Side by side with such efforts to bring to trial leaders of former authoritarian regimes for gross violations of human rights, there has developed the institution of truth commissions established by national or international organizations. Truth commissions reduce the tensions that arise in transitional trials by separating the various functions of learning the truth about the past, of ascertaining individual guilt, and of giving voice to victims. The Truth and Reconciliation Commission in South Africa, for example, was divided into a Committee on Human Rights Violations (victims' testimonies), a Committee on Amnesty (offender's testimonies), and a Committee on Reparation and Rehabilitation. In each committee different procedures were used (1995 Act). It further made the granting of individual amnesty conditional upon providing a full account of the offenses that were committed (Minow 1998). Truth commissions have proved to be far more effective than court proceedings in furnishing a dramatic medium for theatricalizing the new official history since the narratives of victims are rarely interrupted by lawyers and there are incentives for offenders to relate their part in the repression. Indeed, in several countries the commission's proceedings have been broadcast daily, and in others the final report, *Nunca Mais* (Never Again), has become a best seller (Brazil, Argentina.) Truth commissions present us with a kind of political trial in which the balance between politics and justice has been struck in ways more compatible with liberal concerns.

2. *Political Trials in Established Democracies*

The political nature of transitional justice seems from the fact that there are no overarching legal norms that are accepted as legitimate by the two successive regimes. Moreover, in these cases the trials have overwhelmingly been used to fulfill social and political functions other than ascertaining individual guilt. Liberal scholars, as we have seen, have been willing to recognize the political nature of such trials and to

justify it, but have not extended their theories to trials in established democracies. The general view is that in normal times law should endeavor to keep politics out of the courtrooms so that every political trial is perceived as a corruption of the rule of law (which may be termed the pathology thesis). This distinction, however, fails to account for the striking similarities between transitional situations and periods in which there has been a significant increase in political trials in democratic societies.

In the United States political trials have occurred whenever the status quo has been challenged, generally during periods of social and political ferment unleashed by such forces as war, economic conflict, or racial discord (Belknap 1981). For example, the decade that began with the escalation of the Vietnam war in 1965 brought an epidemic of political trials culminating in the Chicago Conspiracy trial (1969–70). This case represents a microcosm of American political justice of the era, as it was directed against representatives of major antiwar groups, youth counter-culture, and the Black Panther Party who all believed that the war was illegal and sought to mobilize the public against it. Although the charges were clearly political (conspiracy to cross state lines with the intent to incite riot), the trial also demonstrated the ability of the defense to politicize the trial and turn it into a forum for social protest by flouting the norms of the courtroom and ridiculing the judge (Ely 1981). In such trials as the Chicago Conspiracy trial the same breakdown of common discourse was manifested as in political trials during the transition to democracy.

The social turmoil and political trials of the late 1960s influenced the development of radical theories of law (Gordon 1982) scholars in critical legal studies, critical race theory; and feminist legal studies began to question the plausibility of the liberal ideal of separating law from politics. For these scholars the very attempt to delimit the boundaries of the category 'political trials' obscures the way in which politics enters every trial and every field of law. They argue that the liberal reliance on a distinct category of political trials often serves to legitimize the status quo. Critical theory understands politics not in the narrow sense of the term (motive of authorities, identity of defendant, etc.) but as the hegemonic ideology that shapes the interpretation of law while presenting it as neutral. The main contribution of critical writings to understanding political trials has been their rejection of the 'pathology thesis' about the relation between law and politics and their systematic efforts to uncover the ideological structures that shape different areas of law (Kelman 1987, Kairys 1982). This broad definition of political trials, however, had its drawbacks because it no longer called for a systematic investigation of the unique features of classic political trials, and shifted the attention of scholars from the court drama and social reception of the trial to the appellate court interpretation of the law.

Other scholars, still committed to the liberal framework, have identified a new form of political trial that emerged during the 1980s and 1990s. While in the old political trial the ruling authorities selected certain individuals to stand for an opposition the state wanted to eliminate, in the new political trial a section of the public turns the trial into a political trial by identifying with the victims (who are not a formal party to the trial) or with the defendant. In these cases the state does not intend a political trial and has very little control over its politicization (Fletcher 1995). The people mobilized around these trials are usually outgroups protesting their marginalization by the legal and political institutions of the state. Examples are famous rape trials and self-defense trials of battered women who killed their abusive spouses in which women's group identify with the victim and politicize the trial. The Rodney King trial and O. J. Simpson trial likewise became political trials in which African-American groups were mobilized to protest against white justice in America. The study of these trials draws particular attention to the role of the media in these cases.

