherapy. In effect, these documents set standards of care, which if ignored, leave the clinician both ethically and legally vulnerable. Health insurance companies and managed care plans are now providing their practitioners with copies of guidelines and asking that they be followed. The implications are clear: failure to provide an empirically supported treatment from these guidelines, when one exists, may constitute malpractice in the eyes of the payor. For example, a number of states have passed, or are in the process of passing, legislation that give guidelines the 'force of law' by protecting clinicians who follow the guidelines from malpractice litigation (Barlow and Barlow 1995).

3. Identifying, Promoting, and Disseminating Empirically Supported Treatments

Recognizing the lack of utilization of ESTs and considering the trends noted above, the Society of Clinical Psychology (Division 12 of the American Psychological Association) established a task force to identify, promote, and assist in the dissemination of ESTs. The original Task Force on Promotion and

Dissemination of Psychological Procedures (now named the Committee on Science and Practice; CSP) was created by David H. Barlow, then president of the Society. The CSP is now a standing committee in the Society of Clinical Psychology, and the work will continue into the future (the most up-to-date reports and a list of committee members are available on the Internet at www.apa.org/divisions/div12).

As noted in a recent paper summarizing the accomplishments and future directions of the CSP (Weisz et al. 2000), there are two broad goals guiding the CSP: to influence both practice and science. Ideally, the influence on practice would be to improve mental health care for the public by encouraging and supporting empirically supported practice and by fostering clinical training that emphasizes reliance on ESTs. As for science, the CSP hopes to stimulate improvement of the quality and clinical utility of treatment research so that it is most relevant to the concerns of clinicians (see Weisz et al. 2000 for specific details).

3.1 Identifying Empirically Supported Treatments

The first mission of the original Task Force was to define criteria to determine whether treatments qualified as ESTs. The following criteria were established (Chambless et al. 1998). For treatments to be considered by the Task Force, research must have been conducted with treatment manuals. This requirement was set because treatment manuals make for better research design, and the use of a treatment manual allows readers to know what specific procedures have been supported. For example, although many interventions fall under the rubric of behavior therapy (e.g., exposure, relaxation training, cognitive restructuring), only exposure and response prevention has been demonstrated as efficacious for obsessive-compulsive disorder. Stating that behavior therapy is effective for obsessive-compulsive disorder does not allow the reader to know what specific strategies were tested and how they were applied. Use of a treatment manual solves this dilemma.

As for whether or not the treatment qualifies as an EST, the Task Force distinguishes between two levels of EST 'well-established' and 'probably-efficacious.' EST status is determined by the results from group design and single-case design studies. With regard to group design studies, to qualify as a well-established treatment, at least two studies conducted by different investigators must qualify as supporting studies. The following criteria must be satisfied in order to qualify as a supporting study: (a1) treatment is superior to pill placebo or psychological placebo, or (a2) treatment is equivalent to an already established treatment; (b) a treatment manual was used in the study; (c) characteristics of the client sample must be clearly specified. A treatment may not meet criteria for well-established

Table 1

Examples of empirically supported treatments

Well-established treatments

Anxiety and stress:

Cognitive behavior therapy for panic disorder with and without agoraphobia

Cognitive behavior therapy for generalized anxiety disorder

Exposure treatment for agoraphobia

Exposure/guided mastery for specific phobia

Exposure and response prevention for obsessive-compulsive disorder

Stress inoculation training for coping with stressors

Depression:

Behavior therapy for depression

Cognitive therapy for depression

Interpersonal therapy for depression

Health problems:

Behavior therapy for headache

Cognitive-behavior therapy for bulimia

Multicomponent cognitive-behavior therapy for pain associated with rheumatic disease

Multicomponent cognitive-behavior therapy with relapse prevention for smoking cessation

Problems of childhood:

Behavior modification for enuresis

Parent training programs for children with oppositional behavior

Marital discord:

Behavioral marital therapy

Probably efficacious treatments

Anxiety:

Applied relaxation for panic disorder

Applied relaxation for generalized anxiety disorder

Cognitive behavior therapy for social phobia

Cognitive therapy for obsessive-compulsive disorder

Couples communication training adjunctive to exposure for agoraphobia

EMDR for civilian post-traumatic stress disorder (PTSD) Rothbaum

Exposure treatment for PTSD

Exposure treatment for social phobia

Stress inoculation training for PTSD

Relapse prevention program for obsessive-compulsive disorder

Systematic desensitization for animal phobia

Systematic desensitization for public speaking anxiety

Systematic desensitization for social anxiety

Chemical abuse and dependence:

Behavior therapy for cocaine abuse

Brief dynamic therapy for opiate dependence

Cognitive-behavioral relapse prevention therapy for cocaine dependence

Cognitive therapy for opiate dependence

Cognitive-behavior therapy for benzodiazepine withdrawal in panic disorder patients

Community reinforcement approach for alcohol dependence

Cue exposure adjunctive to inpatient treatment for alcohol dependence

Project CALM for mixed alcohol abuse and dependence

Social skills training adjunctive to inpatient treatment for alcohol dependence

Depression:

Brief dynamic therapy

Cognitive therapy for geriatric patients

Reminiscence therapy for geriatric patients

Self-control therapy

Social problem-solving therapy

Table 1
Continued

Probably efficacious treatments (continued)

Health problems:

Behavior therapy for childhood obesity
Cognitive-behavior therapy for binge eating disorder
Cognitive-behavior therapy adjunctive to physical therapy for chronic pain
Cognitive-behavior therapy for chronic low back pain
EMG biofeedback for chronic pain
Hypnosis as an adjunct to cognitive-behavior therapy for obesity
Interpersonal therapy for binge-eating disorder
Interpersonal therapy for bulimia
Multicomponent cognitive therapy for irritable bowel syndrome
Multicomponent cognitive-behavior therapy for pain of sickle cell disease
Multicomponent operant-behavioral therapy for chronic pain
Scheduled, reduced smoking adjunctive to multicomponent behavior therapy for smoking cessation
Thermal biofeedback for Raynaud's syndrome
Thermal biofeedback plus autogenic relaxation training for migraine

Marital discord:

Emotionally focused couples therapy for moderately distressed couples
Insight-oriented marital therapy

Problems of childhood:

Behavior modification of encopresis
Cognitive-behavior therapy for anxious children
Exposure for simple phobia
Family anxiety management training for anxiety disorders

Sexual dysfunction:

Hurlbert's combined treatment approach for female hypoactive sexual desire
Masters and Johnson's sex therapy for female orgasmic dysfunction
Zimmer's combined sex and marital therapy for female hypoactive sexual desire

Other:

Behavior modification for sex offenders; Marshall et al. (1991)
Dialectical behavior therapy for borderline personality disorder
Family intervention for schizophrenia
Habit reversal and control techniques
Social skills training for improving social adjustment of schizophrenic patients
Supported employment for severely mentally ill clients

Citations for evidence supporting each treatment can be found in Chambless et al. (1998). Updates of the EST list will be published on the Internet at www.apa.org/divisions/div12

but still satisfy the less conservative criteria for a probably efficacious treatment: two studies show that the treatment is more effective than a waiting list control group, or only one supporting study exists, or if more than one exists, all were conducted by the same investigator. (For details concerning the definition of EST, including use of single subject designs, and resolution of conflicting data, the reader is directed to the Task Force report itself.)

Based upon these criteria, a list of ESTs was published in 1995 (Task Force on Promotion and Dissemination of Psychological Procedures 1995) and two subsequent updates have appeared (Chambless et

al. 1996, 1998). As can be seen in Table 1, the Task Force has identified more than 70 ESTs (Chambless et al. 1998). It is important to note that it is not assumed that treatments without empirical evidence supporting them are ineffective, but instead, in the absence of scientific data, no conclusion can be drawn about its efficacy or lack thereof.

4. Promotion and Dissemination

Deciding upon criteria and identifying ESTs is only the first step in the process towards increasing their

utilization so that the general public benefits. The second step is to call attention to ESTs so that practitioners, health insurers, and the general public is aware of their efficacy (promotion), and to be sure that practitioners are able to use these treatments (dissemination).

4.1 Promotion

As noted by Barlow (1994), despite the considerable data that exist demonstrating the efficacy of psychological interventions, they seem to be taking a backseat to pharmacological approaches in clinical practice guidelines. Why? Perhaps one reason is that, unlike pharmaceutical companies that spend a significant amount of money promoting the use of their treatments to consumers and providers, no such profit motivated organization exists for psychotherapeutic interventions. As a result, many patients are not aware that effective psychological treatments exist, and thus, do not seek them out. Clearly, more effort needs to be focused educating the public about ESTs. As a first step towards this goal, the CSP is about to launch a website listing a description of ESTs for a range of disorders so that 'consumers' of mental health services can find out what types of treatments have been shown to be effective for the problem/disorder for which they are seeking treatment.

4.2 Dissemination

Identifying and promoting ESTs will not solve all the problems noted above. The next step is to ensure that the treatments are available. Unfortunately, as suspected by the CSP, a recent survey of clinical psychology doctoral programs and internship programs revealed that there is insufficient training in ESTs (Crits-Christoph et al. 1995). For example, as noted above, the two of the first-line treatments for depression listed by the AHCPR Depression Treatment Guideline were cognitive therapy and interpersonal therapy. The survey by Crits-Christoph et al. (1995) revealed that among clinical psychology internship programs—the place where clinical psychologists receive the bulk of supervised clinical experience—only 59 percent of programs provided supervision in cognitive therapy for depression, and a mere 8 percent of programs provided supervision in interpersonal psychotherapy. These are two psychotherapeutic treatments listed as first-line interventions for depression in the AHCPR Depression Treatment Guideline, thus, the lack of training in these areas is of significant concern. University doctoral programs were slightly better; 80 percent providing supervision in cognitive therapy and 16 percent in interpersonal psychotherapy. It is

important to note, however, that having supervision available does not require students to receive it. As a result, these numbers do not indicate that 80 percent of students are in fact receiving training in cognitive therapy, and thus, the percentages are an overestimation of the number of students receiving supervision in that approach. For example, only 14 percent of internship programs required training in cognitive therapy for depression and only 3 percent in interpersonal therapy. Unfortunately, training in ESTs for depression is the highest. As noted in the Crits-Christoph et al. (1995) survey, only a handful of programs require training in a range of ESTs. For example, the survey revealed that only 7 percent of internship sites provide supervision in interpersonal therapy (IPT) for bulimia, 5 percent in CBT for social phobia. The numbers for doctoral programs, though higher, are still not all that promising: 21 percent offer supervision in IPT for bulimia, 24 percent in CBT for social phobia. Each of these treatments represents a first-line intervention for the respective disorder (with some of the treatments being the only empirically supported psychotherapeutic intervention), so it is not as though training in other EST approaches is occurring. Unfortunately, training in other ESTs is similar to the low numbers for depression, bulimia, and social phobia.

If training at the graduate and internship level is lacking, one can imagine how difficult it will be to disseminate these treatments to practitioners already practicing in the field. To date, no formal process exists to disseminate and train ESTs to practitioners. A perfect example of the consequence of this is that despite the strong data supporting cognitive behavioral treatment for panic disorder, a recent survey found that the majority of patients with panic disorder receiving psychological treatment receive dynamic psychotherapy (which has not been empirically supported as a first-line treatment) (Goisman et al. 1999). Indeed, as noted by Calhoun et al. (1998) in a recent paper discussing training in ESTs, reaching professionals out in the field is the most problematic area. With a rapidly changing data base, clinicians trained 10 years ago are unlikely to be up-to-date with the newer, empirically supported psychotherapies. Indeed, the majority of references supporting ESTs have appeared in the past 10 years (Calhoun et al. 1998). How can clinicians become motivated to learn ESTs? Even if they are motivated, how can treatments be disseminated in a way to provide high integrity supervision to insure they are properly trained? The CSP plans to devote a considerable amount of effort to develop a model that would facilitate training professionals in ESTs, because as discussed above, this is an essential activity for the survival of psychotherapy as a viable first-line treatment for emotional disorders. For those interested, a list of manuals outlining ESTs is available (cf. Sanderson and Woody 1995; available at www.apa.org/divisions/div12).

5. Criticism of the EST Movement

The movement towards ESTs are not welcomed by everyone within our profession, and indeed, several authors have raised important concerns and criticisms (e.g., Garfield 1998, Kovacs 1995, Nathan 1998) regarding the identification of 'validated' therapies. Although space does not permit a discussion of the specific issues here, in fact, the CSP agrees that there are difficulties and risks in establishing so-called psychotherapy guidelines—or any treatment guidelines for that matter (cf. Pincus 1994 concerning the development of psychiatry guidelines)—yet the CSP and other professional organizations believe the benefits clearly outweigh the risks (Pincus 1994, Sanderson 1995), and thus, will continue the work outline above (cf. Weisz et al. 2000 for a discussion of the future directions of the CSP).

Psychological Treatments: Randomized Controlled Clinical Trials

The randomized controlled trial is one method of ascertaining the effectiveness of a treatment. In its simplest form, a controlled trial consists of the recruitment of a group of participants with particular characteristics and their allocation by chance to one of two treatment conditions. These conditions should

differ only in the treatment procedure A whose effects are being studied. Thus one condition will include A, and the other condition will not. Randomization is used to ensure that events other than treatment that might affect outcome will be equally balanced across the two treatment conditions. If measures of key features of the disorder, for example, the principal symptoms, are taken before and after treatment, then it is possible to test whether the null hypothesis of no effect of treatment A is true or not. While more complex experimental designs are often used, and the choice of the control condition is often difficult, all controlled clinical trials adhere to this basic conceptual form.

1. Development of Controlled Clinical Trials in Psychology

Parallel developments in two clinical disciplines, medicine and psychology, beginning in the 1930s, edged both fields toward the use of controlled trials. In an early study spanning both medicine and psychology (Chappell and Stephenson 1936), the authors demonstrated that an educational group program resulted in greater improvement and less relapse in a group of peptic ulcer patients than the control group, both groups having received the same medical care. Another study, the Cambridge-Somerville Youth Project, begun in the late 1930s and continuing with a long-term follow-up into the 1950s, was one of the earliest trials of a psychological treatment (Teuber and Powers 1953). This large-scale, well-designed study of 650 boys thought to be at high risk of developing delinquency was aimed at evaluating a prevention program. The outcome, as these individuals were followed over time, demonstrated that the treatment group fared less well than the control group in terms of a range of delinquent behaviors. Such negative results, while disappointing, are important because they allow ineffective approaches to treatment to be abandoned.

These early controlled trials were the exception rather than the rule. Most studies of the effectiveness of psychological therapies consisted of treating a series of patients without a control group. Hence, it was impossible to be sure whether the results were due to spontaneous recovery or to the treatment, let alone specific aspects of the treatment rather than a non-specific (placebo) effect. Two developments catalyzed the use of the controlled trial. Hans Eysenck, Professor of Psychology at London University, reviewed the psychotherapy treatment literature in 1952 and again in 1966 (see Eysenck 1952, 1966). On both occasions Eysenck concluded that there was little evidence that psychotherapy was effective, that is, that the results did not exceed the expected rate of spontaneous recovery. While this opinion resulted in a vigorous debate and defense of psychotherapy, including the

addition of a few treatment trials that demonstrated some success for various forms of psychotherapy that Eysenck had not considered, Eysenck's conclusions were widely accepted, reaffirming the need for well-conducted controlled trials. Some, however, argued that the effects of psychological therapies, because they were aimed at 'inner' essentially unmeasurable changes, could never be adequately assessed in a controlled trial. This problem was largely overcome by the next development.

The second, and most important, catalyst for the use of controlled trials of psychological treatments, was the emergence of behavior therapy (see *Behavior Analysis, Applied; Behavior Therapy: Psychological Perspectives* for further details). Eysenck 1966, p. 39) had concluded that 'With the single exception of the psychotherapeutic methods based on learning theory, results of published research ... suggest that the therapeutic effects of psychotherapy are small or non-existent ...' Because behavior therapy was based on learning theory, the focus of treatment was directly on the problem behaviors comprising the clinical syndrome. This allowed for the development of objective measures of treatment outcome (see *Behavioral Assessment* for a fuller discussion of objective evaluation methodology). In addition, because treatment was scientifically based, its practitioners were more likely to use scientific methods, including the randomized controlled trial, to assess the effectiveness of these new treatments.

2. The Flow of Research

Although the controlled trial is the definitive method of ascertaining the effectiveness of a treatment, it is not the only method used in the research process aimed at the development of a new therapy. The first step in the development of a new therapy, the initial formulation of its conceptual basis and procedures, may stem from basic psychological research or theory, and/or from clinical observation. The first step in the development of a new therapy is usually an uncontrolled observational study, namely treatment of a series of patients. If a sufficient number of patients respond favorably to the new treatment, then the next step is to document the treatment procedures in a manual so that it can be replicated by others. The first controlled study may compare treatment to no treatment, a step that is relatively easy to carry out with a small number of patients, providing information as to whether the new treatment is better than doing nothing, and allowing the results to be roughly compared with those of standard therapy for the same condition, if such a therapy exists. One objective method of comparing the effects of different therapies is to calculate the effect size (the change from pretreatment to post-treatment in a group of patients divided by the standard

deviation of the change). An effect size of 0.3 would be regarded as small, one of 0.5 as moderate, and 1.0 as large.

The next step is to ascertain whether the promising new treatment has specific effects over and above what is usually termed the placebo or nonspecific effect (see Sect. 3). Hence, it is important to compare the new treatment to a second treatment containing nonspecific features common to all therapies, but not containing the specific procedures aimed at ameliorating the behaviors being studied. Single case controlled studies may also be useful at this stage of development to more precisely delineate the active components of treatment (see *Single-case Experimental Designs in Clinical Settings*).

Once the new treatment has been demonstrated to have specific effects on a particular disorder, the next step will probably consist of a comparison with the standard therapy for the condition. At this stage related studies are likely to be carried out at different centers. The results of such studies can be compared using a procedure known as meta-analysis in which effect sizes are compared across studies. It may be clear from the results of such an analysis that the new treatment is better or worse than standard treatment, or that it is useful for a particular subgroup of individuals, or that it has advantages such as being less costly but similarly effective. On the other hand the results of such comparisons may be unclear. Some studies may demonstrate positive effects while others may show no effect. Such conflicting results are often due to the initial studies having too few patients enrolled to determine accurately the effectiveness of the new treatment as compared with other treatments. In this case a study involving several clinical sites may be needed to recruit a sufficient number of patients in a short enough time, to obtain more definitive results.

2.1 Multisite Studies

Multisite studies are necessarily more complex to carry out than a study at a single site. They are also more expensive than single-site studies and for that reason should only be entered upon when the preliminary work described above has been completed, and the need for such a study has been precisely formulated. The investigators involved must agree to a common experimental protocol. The treatment(s) being studied must be well documented in a treatment manual and therapists at each of the sites trained in the delivery of the treatments. Moreover, the therapists should be carefully supervised throughout the study to ensure that they are delivering the treatment(s) in accord with the protocol. Tape recordings of treatment sessions may also be audited to ensure fidelity to the treatment. In addition, the assessments used must be carried out in a standard manner and done com-

parably between sites. This may mean that assessors will also be trained and supervised across sites in the particular assessment methods. One advantage of a multisite over a single-site study is that the effects of treatment are examined in different sites that may have unique characteristics in terms of patient population, therapist characteristics, and so on. Hence, generalizability of the results of treatment to the clinical world is greater than in the single-site study.

Another reason to conduct a multisite study is when treatment for a relatively rare disorder is being studied. If the study were to be done at only one site it might take many years before sufficient participants entered the study. A multisite study would provide more rapid results. Another reason for considering a multisite study is when the question of interest shifts to what treatment or treatments might benefit those who do not respond to an initial effective treatment. Because only treatment failures will be entered into such a study, a large number of individuals must be treated in order to generate a sufficiently large sample for the study.

2.2 Effectiveness Research

As noted above, a distinction has arisen between efficacy and effectiveness controlled trials. Trials to establish efficacy are considered to be carried out in refined settings with carefully chosen patients and expert therapists. Effectiveness studies on the other hand are considered to be carried out in clinical practice settings with 'real life' patients and possibly less expert therapists. Some would consider efficacy studies to be of limited value in assessing the outcome of psychological therapies in contrast to effectiveness studies. However, if the flow of research described above is taken into consideration it is evident that efficacy and effectiveness studies lie on a continuum rather than being different types of studies, and that research along the entire continuum is needed. Moreover, the scientific questions being studied differ along the continuum that constitutes the flow of research.

Once a psychological treatment has been established as useful for a particular disorder in a number of single-site studies (efficacy studies) and, if needed, a multisite study, research as to how to transfer the treatment to other settings may be needed (effectiveness studies). This step in the development of a treatment may involve controlled studies of modifications of the treatment. Such modifications may include simplification of the treatment for wider dissemination to less skilled therapists and investigation of the necessary clinic environment to support the therapy. For example, in most controlled trials therapists are carefully supervised, and the question arises whether such supervision is essential to the effectiveness of the therapy. Additionally, the type of

patient encountered in different clinical settings may differ, again requiring modification of the therapeutic procedures. Once these questions have been resolved, often using controlled trials, an effectiveness study can be designed in one or more clinical settings using the staff of such clinics as the therapists, and enrolling all the patients with the particular disorder into the study as they appear in the clinic. A control condition in such cases might be the usual care that participants would receive in such a clinic.

3. Essential Elements of a Controlled Trial

While the basic design of two groups differing only in A (the components of a new treatment) suffices for early stages of research, other questions will need to be addressed. Among the most problematic is how to control for nonspecific elements of psychological treatments. Treatments can be regarded as a package containing both specific procedures aimed at the particular problem, together with elements common to all therapies, such as therapist attention, and therapeutic instructions that include the rationale for therapy together with engendering an expectancy that treatment is likely to be successful.

Research has demonstrated that nonspecific elements lead to significant behavior change. Hence, it is important to know to what extent procedures specific to the therapy contribute to a successful outcome over and above nonspecific elements. This raises problems for psychological therapies because there is no placebo pill. This problem has been solved in several ways. The first solution is to use a nonspecific therapy, that is, one without the specific therapeutic procedures being examined but which also has face validity as a therapy with which to compare the active treatment. Some controlled trials may compare a psychotherapeutic procedure with medication and with a pill placebo as a control condition, thus solving the nonspecific effect question in a different manner. Finally, it is possible to compare a new therapy with a standard therapy for the condition which has already been demonstrated more successful than a nonspecific therapy.

3.1 The Use of Treatment Manuals

The reports of early studies of psychological therapies usually described the treatment in a paragraph or two. Such descriptions are obviously insufficient to allow other investigators or therapists to provide the same treatment to their patients. The treatment manual was developed to solve this problem. Such manuals, now regarded as an essential element of a controlled trial of psychological therapies, describe the treatment pro-

cedures in sufficient detail for others to replicate them. Therapists are carefully trained in the procedures, which the manual facilitates.

There is some controversy regarding the clinical use of treatment manuals, which have now become a common method of disseminating new therapies to clinicians. Some argue that manuals lock the therapist into a rigid method of providing treatment, thus eliminating the opportunity to individualize the treatment. Others suggest that manuals provide essential guidelines for therapists and that the experienced therapist will be able to individualize treatment to the extent necessary. There is relatively little experimental data on the effectiveness of the use of manuals in the clinic; however existing data suggests that manuals are likely to enhance therapy probably by ensuring that the therapist stays on track during the treatment process. See *Clinical Psychology: Manual-based Treatment* for a fuller discussion of this important issue.

3.2 Controlling the Fidelity of Treatment

A further essential element of a clinical trial is a method to ensure that the therapy provided is faithful to the treatment manual. This is usually ensured in two ways. First, therapists are trained in the use of the manual and practice the treatment on several patients before the controlled trial begins. During this period the therapists are supervised by an expert. Second, once the trial begins, therapy sessions are audiotaped, and a random sample of such tapes is audited. The auditor will use a checklist to ensure that all the elements of treatment are being provided, and that no foreign elements have crept in. Regular feedback is provided to the therapists, and the degree of therapist compliance with the treatment protocol should be reported in the paper describing the study.

4. Outcomes of Controlled Trials

There are several potential outcomes from a randomized clinical trial. First and foremost is whether the treatment is effective as compared to the control group; second, whether there are specific predictors as to which patients do best with the treatment under study; third, whether variables that mediate the outcome of treatment can be identified. Such mediators may throw light on how a given therapy works.

4.1 Assessment of the Primary Outcome

The primary outcome for a controlled trial is the main indicator or indicators that characterize the syndrome.

For example, for panic disorder, the number and severity of panic attacks would comprise the main outcome; for depression a measure of the severity of depression; for bulimia nervosa, a measure of binge eating and purging. Because these measures test the primary hypothesis addressed, that is, the null effect of the treatment in question as compared with a control group, the study should stand or fall depending on whether the primary outcome is positive or not. If the primary outcome is positive then secondary measures—usually associated psychopathology—are also examined for the effect of treatment. Because some symptoms such as mild anxiety or depression are normative in a community, the extent to which the treated population now approximates community norms may also be reported.

4.2 Examination of Predictors

It is usual in a controlled trial to assess a series of variables that are hypothesized to affect the outcome of treatment. Examples of potential predictors include: the duration and severity of the problem, the age and social class of the patient, and associated psychopathology. If predictors of sufficient strength are found they may be used in future trials to select patients most likely to succeed with the treatment, thus refining the indications for treatment. In general, the search for such predictors has not been very successful. Usually such predictors are sufficient for a general description of the patient most likely to improve, but not specific enough to identify such patients before treatment begins. An alternative method of prediction is to examine the progress of patients during treatment. In many psychological treatments patients obtain significant benefit early in therapy. Patients who do not demonstrate this early response tend to do poorly. Hence, it may be possible to identify those most likely to do badly with a particular psychotherapy early in treatment and to use a different treatment approach with such patients.

4.3 Identifying Treatment Mediators

A mediator is a variable that is responsible for an effective treatment outcome. Hence, it is a result of a therapeutic procedure that occurs prior to the benefits of treatment and that is significantly related to the outcome. Rather than measuring such variables before treatment begins, as is the case with predictors, potential mediators are measured early in the course of treatment. Potential mediators are usually selected based on precise hypotheses about how the treatment works. The identification of mediators can throw important light on the mechanisms underlying the

effectiveness of a given psychological treatment and may provide insight as to how to improve the treatment. See also *Psychotherapy Process Research* in which interactions between therapist and patient, and their effect on outcome, form the question of interest.

5. Are Controlled Psychological Treatment Trials Useful?

While controversy over the use of controlled trials to evaluate psychological treatments continues, the argument has shifted as to whether such trials can reliably inform clinical work and social policy. Some argue that uncontrolled trials conducted in 'real' clinical settings with real patients would be more informative. This argument ignores the necessity for a sequenced flow of research in the development of a new psychological therapy. Moreover, without a control group, it is impossible to determine whether it is the treatment or some other variable that is responsible for the outcome. Despite this ongoing controversy, the controlled trial has become the accepted method of evaluating the effectiveness of psychotherapy. Most individuals would prefer that their medical treatment was informed by controlled therapeutic trials; similarly, consumers of psychotherapy should demand that these procedures are well tested.

6. Future Developments

It is likely that the use of randomized controlled trials to evaluate the effectiveness of psychological treatments will accelerate. At present a relatively large number of treatment procedures have been identified as effective for specific psychological problems (see *Psychological Treatment, Effectiveness of; Psychological Treatments, Empirically Supported* for a detailed review of such treatments). Many, but not all, such therapies fall under the rubric of behavior therapy. These research efforts have now generated a small, but growing number of multisite trials in which the treatment is put to a more definitive test, compared with another effective psychotherapy, or with medication either separately or in combination with psychotherapy. As is the case in medical research, it would be expected that this trend will continue, and that multisite trials will be increasingly used in psychotherapy research.

Because no one psychotherapy is effective with all those suffering from a particular psychological disorder, research is beginning to examine the efficacy of a second treatment approach for those who fail initial therapy. Moreover, there is much interest in the effectiveness of therapist-supported bibliotherapy.

Such developments may ultimately lead to algorithms guiding the manner in which psychological treatments should be sequenced for the treatment of a given condition. For example, treatment might begin with the least costly treatment followed by increasingly expensive (and probably more effective) treatments for those who fail one or more initial treatment.

In the somewhat further future the biological mechanisms through which psychotherapies work will become a focus of research, ultimately bringing together psychological and biological mechanisms underlying behavior change.

Psychologism, History of

The history of psychologism is the history of an accusation and of a threat. To label an author an advocate of psychologism is to claim that he or she uses psychological concepts and ideas in the wrong place. The accusation first became popular in the German-speaking world with the rise of experimental psychology in the second half of the nineteenth century. The most famous episode in the history of the accusation is the German ‘psychologism controversy’ at the beginning of the twentieth century. It will be the central topic of this article. It is widely accepted that this controversy played an important role in shaping the character of Western philosophy in general and analytic philosophy in particular. It also influenced subsequent debates over ‘sociologism.’

1. The Psychologism Controversy in Early Twentieth-century Germany

From the 1880s onwards, a number of German logicians and epistemologists started to attack some of their philosophical colleagues for presenting and endorsing the following kinds of ‘psychologistic’ arguments:

Logic studies specific ‘laws of thought.’ Psychology is the study of all kinds of laws of thought. *Therefore*, logic is a part of psychology.

Normative disciplines must be based upon descriptive-explanatory disciplines. Logic is a normative discipline with respect to human thinking. Psychology is *the* descriptive-explanatory discipline with respect to human thinking. *Therefore*, logic must be based upon psychology.

Logic is concerned with judgments, concepts, and inferences. Judgments, concepts, and inferences are human mental entities. *Therefore*, logic is a theory about human mental entities.

The touchstone of logical truth is self-evidence. Self-evidence is a human mental experience. *Therefore*, logic is about a human mental experience (and thus a part of psychology).