The focus on group conflict and on the narrative and rhetorical aspects of political trials in on-going democracies provides scholars with the key to understanding their dynamics from a pluralistic perspective. The famous trials of Socrates, Jesus, Dreyfus, and others are examples of heroes unjustly prosecuted, but they can also be viewed as major junctions in the life of the republic where society's conflicting values are played out not only, and not even mainly, through the learned interpretation of the law, but through the human drama in and around the courtroom. In these trials the social conflict is transformed into competing narratives that capture the public's attention and offer an opportunity for collective self-reflection. Through an examination of competing values and loyalties they bring together for public consideration society's basic contradictions (Christenson 1999). From this perspective we can see how political trials, while threatening the rule of law, at the same time may contribute to the development of a more critical and democratic society.

Politics, Formal Modeling of

Positive theories of politics provide explanations for why political phenomena occur in the manner that they do. Examples of such phenomena include which parties or candidates are elected at certain times, what policies legislative bodies adopt, and when and how wars are fought between countries. Formal models complement these explanations by using the language and analysis of mathematics to derive the phenomena as necessary consequences of certain sets of underlying factors. As with mathematical models in other disciplines, the main advantage of such an approach is twofold: to give an unambiguous representation of the relevant moving parts of a theory (the clarity of the argument) and to enforce a logical coherence on a theory (the consistency of the argument). The main drawback is found in the required simplification of the phenomena down to a manageable number of moving parts, and the subsequent possibility of simplifying away the very essence of the problem.

1. The Basic Structure

Most formal models of politics fall in the category of rational choice (e.g., see *Rational Choice in Politics*), where the presumption is that observed outcomes are the result of decisions made by a certain relevant set of individuals. These could be voters and candidates in the first example above, elected representatives and appointed ministers in the second, or heads of state in the third. The general behavioral postulate is that individuals attempt to influence the outcome in a manner reflecting their preferences (tastes, values, etc.) over the set of possible outcomes. For instance, in selecting campaign platforms, a candidate who only cares about winning the current election might look to adopt policies appealing to the greatest number of voters; conversely, a candidate who cares intrinsically about the policies to be implemented might shy away

from politically popular but personally unpalatable alternatives. Whatever their specific form, individuals' preferences are taken to be primitives of the model, and so are held fixed throughout the analytic determination of an outcome. However, different specifications of preferences can give rise to different outcomes. Indeed, to the extent the predicted outcome varies with changes in the underlying individual preferences, one has a potential explanation for any variation in observed outcomes as being due to variation in these preferences. The extent to which these preferences can themselves be modeled as functions of observable parameters, such as wealth or legislative seniority, permits one to generate a theoretical relationship between these parameters and observable political outcomes as well.

The influence of preferences on outcomes occurs through the choices the individuals make. The most common assumption is that each individual's choice is optimal with respect to their preferences, for example, in the above scenario the candidate selects a vote-maximizing policy. This optimality assumption may be far from a realistic representation of individual decision-making, implying as it does that individuals can effortlessly solve what are at times relatively difficult mathematical problems. However, assuming otherwise typically requires the presence of auxiliary factors (for instance, decision costs) to rationalize *non*-optimizing behavior, factors which, while reasonable, tend to create additional complications in the model. Also the optimality assumption allows one to import existing results from optimization theory to aid in the analysis.

As seen in the examples above, most formal models of politics involve more than one individual, and so this individual level of optimization often takes place within the confines of non-cooperative game theory. Such models explicitly describe the interaction among the individuals that ultimately produces a collective decision. This description begins with a 'game form' consisting of (a) the set of strategies available to each individual, and (b) the specification of which outcome occurs when a given profile of strategies is chosen (with each profile consisting of one strategy per individual). Continuing with the electoral setting, one example of a game form is where the set of strategies for a candidate is equal to the set of available policies, a voter's strategy describes which candidate to vote for based on the candidates' chosen policies, and an outcome, consisting of who wins the election and with what policy, is determined by the candidate receiving the most votes. The remaining piece of the puzzle then is the derivation of the individuals' strategies, with the fundamental concept being that of the 'Nash equilibrium.' Note that, even assuming all individuals have well-defined preferences over the set of outcomes, the notion of optimality in this multiperson environment is necessarily conditional, as an individual's best choice of strategy may depend nontrivially on the strategy

choices by the other individuals. For instance, in the electoral game above, the location of a candidate's optimal policy may depend on the voters' behavior as well as the policies endorsed by rivals. A Nash equilibrium is a profile of strategies wherein each individual's strategy is optimal, given the strategies of the others, that is, conditional on the choices by the other individuals, no one individual has an incentive to alter her choice. A Nash equilibrium outcome is thus a collective decision consistent with individually optimal behavior and constitutes the basic object of analysis in any noncooperative model. (In certain game forms, some Nash equilibria are inherently more plausible than others and so refinements of Nash equilibria, such as subgame perfection, are used.)

As with the choice of preferences, the choice of game form is in the hands of the modeler. This choice may be influenced by observable features of the political phenomenon in question, as in the above electoral example. In such situations, there will invariably be a trade-off between making the game form descriptively accurate and keeping the game form analytically tractable. Thus while the electoral rule may easily be incorporated, simplifying the campaign stage of the process to a single choice of policy, thereby avoiding the complexities found in actual elections, may be necessary to guarantee the existence of and to solve for equilibrium outcomes. At other times, there may not exist any such observable features to leverage, an example of which would be when two heads of state are bargaining over land and other resources in the shadow of war. Here one would be hard-pressed to assert that the unstructured negotiations taking place can be definitively captured in any one particular game form. Hence descriptive accuracy is not an issue, and the modeler is relatively unconstrained in the search for a 'good' game form, that is, a game form capable of generating new and valuable insights into the political phenomenon in question.

Yet to the extent that the game form incorporates observable features of the political process and that the equilibrium outcomes vary with these features, one has a second source of variation in outcomes above and beyond changes in preferences, namely, changes in the political process. For instance, the equilibrium outcomes under the above plurality electoral rule may differ from those associated with a run-off rule (where, if no candidate receives a majority of the votes, the two candidates receiving the highest number of votes are paired in a second election, in which majority rule determines the winner) even if the candidates' and voters' preferences are held fixed. This allows one to make statements about the degree to which differences in observed collective choices are due to differences in preferences, or to differences in political institutions. More ambitiously, this type of comparative institutional analysis can be used to predict the effect changes in existing political institutions will have on collective outcomes.

2. An Alternative Approach

While noncooperative game theory has tended to dominate the modeling landscape in recent years, much of the early formal work employed the techniques of cooperative game theory. Rather than explicitly modeling outcomes as the aggregation of individual decisions, under this approach one looks for outcomes that are stable in some sense, with this 'sense' implicitly characterizing the (unmodeled) underlying strategic interaction. Given the normative appeal and frequent use of majoritarian-based political procedures, the focus was primarily on identifying outcomes which are majority-preferred to all others in pair-wise comparisons. Such an outcome would then be immune to changes proposed by any majority coalition, whereas all other outcomes would not.

It turns out that a majority-stable outcome necessarily exists in certain environments, the most compelling being when the collective choice concerns the selection of a single number. For example, suppose the issue before a legislature is the size of the nation's military budget, the set of possible outcomes can be taken to be the set of nonnegative real numbers. Suppose further that the legislators have 'single-peaked' preferences: each has some best number, and the value to them of the outcome falls as one moves away from this best number. Then a stable outcome will exist and, if the number of individuals is odd, will be unique and equal to the median of these best numbers. This 'median voter theorem' has been at the core of numerous and varied empirical studies of collective choice, from local school budgets in the United States to European Union decision-making. Its comparative advantage as a formal model is obviously its parsimony, requiring as it does only a description of how individual preferences over outcomes are related to any underlying parameters of interest (e.g., household income in the local school budget case). Further, by imposing additional assumptions on preferences, one finds that the median voter's preferences coincide with those of the majority over the entire set of outcomes, implying that the median voter is in a literal sense representative of the collective as a whole. The benefits from this result accrue principally to the noncooperative modeler: suddenly a one-dimensional model of the interaction between the US President and the 435 members of the US House of Representatives over the size of the military budget, with majority rule dictating the decision-making among the latter, can be simplified to a two-person interaction between the President and the median member of the House.

The main shortcoming of the median voter theorem of course is its restriction on the set of outcomes to a single dimension. In certain situations this is benign, as in the above example when the policy choice in question consists of selecting the military budget.

However, a policy choice consisting of the distribution of this budget across more than two groups is inherently a multidimensional problem and the conclusions about majority rule for multidimensional problems, relative to their single-dimensional cousins, could hardly be more dramatic. In particular, for most descriptions of preferences, no majority-stable outcome exists (where 'most' has a mathematically precise definition in this setting). As an example of such non-existence, suppose in the above scenario that each legislator cares only about how much their favorite group receives, with one-third of the legislators associated with each of three groups. Then for any distribution of the budget, the legislators for two groups (which together constitute a majority) prefer to take away any amount going to the third group and redistribute it amongst themselves, thereby guaranteeing that no distribution is majority-stable. Furthermore, when no stable outcome exists, not only is there no representative voter but in fact one can construct majority preference cycles throughout the policy space (i.e., policy *a* is majority-preferred to policy *b*, which is majority preferred to policy *c*, which ... which is majority-preferred to policy *z*, which is majority-preferred to policy *a*). Thus when majority rule breaks down, it breaks down completely. Subsequent research has shown that these negative conclusions continue to hold, to a greater or lesser degree, for most non-majoritarian rules as well.