We cannot conceive of a radically different logic. The limits of conceivability are our mental limits. *Therefore*, logic is relative to the human species, and thus a subfield of human psychology.

In some cases there was considerable dispute concerning the question who actually held these views. The first argument can be found in Theodor Lipps and Gerardus Heymans, the second in Wilhelm Wundt, the third in Wilhelm Jerusalem and Christoph Sigwart, the fourth in Theodor Elsenhans, and the fifth in Benno Erdmann. All the accused had published widely on psychological issues, and some of them openly advocated treating psychology as the foundation of philosophy.

Arguments against these and other allegedly psychologistic authors were provided by many writers, amongst them the logician and mathematician Gottlob Frege, the phenomenologist Edmund Husserl, and the Neokantians Hermann Cohen, Paul Natorp, Heinrich Rickert, and Wilhelm Windelband. Of these and the many other critics, Husserl was undoubtedly the most successful. Husserl's arguments appeared in the *Prolegomena* to his *Logische Untersuchungen*. The following arguments figured centrally in the debate:

If logical rules were based upon psychological laws, then all logical rules would have to be as vague as the underlying psychological laws. *But*, not all logical rules are vague. *Therefore*, not all logical rules are based upon psychological laws.

If laws of logic were psychological laws, then they could not be known *a priori*. They would be more or less probable rather than certain, and justified only by reference to experience. *But*, laws of logic are known *a priori*; they are justified by apodictic self-evidence, and certain rather than probable. And *therefore*, laws of logic are not psychological.

If logical laws were psychological laws, they would refer to psychological entities. *But*, logical laws do not refer to psychological entities. And *therefore*, logical laws are not psychological laws.

All forms of psychologism imply relativism. Psychologistic thinkers take logic to be true only for the human species. But this contradicts the meaning of truth. Truths are unchanging, and independent of the human mind.

A good deal of the psychologism controversy concerned the validity and originality of Husserl's arguments. Several commentators maintained that Husserl's first three arguments all begged the question. Others challenged Husserl's claim that the laws of logic did not imply matters of fact. Husserl's critics also denied that truths were eternal or independent of human thought.

The debate over psychologism was vigorous. This can be seen, for instance, from the fact that more than 130 philosophers were accused of advocating psychologism and that there were as many symptoms and definitions of psychologism as there were philosophical schools (Kusch 1995). It was not merely the relationship between logic and psychology that was at issue, but the relationship between psychology and philosophy as a whole. This was a pressing issue not least because the practitioners of the then new (experimental) psychology worked in philosophy departments, and because between 1873 and 1913 the number of full professorships held by these 'psychologists' increased from one to ten. Of the 39 full professorships in philosophy in 1892, practitioners of experimental psychology held three; of the 42 full professorships in 1900 they occupied six; while of the 44 full professorships in 1913 they had already gained 10. Practitioners and advocates of the new psychology sometimes

claimed that psychology provided the key to real progress in philosophy or that it was the heart of philosophy (Ash 1995, Kusch 1995, 1999).

This last-mentioned contention was opposed by a quickly growing group of 'pure' philosophers—led by the Neokantians, and by Eucken, Dilthey, and Husserl. They deemed it harmful to philosophy and its progress that experimental psychology should be regarded as part and parcel of philosophy. To put it another way, these philosophers believed that the role of the philosopher, as suggested by the academic success of experimental psychology, needed purification.

The prolonged debate between the advocates and opponents of psychology as a philosophical discipline was eventually brought to an end by World War I. The war brought about an atmosphere in which attacks on one's colleagues were regarded as utterly inappropriate. Moreover, it also led to a clear division of labor between pure philosophers and psychologists: while pure philosophy concentrated on the ideological task of celebrating the German 'genius of war,' experimental psychology focused on the training and testing of soldiers. After the war, both academic pure philosophy and experimental psychology had to cope with, and accommodate to, an intellectual environment that was hostile to science, rationality, and systematic knowledge. The project of a scientifically minded philosophy with experimental psychology as its central pillar quickly lost support. Advocates and practitioners of experimental psychology therefore had to find new ways of justifying their work. Many of them continued their wartime involvement with applied psychology (Kusch 1995).

2. The Influence of the Psychologism Controversy

2.1 Psychologism and Sociologism

The way the psychologism controversy was fought by the defenders of philosophical purity became an important model for subsequent disputes between advocates and opponents of 'naturalism' (the view that philosophical questions can be answered using the results of the natural and social sciences). Many later arguments against 'sociologism' or 'biologism' closely mirror Frege's and Husserl's ideas.

For instance, in the German-speaking world the psychologism controversy of the first two decades of the twentieth century was followed by the dispute over the nature and philosophical aspirations of the sociology of knowledge. Accusations of 'sociologism' surfaced quickly and 'sociologism' was seen by many as the 'successor' to psychologism. Again many philosophers felt that a special science—this time sociology—was trying to occupy philosophical terrain.

Critics of the sociology of knowledge accused it of both psychologism and sociologism, and in so doing, they drew on Husserl's work in particular. Defenders of the sociology of knowledge tried a similar feat in presenting their work as a bulwark against psychologism (Meja and Stehr 1990). This idea has become a general feature of the field to this day (Bloor 1983). The close link between the two 'isms' has been transmitted to subsequent Anglophone thinking mainly through the work of Sir Karl Popper.

2.2 Psychologism and Philosophy

German-speaking philosophy of the turn of the century exerted a powerful and lasting influence on philosophy in many other countries. Frege's and Husserl's (1970) antipsychologism thus became the dominant view in Western philosophy for much of the twentieth century. This is not to deny that other countries also had their own debates over the relation between psychology and philosophy. In the UK, for instance, George Frederick Stout and James Ward emphasized the philosophical significance of psychology; British Idealists like Francis Herbert Bradley and Brand Blanshard were sympathetic to psychology even though they denied its philosophical credentials; and realists like John Cook Wilson, Bertrand Russell, Herbert Joseph, and Herbert Prichard insisted on a separation. For Prichard, psychology was not even a 'proper science' (Passmore 1994).

The institutional separation of psychology from philosophy eventually removed one important source of conflict. Once institutional separation had been achieved, 'pure' philosophers and 'impure' philosophers (i.e., psychologists) were no longer in direct competition over academic chairs. On the plane of ideas, however, the psychological challenge has remained. Throughout the twentieth century, psychology exerted a powerful pull on philosophers who wished to put philosophy on the sure path of a natural science. Willard Van Orman Quine explicitly called for a return to psychologism in the 1960s. Such calls have kept the psychologism accusation alive. Amongst the accused one can find the names of Rudolf Carnap, Michael Dummett, Peter Geach, Nelson Goodman, Thomas Kuhn, John McDowell, Karl Popper, Wifrid Sellars, and Ludwig Wittgenstein.

It is now common amongst historians of philosophy and psychology to lament the outcome of the psychologism controversy. The separation of philosophy from psychology delayed the development of research programs like 'cognitive science' that combine psychological experimentation with philosophical aspiration.

Psychology and Economics

Economics without psychology has not succeeded in explaining important economic processes and 'psychology without economics' has no chance of explaining some of the most common aspects of human behavior (Katona 1951).

Psychology as the science of human behavior naturally also encompasses the study of economic behavior. From this perspective, there is a considerable overlap between the two disciplines of psychology and economics, as manifested in such subdisciplines as economic psychology, behavioral or psychological economics, economic cognition, and other hybrids. Despite this multiple overlap, both disciplines use rather different approaches, rest on entirely different

assumptions, and focus on different phenomena of interest. This article first portrays the points of contact and difference between psychology and economics. A generalized exchange assumption is then identified as a theoretical interface connecting both disciplines. The implications of this basic exchange assumption afford an organizing framework for a review of empirical research findings.

1. Comparison of the Two Disciplines

1.1 Points of Contact

As disciplines psychology and economics are multiply interrelated. Both serve each other as explanans and explanandum. First and foremost, psychological theories and knowledge have been amply applied to explain problems genuinely studied in economics. Vice versa, economic theory has also been applied to some fields located traditionally more within the realm of psychologists rather than economists. In most general terms, one might say that both disciplines meet in the area of decision making.

Psychological theories and knowledge help to explain how scarce resources are handled so as to satisfy needs. This approach focuses on psychological mechanisms and processes underlying consumption, investment, saving, and other economic behavior. Although early classics of economic theory explicitly or implicitly acknowledged psychological variables, there was no attempt to incorporate the psychological research systematically. Only Katona (1951) recognized that purely economic variables such as income insufficiently explain economic behavior such as consumption. He assumed that psychological variables such as affect, attitudes, expectations, and others intervene between economic stimuli and consumer reactions. Until today, the study of consumer behavior including marketing and advertising (see *Consumer Psychology; Psychology and Marketing; Advertising, Psychology of*) has remained by far the most successful and most pervasive application of psychology to economic behavior. This is particularly so in the area of consumer information processing (CIP), which exclusively relies on psychological theory. CIP deals with how consumers attend to, encode, store, and retrieve product relevant information and how they integrate this information to arrive at a judgment or choice. Examples of other interdisciplinary applications are fiscal psychology, that deals with attitudes towards taxes and the behavior of tax evasion, environmental behavior such as energy conservation or contingent valuation, pricing in business, household saving, and investing.

Whereas psychologists study stock market behavior, Gary Becker (1976) applied a purely economic approach to explain marriage, crime, and having

children—all behaviors that have traditionally been of more interest to psychologists than to economists. By assuming a maximizing utility behavior, stable preferences, and a market equilibrium—the key assumptions in economics—a wide range of human behaviors can be integrated and explained in terms of costs and benefits (Levinger 1965).

Another point of contact concerns the impact of economic variables on states and behaviors that are significant for the individual's well-being such as poverty, debt, or unemployment as related to happiness, physical and psychological health, and suicide. Conversely, more psychological variables such as achievement motivation or religious conviction can have an impact on economic success.

1.2 Points of Difference

As described above, psychology and economics differ not so much in their content domains but in the research methods and theoretical premises and frameworks. First of all, whereas psychologists study *individual* behavior, the research object of economists are *markets*, not individuals or even households. This distinction is most important as other major disagreements and often seemingly irreconcilable differences stem from it. Economists presuppose that markets behave rationally, following rules that maximize utilities. Although individuals may not adhere to these rules—as psychology has shown over and over—the assumption is that irrationalities on the individual level will cancel each other on the market level, resulting in rational markets. This assumption is unrealistic from psychology's view. A whole research tradition has accumulated evidence for how individuals deviate from normative rules not at random but in a systematic fashion. Given such systematic biases in judgment and decision-making, cancellation at the aggregate level becomes an illusion.

Psychology is inductive whereas economics is deductive. Psychologists observe individual behavior in order to test hypotheses concerning the underlying mediating processes. Although these hypotheses are often derived from higher-order theories, these theories are typically domain-specific and controversial, rather than universal and commonly shared. Economists on the other hand are more interested in predictors rather than causes, are more interested in outcomes rather than processes, and share widely accepted key assumptions such as utility maximizing behavior. Based on these key assumptions, economists deduce formalized models to predict particular outcomes. Whether the predictors are causally relevant at the individual level is only of interest to the extent that such causal mediators result in accurate models.

Clearly, this juxtaposition describes the extremes. Economists and psychologists have developed some common ground, combined interests, and a fruitful

dialog, mainly incorporating psychology into economic decision making. Some of this work will be reviewed in the following. However, given that psychology is mainly concerned with individual behavior and economics with aggregate behavior, it is interesting that the mediating link—how individual behavior translates into aggregate behavior—has largely been neglected by both sides and their respective interdisciplinary approaches. Aggregate behavior, however, is clearly not simply aggregated individual behavior. For example, although consumer sentiment predicts consumer spending at the aggregate level—and is indeed a better predictor than income or other economic variables—it does not do so at the individual level.

Research methods constitute an additional source of divergence. Psychological research relies mainly on highly controlled experiments mostly conducted in the laboratory. The experimental situation is quite often rather different from the setting where the corresponding behavior naturally occurs. In particular, economists have questioned whether the use of deception in experiments leads to valid research inferences. Nevertheless, a considerable part of economic research has adopted the experimental method from psychology, with and without deception.

2. Exchange Rules as an Interface for Research in Psychology and Economics

The common denominator of most empirical research in the interface of psychology and economics lies in the assumption of a basic *exchange paradigm* that governs all kinds of research topics such as pricing, marketing, consumer choice, fairness of negotiation, coalition formation, investment, etc. The ultimate goal of economical exchange is to minimize the total input to actions and transactions and to maximize the total output combined over several dimensions or resources (money, effort, time, security, etc.). Within this paradigm, success means to obtain high output from low input, failure means that the output is low relative to the input. Fairness means that different parties' (actors, companies') output–input ratio is balanced. Note that in order to calculate an output–input ratio, it is essential that resources of all kinds be translatable to a joint scale so that effort can be paid in money, security can be traded against reduced profit, information costs are compensated by higher quality, and innovative ideas increase product quality, market price, and organizational efficiency (i.e., reduce workload and coordination loss). Only when all these different kinds of resources can be exchanged and can compensate each other, different action alternatives or decision options can be represented on a monotonic preference scale. Monotonicity or equivalence is indeed a precondition for all rational behavior within this basic exchange paradigm.

The rationality principle that underlies models of economic behavior as well as the irrational tendencies emphasized in psychological approaches revolve around diverse aspects of monotonicity. Indeed, a review of research on psychology and economics can be organized in terms of rules and violations of monotonicity on the one hand and problematic aspects of the underlying normative monotonicity assumptions on the other.

3. Rules and Violations of Monotonicity: Research Examples

3.1 Transitivity of Preference

Any quantitative scaling of economic goods (e.g., products, shares, investment options, job applicants) a, b, c must fulfill the transitivity constraint: If $a < b$ and $b < c$, then $a < c$. For instance, if the price that can be obtained for object b is higher than the price for a , and the price for c is even higher than for b , then c must also obtain a higher price than a . Otherwise, rules of exchange would either break down completely, or the joint scaling of prices, preferences, and attitudes would be severely complicated. However, in reality, this seemingly obvious normative rule can be violated systematically. Psychological models predict intransitivities under specified conditions. In a multi-attribute utility framework, each object a, b, c is characterized by multiple aspects, describing advantages or disadvantages. When comparing a pair or subset of objects, some aspects are more salient and receive higher weights than other objects. Intransitivities can arise when the preference of b over a and of c over b is due to different aspects than the comparison of a and c . For instance, when choosing among three meals in a restaurant, somebody may prefer b over a because b seems more delicious, and c over b because c seems even more delicious. But when comparing c to a , the price difference may become more salient, and a may now be preferred to c because a is less expensive.

3.2 Independence of Context

The independence principle implies that preference orders be invariant over context conditions; if $a < b$ in context x , then $a < b$ should also hold in context y . Again, empirical evidence and multi-attribute theories are in conflict with this premise of consistent exchange. Let a and b represent two cars the value of which is mainly determined by two attributes, performance and economy. Let a be superior in performance and b superior in economy. The relative advantage of either car in one attribute exactly compensates for its disadvantage in the other attribute so that a and b are represented on the same iso-

Figure 1
Graphical illustration of similarity and attraction effects

preference line (Fig. 1). Given such a choice situation, the likelihood of consumers to choose *b* rather than *a* depends crucially on the presence of further alternatives. If the comparison is made in the context of a third car *x* that lies on the same iso-preference line but much closer to *a* than to *b*, then the context stimulus *x* becomes a rival for cars like *a*, inducing a tendency to prefer *b* over *a*. In contrast to this so-called ‘similarity effect,’ a context stimulus *y* that also lies close to *a*, but on a slightly inferior iso-preference line, functions like a decoy that serves to highlight the dominance of *a* over context stimuli and thereby increases the likelihood to choose *a* rather than *b*. This opposite influence of context has been termed ‘attraction effect’ (Huber and Puto 1983). Context effects like these have strong implications for marketing, consumer choice, and investment decisions involving similarly attractive multi-attribute options. For example, by including a new car in the range of an automobile manufacturer, the attraction of an already existing car may increase (attraction effect) or decrease (similarity effect).

3.3 Framing of Decision Options

Verbal labeling or circumscribing of economic targets must not affect their monotonic ordering for rational exchange to work properly. However, countless studies demonstrate preference reversals as a function of mere verbal framing. Decisions under uncertainty often involve the choice between two largely equivalent options, a P-option with a relatively high probability of success but a relatively low outcome, and an O-option with a higher outcome in case of success but a relatively low success probability. The tendency to choose the more risky O-option depends strongly on whether the verbal framing focuses on positive or negative outcomes. If the decision problem is framed positively in terms of possible gains, a

Figure 2
S-shaped subjective value function, according to prospect theory

majority of people would show risk aversion and choose the more secure P-option. If, however, the same decision problem is framed negatively in terms of the possible losses, preference for the O-option becomes more likely.

To account for such framing effects, psychologists and economists refer to prospect theory (Kahneman and Tversky 1984)—a very prominent model of economic choice. In particular, outcome framing effects are commonly explained by the assumption of an S-shaped subjective value function in which both the positive value of gains and the negative value of losses increase in a negatively accelerated fashion, as portrayed in Fig. 2. Twice as extreme an outcome is not worth twice as much, psychologically. The value of winning or losing \$200 is less than twice the value of winning or losing \$100, respectively. Such an S-shaped value function is consistent with the finding that positive outcome framing increases the tendency to choose the P-option (because the higher value of the O-option is worth less, due to the S-shaped function, than the higher probability of the P-option). Negative framing favors the choice of the O-option (because the higher negative outcome of the O-option is less extreme subjectively than the higher probability of the P-option).

3.4 Exchangeability and Compensability of Resources

An essential premise of exchange is that qualitatively different resources can be exchanged and aggregated in a compound value function. Thus, when calculating the lower limit of the price for a product, the costs for

development, production, advertising, and taxing have to be translated onto the same joint scale as the aesthetic appeal, the sonorous brand name, and the scarcity of the product. Monotonicity should not only hold within the singular components, but must also be conserved after exchanges involving different resources.

3.5 Pricing and Choice

One apparent implication of the exchangeability of resources is that differences in attractiveness should correspond to differences in the price that can be obtained for products or goods. A preferred or chosen object should justify a higher price than a less preferred or not-chosen object. However, many experiments show a preference reversal such that whereas the P-option is consistently preferred to an O-option (of the same expected value) on a *choice task*, the O-option is preferred over the P-option on a *pricing task* (Slovic 1995). Although most people prefer the secure P-option when making a choice, they are willing to pay a higher price for the O-option—an often-replicated finding that cannot be derived from prospect theory. One interpretation for the disparity of pricing and choice, though not the only one, is that the pricing task makes the outcome dimension (typically indicated in monetary terms) more salient, whereas the choice task makes the probability of winning more salient.

3.6 Effort and Accuracy

Another implication of considering qualitatively different resources as exchangeable is that amount of work and effort can be paid in money and, likewise, that work load is commonly considered a positive monotonic predictor of quality or returns. Accordingly, investing additional work should increase, and must not decrease, the quality of a product or the accuracy of an organizational decision. Otherwise, the economical value of labor and effort expenditure would be negative, creating a severe exchange paradox. Nevertheless, at least under specified conditions, working or thinking too much can impair rather than improve rational decisions (Wilson and Schooler 1991).

3.7 Information Costs and Expertise

Extending the same principle to information costs, a related implication is that the value of a product, or the future gains to be expected from rational decisions, should increase monotonically with the amount of information gathered, or with the expertise of consultants and decision makers. Information costs, much like production costs, must be subtractable from the gross income on the same monetary scale.

Of course, there is ample evidence to support this plausible assumption as, for instance, evidence showing that the reliability of decisions (e.g., choices among job applicants, prediction of growth, market analyses) increases with the number of diagnostic indicators. However, there is also a notable body of opposite evidence pointing out the less-is-more principle. As Gigerenzer and Goldstein (1996) have shown in pertinent computer simulations, increasing the number of predictors and increasing the complexity and sophistication of algorithms may actually reduce the validity of predictions and decisions. This seemingly paradoxical result can be expected in highly uncertain environments when indicators are error-prone and fallible so that reliance on an increasing number of indicators often means increasing reliance on error variance. To understand the less-is-more effect, the logical principle of rationality has to be replaced by the notion of ecological rationality. Moreover, bounded rationality highlights the need to pit accuracy against information costs and effort load and to be content with ‘satisficing’ rather than optimal actions and decisions.

One particularly intriguing variant of the less-is-more effect pertains to personalized knowledge or expertise. The additional knowledge acquired by experts as compared with lay-people, and the increased costs of expert consultation, may not be justified by a corresponding improvement of products or decisions. For example, at the stock market, experts who are highly informed about shares and market rules may be outperformed by novices simply because experts try to utilize too many fallible indicators (Borges et al. 1999). At the same time, the degree of overconfidence is likely to increase with increasing expertise. Thus, as experience and qualification increases, subjective confidence may increase at a faster rate than accuracy and actual achievement (Yates et al. 1998).

3.8 Monotonicity of Indices

Economical decisions must often rely on indices, such as the daily value of a share on the stock market, as an index of the corresponding company’s (potential) performance. It is commonly assumed that indices correlate highly with the corresponding true properties on the same monotonic joint scale. For instance, it is likely that those companies whose share value index recently outperformed the market are expected to be more successful in the near future than those companies that lately failed to match the market. Indices are thus often regarded as monotonic functions of underlying true properties. However, this seemingly plausible assumption fails to take statistical regression into account, which is the source of many illusions and erroneous predictions. Regression is an inevitable result of error variance. To the extent that the reliability of an index is less than perfect, high index

		Other party		
		Defect	Cooperate	
Own party	Defect	-20 / -20	+30 / -10	Defect
	Cooperate	-30 / +30	-10 / -10	Cooperate

Figure 3
Pay-off matrix exemplifying a social dilemma situation

values are more likely to overestimate and low values are more likely to underestimate the true attribute to be assessed. Therefore, high values (of shares at the stock market) can be expected to be less successful after a while, whereas low values can be expected to be more successful. Ironically, then, investing in funds that recently outperformed the market may lead to less profit than investing in recently less successful funds (Hubert 1999). Thus, the assumption of a positive monotonic relation between an index and the true value of the underlying attribute is counteracted by an inverse relation between the error component of the index and the underlying attribute.

3.9 Absolute and Relative Gains and Losses

When the context, or state of the world, changes, monotonic orderings must be conserved, as already explained with reference to the independence principle. If decision option *a* yields a higher relative payoff than option *b* under condition *x*, and the relative payoff of *a* also dominates *b* under the complementary condition *y*, *a* is assumed to dominate *b* in general. Game theory is concerned with dramatic violations of this rule within social and economical dilemmas. The payoff structure of many negotiation and competition dilemmas is such that the payoff that one party gains from action *a* is higher than the payoff gained from action *b*, regardless of whether another party chooses strategy *x* or *y*. But although $a > b$ given either *x* or *y*, it is wiser and more profitable to choose action *b* rather than *a*. Such a payoff matrix is shown in Fig. 3, with reference to an embargo situation involving two parties each having two options: to cooperate (not delivering any goods) or to defect (violating the embargo to increase own profit). The situation can be exploited if one defects and the other party cooperates (yielding a high +30 payoff). However, if the other party also defects, violations of the embargo are sanctioned (−20). Nevertheless, defecting leads to higher payoff (i.e., lower embargo costs) than cooperating regardless of whether the other party defects (−20 vs. −30) or cooperates (+30 vs. −10). In spite

of the *relative* dominance of defecting over cooperating, given both opponent strategies, cooperation can have a strong *absolute* advantage in the long run, just because defecting is likely to be reciprocated by the other party so that the absolute costs will be clearly higher (−20 or −30) than when the other party cooperates (+30 or −10). Therefore mutual fairness and solidarity is in the long run a more profitable strategy (moderate costs of −10 for both parties) than reciprocal defection (stable pattern of −20 for both parties).

4. Conclusion

The above examples represent only a small subset of possible monotonicity breaks. They illustrate that at the crossroads of psychology and economics interesting research problems emerge wherever the interchangeability principle is violated. This offers a rather fruitful perspective for the role of psychology in economic research. Economists often refer to psychology when the real data do not meet the theoretical predictions. The connotation is that psychology represents irrationality or some source of error which is responsible for the incongruency of economic models and real market behavior. However, the above examples demonstrate that violations of economic assumptions are not necessarily irrational. There may be good reasons for focusing on different features when comparing different products; the regressiveness of indices is an unavoidable problem; and the very fact that buying more information may sometimes lower the quality of decisions reflects the intrinsic uncertainty of the probabilistic world. Rather than attributing violations of rational norms to human deficits, these violations can be as well interpreted as reflecting unrealistic simplifications of the normative models used to investigate economic behavior.

Psychology and Marketing

Marketing is an applied field. It is synonymous in everyday parlance with the economic activity of selling, and especially with advertising. The field, however, is construed differently by most professional practitioners. The American Marketing Association defines marketing as, 'the process of planning and executing the conception, pricing, promotion, and distribution of ideas, goods, and services to create exchanges that satisfy individual and organizational goals' (emphasis added). While marketing draws upon a wide range of social sciences, including anthropology, economics, and sociology, the emphasis on satisfying goals implies that insight into the psychology of the customer is particularly important for the marketer. Thus a company might offer a new microwave oven that is the product of work by electrical and industrial engineers, home economists, financial analysts, etc. A marketer would bring to this effort a focus on how consumers will think about the product and how it will fit with their behavior.

Marketing is hence an applied field in that interventions are designed with regard to the psychological responses of consumers. Marketing research is commonly used to learn more about these responses. In practice this can be as simple, and as particularistic, as surveys asking about product preferences or usage and qualitative research such as focus groups eliciting more in-depth reactions from consumers. Academic researchers typically conduct more complex studies. An example is the work of Simonson (1990) on the variety of brands consumers choose for consumption over multiple occasions. He finds that the set of brands chosen reflects greater variety when the choices for multiple consumption occasions are made at a single point in time (i.e., simultaneously) vs. being made just

prior to each consumption occasion (i.e., sequentially). This observation can be applied to marketing situations such as the design of retail stores. If a store, for instance, is intended as a convenience store to be used for items consumed immediately, it will not be necessary for it to carry as large a selection of products as with, say, a traditional grocery store that is used to build the household pantry inventory.

Psychology and marketing are thus intimately related. Marketing is based on an assessment of psychological response. The goal of marketing research is to enhance the applicability of these assessments to marketing situations of interest. There are two approaches to achieving this goal and each leads to a different view of exactly how psychology and marketing are connected.

1. Effects Application

One approach is that marketing research can focus on *effects application* (EA) (Calder et al. 1981, Calder and Tybout 1999). Research starts with psychological notions and proceeds by creating a research setting that allows the mapping of observed effects directly into situations of marketing interest. If the research setting is similar enough to the 'real' situation, the research is thought to generalize to these situations. From the perspective of this approach, it is important to conduct research with people who match the demographics and other characteristics of target consumers. Likewise the research setting, including independent variable treatments, should match the types of experiences people would have in the marketplace. Effects application studies are applied by extrapolating observed effects to a situation of interest.

The Simonson study described above can be viewed as an example of EA research. The research was no doubt motivated by psychological considerations, such as notions of consumers' desire for variety and their motivation to simplify complex tasks. The important thing is that although this research is motivated by psychological considerations it is the *effect*, greater variety with simultaneous versus sequential purchases, that is of primary interest. And the issue of application hinges on whether the effect can be directly generalized to marketing situations of interest. Because the original study was conducted with student subjects in a laboratory setting, the applicability to purchases in the marketplace might be viewed as suspect. For this reason, Simonson and Winer (1992) sought to enhance applicability by demonstrating the same effect with actual consumer purchase data from in-store scanner records. They looked at whether consumers bought a greater variety of yogurt flavors when they were buying larger quantities of yogurt. The argument from an EA perspective is that scanner data, in which actual

consumers spent their own money in real stores, makes the effect more directly applicable to marketing contexts than the laboratory study.

Other studies in the marketing literature use a related but somewhat different effects strategy. These studies seek to demonstrate the robustness of effects by demonstrating them across a variety of settings. Thus Strahilevitz and Myers (1998) draw upon notions of mental accounting to predict that the promise of a donation to charity will be a more effective incentive for consumer purchase when the product for which the incentive is offered is frivolous rather than practical. They find support for their prediction across three experiments that employ different stimuli. The robustness of the phenomenon, rather than the correspondence between the demonstrations and naturally occurring settings, provides the rationale for applying the effect to marketing contexts.

The EA approach views the relationship between psychology and marketing as follows: psychology provides important examples of psychological phenomena. It is the task of marketing research to investigate these effects in special research settings designed to be applicable to marketing situations of interest. Marketers thus draw from the psychological literature possible effects that must be observed in research settings that, by virtue of their similarity, are applicable to marketing situations. Or, alternatively, enough different settings are used to suggest robustness.

2. Theory Application

A second major approach leads to a very different view of the relationship between psychology and marketing, as well as what indeed it means for a discipline like marketing to be an applied field. This approach is called *theory application* (TA) (Calder et al. 1981, Calder and Tybout 1999). TA studies are designed to be applicable in a different way than are EA studies. The focus is on theory as an explanation of observed effects. It is not the effects that are expected to generalize; it is the explanation. Effects are used to test the theory. It is the theory that is expected to generalize to marketing situations.

This focus on theory testing leads in practice to marketing research studies that look quite different from EA studies. There is no requirement that research participants match consumers on demographic or other characteristics (unless this is relevant to the test of theory), nor is it important that things such as real money or natural marketing contexts be used in TA studies. Moreover, replicating the same effect over many situations is not regarded as particularly informative. This is because TA studies seek only to establish a strong explanation, not to generalize by

virtue of similarity of the research setting and marketing situation or on the basis of robustness. Instead of focusing on whether the greater variety with simultaneous choices effect can be obtained in a setting that sufficiently resembles marketing situations, a TA approach would concentrate on developing the theoretical explanation.