As with the median voter theorem, it is difficult to overstate the impact these 'chaos theorems' have had on the formal modeling of politics. Clearly, in a multidimensional world, the modeler has lost the analytic shortcut of representing a collective's decision-making as being governed by a single individual (or, at least, the logical rationale for doing so). More importantly, the theorems gave rise to a new-found appreciation for political institutions, such as committee systems, restrictive voting rules, and the like as key elements in the determination of collective outcomes. Indeed, such institutions are often depicted as necessary ingredients in any multidimensional model of politics, in that, but for such institutions, collective decision-making would fall prey to the inevitable onslaught of cycling and chaos. This interpretation, while quite popular, appears inconsistent with the central tenet of formal modeling, that of equilibrium analysis, as the chaos theorems are properly seen as nonequilibrium results. Put differently, these theorems do not predict that (as commonly phrased) 'anything can happen,' for as nonequilibrium results they do not predict anything at all. Rather, they demonstrate the impossibility of any general theory of collective behavior based solely on the (majority) aggregation of preferences, and hence the necessity of being more explicit about the decision-making process so as to provide the analytical traction required to formulate a well-posed model. From this perspective, the lesson to be learned from the chaos theorems is one for the modeler of collective

decision-making, rather than as one about collective decision-making itself.

Polling

Opinion polls or surveys are used widely to study the behavior of individuals. Survey researchers select and ask questions concerning individuals' attitudes, behavior, personal characteristics, or other types of information that they can provide as respondents. These responses are counted, analyzed statistically, and evaluated or interpreted in different ways, depending on the types of questions asked.

Academicians and practitioners engaged in opinion polling have preferred to call themselves 'survey researchers,' in contrast to 'pollsters,' who carry out nonacademic polls to predict election results, or report the mass public's or others' opinions and attitudes in the news media, or who work as consultants doing proprietary research, such as market research, for political candidates, political parties (including polls for their presidents), or other clients (Converse 1987, Moore 1992, Jacobs and Shapiro 1995). Polls and surveys are synonymous, but their quality (validity and reliability) can vary widely.

1. 'Straw Polls'

The use of polling had expanded greatly worldwide by the late twentieth century. Its origin and impetus occurred in the United States beginning with election 'straw polls' in the nineteenth century, and developing into modern-day political polling and academic surveys used widely to study social, economic, and political phenomena. Polling was arguably a major part of the rise of quantification in society consistent with Max Weber's writing about the role of calculation and rationality in social life (Herbst 1993). The earliest straw poll counterparts of modern opinion surveys

occurred in the 1824 presidential election, and the use of different types of these in politics and journalism increased until the emergence of more consciously scientific polling in the 1930s (Smith 1990).

These polls took many different forms, including oral counts, handraising, paper ballots, and writing preferences in 'poll books.' The participants were 'self-selected' in ways that were likely to produce a problem known as 'selection bias,' in which the results of these polls would be influenced by the characteristics of those who were able to participate, which might be different from the electorate or population to which the polls' results would be generalized. Reporters and partisans nonetheless treated these polls as indications of candidates' election chances.

2. 'Scientific Polls'

The problems associated with the overall representativeness and accuracy of such polls became clear publicly, when the accuracy of the *Literary Digest's* paper ballot poll, which had predicted the winners in US presidential elections from 1920 to 1932, was called into question by George Gallup and other new and more scientific-minded pollsters, statisticians, and social scientists. Gallup was the most widely known, if not the most important figure (along with Elmo Roper, Archibald Crossley, Paul F. Lazarsfeld, and Hadley Cantril) in 'scientific polling,' and approached polling with a democratic philosophy (Gallup and Rae 1940). While the first national Gallup election poll, done through what became standard in-person interviews did not predict the margin of President Franklin Roosevelt's 1936 election victory over Alfred Landon accurately, it triumphed over the *Literary Digest* in predicting the winner.

The Gallup poll represented the actual electorate far better than did the *Digest*, confirming the superiority of scientific sampling methods. In principle, initially, these methods allowed each potentially eligible adult voter (or eligible respondent, given the research objectives of a particular poll) an equal probability of selection, which was not the case in the *Digest* or other straw polls that allowed self-selection (Squire 1988). The early scientific polls involved sending interviewers to randomly-selected locations and then allowed interviewers largely to select their respondents to fill 'quotas' based on population characteristics to be represented in the poll. This led to selection biases.