It might, for example, be hypothesized in connection with the variety-seeking research discussed above that the simultaneous choice setting is more cognitively demanding than the sequential choice setting and, thus, leads consumers to employ cognitive strategies that simplify the task. Simplification might be achieved by expanding the set of selected items, thereby obviating the need to make finer discriminations among the items. Here we have an explanation of the variety-seeking effect as opposed to the effect itself. Evidence for this explanation, and against rival explanations (i.e., that simultaneous choice makes potential satiation more salient and thereby encourages variety seeking), is the goal of TA research. Application to marketing situations is based on the rigor with which the theory has been tested and how well the theory describes the marketing situation.

Research by Meyers-Levy and Peracchio (1995) provides a good example of TA research. These authors examined the processes that underlie consumers' responses to full color, black and white, and color-highlighted advertisement pictures. Petty and Cacioppo's (1983) elaboration likelihood model (ELM) served as a starting point for Meyers-Levy and Peracchio's theorizing. ELM describes two routes to persuasion: a central route where people are motivated by relevance to process detailed arguments and a peripheral route where people are not motivated to process detailed arguments and instead respond to peripheral cues. Meyers-Levy and Peracchio reasoned that the correspondence between the cognitive resources made available and those required to process the advertisement claim might moderate processing via the central route.

Specifically, when processing motivation is high and the advertisement claim requires few resources to substantiate it, advertisements that include color will be more persuasive than black and white ones. This is expected because individuals will have sufficient cognitive resources to process the color and the color will substantiate and reinforce the advertisement claim. However, when more resources are needed to assess the advertisement claim, either a black and white picture or one in which color is used to highlight only those aspects of the picture that are relevant to the claim, is expected to be more persuasive than a full color advertisement. This is because individuals will lack sufficient resources to substantiate the advertisement claim and process full color information.

Meyers-Levy and Peracchio's hypotheses received support in two laboratory experiments conducted with student subjects. As a result, their integration of ELM

with the notions of cognitive resource matching is preferred to an explanation based on ELM alone. Further, they demonstrate that cues are not *per se* either central or peripheral, but rather depend on the match between the resources required and available. It is Meyers-Levy and Peracchio's theoretical explanation of their effects, rather than the effects themselves, that is applied to marketing contexts beyond the particular one they examined.

As the above discussion makes clear, the research setting and subjects are not of primary interest in TA research, it is the explanation being tested. Meyers-Levy and Peracchio's studies would not generalize to marketing situations based on similarity between the research setting and subjects. However their theorizing might be applied to any number of marketing contexts. This application would use the theory to design an intervention for the situation of interest that according to the theory would work in a desired way. The explanation provided by the theory would predict an outcome but it would do so based on the design of the intervention suggested by the theory.

An example of this kind of theory application may be helpful. Suppose there is an interest in communicating with consumers who are in the market for a new car. Presumably such individuals are motivated to engage in detailed processing of message claims. Meyers-Levy and Peracchio's theorizing would suggest that full color advertisements be used to substantiate and reinforce claims related to styling (which may be apprehended with relatively few resources) but black and white advertisements be employed when presenting detailed information about the car's features and warranty. The design of the advertisements thus constitutes an application of the theory and leads to different expectations for the ads.

The important point about the above application is, again, that it does not depend on matching the settings of studies to the particular concern with advertising. It only matters that the theory has received support and that it describes the marketing situation of interest. Note also that there is always the possibility that there are other, unanticipated factors involved in the situation of interest that may not be taken into account by the theory. In our advertising example, for instance, the color resolution or the particular colors chosen might be unappealing, in which case the use of color might undermine rather than reinforce the style claim. Such possibilities have two implications. One is that any application via TA research has the potential to fail (just as with EA research where it is impossible to match on all differences between the research setting and situations of interest). The other is that it may be desirable to conduct *intervention testing* (Calder et al. 1981, Calder and Tybout 1999), in which more factors are allowed to vary freely than in the typical theory test-oriented TA study. This can increase confidence in the application, but because this will ordinarily be a weak test of the theory, it does not increase support of

the theory *per se*, and the application still depends most critically on the prior TA research.

3. Conclusion

To return to the relationship between psychology and marketing, as we have seen, one account of this relationship is provided by the EA approach. Psychological phenomena motivate EA studies that are applied by virtue of the similarity of the research setting to marketing situations of interest. The alternative TA approach, however, provides a very different perspective. On this view the relationship of psychology and marketing is much more reciprocal and synergistic, as demonstrated in the discussion of Meyers-Levy and Peracchio's (1995) work.

With the TA approach marketing research is primarily engaged in testing psychological theories. This work is no different from the theory-testing work that goes on in psychology. It is only that marketing researchers have selected certain theories for further development and testing; these theories are ones that are considered especially promising for application. This applicability is based on the relevance of the theory to marketing situations. The success of the application depends most critically on the rigor of the TA studies supporting the theory, both within psychology and marketing. As experience with such applications increases, assisted in some cases by intervention testing, there will be an additional source of feedback about theories. It is the cooperative aspect of testing theories, through both TA research and the process of theory application, which constitutes the relationship between psychology and marketing. At the beginning of the twenty-first century, marketing continues to explore both paths to application.

Psychology: Historical and Cultural Perspectives

Psychology occupies a middle position among the sciences, between methodological orientations derived in part from the physical and biological sciences and a subject matter extending into the social and human sciences. The struggle to create a science of both subjectivity and behavior and the effort to develop professional practices utilizing that science's results provide interesting examples for the reach, and also the limits, of scientific ideals in modern life. This article presents a brief account of the social and cultural relations of psychological thought and practice from the eighteenth through the twentieth centuries.

1. Routes to Institutionalization, 1700–1914

From the earliest times philosophical arguments about the nature of humans and of human knowledge have included claims about mental states and psychological processes. Protestant scholastics first used the term 'psychology' in discussions of the relation of soul and body in the sixteenth century. Christian Wolff's systematic accounts of 'rational' and 'empirical' psychology published in 1732 and 1734, respectively, marked out a distinct subject of scholarship, with journals and practitioners, a subject matter and intended methods of study. But that subject generally remained a teaching and research field within philosophy and pedagogy. The introduction of so-called 'physiological' psychology in the middle third of the nineteenth century and the institutionalization of laboratory instruction on the model of the natural sciences soon thereafter had a major impact on the development of the discipline. However, experimental psychology never succeeded in dominating the field entirely. The institutionalization of psychology took different forms in different parts of Europe and the USA.

1.1 Britain and France

Britain was the home of the statistical research practices pioneered by Francis Galton. These practices

targeted not psychological processes assumed to be essentially similar in all individuals, but rather distributions of performances *among* individuals. In *Essay on Human Faculty* (1883) and other works, Galton attempted to show that both physical and mental capabilities are quantitatively distributed in the same way, and that both are therefore inherited to the same—large—extent. In a 1904 paper, Charles Spearman took the approach a step further by distinguishing between 'general intelligence,' or 'g,' a factor underlying all performances in a test series and presumed to be hereditary, and so-called 's' factors accounting for differential performance on specific tests, presumed to be teachable. By the second third of the twentieth century, this emphasis on individual differences expressed in statistical terms had become a predominant research mode in both academic and applied psychology in the English-speaking world. Even so, as late as the 1920s there were only six university chairs for psychology in England. Psychological practitioners of various kinds far outnumbered academics in the membership of the British Psychological Association at the time of its founding in 1901.

In France, philosophers Hippolyte Taine and Théodule Ribot shared a coherent vision of the field as a synthesis of medical and philosophical approaches. However, Ribot's university course in psychology, first offered at the Sorbonne in 1885, was located in the Faculty of Letters rather than the Faculty of Sciences, while the laboratory demonstrations took place in the Faculty of Medicine. Despite this fragmented situation, he encouraged younger scholars, such as the physician Pierre Janet and the biologist Alfred Binet, to adopt a natural scientific approach.

When he became director of the first psychological laboratory in France, located in the Sorbonne's Faculty of Sciences, in 1890, Binet attempted to establish an explicitly biological science of higher mental processes, which he called 'individual psychology.' In 1894 he founded France's first scientific psychological journal, *L'Année Psychologique*. A commission from the Ministry of Education led to his publication, with Theodore Simon, of the first intelligence tests in 1905. The tests' purpose was not to measure intelligence directly—Binet doubted that this was possible—but rather to establish practical criteria for separating 'subnormal' from normal children, in order to provide the former with special education. But schoolteachers opposed the use of the tests in France, and here, as in England, extensive academic institutionalization of psychology did not follow.

1.2 Germany and the USA

Germany is generally regarded as the homeland of scientific psychology. In response to Immanuel Kant's claim that mental events, lacking the attribute of space, could not be measured, Johann Heinrich Herbart presented a program for the measurement of

sensations in 1816. In 1860, physicist and philosopher Gustav Theodor Fechner realized the program, with modifications, in his psychophysics—the measurement of relations between external stimuli and just-noticeable differences in sensation. Working in part with Fechner's techniques and in part with methods derived from laboratory physiology, Wilhelm Wundt established the first continuously operating laboratory for 'physiological psychology,' as he called it, in Leipzig in 1879. Other approaches widely received at the time included the 'medical psychology' of Rudolph Hermann Lotze, Franz Brentano's descriptive *Psychology from an Empirical Standpoint* (1874) and the *Völkerpsychologie* launched in 1860 by Moritz Lazarus and Haim Steinthal, which took an ethnological, linguistic, and historical approach. Other experimenters, such as Georg Elias Müller and Carl Stumpf, worked parallel to Wundt, but pursued quite different research programs.

In Wundt's and other German laboratories, in contrast to the situation in the UK or France, experimenter and subject were generally equal in status and often changed roles. German experimenters employed mechanical apparatus to control stimulus presentation, but they supplemented their data charts with extended records of their subjects' self-observations. In this way they engaged in an instrument-aided version of the self-discovery traditional to members of the German educated middle classes. Thanks to journals such as the *Zeitschrift für Psychologie und Physiologie der Sinnesorgane*, founded in 1890, as well as the Society for Experimental Psychology, founded in 1904 with Müller as first chairman, the 'new psychology' was on firm ground in Germany by 1905. But there was no agreement on the subject matter and methods of the discipline.

One reason for this was what Kurt Danziger (1990) has called the 'positivist repudiation' of Wundt by experimenters, including Müller, Hermann Ebbinghaus and Oswald Külpe. Though Wundt denied that experimental methods were sufficient to study the higher mental processes, these scientists extended apparatus-driven experimental techniques from sensation and perception to memory and thinking. Wundt opposed premature efforts to apply laboratory techniques in real-world situations, but William Stern, Karl Marbe, and others assessed the veracity of witnesses' testimony in court and tested the performances of schoolchildren at different times of day or the skills of industrial workers. In addition, an explicitly humanistic philosophical tradition persisted, with competing conceptions of the subject matter, method, and practical uses of psychology.

At the turn of the century, neo-Kantians and other philosophers attacked the intrusion of 'psychologism' into their field; in 1912, over 110 German teachers of philosophy signed a public statement opposing the appointment of psychologists to professorships in philosophy. But this protest failed, because state

officials were not convinced that the discipline had any obvious link to professional or civil service training. Until the Nazi era, experimenting psychologists in Germany maintained their own laboratories, journals, and association, but generally continued to compete for chairs in philosophy.

Wundt's US students transferred the new experimental psychology from Germany to the USA in the 1880s and 1890s, but the positivistic concepts they employed to justify using such tools were quite different from Wundt's. The sheer size of the country as well as the decentralized structure of the emerging US university supported rapid institutionalization. By 1910 there were more psychological laboratories in the USA than universities in Germany. The founding of the American Psychological Association in 1892 predated that of corresponding European societies. Despite this rapid growth, the new discipline exhibited some continuity with the past. Instruction in psychology had long been part of the required philosophy courses taught by college presidents such as James McCosh at Princeton. These courses and their teachers encouraged an orientation toward moral issues and concentration on useful knowledge rather than the emphasis on empirical foundations for philosophy of mind prevalent in Germany.

Also formative of the discipline in the USA was the work of Darwin and Spencer. Evolutionary thinking reinforced the emphasis on biological functions vs. mental faculties, and also encouraged comparison of adult humans with children and animals. Such views supported evolutionary theories of cognition like those of James Mark Baldwin, and also granted psychologists so inclined the authority to present themselves as agents of human betterment. Education and child study thus came to be of central concern to US psychology; here John Dewey, G. Stanley Hall, and Edward Thorndike were the opinion leaders, though they advanced different research and reform programs.

William James combined science and reform in his own way. Himself an evolutionist in certain respects, he created, with Dewey and James Rowland Angell, a distinctly American functional psychology. Though committed to psychology as a natural science, he criticized the tendency to substitute psychologists' conceptions of reality for their subjects' reported experiences in his classic text, *The Principles of Psychology* (1890). He favored a more expansive conception of the subject matter of psychology, but his later efforts to study the experiences of psychics and mystics with the same objectivity as those of 'normal' adults was not widely accepted. Instead, an emphasis on social usefulness that presupposed an engineering model of science became central to the establishment of psychology in the USA.

Disagreements on the scope and methods of psychology in the USA paralleled those in Germany. A group of experimentalists led by Edward Bradford

Titchener, which began to meet separately from the APA in 1904, did not oppose applied work *per se*, but insisted on rigorous method both within and outside the lab. In contrast, activists like Hall, who pioneered the use of questionnaires in the USA, were less concerned with laboratory-style rigor than with translating moral issues into scientific ones.

In this atmosphere, intelligence testing became more popular in the USA than in France. Henry H. Goddard, director of a training school for so-called 'feeble-minded' children, propagated the tests as instruments of human betterment. Lewis M. Terman revised the Binet–Simon scale for use in US schools in 1915, and thus linked 'mental age' to school class years. This move proved well suited to US schools as sorters of a socially and ethnically diverse population.

1.3 Common Features of the 'New' Psychology

Despite these multiple routes to institutionalization and differences in approach, certain common features of the 'new' psychology can be identified. One of these common features was a reliance on measuring instruments to establish objectivity and acquire scientific standing. With their apparatus for the controlled presentation of stimuli and measuring reaction times, experimental psychologists reconstituted the object to which their efforts were addressed. What had been mental and moral capacities became psychical functions; and the sensing, perceiving, conscious mind became an instrument that functioned, or failed to function, in a measurably 'normal' way.

A second common feature of the 'new' psychology was the use of physiological analogies based in turn on mechanical physics and technology. The term 'inhibition,' for example, blended organic and machine metaphors and applied them to both human action and to society. Soon after scientists and engineers applied the idea of energy conservation to human labor in order to create a science of work intended to make the 'human motor' run more efficiently, Emil Kraepelin and others extended the effort to 'mental work'; Hugo Münsterberg gave the result the name 'psychotechnics.'

A third common feature of the 'new' psychology was a studied vagueness about the mind–body relationship. Many psychologists asserted some version of psychophysical parallelism or claimed a functional relationship of mind and brain, but few were very precise about the nature of that relationship. A fourth common feature was the contested use of the term 'experimental' itself. Until late in the century, the term *psychologie expérimentale* referred in both France and Germany to seances. The experimentalists actively opposed spiritualism and attempted to expose quack practitioners, but James, Pierre Janet, and others studied altered mental states in psychics and mystics.

This broader view was not widely accepted, due to a fifth common feature of the 'new' psychology—a

tendency to restrict its subject matter to topics that could be addressed by the natural scientific methods and apparatus then available, such as psychophysics, sensory psychology, attention span, and retention. One result was an uneasy tension between efforts to preserve the notion of a volitional, active mind and the actual stuff of experimental research—measurable reactions to external stimuli. Another result was the exclusion of social or 'crowd' psychology; measuring instrument experimental methodology was plainly not applicable to group behavior.

A sixth common feature of the new psychological science was its gendered dimension. The head–heart dichotomy and the worship of the (female) 'beautiful soul' persisted through the nineteenth century; but its role in the 'new' psychology was ambivalent. The generalized, 'normal' adult mind that the experimentalists usually claimed to be their subject matter was at least implicitly the common property of both sexes, but the vocabulary and practices of objective science carried unmistakably masculine symbolism.

2. The Era of Competing Schools, 1910–45

The struggle for intellectual dominance in early twentieth-century psychology has been depicted since the 1930s as a battle of competing 'schools.' This view has its uses, but it conveys the false impression that all schools competed on an equal basis everywhere. Behaviorism captured both expert and popular attention in the USA in the 1920s, but the new approach was hardly taken seriously in other countries until after 1945. The 'reflexology' of Russian physiologists Ivan Pavlov and V. M. Bekhterev did not become a dominant approach in psychology even in the USSR until the 1940s. Gestalt psychology and other initiatives from Germany were received with interest but also with skepticism in other countries. Psychoanalysis had established itself as an international movement by the 1920s, but acquired few academic adherents at the time.

In German-speaking Europe, the 'crisis of psychology' announced by Vienna professor Karl Bühler in a 1927 book reflected continuing disagreement about subject matter and methods. The most widely received view internationally was that of Gestalt psychology, developed by Max Wertheimer, Wolfgang Köhler, and Kurt Koffka. They claimed, among other things, that immediately perceived structures (*Gestalten*) and relationships rather than isolated sensations are the primary constituents of consciousness, and employed holistic vocabulary to ground a rigorously natural-scientific world view. Felix Krueger, head of the Leipzig school of 'holistic psychology' (*Ganzheitspsychologie*), emphasized the role of feeling in perception and espoused Neo-Romantic cultural conservatism. William Stern's personalism focused on the individual as a 'psychophysical whole' in a way consistent with political liberalism.

The situation of psychology as a profession in Germany was equally contested. The challenge of philosopher Eduard Spranger's 'humanistic' psychology, as well as alternative professional practices such as handwriting analysis advocated by Ludwig Klages and typological personality diagnostics such as that of Ernst Kretschmer, raised the pressure to develop modern research instruments congruent with German cultural tradition. In Austria, the work of the Vienna Psychological Institute formed a bridge between old and new, theory and practice, Europe and America. Karl Bühler's department of general psychology conducted basic cognition research in the tradition of Brentano. At the same time, in rooms located at the city's adoption center, the institute's department of child and youth psychology, led by Charlotte Bühler, created performance measures for assessing the behavioral development of infants modeled on those of Arnold Gesell at Yale. In addition, Rockefeller Foundation funding supported the sociographic and survey research of the institute's Research Center for Economic Psychology under Paul Lazarsfeld in the late 1920s and early 1930s. All this put the Vienna institute, along with those in Jena and Hamburg, in the forefront of the transition to practice-oriented basic research in German-speaking psychology.

In the USA, multiple versions of behaviorism competed for attention in the 1920s. As proclaimed by John B. Watson in 1913, radical behaviorism excluded consciousness altogether from psychological science in favor of 'prediction and control' of behavior; in his later writings Watson advocated Pavlovian conditioning as a form of social engineering. Far more significant within the discipline at the time were the social science and child development programs generously funded by the Laura Spellman Rockefeller Foundation. The workers in these programs were not doctrinaire behaviorists, but they believed that measuring children's growth and IQ test scores over time would produce scientific norms of human development, and hoped to utilize this knowledge to rationalize society. Critics of behaviorism called on Gestalt psychology for support, while Harvard professor Gordon Allport and other prominent psychologists advocated a person-centered conception of psychology.

The 1930s were dominated by competing versions of neobehaviorism. Edward Tolman tried to integrate purposive motivation and cognitive processes into behavior theory, going so far as to claim that white rats framed 'hypotheses' as to which maze route would yield an expected food reward. Clark Hull developed an elaborate model for learning theory based on what he took to be Newton's physics, and tried to expand the model from the habit hierarchies of classical conditioning to personality theory. Finally, B. F. Skinner developed operant conditioning in the 1930s, producing careful measurements of the relative likelihood of simple behaviors such as rats or pigeons

pressing a bar to obtain pellet, of food under rigorously controlled conditions and suspending all efforts to explain such behavior.

A prominent nonbehaviorist effort to bring systematic theorizing into psychology was that of Berlin émigré Kurt Lewin. Lewin advocated experimental study of ideal-typical behavioral situations, exemplified in his Iowa studies of 'democratic' and 'authoritarian' leadership in children's groups. Lewin and his US competitors shared an admiration for classical physics and a willingness to draw upon philosophy of science, especially operationism and logical positivism, to legitimate their positions. They differed in their basic conceptual foundations and also in the physics they chose to emulate. The competition was resolved only by the rapid fragmentation of the discipline in the 1950s.

In Britain and France psychology remained relatively weakly institutionalized in this period in comparison with Germany and the USA. Yet precisely this situation enabled a wide range of alternatives to US behaviorism to flourish. In the UK, Cyril Burt, originally a London school official and later professor at University College, London, adapted and expanded Charles Spearman's concept of general and specific intelligence in studies of educational performance, delinquency, and so-called 'backward' children. He then developed a mathematical basis for factorial approaches to intelligence and personality testing. Controversy over accusations that he manipulated or even invented some of his twin research and other data did not emerge until after his death. During the same period, Cambridge professor Frederick Bartlett published the pioneering study *Remembering* (1932), in which he established the role of learned schemata in retention and laid the foundations for considering memory as a process of active reconstruction rather than rote recall.

In France, psychology remained divided between medicine and philosophy; there was no separate degree until 1947. One result was that alongside the strictly experimental work of Henri Piéron, Binet's successor as director of the Psychological Laboratory at the Sorbonne, philosophers and sociologists considered psychological issues in broader and less positivistic ways. One example was the debate over Lucien Lévy-Bruhl's concept of 'primitive' mentality, which contributed to the emergence of the 'mentalities' concept of the *Annales* school in history. In French-speaking Switzerland, biologist and philosopher Jean Piaget, building in part upon Eduard Claparède's functional psychology, began his pioneering studies of cognitive development in children.

2.1 Dynamics of Professionalization to 1945

The turning point for the public visibility of professional psychology in the USA came with the mass

use of intelligence tests in the US Army during World War II. The route of application ran here not from the 'normal' to the 'pathological,' but rather from socially marginal populations—the so-called 'feeble-minded' and schoolchildren—to 'normal' adults. The interaction of applied psychology and the professional officer corps reshaped both the aims of intelligence testing, the test instrument itself, and ultimately conceptions of the objects being assessed. Intelligence became not intellectual or problem-solving capacity alone, but a sum of skills and (presumably hereditary) aptitudes for certain kinds of learning.

'Binet testing,' as it was then called, fueled the professionalization of psychology in both the USA and UK during the 1920s. Quantitative assessment and classification instruments spread rapidly in both basic research and professional practice, primarily because the products thus created supported the functions required by administrators, initially in schools and later also in industry and social service agencies. During this period the field became more open to women; but a gender hierarchy emerged, with industrial psychology remaining male-dominated, while female 'Binet testers' and social workers took on more people-oriented functions. During World War II, fields of application included the employment of social psychology in morale research and applied human relations, incorporation of psychophysics and experimental psychology into studies of human-machine interactions, and diagnostic testing in clinical psychology, as well as the use of intelligence and personality testing in personnel management. All this led in turn to significant basic research programs in the postwar period.

The professionalization of psychology in Germany took a rather different course. During World War I, efforts focused on the adaptation of techniques from psychophysics to develop sound-ranging devices, and to test the visual discrimination ability of drivers and pilots. More important after the Nazi takeover of power were the rapid growth of military psychology as a result of German rearmament, and the resulting shift from psychotechnical skills testing to 'intuitive' character diagnosis. The primary purpose here was elite officer selection, rather than sorting large numbers of average recruits. Paper-and-pencil and skills tests were secondary to the extended observation of officer candidates in simulated command situations. The personality characteristics sought had considerable affinities to the traditional virtues of the Prussian officer—the will to command and the ability to inspire troop loyalty. In contrast, diagnostic efforts based on Nazi 'race psychology' could not be translated into professional practice.

In the USA, too, personality diagnostics ultimately became a road to professionalization. However, in contrast to Germany, quantitative methods based on techniques of factor analysis developed by L. L. Thurstone and others predominated, despite com-

petition from 'projective' tests such as the Rorschach in the 1930s and 1940s. The history acquired a gendered dimension in the construction of 'female' and 'male' traits in early personality research.

3. *The Postwar Era: 'Americanization' and the Alternatives*

In the USA, the postwar years saw explosive expansion and differentiation in both the scientific and professional realms. The establishment of a divisional structure within the APA in 1947—already negotiated during the war—reflected this process. Despite the optimism of the time, it proved difficult to subsume all aspects of psychology's protean identity within single university departments or graduate programs. Fragmentation was most obvious in the different research practices institutionalized in experimental, social, and personality psychology.

Cognition returned to the laboratory in this period, supported in part by reliance on methodological conventions patterned on those of the behaviorists, such as rigorous separation of independent and dependent variables, in part by computer-centered models of mental processes. In contrast to the statistical inference techniques and the corresponding computational models of mind that came to be preferred in cognition research, the preferred research tools in educational psychology were the correlational methods pioneered by Galton. A comparable methodological split distinguished neobehavioristic learning theory from experimental social psychology and personality theory. Nonetheless, experimental studies of social influence on perception by Solomon Asch and of prejudice by Gordon Allport, as well as T. W. Adorno and colleagues' *The Authoritarian Personality* study (1950) captured the imagination of many in the field. The popularity of such studies reflected a widespread tendency of the period to psychologize, and thus individualize, social problems. Meanwhile, developmental psychology took the work of Piaget as a touchstone for numerous studies closely related to the practical needs of schools for age-related developmental norms.

By the 1970s, the sheer numbers of psychologists (over 70,000, over 100,000 by the end of the century) had reached levels that could not have been imagined 50 years earlier. The growth was worldwide, but more than two-thirds of the total were Americans. The openness of both discipline and profession to women continues; today more than half the doctorates in the field go to women. Gender divisions also continue, with women being most numerous in developmental and educational psychology and men in experimental, industrial, and personnel psychology. Nonetheless, the broad institutional anchorage of psychology in the USA was more than sufficient to assure that the

research and professional practices instituted there would spread throughout the world, and that alternative viewpoints coming from Asia, Africa, or Latin America would generally be marginalized.

The most important exceptions to the overall trend were the impact of Piaget in developmental psychology, and the reception of work by British psychologists Hans Eysenck and Raymond Catell in personality testing and diagnostics. In cognition research, the work of Bartlett and the achievements of Soviet researchers such as Alexander Luria were mobilized to lend respectability and theoretical sophistication to the resurgent field in the USA. Nonetheless, the all-pervasive influence of computer metaphors and the associated information-processing models were plainly of Anglo-American origin.

The history of the psychological profession after 1945 continued to be affected by contingent local circumstances. The rise of clinical psychology in the USA was originally driven by the need to deal with large numbers of mentally ill veterans after World War II. The new field ultimately brought forth its own basic research in both clinical and academic settings, which led to the emergence of scientific communities based on methodological norms quite different from those of experimental or developmental psychologists. In addition, an eclectic, so-called 'humanistic' psychology movement arose in opposition to both behaviorism and psychoanalysis, and became widely popular in psychotherapy, social work, and the emerging field of counseling psychology.

In Europe, the rise of clinical psychology came approximately 10 years later than in the USA. There, in contrast to the USA, the supremacy of personality diagnostics and its quantitative tools had already been established in basic research before the professionalization of the clinical field. Another important difference was that clinical training in academic settings in Europe was based far more on cognitive and behavioral techniques than on psychoanalysis. Barriers to the academic institutionalization of psychoanalytic research and training were surmounted only in exceptional cases.

What had been a predominantly European field at the beginning of the twentieth century has become deeply dependent on US research styles and professional practices. US predominance has been contested by dissident local-language movements, most notably in France and Germany. Most significant, however, is the contrast between US predominance worldwide and the insecure standing of trained psychologists in the USA itself. Vagueness and confusion in the use of the term 'psychologist' in public discussion have been remarkably consistent over time; the term itself lacks legal protection in any case. The fact that the popularity of self-help books does not depend on whether their authors are psychologists or not indicates that even in the USA, where most of the world's psychologists live and work, trained academics

and professionals can hardly claim hegemony over psychological discourse in the public sphere to the degree that physical scientists can in their fields.

4. Conclusion

Given this situation, it might well be asked why such a shakily legitimated field has acquired such an important role in the twentieth-century. Roger Smith (1998) suggests that the discipline drew its authority from and simultaneously gave voice to a culture and society in which everyone 'became her or his own psychologist' (p. 577). Nikolas Rose (1996) argues that psychological practices make possible particular kinds of social authority, assembled at first *ad hoc*, then grafted onto all activities aimed at simplifying the administration of modern life by producing calculable individuals and manageable social relations, from law and penal administration to education and parenting. No single science or profession has monopolized the codification and certification of these activities.

The predominance of behaviorism in the USA in the middle third of the twentieth century was an episode in a much larger story. However, it is a characteristic episode, for both the discourse of prediction and control and its associated practices have persisted, even as the so-called cognitive revolution reintroduced mentalistic vocabularies. One reason for this appears to be that not only the members of the discipline and profession called psychology, but the modern culture and society in which they function, require and may even desire both technocratic discourse and the instruments that embody and enact it.

Psychology of the Real Self: Psychoanalytic Perspectives

Theories of the self have led to more confusion than understanding in the development of psychoanalytic thinking. Freud's ambiguous use of the term *Ich*, referring to the self both as a whole person—subjective experiential—and to the ego (Strachey 1966) theoretical, more objective and mechanical—led to considerable confusion about the relationship between the self and the ego which persists to the beginning of the twenty-first century.

The matter was further confused (Bettelheim 1982) by the abstract mistranslations of Freud's use of the word soul. An additional factor contributing to the confusion was that Freud and the pioneer analysts mostly worked with neurosis and, therefore, with oedipal levels of conflict. This is a developmental level at which the self had already become autonomous and assumed its functions and capacities. As a result, it did not cause enough of the kind of clinical problems that might have drawn attention.