These and other problems in the early polls, including ceasing to interview weeks before an election, were debated widely among pollsters and social scientists when the polls predicted incorrectly that Thomas Dewey would defeat President Harry Truman in the 1948 presidential election (Mosteller et al. 1949). Gallup and other pollsters improved their sampling methods, and the pollsters and academic researchers,

who were beginning to engage in large-scale public opinion and voting studies at this time, engaged in a concerted and continuing effort to improve and defend their research (see, e.g., Sheatsley and Mitofsky 1992, Mitofsky 1998).

3. Academic Research

University-based survey research had its beginnings in 1939–40 with sociologist Paul F. Lazarsfeld's Office of Radio Research, later renamed the Bureau of Applied Social Research. This history is described by Rossi (1959), Natchez (1985), and especially Converse (1987). Lazarsfeld and his colleagues in *The People's Choice* (Lazarsfeld et al. 1944) did the first sophisticated survey study of presidential elections in 1940 in Erie County, Ohio. This was followed by *Voting* (Berelson et al. 1954), a study of the 1948 election in Elmira, New York. Two of the largest and most widely known research centers that developed the capacity to do long-term national surveys are the National Opinion Research Center (NORC), which was established in 1941 at the University of Denver and moved to the University of Chicago in 1947, and the University of Michigan's Survey Research Center (SRC, Institute for Social Research (ISR)), established in 1946. With the publication of *The Voter Decides* (Campbell et al. 1954), the funding and locus for national election surveys shifted to Michigan's SRC, which led to the publication of *The American Voter* (Campbell et al. 1960) and the continuing series of American National Election Studies and studies based upon them (Nie et al. 1976/1979, Miller and Shanks 1996).

4. Further Expansion

Political polling and market and academic survey research increased after 1948. The early and subsequent public pollsters who provided their survey results to the mass media and other subscribers (for example, Louis Harris and Daniel Yankelovich, among others) had used their political polling as advertising to generate business for their proprietary market and other types of research. Market researchers and other pollsters expanded their work into polling and consulting for political parties and candidates (Moore 1992). Polling experienced its greatest expansion beginning in the 1970s, when it was found that sufficiently representative and accurate polling could be done by telephone (based on experiments comparing polls conducted by phone with those done in-person), eventually leading all the major pollsters to do most of their polling by phone. The most important national news media, which had relied exclusively on polling by public pollsters, began sponsoring and conducting their own polls, establishing their own,

often joint, polling operations or making arrangements to contract-out polls in which they controlled the content and reporting of results (Gollin 1980, Mann and Orren 1992).

5. *Methodology and Technology*

While social scientific polling depends on an understanding and use of scientific sampling to draw inferences about a target population (e.g., national or local, the entire adult population or particular sub-populations, ordinary citizens or elites) polls can be conducted in different ways depending on the research goal, the kind of survey questionnaire to be administered, and the available resources (money and time). In-person national polling (typically randomly sampling geographic locations, then households in these locations, and then random sampling within households) is the most expensive and time-consuming because of travel costs, though these can involve longer surveys and the use of visual aids and secret ballots for responses to sensitive questions. In contrast, election 'exit polls' that are used to project election results and provide the basis for more in-depth statistical analysis of voters' behavior, are short and efficient surveys, based on random samples of voters exiting voting places. Exit polling has occasionally been controversial due to the 'early' reporting of results that might affect the behavior of those who vote later in the day.

Telephone polling (typically using Random Digit Dialing, RDD) is less costly, as it eliminates travel costs and is easier to monitor and validate than in-person interviews; however, it excludes households without telephones, and it has higher rates of nonresponse due to households that are not reached (no answers, busy signals, answering machines, and refusals to participate); it is easier to make contact with respondents and establish rapport through in-person contact. Mail surveys are the least expensive but produce the lowest response rates unless extensive follow-ups are made (Dillman 2000). Low response rates, with their increasing potential for selection or non-response bias, has emerged as the most pressing professional and methodological problem currently facing survey researchers as the result of the proliferation of telephone surveys, telemarketing, and solicitations that interrupt and impose upon people's time (Groves and Couper 1998).

Problems of survey costs and response rates have led surveyors to turn to better technology. The use of computerized RDD and computer-assisted telephone interviewing (CATI) was a major development in improving surveys (making complex surveys, including experimental designs, easier to administer, and eliminating interviewer and data processing errors) and expanding their use. The use of computer-assisted

personal interviewing (CAPI) followed, including the use computers for self-administered surveys allowing for greater assurance of confidentiality for sensitive questions. Recently, there have been increasing efforts to expand sampling and polling through the Internet. While the Internet provides a way of increasing response rates through ease of contact without disruption, for potential respondents whose electronic addresses have been obtained, and through ease in administering surveys, the samples obtained may not be sufficiently representative of the target population, including those without Internet access, or who refuse to make their electronic addresses available for polling (thus echoing the limitation of the straw polls).