However, when analysts turned their attention to patients with psychoses and character disorders, they were confronted with disorders of the self. These patients, development was arrested not at the oedipal but at the preoedipal level and, therefore, their deep difficulties were predominantly with the functioning of the self. The lack of a fully developed conception of the self, which had not previously been an obstacle, now became one.

From this basic conflict there emerged two main-streams of thought with regard to the concept of the self, each of which emphasized one of the two senses in which Freud used the term—either the whole person or as a special part of the mind with its own unique capacities and functions. Those who emphasized *Ich* as ego tended to be working mostly with neurotics and oedipal conflicts and placed heavy emphasis on the structural theory (ego, id, superego).

Those who emphasized the other meaning of the term *Ich*—the self as the whole person—tended to be working with psychoses and character disorders, and preoedipal levels of conflict and difficulties with the self.

This latter group, who emphasized the self as a whole person, further fractionated into a number of subgroups based on varying definitions of the self, its nature, and its functions as follows:

(a) Jung (1953) saw the self as a primordial image or archetype expressing the individual's need for unity, wholeness, and its highest aspirations.

(b) Rank (1929) focused on the psychological aspects of the emergence of the physical self at birth and emphasized separation anxiety as springing from birth trauma.

(c) Adler (1940) saw the life-style (repetitive patterns derived from early childhood) as a defensive overcompensation for inferiority feelings about the self, therefore blocking the emergence of the real, creative self.

(d) Horney (1950) postulated an idealized self which produced a pseudo unity or wholeness that blocked the emergence of what she called the real self.

(e) Sullivan (Mullahy 1970) felt that the essence of the self was determined by its functions: (i) the fulfillment of needs; (ii) the maintenance of security.

A reconciliation of both senses of the use of the word *Ich* or self—whole person and ego—has more recently been undertaken by theoreticians in ego psychology and object relations theory. Hartmann (1958) distinguished between the self as a whole person, the ego as a system (part of the tripartite structure of id, ego, superego), and the self representation as the intrapsychic representation of the self. He also defined narcissism as the libidinal investment of the self representation. Then Jacobson (1964), in order to work with psychotics, carried the concept further by defining the self representation as the unconscious, preconscious, and conscious intrapsychic representations of the bodily and mental self in the system ego. Kernberg (1982) used the term character to refer to the self as a whole person and preferred to use the term self to refer to the sum total of intrapsychic self representations in intimate contact with the sum total of object representations in the ego. In contrast to Hartmann, he felt that the self and object representations are both libidinally and aggressively invested.

Kohut (1971), from his work with narcissistic personality disorders, viewed the self as consisting of fused self objects which were invested with narcissistic libido that had its own line of development separate from the development of object representations and object libido. In other words, there was no separation of self and object, but rather maturation of self objects from primitive to mature forms.

This focus on the self as an intrapsychic entity, when kept in concert with the other perspectives of de-

velopmental object relations theory, can lead to a broader, more inclusive and comprehensive concept of the real self and its disorders. This view reconciles both definitions of *Ich*—the self and the ego—bringing together the personal, subjective experiential with the objective, mechanistic theoretical.

1. The Real Self: Structure, Development, and Function

1.1 Clinical

A few definitions will facilitate discussion of the structure of the real self.

1.1.1 Self-image. The image an individual has of himself at a particular time and in a specific situation. It consists of his body image and the mental representation of his state at the time. This image may be conscious or unconscious, realistic or distorted (Moore and Fine 1968).

1.1.2 Self-representation. A more enduring schema than self-image, constructed by the ego out of the multitude of realistic and distorted self images which an individual has had at different times. It represents the person as he consciously and unconsciously perceives himself and may be dormant or active (Moore and Fine 1968).

1.1.3 Supraordinate self-organizations. Because subjective experiences may be organized by multiple self representations, the 'I' of one state of mind may not necessarily be the same as the 'I' of another state of mind. This term is used for the organization and patterning of the various subordinate self-images and representations (Horowitz and Zilben 1983). It connects them and provides a continuity between them and a sense of unity and wholeness.

2. The Real Self

In keeping with ego psychology and object relations theory, the term 'real self' is used in the intrapsychic sense of the sum of self and object representations with their related affects.

The term 'real' is synonymous with healthy or normal. It is used to emphasize that the representations of the real self have an important conscious reality component even though unconscious and fantasy elements occur. It also indicates that the real self has an important reality function: to provide a

vehicle for self-activation and the maintenance of self-esteem through the mastery of reality.

The term real self also helps to differentiate it from the false selves of the borderline and narcissistic patients that are based primarily on defensive fantasy, not on reality, and are directed toward defense, not toward self-expression in reality. When using the term real self, both the collective subordinate self-representations and their supraordinate organization are referred to.

The real self exists as a parallel partner of the ego and has its own development, its own capacities, and its own psychopathology. The self and the ego develop and function together in tandem, like two horses in the same harness. If the ego is arrested in development, so is the self. One aspect of the self could be viewed as the representational arm of the ego, although it is obviously more than that. Similarly, one aspect of the ego, since it deals with volition and will and with the activation and gratification of individuating wishes, could be viewed as the executive arm of the self. However, it is also obviously more than that as its primary function is maintaining intrapsychic equilibrium.

Erickson (1968) referred to the dual and inseparable nature of the self-ego as follows: Identity formation can be said to have a self aspect and an ego aspect. What could be called the self identity emerges from experiences from which temporarily confused (subordinate) selves are successfully reintegrated in an ensemble of roles which also secure social recognition. One can speak of ego identity when one discusses the ego's synthesizing power in the light of its central psychosocial function and a self identity when the integration of the individual's self role images are under discussion.

To differentiate between personal identity [*or in my terms the real self*—JFM] and ego identity: personal identity is a conscious feeling based on two simultaneous observations: the perception of the self sameness and continuity of one's existence in time and space, and the perception of the fact that others recognize one's sameness and continuity. Ego identity, however, is the quality of that existence in its subjective aspect; it is the awareness of the fact there is a self sameness and continuity to the ego synthesizing methods.

The real self, then, provides an internal repertoire that, although finite and fixed, is varied and flexible enough to blend the need for real self-expression with the external roles required by adaptation.

3. Development of the Real Self

The ingredients or building blocks of the real self consist of the biologic and genetic endowment, the child's experience of proprioceptive and sensory sensations from his or her own body, as well as pleasure in increasing mastery in coping with the environment

plus the interactions with a caring object as described by Mahler and McDevitt (1982).

I will assume the infant has two basic points of reference from which he builds up his self schema: one, his own inner feelings or states forming the primitive core of the self on the one hand and, two, his sense of the care given by the libidinal object on the other hand. Insofar as the infant's development of the sense of self takes place in the context of the dependency on the mother, the sense of self that results will bear the imprint of her caregiving.

Psychoanalytic child observation researchers have traced the emergence of the self in normal children in the first three years of life. The issues of this child observation research are quite complex and beyond the scope of this paper. The contributions of four researchers: Mahler (1975), Stern (1985), Bowlby (1969), and Schore (1994) are briefly summarized.

Mahler (1975) derived intrapsychic hypotheses from observations of the child's behavior. Her work with child psychotics led her to theorize that the child's self emerges from a symbiotic relationship with the mother. She's described this occurring in four stages: autistic, symbiotic, separation-individuation and on the way to object constancy. Each stage brought further separation of the self from the maternal object representation. She emphasized the vital importance of the mother's support for the child's emerging self.

Stern (1985) similarly based his theories of intrapsychic development from observations of the children's behavior. He found that there was no symbiotic stage that the child was prewired to see the mother perceptually as separate from birth and that the child was an active co-creator of its own development in relationship with the primary caretaker. He also described four stages: emerging self, core self, inter-subjective self, and verbal self.

Bowlby (1969), unlike Mahler and Stern, made no intrapsychic hypotheses but limited his findings to what can be observed from the child's behavior, thus providing a firmer scientific base that could be replicated. He theorized that at birth the child had no attachment to the mother, and that the primary task was for the child to find a secure attachment. He divided that attachment into two types—the secure and the insecure. This insecure was then subdivided into avoidant, resistant, disorganized, and disoriented.

Schore (1994), based on neurobiological rather than psychoanalytic research, reported that the development of the brain is experience-dependent on the interaction with the primary caretaker or the mother. The genes are responsible for the physical neurons but it is the interaction with the mother during the crucial early stages of development between 10 to 12 months and 14 to 16 months that is responsible for the wiring of those neurons. It is the wiring that occurs during these crucial stages that helps the self to emerge and to take on its functions in the regulation of affect and socio-emotional relationships. Thus, the mother is

found to be as important neurologically as psychologically.

Although the self becomes autonomous and able to perform its function at three years, further increments are added during the phallic-oedipal phase, latency, and adolescence. As the child passes through each later psychosocial stage, the resolution of it provides certain capacities for the self such as industry, initiative, and generativity as described by Erickson (1968). The whole process of development of the self culminates in the normal identity crisis of adolescence, where the adolescent must test, select, and integrate the self images derived from the crises of childhood in the light of the climate of youth and sexual maturity.

3.1 Capacities of the Self

Simultaneously and in parallel with the maturation of ego functions, and with self and object representations becoming whole, the now whole, separate, real self becomes autonomous and takes on its capacities. These capacities were clinically identified mostly by their impairment and repair in borderline and narcissistic patients. This list is probably far from complete but forms an adequate clinical working scheme:

(a) Spontaneity and aliveness of affect. The capacity to experience affect deeply with liveliness, joy, vigor, excitement, and spontaneity.

(b) Self-entitlement. From early experiences of mastery coupled with parental acknowledgment and support of the emerging self, the sense builds up that the self is entitled to appropriate experiences of mastery and pleasure, as well as to the environmental input necessary to achieve these objectives. This sense, of course, is sorely deficient in the borderline disorder, and pathologically inflated in the narcissistic disorder.

(c) Self-activation, assertion and support. The capacity to identify one's unique individuating wishes and to use autonomous initiative and assertion to express them in reality and to support and defend them when under attack.

(d) Acknowledgment of self-activation and maintenance of self-esteem. To identify and acknowledge to oneself that one's self (in both senses of the term) has coped with an affective state and/or an environmental issue or interaction in a positive, adaptive manner. This acknowledgment is the vehicle for autonomously fueling adequate self-esteem.

(e) Soothing of painful affects. The capacity to autonomously devise means to limit, minimize, and soothe painful affects.

(f) Continuity of self. The recognition and acknowledgment through an effective supraordinate organization that the 'I' of one experience is continuous over time and related to the 'I' of another experience.

(g) Commitment. To commit the self to an objective or a relationship and to persevere, despite obstacles, to attain the goal.

(h) Creativity. To use the self to change old, familiar patterns into new, unique, and different patterns.

(i) Intimacy. The capacity to express the self fully in a close relationship with minimal anxiety about abandonment or engulfment.

(j) Autonomy. The capacity to autonomously regulate self-esteem and socio-emotional relationships.

4. The Healthy and Impaired Real Self

For a clinical example of the operation of the real self, consider a young psychologist who submits his first version of his PhD thesis to his advisory committee and is told that in some areas it lacks information and in others the writing is poor.

Since the cornerstone of his real self is his sense of self-entitlement, he feels entitled to mastery and whatever input that this requires, plus his capacities for self-activation, assertion, and commitment. He realizes at the outset that the purpose of submitting his thesis at that time was to learn its deficiencies so that he could correct them. He then applies his creativity, commitment, and self-assertion to find ways to learn the necessary knowledge and improve his writing. By mastering his reality problem, he has provided an autonomous feedback to support his self-esteem or self-image, a support which is also soundly based on reality.

To extend the metaphor of the psychology student to contrast the operation of the borderline, false defensive self with the real self: Because of his difficulty with self-activation, assertion and commitment, and creativity, the student might procrastinate and delay submitting his thesis way beyond the deadline. The critical comments would be felt as a reinforcement or proof of his inadequate self and would precipitate an abandonment depression to which he would respond by helpless clinging to a teacher or other authority, or by avoiding the project altogether. This, of course, would further reinforce his sense of an inadequate self.

Psychology: Overview

Psychology is both an academic discipline and a profession. The concept of psyche originates from the Greek language and is frequently translated as 'soul.' The term has been used in religious and philosophical treatises since the antiquities, before an academic discipline explicitly designated as psychology was established in the sixteenth century. Until the nineteenth century, psychology was a special field within philosophy. During the first half of the twentieth century, it was institutionalized in universities as an

independent science. In the second half of the century, an increasing number of positions for university graduates with a degree in psychology were provided in public service, business organizations, and private practice. Today, there are approximately 300,000 scientifically qualified psychologists worldwide, most of whom are employed outside academic institutions.

Although psychology often presents itself as a unitary field, it comprises a considerable diversity of domains, theories, and methods. Despite its independent status, psychology shares historical roots and current concerns with other disciplines and professions. Both the ramifications of psychology into diverse branches and its position among related disciplines and professions will be outlined in turn.

1. Conceptions and Fields ('Psychologies') within Psychology

The soul was conceived as the principle which distinguishes the living body from the dead and manifests itself in consciousness and movement, or mind and behavior. The soul and its mental and behavioral manifestations have been studied from various perspectives. The paradigmatic perspective emphasizes theoretical and methodological principles and affiliations to 'schools.' The universal perspective seeks for knowledge that is valid for the human species, or even all vertebrates endowed with intelligence and mobility. In contrast, the differential perspective explores the variations occurring within and between species. In the analytical perspective, researchers refine the existing knowledge by discovering ever more details, while adherents of the holistic perspective endeavor to comprehend higher-order structures. The theoretical perspective calls for the description, classification, and causal explanation of mental and behavioral phenomena. The pragmatic perspective views the soul as the source of happiness, sociability, and efficiency, and raises questions of utility and morale.

Specialized research programs and practical applications have emerged from these perspectives. They have been institutionalized as curricular units, classifications for books and journals, and as divisions within and between scientific and professional associations. Some programs have competed for dominance and presented themselves as complementary 'psychologies' within psychology.

1.1 Paradigmatic: The Three Major Schools

Scientific paradigms are defined by their explanatory principles, the concomitant concepts and terms, and their preferred methods and values. They are established and maintained by a community of scientists that endorse one and only one paradigm. Modern psychology has spawned three major theoretical paradigms: cognitivism, behaviorism, and depth

psychology, all of which continue longstanding philosophical traditions.

In the tradition of rational philosophy, cognitivism regards human beings as reasonable, conscious, reflexive, and self-organizing. In this view, each person is endowed with insight into natural, logical, and social laws, and may utilize their free will and foresight to plan and execute actions directed towards valued goals. Moreover, humans are seen as sociable and communicative. Language is a tool for representing imaginations and intentions both in a person's own mind and in his or her interaction with others. Authors with a cognitive orientation (e.g., Broadbent, Köhler, Piaget) rely on introspection and self-reports (e.g., think-aloud protocols in studies of problem solving), but also collect behavioral data (e.g., operations in the course of problem solving). Typically, cognitivistic studies employ methods from mathematics, physics (e.g., field theory), or engineering (e.g., information theory) to elucidate the intricacies of mind and behavior.

In the tradition of materialism and utilitarianism, behaviorism (in Russia: reflexology) focuses on overt behavior (e.g., locomotion, instrumental acts) elicited by external stimuli (e.g., color signals) and internal stimuli (e.g., thirst), or emitted to take advantage of opportunities in the natural and social environment (e.g., food, praise). According to this conception, a human being is an automaton capable of forming stimulus-response associations (habits) and of adapting to contingencies between acts and their rewards or punishments (reinforcements). Behaviorism assumes innate, species-specific habits, or instincts (e.g., mating). Authors such as Hull, Pavlov, and Skinner have studied the acquisition of new habits and the shaping of behavior by reinforcements. Orthodox behaviorism opposes introspection, and relies exclusively on objective behavioral data.

In the tradition of mysticism, depth psychology posits a pervading influence of unconscious ideas and affects on conscious thought, language, and action. Freud's psychoanalysis, the most popular paradigm within depth psychology, contends that the unconscious originates from personal conflicts in early childhood when anxiety-provoking tendencies (primarily hostility towards the parent of opposite sex) are repressed and rejected from the conscious mind. In his analytical psychology, Jung even postulates an innate, species-specific unconscious consisting of archetypes. These archetypes are explained as fundamental experiences (e.g., motherhood, fire) which have been acquired and transmitted over generations. Depth psychology believes in the power of the enlightened human mind to reveal unconscious contents. However, the revelation of unconscious contents requires skillful interpretations. Beyond straightforward observations, interpretations should offer explanations for the meaning of symbols from the unconscious (e.g., the moon as a symbol of femininity) which are

encountered in dreams and other fantasies, as well as in achievements (e.g., in the arts) and failures (e.g., slips of the tongue).

The three major theoretical paradigms gained wide recognition during the first half of the twentieth century; they were also engaged in mutual antagonisms. However, no final verdict has been reached in the battles for dominance. There were some partially successful attempts to reconcile the conflicting paradigms. At present, conflicts between 'schools' have attenuated and orthodoxy has been superseded by eclecticism. For instance, numerous behaviorists now regard cognitions (e.g., attitudes and beliefs) as determinants of behavior, despite their subjective nature, while cognitive theorists accept the notion of unconscious ideas (e.g., subliminal perceptions).

1.2 Universal, Analytic: General Psychology, Biological Psychology

General psychology investigates universal and basic features of mind and behavior. Originally, it was launched in the spirit of philosophical idealism that acknowledged as scientific only universal and basic statements probing into the essence of matters. Ever since, general psychology has continued the quest for invariances and fundamental notions. It has predominantly pursued four objectives:

(a) Taxonomies. Cognitive functions have been categorized as sensation and perception, imagination and memory, concept formation, reasoning, problem solving, and language. Similarly, behavioral functions were classified as motives, drives, intentions, emotions, motor patterns, and actions.

(b) Structural analysis. Both cognitive and behavioral structures have been researched extensively. An example is semantic networks, that is, organizations of concepts representing domains of knowledge (e.g., automobiles), and action sequences (e.g., mountain climbing).

(c) Functional analysis; that is, the elaboration of the conditions which enable, prevent, and modify cognitive and behavioral processes and their outcomes (e.g., task complexity as a condition of learning).

(d) Formal (e.g., mathematical) models. General psychology designs models of internal mechanisms underlying psychic phenomena (e.g., the model of working memory). These models also serve to explain the effects of salient conditions.

In pursuit of these four objectives, general psychology is striving for progressive refinement. For structural and conditional analyses as well as for tests of formal models, experimental methods have become indispensable. Therefore, general psychology is sometimes equated with experimental psychology.

General psychology can be extended to encompass the exploration of the biological bases of cognitive and behavioral phenomena—the domain of biological

psychology. Using advanced measurement techniques, biological psychology locates and monitors mechanisms and processes of the brain, the peripheral nervous system, the endocrine glands, and other physiological systems which constitute the biological substrate of psychological functions such as language, memory, perception, and emotion, and which mediate cognitive and motivational states such as wakefulness and anxiousness.

1.3 Differential, Analytic: Animal, Developmental, Social Psychology, Individual Differences

Since the eighteenth century, the monopoly of general psychology has been challenged by romanticism, which emphasized the principle of organic growth in the natural world and in cultural settings, and by evolution theory (Darwinism). Both movements viewed variation as a fundamental natural principle. Romanticism and evolution theory provided the intellectual climate for the emergence of new psychological approaches that made variations their object of study:

(a) Animal psychology, also designated as comparative psychology, compared the behavior and the intelligence of species, including humankind. Much of this work was based on the assumption of a mental evolution (i.e., a gradual increase in intelligence from lower animals to humans), and a behavioral evolution (primary instincts like love or hate, transmitted from prehistoric man to modern-day humans, and secondary instincts acquired individually).

(b) Child psychology commenced with the study of mental and behavioral changes in humans during the first years of life, and was later extended to developmental psychology covering the whole life-span. In the beginning, child psychology frequently had an evolutionary background, since child development was interpreted as a replication of the evolution of the human species. Subsequently, evolution theory lost its major impact, and the study of human development continued with a generic interest in the changes that occur during people's lives.

(c) Social psychology documented and reflected the variations in cognitions, habits, and rules that are attributable to culture and social groups within cultures (e.g., the family). It drew cross-cultural comparisons of social structures, above all language, art, customs, power, education, kinship. Favorite topics were the evolution of social structures (social Darwinism) as well as the impact of external (e.g., geographical) factors on social life. Another influential branch was mass psychology that attributed to crowds the loss of rationality. Crowds were described as emotional, expressive, irresponsible, and addicted to charismatic leaders. Finally, social psychology restricted itself to the analysis of three basic issues: social relations (e.g., centralized vs. decentralized groups),

social cognitions (e.g., attitudes, stereotypes), and social processes (e.g., communication, group problem solving).

(d) The psychology of individual differences emerged from theories of human faculties, both intellectual (e.g., reasoning) and moral (e.g., altruism). The study of individual differences benefited from sociometrics which assessed frequency distributions of crime, income, etc. in populations. Measures of intelligence, motivation, and performance were found to be distributed as the Gaussian bell-shaped curve with the mean representing the most frequent case. From the genetic point of view, the positions of parents and their offspring in distributions were compared. Obvious correlations between parents and their children could be attributed to hereditary factors. However, sociocultural factors (e.g., educational style) were also examined as causes for transmissions of mental and behavioral dispositions over generations.

The studies on variations have modified the taxonomies and models from general psychology to account for inter- and intra-individual differences. New models were constructed which consider the ontogenetic, phylogenetic, social, and individual factors governing mental and behavioral variations. Thus, developmental and animal psychology have designed stage models of ontogenetic and phylogenetic changes, and social psychology has developed models of group formation and group cohesion.

Methodologically, differential approaches have conducted experiments, but have also collected a large body of data by field observations and surveys (e.g., longitudinal studies in developmental psychology).

1.4 Holistic: Personality Psychology

While human life manifests itself in a diversity of phenomena that vary with social context and over the life-span, the experience of a unitary mind and of consistency in behavior prevails in human consciousness. Upon this experience the concepts of self and ego are based. These two concepts replace the concept of soul in modern psychology. Self and ego represent an internal system which integrates diverse and even conflicting functions (e.g., inhibition of recollections), developmental stages (e.g., transitional stages from being protected in childhood to assuming responsibility in adulthood), and social roles (e.g., private vs. professional) to establish a sense of personal identity in consciousness and activity.

The unitary structure of mind and the consistency of behavior are the central issues of personality psychology. The concept of personality originally designated the coherent and integrated organization of persons, reflecting their life-long identity and individuality. Thus far, personality psychology has followed the philosophy of holism, that truth and valuable action can only be attributed to complete,

integrated structures. Presently, postmodern approaches question the assumptions of continuous integrality and self-identity. They prefer the assumption of a patchwork personality consisting of discontinuous and even contradictory features (e.g., role conflicts, different attitudes for different settings).

The method of understanding has been advocated as the most useful approach to personality. Understanding has been conceived as a hermeneutic technique that enables direct communication between an observer and his or her object. Adherents of the hermeneutic position have contributed in-depth character studies and biographies. Influential and popular hermeneutic approaches to personality development were provided by depth psychology (see Sect. 1.1). Numerous authors have acknowledged the artistic but have criticized the scientific relevance of hermeneutic contributions. As alternatives, they have proposed more rational models for personality theory. Factor theories of personality and theories of self-regulation have met with great success. Factor theories are based on measurements of individual differences. Employing mathematical techniques, they reduce the variety of measures to a minimum of personality dimensions. Extraversion–introversion and neuroticism are among the most frequently identified dimensions. Theories of self-regulation attempt to conceptualize the processes by which individuals maintain their identity and consistency, as well as those mechanisms through which persons induce or cope with changes in their personality. Central to these theories are self-concept, self-awareness, and self-management.

Due to its diversity of methods and theoretical principles, personality psychology is the most heterogeneous among the fields treated in this article. Its holistic claims, however, have merited its frequent appraisal as the most substantial field in psychology.

1.5 Pragmatic: Applied Psychology

Psychology has served three practical purposes: assessment, intervention, and evaluation. A large number of testing methods are available to assess the intelligence and the personality, as well as the specific aptitudes and attitudes of individuals. Based on these assessments, persons can be selected (e.g., for vocational careers), and classified for specific treatments (e.g., therapy plans). Besides persons, objects (e.g., sales products) and situations (e.g., work places) are also subjected to psychological assessments. Interventions include training, therapy, rehabilitation, and work organization programs. Evaluation refers primarily to public programs (e.g., educational projects, health campaigns). Evaluation methods are designed to monitor outcomes and costs of these programs, and to offer advice on how to improve their efficacy.

Some have claimed that a generic applied psychology can be adapted to all domains of civilization. Indeed, psychological services have been offered for a

plethora of specialized fields such as architectural psychology, sports psychology, and traffic psychology. Firmly established are the following:

(a) Clinical psychology for the diagnosis and therapy of mental and behavioral disorders in individuals, couples, and small private groups. Clinical psychologists typically treat neurotic and psychosomatic disorders (e.g., anxiety, compulsion, high blood pressure), as well as behavioral and social deviations (e.g., aggressiveness, substance abuse).

(b) Educational psychology is predominantly applied in educational institutions (preschool and school programs, special schools, vocational training, etc.), where psychologists advise educators and offer guidance to students. Educational psychologists also deal with educational processes resulting from peer interactions, media exposure, etc.

(c) Work and organizational psychology emphasizes personnel development, training, and work organization in various industries and on the administrative level.

(d) Law psychology is divided into several branches. Forensic psychologists assess witnesses and defendants in court cases; in criminal psychology, the objective is the prevention of delinquency and psychological support for inmates of penal institutions. Moreover, psychologists act as consultants to administrative courts (e.g., by rendering opinions in custody disputes).

(e) Economic psychology encompasses market research, consumer communication, and macroeconomics (i.e., the relationship of income, consumption, and savings).

The traditional view of applied psychology is based on the scientist–practitioner model which assumes that practical expertise is an extension of basic theoretical and methodological expertise. Alternatively, applied psychology may be conceptualized as representing an independent field of practical expertise that originates from the direct interaction with the problems encountered in the various branches of psychology. In this latter view, the scientific value of applied psychology rests on the documentation and analysis of practical problems, and on the validation of psychological procedures and theories. For instance, intelligence tests are not directly derived from basic theories of reasoning. They are carefully selected compilations of various tasks that have long been familiar in educational institutions and workplaces. Psychologists have standardized and validated these tasks to meet specific diagnostic requirements (e.g., school and job entry examinations).

1.6 Conclusions

The programs and paradigms of psychology form a fairly coherent and stable structure. Nevertheless, they exhibit inclinations towards isolating themselves. Typically, fields such as biological and social psy-

chology establish their own research programs, and each field holds its own conferences. Deficits in interdisciplinary exchange have also been claimed to exist between basic psychological research and applied psychology. On the other hand, there is a considerable overlap between various fields of specialization. For instance, research in social psychology may be duplicated in developmental psychology, as development occurs in social contexts and is interpreted to a large extent as a socialization process.

A pervasive feature of psychology is the fragmentation due to differences in perspective and historical background. Traditionally, boundaries between different 'psychologies' have been lamented and have given rise to efforts at unification and integration. Recently, however, disintegration and deregulation have also been interpreted as the results of diversity and subjectivism, and the fragmented state of psychology has been defended as a desirable adaptation to postmodern culture.

2. The Position of Psychology among Academic Disciplines and Professional Fields

Psychology has often been hailed as the heart of the life sciences. Psychological problems, methods, and theories relate to the humanities as well as to the social and the natural sciences. From the humanistic point of view, psychology is the basis of all scientific inquiry, since it studies the human mind as the source of knowledge. Furthermore, it provides the foundation for moral conduct as it elucidates the human condition.

Until the nineteenth century, scientific research of mind and behavior, and of individuals and cultures was conducted primarily under the label of philosophy. Moreover, psychological doctrines have been cultivated in law schools, medicine, and theology. In the late nineteenth century, psychology was institutionalized as a specialized academic discipline, along with other methodologically and theoretically advanced fields from the philosophical faculty such as linguistics, history, ethnology, sociology, and biology. A similar development took place in the practical domain. When psychology became a profession, some related branches of practice had already been firmly established (e.g., teachers in public schools). With an academic and professional system steadily growing and splitting into branches, psychology followed two courses. As an independent scientific discipline and profession, psychology develops specific theories, methods, and practical techniques to cultivate an exclusive expertise. In terms of its interdisciplinary position, various related disciplines and professions continue to contribute psychologically relevant findings and methods.

In the second part of this article, the position of psychology among academic disciplines and social

service professions will be examined. Both disciplinary and interdisciplinary projects will be regarded within four contexts.

2.1 The Metaphysical Context: Psychology, Theology, Occultism, Epistemology

Soul is a central concept in psychology and in theology. Theology defines the soul as an immaterial substance inherent in individuals. As far as the theological conception of the soul is holistic, it corresponds to the notion of a unitary self in personality theory (see Sect. 1.4). Unlike psychology, however, theology assumes a metaphysical world of external wisdom and ultimate values as the origin and destination of the soul. Moreover, theology posits interactions between the soul and metaphysical agents (e.g., gods, angels). This belief extends to miracles beyond rational explanation (e.g., resurrection from the dead), and to particular vicissitudes of the soul (e.g., creation, condemnation, and redemption).

While psychology as a modern doctrine refrains from metaphysical speculations, it does consider religious experiences and practices from a theoretical and a practical point of view. With regard to the former, a field designated as psychology of religion analyzes religious experiences and practices as social cognitions and customs. Regarding the latter, ministers are trained in pastoral psychology that is aimed at improving their ability to cope with the demands of their profession. Psychological programs, especially psychotherapy, may include religious notions and exercises to serve clients who are believers. Most churches agree with psychology in respect to the desirability of mundane peace and harmony. Therefore, clerical counseling services include or cooperate with psychological agencies. During and after natural and technical disasters (e.g., earthquakes, airplane accidents), members of the clergy and psychologists trained in emergency psychology join to provide immediate help to victims and their families.