6. *Sources of Error*

Beyond statistical sampling error and nonresponse bias, there are other sources of error in surveys that are not easily quantified. The responses to survey questions and measurement of opinions and behavior can be affected by how questions are worded, what response categories are offered (e.g., whether a middle category or a don't know or no opinion response is offered or allowed), and whether questions should have fixed or forced choices, or whether questions should be asked and responses recorded as open-ended questions in which respondents can offer any answer they choose. Further, there may be 'context effects' that are produced by the order in which questions are asked, so that the way respondents answer questions may be influenced by what they had thought about and responded to in previous questions (Schuman and Presser 1981, Asher 1998).

A major source of error can occur depending on how research problems are formulated or specified, as when researchers assume respondents have familiarity with the object about which they are asked to offer an opinion or response. Care needs to be exercised in drawing inferences about actual behavior from survey measures of opinion, and self-reports of future—or even past—behavior. Reported voting in an election after the fact may not match actual behavior based upon data on 'validated' votes. Difficulties may also arise in how poll results are reported, such as when journalists or researchers themselves do not report enough information about their survey data and methods to allow their audiences or readers to evaluate their results (Cantril 1991, Traugott and Lavrakas 2000).

7. *Contributions to Knowledge*

The uses of surveys, how to improve polling methods, and how survey researchers should practice and report about their craft are matters that have been the

concern of the professional associations and journals established by those actively involved in the field of survey research. These include the American Association for Public Opinion Research and its journal, *Public Opinion Quarterly*; the World Association for Public Opinion Research and its journal, *International Journal of Public Opinion Research*; the Council of American Survey Research Organizations; and the National Council on Public Polls. In addition, political science, sociology, and other social science journals also publish survey studies widely.

The early voting and public opinion studies by Lazarsfeld and others were highly sensitive to methodological issues in survey research, and this led to the development and use of panel surveys (the interviewing of the same respondents over two or more points in time) and complex research designs. In addition to contributing to a large body of knowledge about the influences on voting, survey research contributed from its inception to the understanding of other forms of social and political attitudes and behavior, ranging from Samuel Stouffer's studies of *The American Soldier* (Stouffer et al. 1965 [1949]) and attitudes toward communism (Stouffer 1955), to studies of long-term trends in public opinion which utilize all the available polling data since the 1930s (Page and Shapiro 1992, Mayer 1993).

While academic researchers have made substantial use of data collected by academic survey organizations (especially the NORC General Social Surveys conducted since 1972, and the American National Election Studies covering every presidential and congressional election since 1952), increasingly they have used data made available by the public and mass media pollsters. The major archives for these data are the Roper Center for Public Opinion Research (University of Connecticut), the Inter-university Consortium for Political and Social Research (ISR, University of Michigan), and the Louis Harris survey and state poll archive at the Institute for Research in Social Science (University of North Carolina). These archives and the many polling organizations nationwide have also established and expanded access to their survey data through websites on the Internet.

Polynesia and Micronesia: Sociocultural Aspects

The two geographical areas commonly referred to as 'Polynesia' and 'Micronesia' consist of a scattering of relatively small and widely disseminated islands across the central, south, and northwestern Pacific Ocean. The two areas are complementary to Melanesia, the third area customarily recognized in the insular Pacific. Together, the three areas are commonly referred to as the 'Pacific Islands' or 'Oceania,' although these categories, particularly the latter, occasionally include Australia and Tasmania, and occasionally the larger islands of Southeast Asia. While some geographical, social, cultural, linguistic, and historical generalizations can be made about each of them, Polynesia and Micronesia are meaningful entities beyond simple areal demarcations only as a result of historical contingencies, in which the history of Western colonialism in the Pacific figures prominently.

1. General Identification

The terms 'Polynesia' and 'Micronesia' are convenient labels for geographical areas whose social, cultural, archeological, historical, political, and linguistic significance is somewhat arbitrary. In modern-day usage, the term 'Polynesia' refers to all island and island groups falling within a large triangular area whose apexes are New Zealand to the south, Hawaii to the north, and Rapanui (Easter Island) to the west. The largest islands and island groups of the region are Tonga, Samoa, Rarotonga and the Southern Cooks, Tahiti and the Society Islands, the Marquesas, and Hawaii, in addition to the much larger New Zealand. Politically or culturally notable smaller islands include Niue, Wallis and Futuna, Tuvalu, Tokelau, the Northern Cooks, Rapanui, Pitcairn Island, and the Tuamotus, Austral, and Gambier Islands.

In addition, a geographically heterogeneous group of about 18 islands and sections of islands are commonly identified as 'Polynesian Outliers' societies because they are located outside of this triangular area: in Melanesia to the west (e.g., Takuu off Bougainville Island, Sikaiana and Rennell in the Solomon Islands, Mae and Mele in Vanuatu) and, in the case of two islands (Nukuoro and Kapinga-

marangi), in Micronesia to the northwest of the Polynesian Triangle.

Micronesia forms a wide arc of small islands spanning from the western region of Insular Southeast Asia to the Central Pacific, comprising the following island groups: Palau and outlying islands, Guam and the Mariana Islands, Caroline Islands, Marshall Islands, Gilbert Islands, and two isolated islands, Nauru and Banaba (Ocean Island). Contemporary political considerations may include island groups of the Central Pacific like the Phoenix and Line Islands; although geographically located in the Polynesian Triangle, these islands, which were not permanently inhabited until the modern age, are governed by Kiribati, the modern state based in the Gilbert Islands. With the exception of Guam, the islands of Micronesia are small, although some of the largest atolls in the world are found in the region (e.g., Kwajalein in the Marshalls).

Islands of many different types are found in Polynesia and Micronesia: a few continental islands (e.g., Guam); volcanic structures, some of which can be substantial in size (e.g., Hawaii); raised coral islands of different types (e.g., Tonga); atolls (e.g., Kiribati); and combinations of these.

2. The Historical Contingency of Labels

The societies of each of the two regions share a number of characteristics with one another, although it is impossible to arrive at a list of necessary and sufficient conditions that would determine whether a given society should be identified as Polynesian or Micronesian, or as something else. The reason for this is twofold. First, commonalities among the societies of both areas are balanced by important patterns of variation (to the extent that no feature of social organization, for example, will be found in all societies in question). Second, many societies in other areas of Oceania display sociocultural characteristics identical to those prevalent among Polynesian or Micronesian societies. Perhaps the least controversial criterion for 'Polynesian-ness' is language: all languages spoken natively in the islands are more closely related to one another than to any other language. Indeed, the reason for identifying Outlier societies as Polynesian is primarily linguistic: all Outlier communities speak languages that are most closely related to the languages spoken on islands of the Polynesian Triangle. In terms of social organization and culture, however, Outlier communities vary widely, from bearing considerable similarity to the rest of Polynesia (e.g., Tikopia) to having much more in common with their more immediate non-Polynesian neighbors (e.g., the Polynesian-speaking villages of Ouvea, Loyalty Islands).

Yet even this criterion is not devoid of caveats: on the boundary between Melanesian Fiji and Polynesian Tonga, historical linguistic evidence suggests a con-

tinuum of gradual linguistic differentiation rather than a clean break. Furthermore, linguistic factors are of little use as determiners of what Micronesia includes and what it does not: all languages spoken in the area are related to one another, but some (e.g., Chamorro of the Marianas and Palauan) are historically closer to languages spoken outside of Micronesia (e.g., in the Philippines) than to the other languages of Micronesia.

Two additional issues further complicate the problem. First, many Polynesian and Micronesian societies are increasingly diasporic, and significant communities of Samoans, Wallisians, Cook Islanders, Caroline Islanders, for example, are well established in New Zealand, Australia, the United States, and the metropolitan centers of Oceania. In some cases, emigrant communities are much more populous than the island-based communities. Second, the characterization of some areas of the region as 'Polynesian' or 'Micronesian' is historically well motivated but, from a contemporary perspective, is part and parcel of acrid political debates. Such is the case of Hawaii, New Zealand, and Guam, where the original Polynesian or Micronesian inhabitants, as well as recent migrants from other Pacific Islands, today form numerical and political minorities, albeit vocal ones in terms of identity politics. These observations highlight the problems associated with attributing human significance to the definitions of Polynesia and Micronesia.

To say that the regions are arbitrarily defined does not mean that their characterization is haphazard. Rather, the definition of sections of the globe as 'Polynesia' and 'Micronesia' is deeply embedded in a history of elaboration of certain differences and similarities and the obscuration of others to suit politically dominant agendas, of the kind that suffuses any characterization of the 'other.' In this case, this history is that of Western colonial hegemony and of the intellectual endeavors that ran alongside it. When Enlightenment-era Europeans invented it, the term 'Polynesia' ('many islands') was applied to the entire Pacific region. In the course of the nineteenth century, it became more common to restrict the term to its current referent, and to contrast it with the newly coined 'Micronesia' ('small islands') and 'Melanesia' ('black islands'). As the etymology of the latter term indicates, race and its various associations figured prominently in the newly created finer distinctions. The term 'Polynesia' came to embody (mostly positive) images of noble fair-skinned otherness already prominent in the Enlightenment and early Romantic intellect, in contrast to Melanesia in particular, which Westerners deemed to be dominated by dark-skinned and uncivilized savagery (Smith 1985, Thomas 1989).