While religious beliefs were discounted as superstitions in the era of enlightenment, some authors continued to believe in the existence of immaterial beings (e.g., spirits, demons) and rationally inexplicable phenomena (e.g., accurate prophecies, communication with spirits, movement of physical objects by spiritual forces). The movement of occultism suggested that these phenomena may be based on natural conditions that have thus far eluded all scientific scrutiny (e.g., 'animal magnetism'). Parapsychology has resumed the investigations of occult phenomena. Numerous studies have revealed deception as the origin of allegedly supernatural events. Nevertheless, there have remained some unusual demonstrations and reports that could not be explained scientifically.

In accord with epistemology, the field of metaphysics has not been fully abandoned in modern

psychology. Beyond religious beliefs, metaphysics has been interpreted as cognitive contents that transcend personal experience. In this sense, the metaphysical approach is maintained in nativistic theories of psychology such as the assumption of archetypes in analytical psychology (see Sect. 1.1) that allegedly are transmitted to the unconscious from preceding generations. Moreover, fundamentals of perception and reasoning (e.g., the dimensions of space and time, the concept of causality) have been postulated which serve as prerequisites for the acquisition of new experiences, but are not the result of individual experience.

2.2 The Cultural Context: Psychology, the Humanities, and the Social Sciences

Psychology has shared topics with all the humanities and social sciences. Linguistics is an example. The relationship between language, mind, and society has long been deemed worthy of scrutiny. Consequently, the interest in language as the object of research is common to a variety of disciplines (e.g., sociology, history). While their priorities differ, their efforts converge in providing a comprehensive, interdisciplinary understanding of language. Psychological principles are posited by many authors as providing the basis for the structure of languages (e.g., memory capacity, interactive minds). In psychology itself, language is also an important topic. Cognitive, developmental, social, and other fields of psychology investigate verbal representations and verbal behavior (e.g., words and concepts, language development in children). Within some psychology departments, the study of speech comprehension and production (both oral and written) has been institutionalized as a special field called psycholinguistics. However, the intricacies of specific languages (e.g., Dutch, Chinese) usually remain unexplored in psychological research. Expanding expertise pertaining to the grammar, vocabulary, morphology, and literature of a plethora of modern-day, as well as ancient languages has spawned language-specific research and training. This has been institutionalized in language departments that conduct extensive studies on specific languages. Moreover, many language departments pursue a program of linguistics that elaborates general theories of language.

A similar example from the social sciences is ethnology. Culture-specific lifestyles and beliefs have been salient topics in the discussion of human nature and human interactions on all levels of complexity (e.g., parent–child relationships, government of states). Much emphasis has been placed on comparing ‘primitive’ with ‘civilized’ lifestyles, in the hope that such studies would reveal the evolution of humankind. Frequently, cultural studies have been assigned to psychology, and psychological principles were invoked to explain diverse cultural phenomena. Jung (see Sect. 1.1), for instance, has found evidence for archetypes in folk mythology. Widespread interest in

foreign and primitive cultures has inspired research expeditions to distant countries. Such projects have provided invaluable information on human cultures (including their geography, language, technical skills, etc.). Moreover, they have led to the development of advanced research methods. A result of these efforts has been the establishment of fields such as ethnology and anthropology. Related disciplines, including psychology, have contributed to and benefited from ethnological research. Within psychology, there still exists the subdivision of cross-cultural psychology.

2.3 The Natural Context: Psychology, Biology, Physiology

Some psychological research has been initiated during the nineteenth century by biologists and physiologists in order to study brain functions which eluded the research methods of the time. Physiological psychology was promoted as a new scientific discipline that employed experiments to investigate higher mental functions (e.g., sensation, attention, learning). By the end of the twentieth century, brain research, neurophysiology, and biochemistry have come closer to the explanation of how cognition and behavior are represented in and controlled by the nervous system. Above all, brain research has determined the location of psychologically relevant neural functions (e.g., centers for speech production and comprehension), and has elucidated the organization of neural networks that interact during psychological processes (e.g., links between cortical correlates of perceptions and subcortical correlates of emotions in the appraisal process). Equally vital is the understanding of the hormonal control of arousal in the nervous system (e.g., due to adrenaline discharge), including the regulation of the sleep–wake cycle, alternations between activity and relaxation, and mood changes. In order to continue the research in this area, a new field called neuropsychology has been established.

The study of individual differences was instigated by efforts to ascertain the inheritance of character traits and skills (including deviant character and ingenuity). Studies on phenotypes have demonstrated the substantial influence of genetic factors on personality and behavior. Biological research programs are close to unraveling the mystery of the genetic code that is the substrate of inherited cognitive and behavioral dispositions.

Ethology deserves to be mentioned as a traditional interface between psychology and biology. It focuses on species-specific behavior with an emphasis on adaptation to the environment. Central issues are instincts as long-term, species-specific adaptations of drives and related behavior patterns (e.g., sex drive and mating behavior), and key stimuli eliciting instinctive behavior (e.g., the scheme of childlike characteristics which triggers affectionate behavior). Currently, ethological studies in biology outnumber

those in psychology, as the latter discipline has turned to questions of individual learning and socialization. However, psychology, in particular animal psychology and biological psychology (see Sect. 1.2) has continually incorporated ethological findings into its theories. The existence of neural and hormonal correlates of instinctive behavior has long been postulated, and neurophysiological research is in the process of providing the evidence for these assumptions.

2.4 The Context of Healthcare: Psychology and Medicine

Health is a physical and a mental state. Physical ailments have a psychological impact, and psychological disorders may cause physical diseases. The role of psychosocial factors has long been recognized in medicine, and special categories of neurotic and psychosomatic diseases have been defined. Neuroscience has demonstrated the effects of psychological stress on the immune system, and the new field psychoimmunology has been established.

The treatment of neurotic and psychosomatic disorders has become the domain of certified therapists trained in clinical psychology (see Sect. 1.5) rather than medicine. These therapists implement psychological diagnostic procedures and therapies such as cognitive and behavior therapy. A rapidly growing field in the health services is health psychology that designs, conducts, and validates programs of disease prevention (e.g., dental care, breaking nicotine addiction) and rehabilitation (e.g., after myocardial infarctions).

While all these psychological fields center on patients, another approach focuses on physicians: medical psychology. Obviously, diagnostic and therapeutic procedures may engender unconventional and emotional interactions between physicians and patients, and the outcome of treatments may depend on the social skills of physicians. Therefore, medical psychology studies and attempts to enhance doctor–patient relationships. For instance, doctors are advised on how to cope with stressful experiences (e.g., death of patients), and with problems of intimacy (e.g., during urological examinations).

2.5 Conclusions

There exists a tripartition of psychologically relevant research and practice: (a) generic involvement in topics which various fields of psychology (e.g., developmental, social psychology) share with other disciplines (e.g., sociology, pedagogy, biology), (b) specializations in object-centered disciplines (e.g., linguistics, ethnology, neurophysiology), and (c) specializations within psychology (e.g., psycholinguistics, cross-cultural psychology, neuropsychology). A complex network of

academic disciplines and social service professions has flourished in recent years, and within this network psychology occupies a respectable position with links to a variety of related fields.

However, the existing interdisciplinary network has also been criticized on the grounds of insufficient cooperation and of causing paralyzing conflicts. In particular, overlapping research in psychology and other independent disciplines has been indicted as a waste of resources. Why must there be linguistics and psycholinguistics, ethnology and cross-cultural psychology, neurophysiology and neuropsychology, organizational psychology and sociology, pedagogy and educational psychology, etc.? There are voices that advocate a re-integration of the presently diverging branches of the humanities, the social and the natural sciences. Some view psychology as the designated leader in this movement. Presently, however, the vision of a department of psychology pervading the entire university is highly unrealistic.

In regard to interdisciplinary integration, the attitudes diverge also within psychology itself. Some psychologists pride themselves in the academic and professional identity which psychology has achieved by its own methodological and theoretical approaches, and therefore stand opposed to a comprehensive integration, while others emphasize the benefits to be gained by merging resources with related disciplines. Two new interdisciplinary fields are exemplary for the movement towards integration: cognitive science and neuroscience. The highly sophisticated methodology of these disciplines (e.g., computer technology, high-resolution measurements of brain processes) may provide answers to fundamental psychological problems and may facilitate the development of revolutionary practical applications (e.g., decoding the memory traces in the brain could advance more effective learning procedures). However, major objections against a full integration of psychology into the new fields of cognitive science and neuroscience remain: mind may be more than a complex web of biological and technical structures and processes.

Psychometrics

Modern test theory makes free use of the idea of a latent variable to explain answer choices in each test item. A latent trait can be transformed by any smooth order-preserving function, and thus does not have the measurement structure that is often mistakenly attributed to it. The notion of a manifold is used to explain this one-dimensional structure. This manifold is not a latent variable, however, and arc length or distance along this manifold from a fixed point is a measure of ability or trait level that is manifest. This arc length measure is suggested as an alternative to latent trait values in order to avoid the confusion that the idea of a latent trait often causes.

1. Introduction

Terms like 'psychometrics' are constantly-moving targets for one seeking a definition, but some frequently encountered features of psychometric data are indicated in the next section. But many readers will think of test scores as prototypical data. What characteristics of the people taking tests do test scores and the data that are used to compute them reflect? Test scores are numbers, but not all the structure of numbers are meaningful representations of something about examinees. Section 3 considers how test scores define nearness or proximity of examinees, and the status of the algebraic operations of summing and differencing. Section 4 relates the psychological concept of a trait to the mathematical notion of a curve in high-dimensional space or a manifold, and considers arc length along this curve as a type of measurement.

2. Definitions and Common Themes

According to one popular dictionary, psychometrics means 'mental measurement.' But we need a better definition, since the status of both mind and measurement as concepts are no longer as unequivocal as they were at the beginning of the twentieth century. This article considers as psychometric most quantitative models for the behavior of humans and other animals that is controlled by the central nervous system.

Defined as broadly as this, it may seem surprising that there are any themes that seem to be common to psychometric research. Nonetheless, there are a few, and they may be motivated by the following questions:

What variables should be observed? In the natural sciences, where seven constants are said to define the universe, which variables to observe is seldom an issue. But in behavioral research, variables are made to measure by researchers, often in the form of tests or scales developed to reflect vaguely defined concepts such as 'depression' or 'ability.' For any popular concept, there are likely to be dozens and even hundreds of such measures available.

What does a variable value mean as a measure? That is, what information can be considered useful in a set of test scores, response times, or other observations, and what can be considered irrelevant? Stevens (1946) proposed a classification into nominal, ordinal, interval, and ratio scales according to the amount of algebraic structure usable in the data. Viewing test scores as nominal scales only treats numbers as labels for examinees. Ordinal scales represent their order structure or ranking. Interval scales also reflect a stable property of the examinees in the ratio of differences, and ratios of scores are meaningful for ratio scales. But so many writers have criticized this system as inadequate that this issue needs revisiting here, at least briefly.

How many variables should be observed? Judging by research reported in widely read journals, a great number. Because it is difficult to decide which measure of, say, intelligence to use, researchers tend to use several, hoping to cover the ground and perhaps to head off complaints from supporters of particular measures. Moreover, access to replicates, usually people, is often expensive and may involve ideological and political sensitivities. Consequently, psychometric data are often high dimensional, especially relative to sample sizes typically used. Researchers may hope that they can compensate for limited sample sizes by observing more variables; but this belief is both naive and dangerous.

Is there some simple low-dimensional structure in the high-dimensional data? Often a one-dimensional structure is assumed, as when choices on tens or even hundreds of test items are reduced to a single test score, but in other cases special psychometric technology is applied to data to reveal both the low dimensionality implicit in the data, and how the data are approximated within this low-dimensional structure. Principal components or factor analysis is, therefore, a standard tool in behavioral research.

3. What does a Psychometric Measurement Mean?

It is fair to say that most researchers don't concern themselves with this question, but it is a hard issue to avoid, since sooner or later numbers are interpreted, and usually by people whose limited exposure to these issues makes them vulnerable to misinterpretation of

the results. Is a change in score from 10 to 5 on a depression scale as important as one from 30 to 25? Probably not, but is there at least some useful information in score changes such as these?

A psychometric measurement system is a mapping from a set of people into some system of numbers. It has a purpose, namely to use some of the structural characteristics of numbers to reflect or represent analogous characteristics of people. For example, assigning a social security number just distinguishes one person from another, but assigning a test score tends to mean much more, and at least is intended to reflect an order relation presumed to hold among people. But numbers, and especially real numbers, are structured in many different ways, and the question is; which of these ways should be considered as reflective of characteristics of people, and which should be ignored?

Mathematics, at least as an applied science, is the study of structured sets. By sets, of course, we mean collections of people, drawn from some population X , including the set of nobody, which we indicate by $\emptyset$. Sets A and B can be combined in two ways: unions $A \cup B$, meaning the people who belong to either A , B , or both; and intersections $A \cap B$, meaning only the people who belong to both.

There are three main types of structure that pre-occupy mathematicians:

(a) topological: structure that defines nearness or neighborhoods,

(b) measure or probability: structure that defines size, and

(c) algebraic: rules for connecting two or more elements, that is, identifying certain pairs, triples, etc.

These structures are increasing in level of organization, with topological being in a sense minimal, and algebraic being the most sophisticated.

We shall have a look at topological structure because it seems important in explaining why test scores are so widely accepted as psychometric variables, and is an aspect of measurement that Stevens and other writes have neglected. But measure and algebraic structure are left for others to others to deal with. (See *Memory Models: Quantitative*.) Test scores are by and large accepted by both ordinary citizens and researchers as useful summaries of human behavior. Why this is so, in spite of their murky status among philosophers, mathematicians, and statisticians, probably derives from their topological structure and its relation to analogous properties of behavior that seem to us reasonable.

Topology has a bad reputation for being abstruse, but it deals with a type of structure corresponding to intuitions rooted in experience. Topology is about nearness or neighborhoods defined within a population X of people. One may also think of the topology of X as its *texture*, and in these remarks we will consider whether test scores have gained their accepted

place in most cultures because they reflect assumptions of a textural nature about how people vary.

A topology is a family T of subsets drawn from a set X such that:

(a) both nobody $\emptyset$ and everybody X belong to T ;

(b) the union of no matter how many sets in T is also in T ; and

(c) the intersection of a finite number of sets in T is also in T .

Sets in T are called *open*, and any open set containing a specified person is called a *neighborhood* for that person. For example, a person's neighborhood can be defined as those other persons sharing the same postal code, or having gone to the same university, or inhabiting the same dwelling, or of the same age, or any combination of these characteristics. Or, in this context, as those who have been assigned the same score on a test. The second part of the definition of a topology ensures that neighborhoods can be expanded as far as needed, even to include everybody, and the third says that neighborhoods can be shrunk, but only a finite number of times. What happens when we expand and shrink neighborhoods is the essential practical issue that the topological structure seeks to address.

Since the topology of test scores may reflect something of the topology of the people assigned the scores, let's switch to considering the topology of test scores, and ask whether this reasonably captures something about the population to which they are assigned. Because test scores are real numbers, an open set is defined as the set of test scores between two limits, and this topology is of a specialized variety called *metric*. Of course, test scores also define a topology of the examinees that have taken them, since we can define an open set of examinees as one containing all examinees whose test scores are within specified limits.

Figure 1 illustrates examinee neighborhoods for a score of 2 on a 50-item test, with the neighborhoods being defined by three different test-scoring strategies. The test is simulated, but this does not matter. Nor does it matter that we have chosen the relatively extreme score of 2; neighborhoods for more average scores will show the same features as shown in these three plots, but with less compelling graphics.

The points labeled E display what can be called an *even* topology on examinees. They indicate the number of examinees among 1000 whose scores differ from 2 by varying amounts. Each score separation value therefore defines a neighborhood. Everybody is, for example, no more than 48 points from 2, and the size of these neighborhoods shrinks smoothly as we reduce the score separation, until we see that only a few people are less than 5 points away from 2. We call this an *even* topology because neighborhoods shrink smoothly.

Suppose, now, we arbitrarily add 10 to all scores of 30 or above. This doesn't change the order of the

Figure 1

Number of examinees with scores separated by various amounts from a score of 2 according to three different topologies for a 50-item test given to 1000 examinees. Points labeled E have the even topology, corresponding to scores without gaps or lumps, those labeled G have the gap topology, and those labeled L have the lump topology

scores, but it certainly changes the neighborhoods. The points labeled G show that neighborhood size fails to shrink for score separations between 28 and 38 because of the gap in the scores. This is a *gap* topology. If the population being scored had such a gap, it would mean that there would be nobody capable of producing a set of choices on items corresponding to a test score between 30 and 40.

Or, alternatively, let us combine all scores between 30 and 40 into 30, and subtract 10 from all scores above 40. The neighborhood plot is shown as points labeled L, and we see that neighborhood size shrinks abruptly for score separations above 28 with respect to a score of 2. This is a *lump* topology because, put in people terms, there is a large group of examinees who will necessarily produce identical scores. Do people lump up in this way with respect to their behavior? Perhaps sometimes, but mostly not.

Both the gap and lump topologies that are shown in Fig. 1 are defined by test-scoring methods that preserve the order of test scores, but most of us would not be happy attributing either of these textures to subsets of people. We like to imagine that people are evenly distributed in the sense that (a) if we observe enough behavior, only a very small number of people will display identical behavior, and (b) nevertheless all behavior patterns are potentially exhibited by someone. This is the sense in which the even topology determined by most test scoring methods defines a texture for the population that has neither gaps nor lumps, and tends to correspond to intuitions that we have about how performance on a test is related to the ability that it is supposed to reflect.

A transformation that leaves topology unchanged is called *continuous*, a term that we may roughly translate into *smooth*. If there are no gaps or lumps, then, for example, substituting $y = \exp(x)$ or $z = \exp(x)/[1 + \exp(x)]$ for score x will not introduce lumps or gaps, whereas the two transformations indicated above will, and are clearly not smooth.

Stevens' ordinal scale is, then, too simple. It says too little about the texture of either the data or the population generating the data, and something like the concept of an even topology is needed to explain why those who work with test scores are clearly so comfortable with them as descriptions of the behavior of people.

4. Latent Traits and Manifolds

Few who have worked with colleagues in departments of psychology or faculties of education, or taught statistics to students in these places, will quarrel with the statement that finding low-dimensional structure in high-dimensional data is perhaps the central statistical challenge in these fields. Consequently,

statistical procedures such as stepwise regression, principal components analysis, and structural equation modeling are essential in most contemporary research, and new methods for this problem appear regularly in our methodology journals.

The latent trait is one way to motivate the concept of a low dimensional structure. Test and scale designers often appeal to constructs such as 'proficiency,' 'intelligence,' and 'creativity' in describing what scores on their instruments mean, and freely appeal to a conceptual link between usually unidimensional test scores and these constructs. Of course, it is only test scores, and the choices that generate them, that we can actually observe, and so these constructs are said to be latent or unobservable variables whose structure is reflected in these test scores. Similarly, early factor analysts liked to refer to collections of such latent traits that generate the observed tendency for rather large number of test scores to exhibit low dimensional correlational structure. The five variables in the NEO Personality Inventory, introversion, agreeableness, conscientiousness, neuroticism, and openness, (Costa and McCrae 1985) used in personality research are one of the more successful outcomes of this type of thinking.

Figure 2 displays three *item characteristic curves* for an actual test, these being defined as the relation between the probability $P_i(\theta)$ of getting test item i correct to one's position along a one-dimensional continuum θ . Continuum θ is not observed, but rather inferred from the data. These three curves were estimated by a nonparametric technique described in Ramsay (1991). Probabilities of success on these three items are displayed as functions of four different types of continuum: the first extending over the whole real line; the second containing only nonnegative numbers; the third within the unit interval $[0,1]$; and the fourth to be explained below. Now, since we are not actually observing θ , there is no deep reason for preferring one of these continua over the others, so that the transformations taking us from one to any other are all legitimate modifications of this model. What are not arbitrary, however, are the probability values $P_i(\theta)$ themselves. These are anchored in the data, and must conform to actual proportions of success for groups of people who have neighboring values of θ or, since smooth transformations preserve topology, neighboring values of either a transformation of θ , or of test scores themselves.

Consequently, the upper panel of Fig. 3 shows what is invariant with respect to transformations of θ . By plotting probabilities against each other, we see that probabilities of success migrate smoothly within the unit cube. The sinuous curve that this figure displays also has the even topology in the sense that it has no gaps or lumps. In this plot, the role of θ or any of its transformations has disappeared, except of course, for its topology, since the curve has inherited the even topology of real numbers.

Figure 2

The probabilities of success on three test items as a function of positions on four types of traits. Traits in the upper right and lower left are transformations of that in the upper left, and the trait in the lower right, arc length, is observable rather than latent

The curve in Fig. 3 is a *manifold* in mathematical jargon. Indeed, a smooth manifold, and, if we can compute derivatives of item characteristic curves, a *differentiable manifold*. The subdiscipline dealing with such structures is *differential geometry*. The variable, or any smooth transformation of it, is called a *chart* for the manifold. And with good historical reason, too, since a familiar example of a two-dimensional manifold is the surface of the earth, and latitude and longitude are used to chart this structure, but this is only one example among a large number of alternative charting systems used by cartographers.

What is essential here is that the notion of a manifold captures both the even topological texture discussed in Section B, and something else that is much stronger. Any latent variable charting the manifold can be freely transformed by a smooth and order-preserving function. But there is one charting system that is intrinsic to the manifold, and therefore not at all latent. This is *arc length* s , the distance along the manifold from its beginning, or from any designated point within the manifold. It measures how far

someone at the lowest level of performance has to go within probability space to get to a specified performance criterion. Sums and differences of arc lengths can be calculated, and this makes s a ratio scale variable in Stevens' sense. Indeed, it is more, since s cannot be multiplied by an arbitrary positive constant, and it therefore is an *absolute* scale. Each examinee has an s -value, and, since values of s also possess a measure structure, we can approximate the distribution of these values. The probability density function for s is shown at the bottom of Figure 3. It may be argued that arc length s is the *natural* or *intrinsic* measure of test performance. For further discussion of the manifold perspective on modern test theory, see Ramsay (1996). (See also *Fechnerian Psychophysics* for another application of this concept.)

Of course, this is a rather elementary, albeit enormously important, example of a manifold. What comes out of a principal components analysis of p variables is a flat k -dimensional manifold, although there are certainly researchers who have considered how to construct curved manifolds. Multidimensional

Figure 3

The curve in the upper plot results from plotting probabilities of success for the three items in Fig. 2 against one another. This curve is called a probability manifold. Numbers indicate various trait values on the scale of θ indicated in Fig. 2. The lower panel displays the distribution of trait values

scaling uses distance information, which is essentially topological, to identify similar flat structures, but within which interesting curved substructures are often easily visible.

The advantages of manifolds, as opposed to latent variables, are:

(a) Manifolds are manifest. One can understand how they relate to the data.

(b) Manifolds have topological, measure-theoretic, metric, and algebraic structures that justify using operations such as computing derivatives, for example, to measure the amount of information conveyed by an item about an examinee.

(c) Manifolds do not confuse people. Nobody is misled in using sums, differences, and other operations within these manifolds, whereas the same operations applied to latent variables do not survive the legitimate (i.e., continuous, differentiable, etc.) transformations that may be applied to them.

(d) There is an established, and even rather old, body of mathematical theory, namely differential

geometry, that can be used to develop new methods for data analysis.

It may be that we need to replace models expressed in terms of latent traits by explicit references to the manifolds that they implicitly define.

Psychoneuroimmunology

In defending the organism against the invasion of foreign material, the immune system is critical for the maintenance of health. In times past, the immune system was considered a self-regulating, autonomous agency of defense. Research conducted since the mid-1970s, however, has revealed that immunoregulatory processes are influenced by the brain and that neural and endocrine functions and behavior are influenced by the immune system. Psychoneuroimmunology, then, is the study of the interactions among behavior, neural and endocrine function, and immune system processes (Ader 1981a). The basic premise underlying psychoneuroimmunology is that adaptive responses reflect the operation of a single, integrated network of defenses. While each component of this defensive network evolved to serve specialized functions at special times, each also monitors and responds to information derived from the others. Thus, it is not possible to achieve a complete understanding of immunoregulatory processes without considering the organism and the internal and external environment in which immune responses take place. The evidence for brain-immune system interactions, with particular but selected emphasis on the role of behavioral and psychosocial factors in modulating immune function, is the subject of this article.

First, however, a brief reminder that the immune system's defense of the organism against foreign, 'nonself' material (antigens) is executed by white blood cells, primarily T and B lymphocytes, capable of responding clonally to antigens and retaining the 'memory' of that encounter. Antibody-mediated immunity refers to the exposure of antigens to bone-marrow derived B cells which produce antibodies that protect the organism against extracellular infectious agents. Cell-mediated immunity is provided by thymus-derived T cells that defend against intracellular parasitic and viral infections. An integrated immune response actually involves interactions among

specialized subpopulations of T cells (e.g., helper, cytotoxic), B cells, other white blood cells such as macrophages, and substances (cytokines) secreted by activated immune cells. Lymphocyte proliferation in response to *in vitro* stimulation by mitogens (plant lectins) that preferentially influence T and/or B cells is a measure of the capacity of these lymphocytes to divide in response to nonspecific foreign stimuli. Natural killer (NK) cells are large, granular lymphocytes that are implicated in tumor metastases and in the recognition and defense against viral agents without having had prior experience with that antigen.

1. Historical Perspective

The first sustained program of research on brain-immune system interactions was initiated by Russian investigators in the 1920s. Derived directly from a Pavlovian perspective, these investigators studied the conditioning of immune responses. There was reliable evidence for conditioned alterations in nonspecific immunologic reactions; the evidence for a conditioned change in antibody production was less convincing (Ader 1981b). Early studies on the effects of brain lesions on anaphylactic responses began in the 1950s and were pursued by investigators in the former Soviet Union and in the United States who studied the effects of hypothalamic lesions and electrical stimulation on several parameters of immunologic reactivity.

In the 1950s and 1960s, Fred Rasmussen, Jr., a virologist, and Norman Brill, a psychiatrist (the first such interdisciplinary collaboration), began a series of studies on the effects of stress (avoidance conditioning, physical restraint, electric shock, social 'crowding') on susceptibility to experimentally-induced infectious diseases (e.g., Rasmussen et al. 1957). Depending on the nature of the stressor, these stimuli increased susceptibility to some viral infections and decreased susceptibility to others. These experiments stimulated only a few other investigators to study the effects of early life experiences and stressful psychosocial circumstances on susceptibility to infectious and neoplastic diseases in animals.

In the 1970s, things began to change. Several dramatic observations led to sustained research on the relationship between the brain and the immune system. Hadden et al. (1970) documented the existence of receptors on lymphocytes, providing the first observations linking the immune system to the sympathetic nervous system; Ader and Cohen (1975) demonstrated behaviorally conditioned suppression of the immune system; Bartrop et al. (1977) described immunologic effects associated with the bereavement that followed the death of a spouse; Besedovsky and Sorkin (1977) began their studies of a neuroendocrine-immune system network and the effects of immune responses on neural and endocrine function; the sympathetic innervation of lymphoid tissues was documented

(Felten and Felten 1991); and Blalock and Smith (1980) showed that lymphocytes, themselves, were capable of producing neuropeptides. These seminal studies provided the impetus for new research on receptors for hormones and neurotransmitters on lymphocytes, the effects of sympathetic nervous system (SNS) activity on immunity, conditioned immune responses, depression and immunity, the effects of stressful life experiences on immune function and resistance to disease, psychosocial factors in the progression of AIDS, and immunologic effects on behavior.

2. Brain-Immune System Communication

Two pathways link the brain and the immune system: autonomic nervous system activity and neuroendocrine outflow via the pituitary. Primary (bone marrow, thymus) and secondary (e.g., spleen, lymph nodes) lymphoid organs are innervated with sympathetic nerve fibers that form close neuroeffector junctions with lymphocytes and macrophages and release a variety of neuropeptides. The stimulation or interruption of these connections can influence immune responses. Chemical sympathectomy, for example, suppresses antibody- and cell-mediated immunity; hypothalamic lesions generally inhibit and stimulation potentiates immunologic reactivity.

Conversely, activation of the immune system is accompanied by changes in hypothalamic, autonomic, and endocrine processes. There is, for example, an increase in the firing rate of neurons in the hypothalamus that corresponds to the time of peak antibody production; sympathetic activity (turnover of norepinephrine) is increased in the spleen and hypothalamus; and immune responses initiated by viral infections are associated with increases in circulating levels of ACTH and corticosterone.

Because lymphocytes carry receptors for a variety of hormones and neuropeptides, the cellular interactions that mediate humoral and cellular immunity can be modulated by the neuroendocrine environment in which these responses occur. Lymphocytes bear receptors for corticotropin-releasing factor (CRF), ACTH, and endogenous opioids. There are direct immunomodulatory effects of CRF and ACTH, but their major *in vivo* effects are exerted through interactions with other hormones and immune system products, the most conspicuous of which is the release of adrenocortical steroids. There is an extensive literature documenting the anti-inflammatory and immunosuppressive effects of corticosteroids—at least in pharmacologic doses. At physiologic doses, adrenocortical steroids are essential for normal immune function and, depending on steroid concentration, antigen concentration, and the temporal relationship between hormonal and antigenic stimulation, corticosteroids can be immunoenhancing.

Recent data have also shown that lymphocytes activated by antigenic stimuli are capable of producing neuropeptides and hormones. Thus, the brain is capable of detecting and responding to signals released by an activated immune system. Cytokines, nonantibody messenger molecules released by activated immune cells, besides regulating cellular interactions, are another means by which the immune system communicates with the CNS and, thereby, influences behavior. The precise site(s) at which cytokines act within the brain has not been elaborated. Nonetheless, it is known that cytokines are electrophysiologically, endocrinologically and behaviorally active. Symptoms of sickness, for example, decreased activity, loss of interest in the environment, reduced food intake, fatigue, and cognitive disorders and affective changes can be induced in healthy subjects by the central or peripheral injection of proinflammatory cytokines. Indeed, the recent therapeutic use of interferons in human disease has been associated with neurologic and psychiatric side effects (Meyers 1999).

At the neural and endocrine levels, then, there is abundant evidence of interactions between the brain and the immune system.

3. Behavioral Influences on Immune Function

3.1 Effects of 'Stress' on Immune Function

The link between behavior and immune function goes back to the earliest observations of a relationship between psychosocial factors and susceptibility to immunologically mediated disease processes. There is compelling evidence that psychosocial factors influence the onset or severity of rheumatoid arthritis and other autoimmune diseases, diseases effected by immune reactions generated against an individual's own tissues. Similarly, stressful life experiences are associated with increased susceptibility to infectious diseases and the reactivation of latent viral infections. The death of a spouse, for example, has been associated with depression and an increased morbidity and mortality in response to diseases presumed to involve immune defenses. Bereavement and/or depression is also accompanied by a depression of immune function (reduced lymphoproliferative responses, impaired NK cell activity). In none of these instances, however, has it been demonstrated that these health effects are the result of stressor-induced changes in immune function (see *Stress and Health Research*).

Other 'losses,' such as marital separation and divorce and other chronic stressors such as caregiving for disabled patients, have also been associated with decreases in lymphocyte function and NK cell activity and a depressed antiviral response to an influenza immunization. In individuals seropositive for Epstein-Barr virus (EBV), there is also an increase in anti-EBV

antibody titers reflecting compromised cell-mediated immune system control over the latent virus. Even more seemingly innocuous circumstances such as taking examinations results in a transient increase in levels of distress and a corresponding decrease in lymphoproliferative responsiveness, NK cell activity, percentage of helper T-lymphocytes, and interferon production by stimulated lymphocytes. Exam periods are also associated with elevated EBV titers and an increase in the incidence of self-reported symptoms of infectious illness.

Clinical studies have described an association between some immunologically mediated diseases and clinical depression. Multiple sclerosis (MS), a T cell mediated autoimmune disease, is associated with depressive states. Systemic lupus erythematosus (SLE) is a B cell mediated autoimmune disease in which depression is frequently reported. Depressive features have also been described in HIV-infected individuals. Thus, considerable attention has been given to the effects of clinical depression on immune function. Based on a meta-analysis of the literature (Herbert and Cohen 1993), depression is reliably associated with a decline in both enumerative and functional measures of immunity such as lymphoproliferative responses and NK cell activity. Depressed patients also show elevated antibody titers to herpes simplex virus (HSV) and cytomegalovirus and a decreased ability to mount a specific cell-mediated response to varicella zoster virus. The decline in cellular immunity is comparable to the decline observed in elderly patients who are more susceptible to herpes zoster infection than younger adults (Irwin et al. 1998). Other measures of immune function in depressed patients are characterized by a high variability within and between studies.

Typically, acute laboratory stressors such as unsolvable puzzles or public speaking have been reported to increase numbers of cytotoxic lymphocytes and the number and activity of NK cells along with a decrease in lymphoproliferative responses. These data, too, are characterized by high variability that is, at least in part, related to individual differences in autonomic nervous system reactivity. For example, subjects who are characterized as high SNS reactors in response to an acute laboratory stressor show a greater decrease in lymphoproliferative responses, a greater increase in the number of suppressor/cytotoxic T cells and, perhaps, a greater increase in NK cell activity than low reactors.

It is clear that, while stressful life experiences influence immune function in humans, there are large individual differences due, presumably, to personality and dispositional factors that influence the individual's perception and appraisal of the environmental circumstances, the individual and social resources available to cope effectively with the demands of the environment, and the biological substrate upon which the stressful stimuli are superimposed.

Most of the evidence for stress-induced alterations in immunity comes from basic research on animals. Stressors such as restraint, electric shock, avoidance conditioning, and noise can disrupt immune function and increase susceptibility and/or mortality to a variety of infectious agents (e.g., HSV, influenza, Coxsackie virus, Sindbis virus) or allow an otherwise inconsequential exposure to a pathogen to develop into clinical disease (Moynihan and Ader 1996, Sheridan et al. 1994).

In contrast, though, some of these same stressors *decreased* susceptibility to poliomyelitis virus infection, experimental allergic encephalomyocarditis and *Plasmodium berghei*, a rodent malaria. Stressful life experiences also exert a protective effect on the development of experimental allergic encephalomyelitis, a murine model of MS. In the case of experimentally induced arthritis, increased or decreased susceptibility depends on the experimental model of arthritis and the nature of the stressor.

Prenatal and early life experiences such as interruptions of mother-young interactions, the social environment in which animals live, exposure to predators or pheromones emitted by stressed conspecifics, and subjecting animals to environmental conditions over which they have no control (e.g., physical restraint, electric footshocks, forced exercise) are among the psychological and social manipulations that alter neuroendocrine states and modulate immune responses. Antibody production is generally suppressed by such stressful stimulation.

Although differential housing (frequently mislabeled as 'crowding' or 'isolation') may not qualify as a stressor, the manner in which animals are housed or a change in housing conditions is sufficient to influence the antibody response to different antigens. Primary and/or secondary antibody responses in rodents are suppressed by restraint or electric shock stimulation, depending on the nature of the antigen and the timing of the stressor in relation to the antigenic stimulation. Other stressors, however, are associated with enhanced antibody production. Similarly, cell mediated processes (e.g., graft rejection, delayed type hypersensitivity reactions) and nonimmunologically specific responses (e.g., lymphocyte proliferation in response to mitogens, NK cell activity, cytokine production) generally are suppressed in animals subjected to stressors but, again, the nature and timing of the stressor, the particular response being measured as well as the species, strain and sex of the animal will determine the direction and magnitude of the effects.

A few attempts have been made to discriminate between stressors over which the individual does or does not have control, for example, avoidable vs. unavoidable, escapable vs. inescapable, signaled vs. unsignaled electric shock in animals. Although differences have been observed in some studies, the results have been contradictory. In humans, too, studies involving control—or perceived control—over stress-

ful stimulation have yielded inconsistent results. Given the number of variables identified as having an effect on the assessment of immunologic reactivity, however, there are insufficient data to warrant any conclusions at this time.

While many hypotheses have been proffered, the neuroendocrine mechanisms presumed to mediate the effects of stressful life experiences on immune function remain elusive. For one thing, our understanding of neuroendocrine-immune system interactions under normal and stressful conditions is incomplete. Glucocorticoids, for example, are generally immunosuppressive, and it is generally assumed that corticosteroid elevations, the most common manifestation of the stress response are responsible for the immunosuppression associated with stressful life experiences. There are many examples of stress-induced, corticosteroid-mediated alterations of immune responses. But, there are very many other observations of stress-induced alterations of immunity that are independent of adrenocortical activity. Intermittent and continuous schedules of inescapable electric footshocks, both of which elevate corticosterone levels, effect an analgesic response to subsequent footshock. Only the intermittent shock, however, is an opioid-mediated analgesia and only the intermittent footshock suppresses NK cell activity, illustrating the immunomodulating potential of endogenous opioids.

Even without being able to detail the extensive literature, it is clear that the response to stressful life experiences involves complex neural, endocrine, and immune response interactions (Glaser and Kiecolt-Glaser 1994, Rabin 1999). Different stimuli commonly referred to as stressors—and commonly thought to elicit a representative ‘stress’ response—can have different effects on the same immune response. Conversely, the same stressor can have different effects on different immune responses. Also, the intensity and chronicity of the stressor are among the several parameters of stimulation which influence immune responses. In general, then, we have an incomplete picture of the direction, magnitude, and duration of the effects of stressful life experiences on immunity. We do, however, know something about the factors that contribute to the observed variability. They include:

- (a) the quality and quantity of stressful stimulation;
- (b) the capacity of the organism to cope effectively with stressful circumstances;
- (c) the quality and quantity of immunogenic (or pathogenic) stimulation;
- (d) the temporal relationship between stressful stimulation and immunogenic stimulation;
- (e) the parameters of immune function and the sample times chosen for measurement;
- (f) the experiential history of the organism and the prevailing social and environmental conditions upon which stressful stimulation and immunogenic stimulation are superimposed;

- (g) a variety of host factors such as species, strain, age, sex, nutritional state and current disease; and
- (h) interactions among these several variables.

3.2 Conditioning Effects

Behaviorally conditioned alterations of immune function provide one of the more dramatic lines of evidence linking the brain and the immune system. In a prototypical study (Ader and Cohen 1975), a novel, distinctively-flavored drinking solution (e.g., saccharin), the conditioned stimulus (CS) is paired with the injection of an immunomodulating drug, the unconditioned stimulus (UCS). When animals are subsequently injected with antigen, some of them are re-exposed to the CS, alone. When the immunosuppressive drug, cyclophosphamide (CY), was used as the UCS, conditioned animals re-exposed to the CS showed an aversion to the saccharin solution and an attenuated antibody response relative to conditioned animals that were not re-exposed to the CS or nonconditioned animals that were exposed to saccharin. Several independent investigators have verified and extended these findings.

The effects of conditioning have been consistent under a variety of experimental conditions (Ader and Cohen 2001). Studies have documented the acquisition and/or extinction of conditioned nonspecific host defense responses such as NK cell activity and different cell-mediated as well as antibody-mediated immune responses using different unconditioned and conditioned stimuli. Also, conditioning is not limited to changes associated with taste aversion learning; several studies have described the acquisition and extinction of conditioned ‘stress’ effects. Moreover, there is no consistent evidence of a relationship between conditioned behavioral and conditioned immune changes. Taste aversions can be expressed without concomitant changes in immune function, and conditioned changes in immunologic reactivity can be obtained without observable avoidance conditioning. Also, the available data indicate that conditioned immunosuppressive responses cannot be attributed to either stress-induced or conditioned elevations of adrenocortical steroids.

The acquisition and extinction of a conditioned *enhancement* of immunologic reactivity have been observed using antigens rather than pharmacologic agents as UCSs. In the first such study (Gorczynski et al. 1982), CBA mice were anesthetized, shaved, grafted with skin from C57BL/6J mice, and left bandaged for 9 days. In response to the grafting of allogeneic tissue, there was, as expected, an increase in the number of precursors of cytotoxic T lymphocytes (CTLp) that could react against the foreign (nonself) tissue. The conditioning procedures were repeated when CTLp numbers returned to baseline levels. On the fourth such trial, the procedures were repeated again, but the tissue graft was omitted. Approximately half the

animals in each of several experiments showed an increase in CTLp in response to the grafting procedures alone. Half of the 'responder' mice were given additional conditioning trials and half received extinction trials (sham grafting). When tested again, all the animals given additional conditioning trials showed the conditioned increase in CTLp whereas none of the 'responder' mice that experienced unreinforced trials showed a conditioned response.

In another study on conditioned immunoenhancement, mice were immunized repeatedly with low doses of a common laboratory antigen following exposure to a gustatory CS. Three weeks after the last trial, half the animals in each of the several groups were re-exposed to the CS, alone, or were re-exposed to the CS in the context of a low-dose booster injection of the same antigen. The latter groups were added to determine if conditioning could be more sensitively indexed by asking if a CS could potentiate the effects of a minimally effective dose of antigen rather than initiate the production of antibody by itself. In this experiment, neither the CS nor the booster dose of antigen, alone, were sufficient to elicit a robust antibody response. However, antibody production was enhanced when conditioned mice were re-exposed to the CS in the context of re-exposure to a minimally immunogenic dose of that same antigen. Recently, others have observed a conditioned enhancement of antibody production after a single conditioning trial and without the need for a booster injection of antigen.

Data on conditioning in humans is limited. The anticipatory (conditioned) nausea that frequently precedes immunosuppressive cancer chemotherapy was also associated with anticipatory suppression of proliferative responses to T cell mitogens. In healthy subjects, the pairing of a distinctive flavor with injections of adrenaline resulted in an enhancement of NK cell activity when subjects were subsequently re-exposed to the CS alone. Preliminary data on cell-mediated immunity derived from a study in which subjects were repeatedly injected with tuberculin obtained from a green vial and with saline drawn from a red vial. On the test trial, the contents of the vials were switched. Saline administered to the arm previously treated with tuberculin did not elicit a skin reaction, but there was an attenuated response in the arm previously injected with saline. These studies lend credence to earlier anecdotal reports of what would now appear to be examples of conditioned alterations of immunologic reactivity in human subjects or patients.

4. Biologic Impact of Behaviorally-induced Alterations of Immune Function

Many studies have related stressful life experiences to changes in immunity and/or changes in the onset or progression of disease (Biondi and Zinnino 1997), and

these correlational studies are, indeed, provocative. The association between stressful life events and increased morbidity and the association between stressful life events and alterations in immune function do not, however, establish a causal chain linking stressful life events, immune function, and health or disease. There are, at present, few, if any, human studies in which altered resistance to disease has been demonstrated to be a direct result of biologically relevant changes in immune function induced by psychosocial or stressful life experiences. Such data are being collected from animal models of spontaneously occurring disease or models in which it is possible to precipitate adaptive responses to immunogenic stimuli experimentally.

In mice infected with influenza virus, for example, there is a delay in the production of virus-specific antibody in restrained relative to unrestrained animals. In mice inoculated with HSV, prolonged periods of restraint or repeated periods of electric shock suppressed NK cell activity and the development of HSV-specific cytotoxic T lymphocytes. Also, higher titers of infectious virus were recovered from the restrained mice. Other recent studies have shown that psychosocial factors can reactivate latent HSV. While restraint was ineffective, disruption of the social hierarchy within a colony of mice by repeatedly introducing an intruder into a group cage increased aggressive behavior, activated the hypothalamic-pituitary-adrenal axis (HPA), and resulted in reactivation of latent HSV in more than 40 percent of the latently infected animals.

In an NK-sensitive tumor model in which lung metastasis is related to NK cell function, it has been found that, depending upon when the stressor was imposed in relation to the effect of NK cells on the metastatic process, forced swimming, acute alcohol intoxication and social confrontations decreased NK cell activity and increased lung metastases. This finding is consistent with strain, age, and sex differences in NK cell activity and the development of lung metastases.

In defending the organism against infection, inflammatory processes are an essential component in the healing of wounds. Both the SNS and the HPA axis are capable of modulating inflammatory and immune processes. Thus, stressful life experiences would be expected to influence wound healing as, in fact, it does. Chronically stressed caretakers of Alzheimer's patients took 24 percent longer than control subjects to heal a standard, experimentally produced wound in the skin, and there was a 40 percent delay in wound healing in dentistry students tested just before an examination period (when perceived stress was high) compared to healing during a summer vacation (when perceived stress was low). Paralleling this human research, recent animal studies have found that mice restrained for 3 days before and 5 days after wounding showed a reduced inflammatory response, an elevated

corticosterone level and a dramatic delay in the rate at which the wounds healed.

These animal models of wound healing, NK-sensitive tumors and reactivation of latent virus infection will enable research designed to examine the mechanisms underlying the effects of stressful life experiences and determine whether they are, as suggested, due to behaviorally-induced alterations in immune function.

The spontaneous development of a systemic lupus erythematosus-like disease in New Zealand mice was used to assess the biologic impact of conditioned alterations in immune responses since a suppression of immunologic reactivity would be in the biological interests of these animals. Half the weekly treatments received by the lupus-prone mice consisted of saccharin plus an ip injection of saline (the CS) rather than the CS plus an injection of cyclophosphamide. Under this pharmacotherapeutic regimen, the onset of disease was delayed using a cumulative amount of immunosuppressive drug that was not, by itself, sufficient to alter progression of the autoimmune disorder.

Consensual validity for these observations was provided by a study in which re-exposure to a CS previously associated with CY accelerated mortality in conditioned mice in response to a transplanted plasmacytoma. It has also been shown that protection against adjuvant-induced arthritis could be achieved by exposing animals to a CS previously paired with an immunosuppressive drug or with a stressful (immunosuppressive) experience. Among mice previously conditioned by the pairing of a CS with an immunosuppressive drug, re-exposure to the CS following transplantation of allogeneic tissues prolonged survival of the allografts. Clearly, conditioned immunologic effects can have a profound biologic impact on the development of autoimmune disease, neoplastic processes, and graft survival. Thus far, there is only one clinical case study in which a conditioning protocol was successfully used to reduce the total amount of cytoxan used in the treatment of a child with SLE (Olness and Ader 1992).

5. Conclusions

'Psychoneuroimmunology' is an interdisciplinary field of study that has developed and now prospers by exploring and tilling fertile territories secreted by the arbitrary if not illusory boundaries of the biomedical sciences. Disciplinary boundaries and the bureaucracies they created are biological fictions that can restrict imaginative research and the transfer and application of technologies. They lend credence to Heisenberg's assertion (1958) that 'What we observe is not nature itself, but nature exposed to our method of questioning' (Ader 1995).

A paradigm shift is occurring, however. Based on research conducted since the mid-1970s, it has become evident that immunoregulatory processes can no longer be studied as the independent activity of an autonomous immune system. We now know of at least two pathways through which the brain communicates with the immune system: autonomic nervous system activity and neuroendocrine outflow via the pituitary. Both pathways generate chemical signals that can be perceived by the immune system via receptors on the surface of lymphocytes and other immune cells. Conversely, an activated immune system generates chemical signals that can be perceived by the nervous system. Thus, there is a bidirectional exchange of information between the brain and the immune system and all immunoregulatory processes take place within a neuroendocrine milieu that is responsive to the individual's perception of and adaptive responses to physical and psychosocial events occurring in the external world.

It should not be surprising, then, that stressful life experiences or Pavlovian conditioning could influence immune function. The conditioned suppression or enhancement of immune responses has been demonstrated in different species and under a variety of experimental conditions. Also, stressful life experiences influence immune function. Both conditioning and stressful stimulation exert biologically meaningful effects in that they appear to be implicated in altering the development and/or progression of immunologically mediated disease processes. While these are reproducible phenomenon, the extent to which one can generalize from one stressor or from one parameter of immune function to another is limited. Also, the direction and/or magnitude of the effects of behavioral factors in modulating immune responses depend on the nature of the behavioral circumstances; the nature of the antigenic stimulation and the temporal relationship between them; the immune response and time at which it is measured; a variety of host factors; and the interactions among these variables.

The neuroendocrine pathways underlying the effects of conditioning or stressful life experiences on immune responses are not yet known. It would appear, though, that the neural and endocrine changes associated with changes in behavioral states and the network of connections between the brain and the immune system provide multiple pathways through which behavioral processes could influence immune defenses. The existence of these bidirectional pathways reinforces the hypothesis that immune changes constitute an important mechanism through which psychosocial factors could influence health and disease.

Psychopharmacotherapy, Costs of

Psychopharmacotherapy is one of the mainstays of the treatment of psychiatric disorders besides social therapy and psychotherapy. Psychiatric disorders essentially comprise the affective disorders (depression, bipolar, i.e., manic-depressive disorder), the schizophrenias, the anxiety disorders (panic disorder, generalized anxiety, post-traumatic stress disorder, obsessive-compulsive disorder, social phobia), the eating disorders (bulimia and anorexia nervosa), the substance abuse and dependence disorders including alcoholism, the personality disorders, and the dementias (with Alzheimer-type dementia being the cause in about 70 percent of cases). They are highly prevalent (Table 1) and frequently take a chronic or chronic remittent course. Therefore, it is easily understandable that the total costs of psychiatric disorders compare very well with the costs of the leading somatic illnesses (Table 2). The prevalences of depression and of the eating disorders are increasing. The WHO burden of illness study (Murray and Lopez 1997) suggests that depression will be the leading cause of disability in the developed countries in 2020. Psychiatric disorders (except the dementias) manifest in early adulthood thus limiting the abilities of patients for social achievement.

Psychopharmacotherapy essentially comprises seven classes of drugs:

- (a) neuroleptics for the treatment of psychotic states, especially the schizophrenias;
- (b) antidepressants for the treatment of depression of whatever origin as well as for the long-term treatment of anxiety disorders;
- (c) mood stabilizers (lithium, some anticonvulsants) for the short-term treatment of mania and for the long-term relapse and recurrence prevention of affective disorders;
- (d) minor tranquilizers (essentially benzodiazepines) for the short-term treatment of anxiety and agitation of whatever origin and of alcohol withdrawal syndromes;
- (e) hypnotics (essentially benzodiazepines and benzodiazepine-like drugs) for short-term treatment of insomnia;
- (f) anticraving compounds (bupropion for smoking cessation, acamprosate for alcohol abstinence, opiate antagonists for alcoholism and opiate dependence) which, however, are not yet approved in all countries; and

Table 1

Annual rate of behavioral disorders in the USA
(adapted from NIMH)

Disorder	Percent afflicted
Anxiety disorders (all)	13
Depressive disorders (all)	10
Alcohol abuse/dependence	7
Drug abuse/dependence	3
Severe cognitive impairment	3
Antisocial personality	2
Schizophrenia	1
Somatization	0.2

(g) cognition enhancers (nootropics such as piracetam, ginkgo biloba) for the nonspecific treatment of dementias and acetylcholinesterase inhibitors specifically for Alzheimer-type dementia.

Concerning the eating disorders, only one drug, the antidepressant fluoxetine, is approved for supportive treatment of bulimia.

Psychopharmacotherapy competes with psychotherapy in the treatment of mild to moderate depression and the anxiety disorders. The relative merits of both alternatives are subject to debate which is fueled by a lack of scientific data, ideology, and economic interests of the health care providers involved. As a rule of thumb, pharmacotherapy and psychotherapy may be thought not to be alternatives but supplements whenever a psychiatric disorder is moderate to severe, although a synergistic action remains to be definitely proved.

Life expectancy increased dramatically in the twentieth century, and this was accompanied by an increase in the prevalence of age-associated diseases. In the field of psychiatry these are the dementias. Thus, although the number of healthy life years is generally increasing, the prevalence of chronic diseases is increasing in parallel. Consequently, the demand for health care services is increasing. Costs for drug therapy are increasing overproportionately because drug development has become increasingly complicated and costly. The mean investment necessary for developing a single new chemical entity to approval amounts to about US\$500 million.

Worldwide, health care is one of the most rapidly growing markets with positive impacts on employment. Nevertheless, governments internationally tend to restrict the growth because at least part of it is publicly funded. The fundamental but unanswered question is what proportion of the gross domestic product society is willing to invest in health care. Obviously, however, most people value health and thus health care very highly. Thus, disorders, i.e., the patients suffering from them, compete for limited resources. Economic criteria have become a third dimension besides efficacy and effectiveness as well as tolerability and safety when selecting between treatment options. It is easily conceivable that psychiatric disorders, faced with persistent stigma, have a hard standing in this competition.

Pharmacoeconomics, a young scientific discipline, has developed a sound scientific basis for the evaluation of the economic dimension (Gold et al. 1996). This is indispensable in the interests of an ethically justifiable allocation of resources. The question is

Table 2

Estimated annual total costs of some psychiatric and somatic diseases (American Diabetes Association 1996, American Heart Association 1998, Davidson et al. 1999, Greenberg et al. 1993, 1999, Whetten-Goldstein et al. 1998)

Disease	Estimated total cost (\$US billion)	Year considered
Schizophrenia	33	1991
Depression	43.7	1990
Bipolar (manic-depressive) disorder	25.6	1991
Alcoholism	98.6	1991
Anxiety disorders	42.3	1990
Alzheimer's disease	87.6	1991
Coronary heart disease	43	1990
Coronary heart disease	99.8	1999
Cancer	104	1991
Acquired immunodeficiency syndrome (AIDS)	66	1991
Multiple sclerosis	100.8	1994
Diabetes mellitus	91.8	1992
Hypertensive disease	33.3	1999
Congestive heart failure	21	1999
Stroke	45.3	1999

whether a new, more costly drug allows one to achieve better outcomes so that it is worth its higher costs. In principle, a new drug might even spare money in that the better outcome might help avoid costly, higher-level health care such as inpatient treatment and reduce indirect costs, e.g., by less absenteeism.

1. Basic Terms of Pharmacoeconomics

Pharmacoeconomics is the science of measuring *costs* and *outcomes* associated with the use of pharmaceuticals in health-care delivery. Its objective is to improve public health through rational decision making when selecting among alternative therapies, e.g., for formularies and their impact on costs and outcomes. Several methodological guidelines have been published (e.g., CCOHTA 1994).

Outcomes are the possible end result of a particular treatment. Outcomes depend on the *effectiveness* of the treatment under the influence of all the confounding variables in real life. Therefore, costs have to be measured under real-life conditions. In contrast, the experimental *efficacy* trials are designed to eliminate as completely as possible all confounding influences. The outcome parameter chosen should have high everyday relevance, e.g., the rate of full remissions of depression.

Costs are the resources consumed by the illness and by its treatment. *Direct costs* are those directly related to treatment such as prescribed medication, self-medication, consulting the physician, blood tests, transportation, psychotherapy, occupational therapy, informal care by relatives, etc., as well as costs for hospital and nursing-home treatment. *Direct costs* include those for diagnosis and treatment of side effects and complications of the initial therapy. There is methodological controversy as to whether the costs of social support (welfare, unemployment benefit, disability pension, housing benefit, etc.) should be included in the direct costs. A complete evaluation of direct costs should consider the opportunity costs, i.e., the lost potential of the resources invested to provide more efficient benefits in other fields.

Indirect or future costs are those related to lost productivity due to illness, i.e., due to absenteeism, premature pensioning because of disability, and premature death (e.g., by suicide) as well as those related to health care consumption during the years of life gained owing to the intervention. Concerning psychiatric disorders, costs of violence and crime also have to be considered. *Intangible costs* comprise those attributable to impairments of the quality of life, e.g., of the patients themselves and their relatives and acquaintances involved in the care.

The economic impact of treatment extends into the future. If costs and benefits accrue during different periods, costs and savings have to be discounted for the remaining life-span of the patient sample in question. Discount rates are supposed to reflect the

rates of return on private-sector investments and are generally set at 3–5 percent.

If the costs are low and the outcomes excellent the decision in favor of the treatment is obvious as is its rejection if the costs for poor outcomes are high. Therefore, pharmacoeconomic analyses make sense only when both the costs and the quality of treatment are high or low. The economic *efficiency* then is the ratio of costs divided by the outcomes. When allocating resources the drug yielding the most favorable outcomes at the lowest cost will be favored.

2. Types of Pharmacoeconomic Analysis

The basic requirement of a pharmacoeconomic analysis is the definition of the perspective, e.g., that of the patient, the health care provider, the health insurance as the payer, or the societal perspective of government. The categories of costs to be considered depend on this perspective. For example, from a provider's perspective, the value of an antidepressant drug under capitation may be expressed in terms of cost per reduction in some depression scale score. From the patient's perspective, the value may be in cost per full treatment response with least side effects. From the societal perspective, the value may be in cost per patient returning to continuous employment at or above the level of previous education. Simply to compare the daily costs of medication does not fulfill the criteria of pharmacoeconomic analysis.

The principle types of analysis include cost-minimization analysis, cost-effectiveness analysis, cost-utility analysis and cost-benefit analysis. *Cost-minimization* analysis (CMA) assumes that the interventions in question yield identical outcomes; this is rarely valid. *Cost-effectiveness* analysis (CEA) compares the costs of alternative treatments in terms of a specific health outcome such as life-years gained, e.g., by reducing mortality from suicide, or responder rates. *Cost-utility* analysis (CUA) adjusts the life-years gained by some measure for quality of life. Thus, the results of CUA are typically expressed as costs per quality adjusted life years (QALYs). Quality of life is assessed either by some rating scale for health-related quality of life or, more typically, by determining the preferences of patients suffering from specific diseases for one or the other disease state as opposed to perfect health where perfect health is set as '1' and death as '0.' In *cost-benefit* analysis (CBA), the QALYs gained are transformed into monetary terms using the human capital approach or willingness-to-pay approach.

As there is no one-to-one relationship between therapeutic intervention and outcome and its financial sequelae, the impact of these uncertainties has to be estimated. This is done by *sensitivity analysis*, where key variables are systematically modified and the economic consequences calculated yielding best- versus worst-case scenarios.

3. Pharmacoeconomic Study Designs

There are two principle approaches to pharmacoeconomic analysis: the clinical trial approach (experimental or observational), and the modeling or systems approach. The former means gathering cost data (retrospectively or, preferably, prospectively) in clinical trials. The latter '*in vitro*' approach applies decision-tree analysis to data available from published literature and databases.

Current guidelines favor the clinical trial approach as the 'gold standard.' Modeling, however, can overcome limitations implicit in clinical trials. These include the selection bias concerning the patients recruited in randomized, strictly controlled, and therefore artificial efficacy trials, thus limiting generalizability. Furthermore, their observation period rarely exceeds a few months whereas economic consequences may extend far into the future. Efficacy trials necessarily are underpowered for economic analysis because sample size estimation is based on the critical difference and variability of the efficacy parameter. Obviously, the critical difference and variability of economic data will fundamentally differ. Clinical trials using the mirror image design, i.e., comparing costs and benefits in a defined period before and after administering a specific drug, are of limited value because at least in psychiatric disorders there is a spontaneous decrease of the costs per outcome during the course of illness irrespective of the mode of treatment.

The putatively best experimental design is a prospective, randomized, 'naturalistic,' i.e., non-blind, adequately powered clinical trial. Both principle approaches, the clinical trial approach and modeling, have their weaknesses and strengths so that they are not really exclusive alternatives but complementary.

Friedberg et al. (1999) found that studies sponsored by drug companies were less likely to report unfavorable results than studies funded by nonprofit organizations. This finding could be due to various sources of bias which, however, if present, still have to be identified.

The organization of health-care supply, the health-care utilization patterns, and the prices differ considerably between and even within cultures. Therefore, the results of pharmacoeconomic analyses cannot simply be transferred from one health care market to another.

4. Pharmacoeconomic Findings with Neuroleptics

Since the 1990s new neuroleptics have been introduced (amisulpride, clozapine, olanzapine, quetiapine, risperidone, sertindole, zotepine), although not yet approved in all countries. These compounds are called 'atypical' because they have a lower incidence of extrapyramidal side effects (e.g., Parkinsonism) than conventional neuroleptics (e.g., haloperidol, fluphenazine).

Moreover, they possibly have superior efficacy concerning cognitive dysfunction and so-called negative symptoms as well as quality of life in schizophrenia. These advantages might improve compliance, which is most important in long-term relapse and recurrence prevention. The costs of daily treatment with atypical neuroleptics exceed those of conventional neuroleptics by a factor of 2–8 depending on the compound and the country considered. On the other hand, neuroleptic medication costs generally make only about 4–8 percent of direct costs.

The pharmacoeconomic analyses actually available for neuroleptics are limited to amisulpride, clozapine, olanzapine, risperidone, and sertindole in schizophrenia. The majority of studies address clozapine, olanzapine, and risperidone. The costs are mostly considered from the payer's perspective, i.e., addressing direct costs. Most are cost-effectiveness analyses, some cost-utility analyses. The majority follow the modeling approach. The economic analyses based on clinical efficacy trials have the limitations discussed above, especially those restricting the analysis to study completers. This is far from the naturalistic, real-world approach necessary. There is only one randomized, naturalistic, adequately powered trial comparing clozapine with conventional neuroleptics, where clozapine significantly reduced the frequency and duration of inpatient treatment; the cost data are to be reported. All in all, the current evidence suggests that clozapine is cost-effective for neuroleptic-refractory schizophrenia and that olanzapine and risperidone therapy may be cost-neutral despite higher medication costs (Revicki 1999). Nevertheless, the access of patients to the new therapeutic chances is restricted on economic grounds, although this varies internationally.

5. Pharmacoeconomic Findings with Antidepressants

Since the 1980s, a number of new antidepressants have been introduced (selective serotonin reuptake inhibitors (SSRI): citalopram, fluoxetine, fluvoxamine, paroxetine, sertraline; the selective norepinephrine reuptake inhibitor reboxetine; the serotonin–norepinephrine reuptake inhibitor venlafaxine; the norepinephrine auto- and heteroreceptor blocker mirtazapine; the reversible and selective inhibitor of monoamine oxidase moclobemide), although not yet approved in all countries. Their efficacy is comparable to that of traditional tricyclic antidepressants (TCAs such as amitriptyline, imipramine, desipramine, nortriptyline), but owing to selectivity their tolerability and safety are superior. Safety is of specific concern in view of the suicide risk, although antidepressants are involved only in the minority (< 10 percent) of suicides. These advantages help reduce drop-out rates although to a limited degree (about 25 percent versus

29 percent). Nevertheless, this might be particularly relevant in long-term recurrence prevention which is necessary in about 60 percent of patients in whom antidepressants are indicated. There is a dramatic underrecognition and undertreatment worldwide (Davidson et al. 1999, Tylee et al. 1999). Undertreatment causes a doubling of direct costs due to increased utilization of other medical services (Manning and Wells 1995) and increases indirect costs due to absenteeism. The advantages of innovative antidepressants might increase acceptability and thus utilization of antidepressants. The costs of daily treatment with selective antidepressants, however, exceed those of TCAs by a factor of 2–20 depending on the compound and the country considered. On the other hand, antidepressant medication costs generally constitute only about 3–6 percent of direct costs.

Pharmacoeconomic analyses published cover all innovative antidepressants except reboxetine. All but one (Gould et al. 1995) are restricted to depression. The costs are mostly considered from the payer's perspective. Most are cost-effectiveness analyses, only a few cost-utility and cost-benefit analyses. There are no randomized, open-label, naturalistic, adequately powered trials but some studies analyzed large, complete samples of HMO participants. By far the majority follow the modeling approach. There are some outstanding analyses in which classes of compounds are compared (e.g., CCOHTA 1997, Casciano et al. 2000). Overall, the current evidence suggests that extended-release venlafaxine might be more cost-effective than SSRIs and that the cost-effectiveness of SSRIs might equal or even exceed that of TCAs, despite higher medication costs (Conner et al. 1999, Casciano et al. 2000). However, more research is needed before this can be taken for granted. Accordingly, there is debate as to whether the access of patients to innovative antidepressants should be restricted or whether they should be recommended as first-choice drugs (CCOHTA 1997).

The limited evidence available suggests that psychotherapy is more likely to be cost-effective the more severely afflicted the patients are (Gabbard et al. 1997). The cost of psychotherapy is about 3–6 times higher than that of antidepressant drug therapy. One modeling study (Antonuccio et al. 1997) suggests, however, that cognitive behavioral therapy (CBT) might be more cost-efficient than fluoxetine treatment of depression owing to lower recurrence rates after psychotherapy. In a CUA based on a randomized controlled trial (Lave et al. 1998), nortriptyline was slightly superior to interpersonal psychotherapy (IPT). One meta-analysis (Gould et al. 1995) suggests that CBT is superior to imipramine and cost-effective in panic disorder. Economic analyses addressing the relative merits of pharmacotherapy and psychotherapy are completely lacking for prominent diseases such as obsessive-compulsive disorder, generalized anxiety, and social phobia.

6. Pharmacoeconomic Findings with Mood Stabilizers

Mood stabilizers by definition reduce the risk of relapses and recurrences and thus putatively hospitalization. Therefore, they may be expected to reduce direct costs (about 60 percent for hospitalization). Lithium is the only drug reducing mortality essentially by reducing the suicide rate (Ahrens 1997). Only a few pharmacoeconomic analyses have been published. Lithium was more cost-effective than carbamazepine from the payer's perspective in a modeling approach based on retrospectively gathered data from a randomized controlled clinical trial (Dardennes et al. 1999). Valproate was more cost-effective than lithium over 1 year from the payer's perspective in a modeling approach (Keck et al. 1996); the prophylactic efficacy of valproate, however, remains to be established.

7. Pharmacoeconomic Findings with Tranquilizers and Hypnotics

There are almost no economic analyses published on tranquilizers or hypnotics. Yuen et al. (1997) found that hospital stay was longer and costs were higher in elderly people if sedative-hypnotic medications were prescribed, even if prescription adhered to established guidelines. Research is needed especially to clarify whether the higher costs of the newer hypnotics (zaleplon, zolpidem, zopiclone) compared with benzodiazepines are economically justified.

8. Pharmacoeconomic Findings with Anticraving Drugs

Long-term acamprosate adjunctive to conventional therapy was found to be cost-effective in the treatment of alcoholism in the German setting in a single, retrospective modeling study (Schädlich and Brecht 1998). Opiate antagonists (Howard et al. 1996), opiate agonist (methadone) substitution, and bupropion have not been evaluated economically.

9. Pharmacoeconomic Findings with Cognitive Enhancers

There are no economic analyses published on nootropics. The acetylcholinesterase inhibitors donepezil (Foster and Plosker 1999) and rivastigmine (Fenn and Gray 1999) seem to be at least cost-neutral, especially by delaying the need for institutionalization. The current evidence is restricted, however, to a few observational studies and modeling analyses using the cost-effectiveness approach from the payer's perspective.

tive. Economic analyses on galanthamine, an acetylcholinesterase inhibitor and nicotinic agonist expected to be approved, remain to be published.

10. Conclusions and Some Precautions

The innovative neuroleptics and antidepressants not only have the potential for a balance of costs despite higher costs of medication, but might even save direct costs essentially by reducing the risk of institutionalization owing to lower drop-out rates in comparison with traditional compounds. This conclusion, however, is based essentially on decision analyses, i.e., modeling. More research, particularly large-scale, randomized trials under naturalistic conditions, is needed. From a systemic perspective, the potential cost savings can only be realized if the institutions concerned, e.g., hospitals, reduce their capacities accordingly. About 80 percent of the costs of hospitals are common costs, mostly wages and salaries. Whereas in a free health-care market the savings might be realized by market forces, in systems bound in economic welfare a political will is needed to enforce the inevitable dismissal of staff.

Psychopharmacotherapy: Side Effects

Psychopharmacotherapy refers to the treatment implications of the science of psychopharmacology. Psychopharmacology is the study of drug-induced alterations in the cognitive function and behavior of humans that aims to develop treatment strategies for neurological and psychiatric disorders. Rapid technological progress has led to an abundance of scientific techniques in neurochemical and animal studies on the interaction between drug action and behavior (Feldman et al. 1997).

Most psychoactive drugs exert their effects first by interfering with the communication between nerve cells (neurons). At the molecular level this occurs by their interaction with receptors of neurotransmitters located on the surface or inside the neuron. This step initiates a cascade of events that eventually lead to alterations in the neurotransmitter and/or hormonal systems. Nonspecific drug action at any level in this process results in side effects.

The term side effect implies an undesirable (adverse) drug effect; a particular side effect of a drug for a given condition may be a desirable one for another condition. For instance, benzodiazepines may be prescribed for anxiety disorders, but as a side effect they cause sedation. On the other hand, they may also be prescribed for the treatment of insomnia as a primary indication. Indeed, the psychoactive potential of several drugs was discovered as a result of unexpected but beneficial side effects on psychiatric patients who were taking these drugs for other therapies (see below). The spectrum of drug effects originate largely from their effects on multiple neurotransmitter systems, and the interactions of these systems with each other and other sites of action in the central nervous system.

At times it is a challenge in the practice of psychiatry to be able to determine if a given behavior is a

symptom of an illness or a side effect of drug treatment, as the latter may mimic the former. For instance, untreated patients with schizophrenia frequently display decreased spontaneity, lack of motivation, and social isolation. These symptoms resemble some of the extrapyramidal system side effects induced by conventional antipsychotics. A practical management of this potential difficulty involves careful assessments of the patient's functions e.g., sleep patterns, daily living routines, and sexual function prior to treatment.

1. Historical Perspective

Treatment with substances that alter mood, thinking, and cognition date back to prehistoric times (Spiegel 1996). Various psychoactive substances have been used in religious ceremonies, rituals, and for healing of pain.

Alcohol is the oldest drug used for its calming and sedative effects. The disinhibition caused by alcohol is described in the first book of the Old Testament. Apart from consumption in social settings, alcohol was introduced for medical use in the nineteenth century as a general anesthetic. The narrow therapeutic index (the ratio of toxic over desired dose) of alcohol limited its usefulness for this purpose.

Opium (*papaver somniferum*), hellebore, and *rauwolfia* roots are among the oldest compounds that were extracted from plants in prehistoric and ancient times. Morphine was isolated from opium in the beginning of the nineteenth century and has been available as an analgesic with considerable addiction potential.

In ancient times, different forms of hellebore root were used as emetics, laxatives, and for mental conditions such as mania and melancholy. Risk of seizures limited its use.

Rauwolfia serpentina roots were used by Indians to treat snake bites and also in some mental conditions. Reserpine, a *rauwolfia* alkaloid was noted to have a calming effect in patients with schizophrenia. Because reserpine induces severe depression as a side effect, its use as an antipsychotic has been abandoned.

Cocaine is an alkaloid derived from the shrub *Erythroxylon coca*; it originated in South America where it was used for its stimulating effects. It was isolated in the nineteenth century and is still used as a local anesthetic. Paranoid delusions, hallucinations, seizures, and dependency are some of the adverse effects of cocaine.

The discovery of psychoactive medications has resulted from the side effect profiles of drugs used in medicine. For instance, the antipsychotic chlorpromazine was initially used to help patients with presurgical preparation and as an adjuvant to anesthetics. Its sedative and calming effects easily found its way to treatment in psychiatric disorders as a primary

indication soon after its antipsychotic properties were discovered. Similarly, iproniazid (an antidepressant of the monoamine oxidase inhibitor (MAOI) type) was originally developed as a drug for the treatment of tuberculosis. In clinical drug trials, patients treated with this drug were observed to become stimulated and cheerful. This observation led to the investigation of the antidepressant effect of iproniazid.

2. Genetic Factors and Side Effect Vulnerability

Side effects are not uniformly observed in everyone. While some patients never develop a certain side effect, others are affected from day one of treatment. The strongest determinant of this interindividual variation is believed to be in the genetic complexion. Variations in the sequence of the DNA called polymorphisms are believed to play a role in expression of a wide spectrum of reactions to drugs: from full response to non-response; minimal to severe side effects. The completion of the Human Genome Project will aid in the identification of patient subgroups according to their drug response patterns. For instance, certain variations in the gene that codes for the enzyme CYP2D6 lead to slow metabolism of some drugs such as tricyclic antidepressants, therefore these patients run higher levels of drugs and are more vulnerable to side effects (Schatzberg and Nemeroff 1998). The application of pharmacogenetics will be the identification of drugs that will be both efficacious and well tolerated for each individual according to his or her genetic makeup.

3. Assessment and Management of Side Effects

Compared to the rating scales used to assess the symptoms of diseases, there are relatively few rating scales for the assessment of side effects. The most comprehensive of these is the Systematic Assessment for Treatment Emergent Events which has been designed for use in clinical drug trials. Udvalg for Kliniske Undersøgelser Side Effect Rating Scale is also comprehensive and was developed for use in clinical trials and in routine practice. The Rating Scale for Extrapyramidal Side Effects (Simpson–Angus Extrapyramidal System Scale), Barnes Akathisia Rating Scale, and Abnormal Involuntary Movement Scale were developed to measure the extrapyramidal system side effects, akathisia, and dyskinetic movements, respectively, that are associated with antipsychotic drug use (American Psychiatric Association 2000). Even though each side effect ultimately requires individual management, a comprehensive approach is vital for general management. Such an approach involves a baseline assessment, careful choice of medication, patient and family education, minimization of the number of drugs (to decrease potential side effects and to avoid drug interactions), single

bedtime dosing, the availability of clinicians to discuss the side effects, adjustment in dosage, counteractive drug treatment, and continuous assessment.

4. Noncompliance

Among factors that play a role in treatment non-compliance, such as denial of the illness and lack of supervision, one of the strongest predictors is early onset and persistence of side effects. Noncompliance by itself is a predictor of relapse in patients with chronic mental disorders who are recommended to receive lifelong maintenance treatment. One of the studies in this area found that half of the schizophrenic patients took less medication than recommended, and the reluctance was associated with the side effects of antipsychotic drugs (Van Putten 1974). On the positive side, many studies indicate improvement in treatment compliance with patient education. Particular approaches in patient education have been proposed that maximize the information conveyed while avoiding suggestibility (Balon 1999).

5. Classification of Side Effects

One of the common characteristics of psychoactive drugs is their capability to cross the blood-brain barrier and reach the central nervous system. Consequently, side effects of psychoactive drugs may be generated both centrally and peripherally. Here, the distinction between drug action and drug effect is also relevant: drug action refers to alterations produced by the drug at the molecular level, whereas drug effect (as well as side effect) refers to the observed reactions of the organism. Below, we will examine the behavioral side effects of psychoactive medications; a review of physiological systems is beyond the scope of this chapter and can be found elsewhere (Schatzberg and Nemeroff 1998).

5.1 Autonomic

The autonomic nervous system controls homeostasis in the different functional systems in the body mostly through involuntarily mechanisms. Major neurotransmitter systems involve those of acetylcholine and norepinephrine (β or α receptors).

Autonomic side effects of psychoactive drugs are most commonly due to *anticholinergic effects*. Because acetylcholine is widely distributed in the central and peripheral nervous systems, adverse anticholinergic effects can be observed both behaviorally and systemically.

Most antiparkinsonian (benztropine, trihexiphenidyl) and the majority of the antidepressant and antipsychotic drugs produce anticholinergic effects.

Among the tricyclic antidepressants, tertiary amine tricyclics (amitriptyline, clomipramine, doxepin, imipramine, trimipramine) produce more anticholinergic side effects compared to secondary amine tricyclics (desipramine, nortriptyline, protriptyline) and tetracyclic antidepressants (amoxapine, maprotiline). Compared to tricyclic antidepressants, anticholinergic side effects with selective serotonin reuptake inhibitors (SSRIs) are minimal. Conventional low-potency antipsychotics (drugs in this category, such as chlorpromazine, thioridazine, and mezoridazine require higher doses to produce equal efficacy than the high-potency antipsychotics) have significant anticholinergic properties compared to high-potency antipsychotics (fluphenazine, haloperidol, perphenazine, pimozide, thiotixene, trifluoperazine). Among the new generation antipsychotics, clozapine has the most potent anticholinergic effects, as well as having properties of acetylcholine release. Olanzapine also possesses anticholinergic effects, but less than clozapine. Risperidone, quetiapine, and ziprasidone have minimal anticholinergic activity. Peripheral anticholinergic effects include warm skin, flushing, dryness, dilated pupils (and blurred vision), increased intraocular pressure, dry mouth (if unrecognized this can cause dental problems, such as caries), tachycardia (increased heart rate), reduced acid secretion in the stomach, reduced pulmonary secretions, diminished bowel motility (constipation), urinary retention, and delayed or retrograde ejaculation.

Central anticholinergic effects of psychoactive drugs involve features such as memory impairment, confusion, disorientation, delirium, visual hallucinations, and worsening of preexisting psychotic symptoms. Combination of psychoactive drugs with anticholinergic effects, such as a tricyclic antidepressant, and a low-potency antipsychotic will highly increase the likelihood of an adverse reaction. Geriatric patients are particularly sensitive to anticholinergic side effects and deserve special consideration in the choice of psychoactive drugs and evaluation of a deteriorating course of their clinical situation (see *Antidepressant Drugs*).

5.2 Dependence

Dependence is an important component of the side effect spectrum of some of the psychoactive drugs (barbiturates, benzodiazepines). The *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition* defines substance dependence as a maladaptive pattern of substance use, leading to clinically significant impairment or distress, as manifested by three or more of the following criteria: tolerance, withdrawal, consumption of large amounts or over a longer than intended time period, persistent desire to cut down, significant effort to obtain the substance, social,

occupational sacrifice, and continued usage despite known hazards. It is of note that in this definition a biopsychosocial approach is undertaken. The treatment models for dependency are conducted in a multidisciplinary fashion that address physical, psychological, and environmental factors. Chronic drug use involves tolerance, physical dependence, and psychological dependence. Even though related, tolerance and physical dependence are different concepts:

Tolerance refers to the need of increased amount of a drug with repeated usage in order to achieve the same magnitude of effect. Interestingly, not all of the behavioral effects of drugs show similar tolerance patterns; in the case of benzodiazepines, for instance, tolerance develops for the sedative effects, but not for the anxiolytic effects. Tolerance is a reversible condition; abstinence from the drug over a period of time will reduce the amount of drug needed to exert the particular effects. Cross-tolerance is a phenomenon where the tolerance for a particular drug effect operates for another drug effect as well. It is demonstrated by the diminished anticonvulsant effects of the barbiturates in people with chronic alcohol use. Both changes in cellular physiology and behavioral conditioning systems have been postulated as underlying mechanisms for the development of tolerance.

Physical dependence refers to the condition where withdrawal symptoms emerge upon discontinuation of the drug. Withdrawal symptoms are specific to different drugs and quite unpleasant, so that continued use is sought to avoid them. Most withdrawal symptoms are separate from the ones in the intoxication state and can be identified without difficulty.

5.3 Endocrinological and Metabolic

Most antipsychotics elevate serum prolactin secondary to the blockade of dopamine. Increased prolactin may cause menstrual irregularities in females, gynecomastia (abnormal enlargement of the breast) in males, and galactorrhea (spontaneous milk flow) in both females and males. Amenorrhea (complete cessation of menses) occurs frequently in women taking antipsychotics. These changes persist with treatment and resolve with discontinuation. Galactorrhea and amenorrhea may also be observed with tricyclic antidepressants.

Hypothyroidism (decreased function of the thyroid gland) may be associated with long-term lithium therapy. The elderly and females are at greater risk for lithium-induced hypothyroidism. Weight gain is a common side effect of antipsychotics, particularly of new generations (clozapine, olanzapine, risperidone, sertindole, quetiapine), cyclic antidepressants, MAOIs, and SSRIs. Impact of weight gain on general health in the long run remains to be determined. In contrast, stimulants (amphetamine, dextroamphet-

amine, methylphenidate), and certain SSRIs are associated with appetite suppression and weight reduction. Stimulants are also associated with adverse growth effects (height and weight suppression); however, these effects are compensated with drug holidays.

5.4 Insomnia

Insomnia is the most common transient side effect of stimulants and MAOIs.

5.5 Neurological/behavioral

5.5.1 Cognitive effects. Even though the motor and cognitive functions of the brain do not operate independently from each other, specific neuropsychological tests that capture primarily motor or cognitive functions have been applied to measure the effects of psychoactive drugs in these domains. While some studies of conventional antipsychotics showed worsening performance on psychomotor speed, attention, and working memory, recent publications do not support a significant worsening in working memory, but even indicate improvements in some attentional measures (Goldberg and Weinberger 1996). The only double-blind study comparing the new generation antipsychotic clozapine and the conventional antipsychotic haloperidol revealed a significant interaction on measures of executive/attention and visuospatial functions. Further analysis revealed that these effects resulted from worsening performance of the haloperidol treated patients. Patients treated with clozapine showed an insignificant improvement (Buchanan et al. 1994). Anticholinergic doses have been associated with poor verbal learning, verbal fluency, and motor speed. Lithium may also interfere with memory and motor speed functions. Benzodiazepines may cause slowed cognitive function, impaired memory, and behavioral disinhibition.

5.5.2 Motor effects. Conventional antipsychotic drugs (haloperidol, fluphenazine), and to a lesser extent, new generation antipsychotic drugs (risperidone, olanzapine), some of the selective serotonin reuptake inhibitors (sertraline, fluoxetine), and cyclic antidepressants (amoxapine) affect motor functions of the extrapyramidal system. Acute conventional antipsychotic treatment interferes with simple repetitive motor tasks such as finger tapping. These effects are related to the drugs' dopamine blocking properties in the basal ganglia. Lithium and valproic acid may cause hand tremors. Stimulant use may be associated with development or worsening of tics.

Acute motor effects of the conventional antipsychotics include parkinsonism, dystonic reactions, and akathisia. The major chronic effect of antipsychotic use is tardive dyskinesia. *Parkinsonism* is a word derived from Parkinson's Disease, which is characterized by tremor, rigidity, and bradykinesia (slowed movement). All three features are observed in susceptible patients in the initial phases of treatment. Tremor with a regular rate may be observed in the hands and feet, and is present at rest. Tremor around the mouth also occurs. Akinesia (absence of movement) of the facial muscles sometimes lead to lack of expression which is known as masked face. Patients walk slowly, sometimes with shuffling, short steps, and the normal arm swing is diminished. Rigidity of muscles can be felt on examination; cogwheeling (increased tone in all directions of movement and superimposed ratchet-like resistance) may be elicited. Handwriting is characteristically small and tremulous.

One of the most disturbing side effects of antipsychotic medications (mostly of the high-potency conventional ones and some of the new generation antipsychotics) is akathisia, a subjective experience of motor restlessness. Patients complain of not being able to sit still, they pace in hallways, constantly move their legs to help the discomfort. They describe it as '... I want to run a hundred miles ...' Significant akathisia may lead to insomnia because of having trouble lying in bed. It may be accompanied by a feeling of anxiety and agitation. Restlessness and agitation are frequently observed as part of psychosis in the absence of any drug treatment. Drug-induced akathisia therefore is very important to diagnose differentially for appropriate treatment. If it is mistaken as psychosis-related agitation, increased antipsychotic drug dose will only make it worse. Akathisia has been identified as a predictor of antipsychotic noncompliance. Several treatment options are available.

Acute dystonic reaction is another side effect of the conventional antipsychotics that requires immediate treatment. Dystonic reactions consist of abruptly developing muscle contractions which frequently involve the muscles of the face, tongue (protrusions, twisting), neck (spasmodic torticollis), jaw (trismus), eyes (oculogyric crisis, blephorospasm), and limbs. It is most common in young men in the initial phases of treatment. It is treatable with anticholinergic and antihistamine drugs. Prophylactic treatment with these drugs may increase the chances of compliance.

Tardive dyskinesia is a long-term side effect of conventional antipsychotics characterized by involuntary choreiform (random, brisk) or athetoid (slow, regular continuing twisting) movements of the head, face, tongue, limbs, and the trunk. These movements may range from mild and unrecognized to severe and incapacitating. Movements around the mouth are the most common. Dyskinesia may be exacerbated with stress and disappears with sleep. About 10–20 percent of patients treated with conventional antipsychotics

for more than a year develop tardive dyskinesia. Children, women, the elderly, patients with brain damage or mood disorders constitute high-risk groups. While tardive dyskinesia is associated with antipsychotic use, 1–5 percent of patients with schizophrenia who lived before the antipsychotic era have been reported to exhibit similar dyskinetic movements. Thus, tardive dyskinesia may be related to the pathophysiology of schizophrenia. The new generation antipsychotics (clozapine, olanzapine, risperidone, quetiapine) have significantly lower incidence of extrapyramidal system side effects and tardive dyskinesia compared to the conventional antipsychotics. This is a feature of the new generation antipsychotics that distinguish them from the conventional antipsychotics. Numerous animal studies have demonstrated that clozapine fails to induce extrapyramidal system related movements, and it is the only antipsychotic that might have a potential to prevent tardive dyskinesia from deteriorating (see *Schizophrenia, Treatment of*).

5.5.3 Sedation. Sedation is a common side effect with most antipsychotics, mood stabilizers, benzodiazepines, barbiturates, and antidepressants (tertiary amine cyclic antidepressants, MAOIs, trazodone, sometimes with other SSRIs, venlafaxine, and nefazodone). In particular clinical situations, such as severe agitation, sedation may be desirable, whereas in others such as a negative symptoms of schizophrenia (affective flattening, lack of spontaneous speech, avolition), or depression with hypersomnia, it would not be. The choice of drug therefore largely depends on the clinical necessity. In undesirable conditions (night time dosing, reduction in dose) switching to a less sedating medication is considered.

5.5.4 Seizure. Antipsychotic drugs, particularly the ones with low potency reduce the seizure threshold. In a patient with no history of seizure disorder, incidence is low and no prophylactic treatment is warranted. Patients with a history of seizure disorder deserve special consideration. Clozapine increases risk of seizures in a dose-related fashion. Anticonvulsants such as valproic acid can benefit the patient to continue treatment with clozapine. Among the antidepressants, clomipramine and amoxapine may lower the seizure threshold while incidence of seizures with SSRIs is low, but present. Tricyclic antidepressants, MAOIs, anticonvulsants, lithium, and antipsychotics may also induce myoclonic (irregular rapid muscle contraction) movements.

5.5.5 Hypomania/mania. Even though it remains controversial, one of the important side effects of antidepressant treatment is the induction of hypomania/

mania. In a patient with no history of mania, undergoing antidepressant treatment, emergence of manic features merits consideration of the possibility of drug-induced mania. In patients with bipolar disorder, on the other hand, the risk of mania induction with sole antidepressant (in the absence of a mood stabilizer) treatment is established.

5.5.6 Delirium. Infrequently, worsening of psychosis, confusion, and agitation may occur with antipsychotic treatment. Most cases are, however, associated with concomitant anticholinergic use.

5.5.7 Neuroleptic malignant syndrome. This is a potentially life-threatening complication of the antipsychotic treatment characterized by muscle rigidity, hyperthermia, mental state changes (stupor, agitation, confusion), and autonomic dysfunction (blood pressure instability, increased pulse, respiration, sweating). The incidence is about 0.1 percent of patients exposed to conventional antipsychotics. High-potency antipsychotics may have a higher risk than low-potency antipsychotics, even though rarely it has also been reported with clozapine. Rhabdomyolysis (muscle necrosis) may occur that leads to myoglobinuria (passing a muscle-related protein—myoglobin—in urine) and subsequent renal failure. Mortality may approach 12 percent. Immediate intervention is necessary.

5.6 Placebo Effects

A placebo is a pharmacologically inactive agent administered in a group of patients in a double-blind clinical trial to improve the true estimate of the active agents efficacy and side effects. Placebo effects may be relevant to the concept of side effects from the perspective of experiences of drug effects in the absence of drug action. Substantial evidence suggests emergence of physiological changes associated with placebo administration. While placebo drug efficacy approaches significant percentage of patients in some clinical trials, incidences of side effects are also variably present (see *Placebo Studies (Double-blind Studies)*).

5.7 Sexual

In males impotence, decreased libido, changes in quality of orgasm, priapism (painful erection), and erectile and ejaculatory disturbances have been reported with antipsychotic use. In women orgasmic dysfunction and decreased libido are frequently observed with antipsychotic treatment. Sexual dysfunction associated with SSRI use impairs quality of life, and is a reason for noncompliance. Bupropion and nefazodone may have a more favorable profile com-

pared to TCAs, MAOIs, and venlafaxine. In contrast, some antidepressants are prescribed for the treatment of premature ejaculation.

6. Quality of Life and Side Effects

The World Health Organization has defined Quality of Life as:

'An individual's perception of their position in life in the context of the culture and value systems in which they live and in relation to their goals, expectations, standards and concerns. It is a broad ranging concept incorporating in a complex way the person's physical health, psychological state, level of independence, social relationships, personal beliefs and their relationship to salient features of the environment' (WHOQOL 1995).

This definition emphasizes a comprehensive approach in the assessment of quality of life. Disciplines of medicine, particularly cancer research have concentrated on global measures of quality of life, as symptom improvement by itself does not account for it. In psychiatry, the slow pace of research in this area may be due to difficulties of valid and reliable quality of life assessments from psychiatric patients. Pioneered by Lehman (Lehman et al. 1982), renewed interest has led to research in debilitating psychiatric disorders such as schizophrenia and demonstrated the significance of a multidisciplinary treatment model. While the strongest predictor of symptom improvement is identified as compliance with recommended drugs, its sole impact on quality of life in the long term is yet to be elucidated. The issue gets complicated due to the side effect profile of psychoactive drugs, which may mimic the symptoms of diseases, and also due to the direct impact of side effects on quality of life. For patients with schizophrenia, symptoms, their severity, and subjective distress caused by side effects accounted for half the variance in quality of life (Awad et al. 1997).

In one study where 53 schizophrenic outpatients treated with depot neuroleptics were studied, 70 percent complained about side effects when 94 percent were found to experience them. Among the patients who denied having side effects, 87 percent had some form of it (Larsen and Gerlach 1996).

The recognition of the negative impact of tardive dyskinesia on, for instance, patients' self esteem, incapacity, and perception by society has been essential towards targeting more favorable treatments. The introduction of new generation psychoactive drugs, particularly antidepressants and antipsychotics is therefore encouraging. Such drugs have not only led to superior efficacy, but also have more favorable side effect profiles. However, there remains significant room for further improvement in side effect profiles of psychoactive drugs.

Psychophysical Theory and Laws, History of

1. Introduction

Psychophysics is a scientific approach to the measurement of mental processes. The empirical laws of psychophysics are based on such measures as the magnitudes of stimuli just noticeably different from

each other, the proportion of errors made when comparing two stimuli, the time required to complete such judgments, and self-reports of the confidence in comparative judgments or the strength of a stimulus. Some laws define relations between physical events and their mental representations such as sensations and feelings. The theories of psychophysics provide explanations of these empirical relations and suggest neural mechanisms that give rise to experimental results.

2. Nineteenth-century Psychophysics

The first law defined the 'just noticeable difference' (jnd) in sensation. A jnd occurred, phenomenally, when an increment in the size of a physical stimulus evoked a sensation of a difference in magnitude. The German physiologist Ernst Heinrich Weber (1834, 1846/1978) discovered, for many sense modalities, the increment in a physical stimulus needed to evoke a jnd. Leipzig physicist Gustav Fechner (1860) quantified Weber's observations and created the First Law of Psychophysics, Weber's Law,

$$\Delta s/S = c \quad (1)$$

where S is the magnitude of the physical stimulus, Δs is the increment, and c is called Weber's Constant. For discriminating lifted weights $c = 0.043$. Thus, an initial weight of 1000 g will require an increment of 43 g (to $S + \Delta s = 1043$ g,) before the new weight will feel just noticeably different from 1000 grams.

The subjective nature of these self-reports led Fechner to wonder whether the person experiencing a just noticeable difference could identify which of the two stimuli, S or $S + \Delta s$, was larger. Fechner discovered that two stimuli may feel just noticeably different, but may be identified correctly in only about 75 percent of the comparisons made. Fechner described these experiments and officially established the field of psychophysics in the two-volume *Elemente der Psychophysik* (1860/1966).

In *Elemente* Vol. 1, Fechner created a theory of how humans comparing two sensory stimuli, such as a pair of lights for brightness, two weights for heaviness, or two lines for length, make errors in their judgments. The theory assumed that the sensory system provided the mind with measurements of the external world. However, the process by which the sensory/nervous system created an internal sensory representation of an external physical stimulus introduced error into the measurement. A fixed weight might at one time feel heavier, or lighter, depending upon the amount of error added to, or subtracted from, the true sensory value for the external stimulus. Extending the theory of error created by Gauss in 1809 for physical measurement devices, Fechner invented a theory of judgment about invisible mental events that allowed

him to measure the size of the error in the nervous system.

Figure 1 illustrates the essential features of Fechner's theory as it applies to the comparison of two just noticeably different weights, W_a and W_b . Along the abscissa are true sensory values, μ_a and μ_b , for the two weights undergoing comparison by lifting each once. Two Gaussian (Normal) probability distributions describe the error of sensory measurement and surround the true sensory values of μ_a and μ_b . Fechner postulated that a (decision) threshold, T , for deciding which weight was the larger existed exactly midway between μ_a and μ_b , that is at

$$T = \mu_a + (\mu_b - \mu_a)/2 \quad (2)$$

A lifted weight sensed to be greater than this threshold was thought to be the heavier weight.

The shaded area of Fig. 1 to the right of T represents the probability of making an error of judgment in deciding that the smaller of two stimuli was in fact the larger. The symmetric nature of Fechner's theory predicts that the probability of judging the larger of two stimuli to be the smaller equals the same probability, and is shown by the shaded area to the left of the threshold, T . The two error probabilities increase as the variability in the sensory system increases. Such an increase in variability causes a greater spread in each Gaussian probability distribution.

Fechner's goal was to measure the invisible variability of the sensory system in units of the physical stimuli. As a measure of variability Fechner chose the value $\sqrt{2}\sigma$, Gauss's measure of the spread of the Gaussian distribution. The value of σ , a parameter of the Gaussian probability distribution, creates a scale of measurement units along the abscissa of Fig. 1. The unknown value for T is located an unknown number of σ units above the true sensory value μ_a . But, once the probability of an error of judgment is known, one can determine from tables (many created by Fechner) the corresponding distance in σ units of the (decision) threshold T above the true sensory value μ_a . For example, if the probability of an error in judging which weight is larger equals 0.25, then the (decision) threshold, T , is 0.674σ units greater than the true sensory value μ_a .

To determine the value of σ , Fechner replaced the unknown values of μ_a and μ_b by the physical values that gave rise to them, W_a and W_b . The distance from μ_a to T is defined as $t = 0.675\sigma$. That is,

$$t = 0.675\sigma = (W_b - W_a)/2, \quad \text{or} \quad \sigma = (W_b - W_a)/(2 \cdot 0.675) = (W_b - W_a)/1.35 \quad (3)$$

Using the example above, the smaller of two just noticeably different weights equaled 1000 g and the larger 1043 g (and the probability of an error equaled 0.25). Thus the measure of variability is

$$\sigma = (1043 \text{ g} - 1000 \text{ g})/1.35 \approx 32 \text{ g} \quad (4)$$

Figure 1

Fechner's theory of mental judgment proposed that Gaussian variability perturbed nervous system transmission of peripheral sensory stimuli. Weight W_a was incorrectly judged heavier than weight W_b whenever the sensory value for W_a exceeded the value T . Similarly, W_b was incorrectly judged lighter than W_a whenever the sensory value for W_a was less than T . The probabilities of an error are represented by the shaded areas to the right and left of T .

Fechner summarized these ideas in a famous formula that is the Second Law of Psychophysics:

$$t = hD/2 \quad (5)$$

Here $h = 1/\sqrt{2}\sigma$ and D equals the difference between two physical stimuli, $W_b - W_a$.

The term h measures the sensitivity of the system. When σ is large, indicating great sensory variability and a small value of h , many errors occur and the system is said to be insensitive. A small value for σ leads to few errors, a larger value for h , and the system is said to be more sensitive. This first method of measuring the invisible, internal, variability of the sensory system established psychophysics as a truly scientific discipline. Measuring the unknown variability of the sensory/nervous system in units of physical stimuli marks a revolution in the scientific investigation of the human mind. This powerful theory became the basis for the fields of experimental psychology and statistical hypothesis testing.

Fechner also theorized, in *Elemente* Vol. 2, about a measure of how much sensation a stimulus generated. Placing each jnd in a sequence is a way of adding together phenomenally equal units of sensation. Using Weber's Law as a base, Fechner argued that on a continuous scale of sensation Weber's Constant,

$$c = \Delta s/S \quad (6)$$

is a differential equation. Integrating the differential equation is equivalent to adding together the jnds of

sensation increments to obtain a total amount of sensation. The result of the integration is called Fechner's Law of Sensation: the total amount of sensation generated by a stimulus is

$$\xi = k \cdot \log_e(S) \quad (7)$$

where S is the magnitude of the stimulus and ξ is the amount of sensation.

Fechner's Law is perhaps the most widely known of any psychophysical law. Yet criticisms of Fechner's idea never abated (Krueger 1989, Lockhead 1992, Murray 1993). The notion of adding together jnds to create a yardstick of sensory measurement is appealing, but the 'law' provides for no independent experimental means for testing its prediction. How is internal sensation to be measured? Or as Laming (1997) wonders, 'Can sensation be measured?'

The father of American Philosophical Pragmatism, C. S. Peirce, put Fechner's ideas to another test. Peirce argued that the sense of confidence in a judgment was a sensation directly related to the probability of making a correct judgment. Peirce's Law states that if C is the average confidence in a judgment and p is the probability of making a correct judgment, then

$$C = k \cdot \log_e[p/(1-p)] \quad (8)$$

Like Fechner's Law there is a logarithmic relation between two variables. But, in this case each variable can be measured through direct experimentation. Peirce and Jastrow (1884, see Link 1992, Vickers 1979), and later experiments, confirmed this prediction.

The profound impact of Fechner's Psychophysics led to Wilhelm Wundt's 1879 creation of the first psychological laboratory at Leipzig University. A new student, James McKeen Cattell, proposed a new measure of the amount of sensation generated by perfectly discriminable stimuli, as opposed to jnd stimuli. Reaction time, RT, the time taken to respond to the presence of a stimulus, could measure stimulus strength. Cattell's experiments showed remarkable decreases in response time as stimulus magnitude increased. Later Piéron (1914, see Welford 1980, Luce 1986) proposed the general principle: Piéron's Law:

$$RT = a + kS^{-\beta} \quad (9)$$

where a is a constant due to non-sensory effects, k and β are constants, and S is physical stimulus intensity.

3. Twentieth-century Psychophysics

Yet, measuring the magnitudes of perfectly discriminable stimuli remained elusive. Thurstone (1955, Bock and Jones 1968) proposed that every stimulus projects a value on an internal psychological continuum. For example, stimuli such as crimes may vary on a continuum of the seriousness of that crime. When asked to judge which of two crimes is more serious, a subject will compare the two crime's seriousness values and choose the crime with the greater seriousness value. This is the famous Law of Comparative Judgment.

Crimes vary in their degree of seriousness for each subject, but for a fixed subject each crime's seriousness is fixed. For a fixed crime, individual differences across subjects created variability in the seriousness of crime. Thurstone represented this variability by a Gaussian distribution of seriousness values. For a group of subjects the theory is formally identical to Fechner's, but the emphasis on measuring stimulus values, rather than variability, led to a powerful new direction in psychophysical research.

Thurstone proved that by comparing all stimuli against each other, each stimulus could be measured on the psychological continuum. Now, mental phenomena as elusive as attitudes could be measured. In an application to classical psychophysics, Guilford (1954) used the method to determine heaviness values for difficult-to-discriminate lifted weights.

Perplexing irregularities in the ordering of probabilities in the full paired comparison matrix were the basis for Clyde H. Coombs to propose an important extension of the Law of Comparative Judgment, the Theory of Ideal Comparisons. Rather than comparing two stimuli against each other, Coombs (1964) proposed that each stimulus was compared against an ideal defined on a psychological continuum. Choosing between two stimuli equally distant from the ideal led to indifference with respect to them and the peculiar response proportions in the paired comparison matrix. For example, a continuum of shades of gray may

contain an ideal gray. But, two shades of gray equally distant on either sides of the ideal would be equally preferred. The subject faced with choosing either of these stimuli would be indifferent to them and chose either with probability 0.50.

In spite of its immense value the Law of Comparative Judgment said nothing about how response time or confidence should vary when stimuli are compared against each other. D. M. Johnson (1939, see Link 1992) combined choice, confidence, and response times (RT) in an experiment on judgments of differences between line lengths and discovered Johnson's Law:

$$RT = a(10)^{b(1-C)} \quad (10)$$

where $0 \leq C \leq 1$ is a measure of confidence and a and b are constants. Johnson's Law, together with Peirce's Law, suggests a relationship between confidence and response probability.

S. S. Stevens (1975) dismissed the theoretical reasoning leading to Fechner's Law and the Law of Comparative Judgment, and proposed an alternative formulation for determining the amount of sensation generated by a single stimulus. For Stevens 'equal stimulus ratios produce equal sensation ratios.' This idea is the basis for the famous Power Law of Sensation,

$$\xi = \lambda S^\gamma \quad (11)$$

where ξ is the strength of response to a stimulus of intensity S , λ is a non-sensory scaling constant and γ measures the effects of peripheral sensory transducers that are unique to a sensory modality. Stevens (1975) determined Power Law exponents for many sensory quantities and gave convincing evidence of the satisfactory representation of stimulus strength provided by the Power Law.

Although the Power Law contradicts Fechner's Law, the Power Law must be consistent with Weber's Law. Link (1992) derived from the Wave Theory of Difference and Similarity the prediction that Stevens' exponents and Weber's Constants are reciprocals of each other. Using values reported by Teghtsoonian (1971, see Link 1992) the prediction held for sensory quantities investigated by Stevens such as shock, heaviness, loudness, finger span, vibration, saturation, taste, and brightness. Ekman's Law provides yet another relation between jnds and the Power Law by asserting that increments in sensation on a psychological continuum are a linear function of sensation magnitude, as if Weber's Law applied to both the psychological continuum and the physical stimulus continuum. Gescheider (1997) shows how Ekman's Law leads to Stevens' Power Law.

Cognitive factors also affect the magnitude of response. Baird (1996) suggests that beyond the sensation effects caused by the peripheral nervous system are cognitive factors that demand a reinterpretation of the Power Law. Proposing a Comple-

mentarity Theory of Psychophysics, Baird accounts for a wide variety of experimental results unaccounted for by the Power Law. In a different approach, Norwich (1993) developed a general theory of the sensory language of the brain. Using the fundamental equation,

$$F = kH \quad (12)$$

where F is a perceptual variable, k is a positive constant and H is a measure of entropy, Norwich derives both the Power Law and Fechner's Law from the same basis.

Fechner's proposal that the (decision) threshold, T , was halfway between the means of the two sensory distributions shown in Fig. 1 proved too restrictive. A major advance in traditional psychophysical modeling occurred when Tanner, Swets, and Birdsall (1954, see Swets 1964) allowed the decision threshold to vary. Calling the decision threshold a response criterion, c , the authors ushered in a new era of psychophysical studies. Experiments showed how a nonsensory component of performance, response bias, affected the position of c . This Theory of Signal Detection and Recognition greatly expanded the applications of psychophysical methods.

For choices between many stimuli Luce (1959, see Falmagne 1985) created the Choice Axiom. Let $S_1, \dots, S_n$ be a set of commensurate stimuli. Luce's Choice Axiom states that the probability of choosing stimulus S_i is

$$W(S_i)/(\sum_n W(S_n)) \quad (13)$$

where W_i is the psychophysical value of stimulus S_i . For example, given five breakfast cereals, $B_1, \dots, B_5$, the probability of choosing cereal B_i is

$$p_i = W(B_i)/(\sum_n W(B_n)) \quad (14)$$

Luce's Choice Axiom receives support from numerous experiments in psychology and economics.

The majority of psychophysical theories and experiments focus on the ability to discriminate between stimuli rather than on the similarity between them. Shepard (1957, see Borg and Lingoes 1987) proposed that similarity between two stimuli, (S_i, S_k) , is a continuously changing negative exponential function of the distance, d_{ik} , between them. The probability of correctly identifying a particular stimulus from a set of n stimuli is often assumed to be

$$p_{ik} = \exp(-d_{ik})/\sum_n \exp(-d_{in}) \quad (15)$$

a form similar to Luce's Choice Axiom.

Following Thurstone's suggestion that there are many underlying psychological continua, Anderson (1981) proposed an Information Integration Theory of how sensory values on different dimensions are combined to create perceptual experience. Anderson's cognitive algebra creates perceptual magnitudes from

a linear model of sensory values defined on the dimensions on which a stimulus projects its values. Subjectively, a fine dinner is a sum of the psychological values of its many components.

4. Conclusion

During nearly 185 years, the field of psychophysics introduced new measurements of, and theories about, mental processes. Following Weber's discovery of the jnd, Fechner created Weber's Law, the field of psychophysics, and a theory of error in sensory comparisons. Thurstone introduced the idea of psychological continua on to which stimuli project psychological values. Comparisons between two psychological values led to the Law of Comparative Judgment and measurements of stimuli not defined on a physical scale. Anderson proposed a cognitive algebra for adding psychological values combined across several such psychological continua.

Fechner's Law, that the amount of sensation equaled a logarithmic transformation of the physical stimulus intensity, provoked continual controversy. Piéron showed that the time required to respond to the presence of a stimulus obeyed a power law of stimulus intensity. Stevens proposed that the amount of sensation obeyed a Power Law with an exponent unique to a sensory modality.

But cognitive factors were also shown to affect judgments of stimuli. Coombs proposed that psychological values were compared against ideals rather than against each other, and suggested a method of locating an ideal. Signal Detection Theory provided for a decision criterion that could vary in response to cognitive factors. Theoretical ideas suggested new experiments. New empirical discoveries challenged old theories. Now, at the beginning of the twenty-first century, psychophysics is poised for major theoretical advances toward more refined and more extensive measurements of mental processes.

S. W. Link

Psychophysics

How might the human mind be studied, scientifically?

It is a commonplace notion that the brightness of a light, the loudness of a sound, or the heaviness of a weight is one thing, and the luminance, the sound pressure level, or the physical weight in gm quite another. If a way could be found to measure brightness, loudness, and heaviness—not the physical attributes of luminance, sound pressure level, and weight, but the subjective experiences they engender—then such measurements might provide the foundation for a scientific study of the mind, analogous to physics.

The name of this enterprise is *psychophysics*. It has led to two quite distinct traditions of experimental research that I call *sensory discrimination* and *sensory judgment*.

1. Sensory Discrimination

Fechner ([1860] 1966) conceived the idea of using the ‘just noticeable difference’ (JND) between two stimulus magnitudes as the unit of subjective measurement. Earlier, Weber ([1834, 1846] 1978) had enunciated the law that now bears his name. If X_1 and X_2 are two sensory magnitudes such that X_2 is just noticeably greater than X_1 , then

$$(X_2 - X_1)/X_1 = \text{constant.} \quad (1)$$

Writing the constant, which is known as the Weber Fraction, as Θ ,

$$X_2 = X_1(1 + \Theta) \quad (2)$$

or

$$\ln X_2 - \ln X_1 = \ln(1 + \Theta), \quad (3)$$

another constant, which Fechner identified as the subjective value of a JND. It follows that the subjective experience of stimulus magnitude increases as $\ln X$, a relation known as Fechner’s Law.

1.1 Psychophysical Methods

The project of measuring subjective sensation by means of Eqn. (3) depends on accurate measurement of JNDs. Fechner directed systematic research towards the development of three methods.

1.1.1 The method of limits. Envisage that X_2 , greater than X_1 , is reduced progressively by small amounts until it is judged ‘equal’ and then by further small amounts until it is ‘less than’, or the process might be reversed with X_2 initially less than X_1 . This procedure identifies ‘thresholds’ above and below X_1 at which the judgment changes.

1.1.2 The method of average error. Envisage that X_2 is adjusted until it is judged ‘equal’ to X_1 , which is fixed. The probable error of adjustment can then be used as an alternative to the upper and lower thresholds identified by the method of limits.

1.1.3 The method of constant stimuli. Envisage that various X_2 s are presented together with a fixed X_1 and the subject asked to say which is greater. It turns out that the probability of a correct judgment increases smoothly with the difference between X_1 and X_2 . That relationship is known as the *psychometric function*.

1.2 Signal-detection Theory

The hundred years following Fechner's seminal work were spent arguing, first, how properly to analyze the judgments from these three psychophysical methods and, second, what the relationship between them was. That argument was resolved only with the advent of signal detection theory, which showed that these were the wrong questions to be asking. To put the matter succinctly, the presentation of a stimulus, be its magnitude X_1 or X_2 , provides the subject with information whether the stimulus magnitude is, in fact, X_1 or X_2 . This information is a random variable with a different distribution depending on which stimulus is presented. The optimum strategy for the subject is to report ' X_2 ' when the information in favour of X_2 exceeds a certain criterion and ' X_1 ' otherwise.

Signal-detection theory brought the idea of hypothesis testing by bisection of the likelihood-ratio (Neyman and Pearson 1933) into psychological theory. It identified two fundamental factors in sensory discrimination; there is (a) the information afforded to the subject (a property of the stimuli to be discriminated), and (b) the decision criterion (which is at the subject's disposal). These two factors are confounded in the traditional psychophysical methods.

It is common to model signal detection in terms of two normal distributions (unit variance, difference of mean d'), but it should be borne in mind that this is a *model* of the information and its function is simply to facilitate calculations. Nevertheless, in that spirit, let the mean of the distribution representing magnitude X be $\ln X$ and let the variance be $[\ln(1 + \Theta)]^2$. If a JND be defined as that stimulus difference which gives $d' = 1$, Eqn. (3) is obtained.

We cannot say, however, that signal-detection theory validates Fechner's Law (Eqn. (3)) because the signal-detection model is no more than a model and any other model delivering the same numerical predictions, more or less, will do as well. Such another model is composed of χ^2 distributions multiplied by scaling factors proportional to the magnitudes of the stimuli. It arises in this manner.

1.3 Differential Coupling

Weber's Law (Eqn. (1)) holds rather accurately for discrimination between two separate stimuli (two flashes of light in darkness, two bursts of noise in silence), and for many stimulus attributes, down to, but not below, absolute threshold. The amplitude of a pure tone (but not Gaussian noise) and the contrast of a sinusoidal grating are known exceptions. But if the task is to detect a flash of light added to a pre-existing background, the relationship is more complicated. For the detection of a sinusoidal grating van Nes and Bouman (1967) demonstrated a square-root relationship up to a transition illuminance, above which

detection conformed to Weber's Law, and the transition illuminance increased as the square of the wave-number of the grating. In addition, the psychometric function for detection is steeper than that for discrimination between two separate stimuli; and the Weber fraction for discrimination increases when one of the stimulus magnitudes lies below the absolute threshold. In short, Weber's Law, on which Fechner's Law is based, is just one component of a large body of related phenomena, a body sufficiently large and complex as to admit substantially only one explanation.

(a) The sensory pathway is differentially coupled to the physical stimulus so that only changes in sensory input are available as a basis for discrimination. When the two stimuli to be distinguished are presented separately, that means intrinsic random variability only. The energy of that intrinsic variability (a sample of Gaussian noise) has a χ^2 distribution multiplied by the noise power density, which, in this case, is proportional to the stimulus magnitude X . The logarithm of a χ^2 variable is, to a very good approximation, normal with variance independent of X . Weber's Law falls directly out of differential coupling.

(b) The steeper gradient of the psychometric function for detection is equivalent to the interposition of a square law transform, which, in turn, is directly analogous to the phenomenon of low-signal suppression in radio reception (Davenport and Root 1958). The stimulus to be detected adds a small perturbation to the Gaussian noise giving a noncentral χ^2 distribution of energy. The resultant central/noncentral χ^2 model accommodates additional phenomena within the general theory and is to be preferred to the logarithmic model underlying Fechner's Law. The distributions in this model are everywhere scaled in proportion to physical stimulus magnitude, so that there is no empirical justification (arising from the study of sensory discrimination) for any measure of sensation distinct from the physical (Laming 1997, Chaps. 3, 4).

(c) The differential coupling is realized in the balanced excitatory/inhibitory receptive fields of sensory neurons. The low-signal suppression is a consequence of transmission by all-or-none action potentials of one polarity only. The theory of sensory discrimination describes the flow of information through the early stages of sensory pathways and annexes that preconscious component of perception to the physical domain. There is no possibility of basing a scientific study of the mind on resolving power.

2. Sensory Judgment

A very wide range of sound energy levels are encountered in nature and sound pressure level is measured on a logarithmic scale; 10 decibels equates to a 10-fold

increase in power. If Fechner's Law were valid, people should say that 100 dB (a subway train entering a station) should sound twice as loud as 50 dB (quiet conversation in a library). Most people would say that the subway train is much more than twice as loud. Around 1930 this posed a problem for acoustic engineers explaining sound levels to their clients and led to the development of the *sones* scale (Stevens 1936). Loudness in sones increases twofold for each 10 dB increase in sound power.

2.1 Stevens' Power Law

Stevens (1957) returned to the problem of subjective measurement in the 1950s with three new experimental methods.

(a) *Magnitude estimation*, in which subjects assigned numbers to stimulus magnitudes;

(b) *Magnitude production*, in which subjects adjusted a variable stimulus magnitude to match a given number; and

(c) *Cross-modality matching*, in which subjects adjusted a stimulus magnitude on one continuum to match a given magnitude on another.

Taking the numbers assigned to the stimuli to be direct measures of subjective sensation, Stevens found that

$$N = aX^\beta, \quad (4)$$

where N is the mean assignment, a a constant, and β an exponent typical of the stimulus attribute. Equation (4) is known as *Stevens' Power Law* and its validity has been demonstrated for more than 30 different attributes.

2.2 Explanation of the Power Law

It is tempting to suppose, as Stevens did, that the sheer volume of experimental demonstration cracks the problem of subjective measurement. But those experiments invariably employed a geometric ladder of stimulus values. If subjects could be induced to assign numbers in like manner (to 'judge ratios'), then a power law relationship is inevitable, simply by regression of log number onto log stimulus magnitude. There are several reasons for supposing that this is all Eqn. (4) tells us.

(a) The power law relation can be perturbed by spacing the stimuli other than geometrically.

(b) The subjects in Stevens' laboratory consistently used numbers extending over a range of about 1 to 30. The estimate of the exponent β can therefore be calculated from the log range of stimulus values employed.

(c) Instructions to subjects are invariably illustrated with numerical examples. A wider spread of numbers in those examples, but examples which conform to the same nominal scale, produces a wider spread of

estimates in the experiment and therefore an increased value of β . Subjects accept guidance about how wide a range of numbers they should be using.

(d) The variance of the numerical assignments in experiments from Stevens's laboratory is about 100-fold greater than the equivalent variability implicit in sensory discrimination.

(e) But that variability is much reduced when two similar stimulus values (± 5 dB) are presented in succession. The correlation between successive log numerical assignments (then about +0.8) implies that each stimulus is used as a point of reference for the succeeding judgment.

So magnitude estimates are very imprecisely determined and are easily influenced by extraneous factors. Good power law data depends on balancing these extraneous influences by appropriate randomization of the schedule of stimulus presentations.

2.3 Relative Judgment

The correlation (e) above supports a theory of relative judgment in which each stimulus is compared to its predecessor. More to the point, that comparison is little better than ordinal; we can say that this sound is louder/softer/about the same as the previous one, but that is all. This idea (Laming 1984) accounts for several otherwise quite unrelated phenomena, including the quantitative variation of the autocorrelation (e) with stimulus differences. By focusing on the precision with which such judgments are made, this idea also relates magnitude estimation to category judgment and absolute identification—the stimuli and the subject are the same, only the response categories are different—and especially to the often repeated finding that the amount of information in a category judgment is limited to 2.3 bits, which is equivalent to the use of no more than five categories without error (Garner 1962, Chap. 3). But if human judgment is ultimately no better than ordinal, it affords no possibility of establishing a metric internal to the mind that is distinct from the physical.

3. How Might the Human Mind be Studied?

There are three ways in which these traditions of research might be continued.

3.1 Information Theory

(Note that I refer here to the mathematical theory of statistical information, not to the information theory (properly *communication theory*) of Shannon (1949), nor to the colloquial use of 'information' which has subsequently become fashionable in psychology.)

Discriminations between two separate stimuli conform accurately to the normal, equal variance, signal detection model (Tanner and Swets 1954). In that

model the parameter d'^2 measures the mean information afforded by a single presentation of either stimulus. A discrimination between two indistinguishable (identical) stimuli provides a natural zero; two looks at the same stimulus (cf. Swets 1964), or two simultaneous, correlated, signals, provide a natural concatenation of separate means; and a comparison between the informativeness of two different discriminations can easily be fashioned from statistical analysis. These are the criteria needed to establish ratio-scale measurement, and it is ratio-scale measurement of fundamental quantities such as mass, length, and time that has enabled the physical sciences to develop their present-day precision.

With that lesson in mind, psychologists have long striven to establish their own scales of measurement, but hitherto have always lacked empirical foundations sufficient to establish a ratio scale (Michell 1999). The parameter d'^2 bids fair to provide the first ratio-scale measure of specifically psychological origin; other ratio scales in psychology have been borrowed from extraneous disciplines. By this means experimental performance may be related to physical parameters of the stimuli (see Laming 1986, 1988).

3.2 The Precision of Sensory Judgment

Magnitude estimation and category judgment may be meaningfully analyzed using a multistimulus elaboration of the normal signal detection model, with a separate normal distribution for each stimulus value (the Law of Categorical Judgment, Case IC; Torgerson 1958). The inverse variance in units of log stimulus magnitude measures the precision of the judgments. That precision varies inversely with the square of the log stimulus range and also depends on the randomness of the stimulus presentation schedule. An 'analysis of variance' of sensory judgment provides a second vehicle of enquiry.

Inverse variance is Fisher's (1922) measure of information and is closely related to d'^2 . So this second suggestion employs the same mathematical theory as the first, but now directed toward the relationships between different experimental paradigms, including the classical psychophysical methods listed above. The lesson to be absorbed is that a magnitude estimate provides some limited information about the subject's assessment of the stimulus, but is never to be taken at its face value.

3.3 Sequential Interactions

It has been known since 1920 that successive psychophysical judgments are statistically related, but there is, as yet, no theoretical understanding what those interactions signify. Aggregate performance in

an experiment results from a pattern of sequential interactions driven by a (usually) random sequence of stimulus values. Trial-by-trial analysis provides a third way to study the mechanics of the human mind.

3.4 Internal Sensation

But none of these approaches measures subjective sensation. Internal experience is private to the subject; it cannot be shared with the experimenter except to the extent that it can be expressed in terms of some feature of the external world perceptible to both. Experimental paradigms are simply schemes for expressing that otherwise private experience. The strictly limited precision of any and every subject's judgments suggests that there is no more precise internal metric to be expressed.