3. Initial Human Settlement

The prehistory of Polynesia can only be understood in the context of human movements in the Pacific region since about 3500 BP. Around that date, a wave of

people appears to have traveled gradually from west to east from Southeast Asia, settling islands of Melanesia, some of which were already inhabited while others were not. The most salient archeological evidence for this conjecture is a lowly style of decorated pottery referred to as 'Lapita,' fragments of which are found in insular Melanesia and Western Polynesia, carbon-dated to 3500–2000 BP. Lapita pottery makers and users appear to have been accomplished long-distance sailors, fisherfolk, and agriculturalists, to have organized their communities in hierarchical fashion, and to have spoken languages ancestral to most languages of insular Melanesia and Polynesia.

They reached Fiji, Tonga, and Samoa around 3000 BP, an area in which, according to some researchers, migrations may have 'paused' for a while (while maintaining active contact both externally and with the West from where they had come). Such a 'pause' would have allowed a social, cultural, and linguistic distinctiveness to emerge that would eventually become what is now recognized as Polynesian distinctiveness.

From the Fiji–Western Polynesia area, early Polynesians settled the rest of Polynesia in the course of the following two millennia, finally reaching Hawaii in about 650 AD and New Zealand around 1000 AD (Bellwood 1979, Kirch 1996). There is no convincing evidence of any subsequent prehistorical human settlement in Polynesia other than the Lapita potters and their descendants, although they intermarried with their non-Lapita-making neighbors, forming as diverse a genetic pool as is found in any other part of the world.

Micronesia's prehistory is much more heterogeneous and complex than that of Polynesia, and less well understood. Evidence of human settlement in the Mariana Islands dates back to approximately 4000 BP. The archeological record indicates a Southeast Asian connection for this early population, as does relatively more recent evidence gathered on Palau and Yap. The rest of the Caroline Islands, the Marshall Islands, and the Gilbert Islands were settled by a northwestward back-migration from eastern Melanesia. Languages spoken in this region, commonly referred to as 'Nuclear Micronesian,' exhibit greater linguistic homogeneity than other Micronesian languages, suggesting a more focused history of prehistoric settlement.

4. Contacts and Movements

It is difficult to issue brief general statements about the history of Polynesia and Micronesia since colonial encroachment because of the diversity of experiences and heterogeneity of influences. European travelers began sailing through Polynesia and Micronesia early in the Age of Discovery, making contacts with Islanders that were sporadic except in Guam and the Marianas, which were situated strategically on the sea

road between the Philippines and the New World. Spain claimed the islands in the mid-sixteenth century, a move which was followed by the virtual decimation of the Islanders, through disease, slaughter, and forced resettlement.

Contacts between Westerners and Islanders in both Polynesia and Micronesia began earnestly at the end of the eighteenth century, and often had equally tragic consequences on the island populations. Enlightenment-era travelers, spurred on by complex and sometimes contradictory motivations, roamed Polynesia in particular, making contact with Islanders in a variety of fashions that ranged from the hostile to the very friendly. They were soon followed by Christian missionaries (who would eventually succeed in converting all of Polynesia and Micronesia), adventurers and traders, developers seeking to establish plantations and other large-scale ventures, whalers, and of course governments seeking to establish colonies and spheres of influence, often under the pretext of protecting their citizens. In Polynesia, the key players (big and small) in the nineteenth century were predominantly British and French, to which American and German interests added competition later in the century. In Micronesia, Spain continued to hold political and economic sway, until it was completely displaced at the end of the century by the United States and Germany.

A notable consequence of Westerners' increasing visibility in nineteenth century Polynesia was the consolidation of hitherto politically fragmented chiefdoms. In Tonga, Tahiti, and Hawaii (and to a lesser extent Samoa), ambitious and astute chieftains utilized the new tools that Westerners introduced to the islands (trading goods for firearms, protection for religious conversion) to defeat their contenders and impose their rule over entire islands and island groups, establishing themselves as sovereigns under the protection of Western powers. Of these kingdoms, only Tonga remains to this day.

By the dawn of the twentieth century, European powers had divided Polynesia and Micronesia (as well as Melanesia) into sphere of colonial domination and influence. The end of World War I somewhat reshuffled the distribution of these spheres, introducing Japan as a colonial power in Micronesia (except the Gilbert Islands, which by then had become a British colony). World War II had a profound and dramatic effect on all of Micronesia, which was the stage of some of the fiercest battles, as was Melanesia. In contrast, Polynesia (other than Pearl Harbor in Hawaii) remained in the background of the conflict.

powers, particularly Great Britain, which by then had also delegated some of its colonial authority to Australia and New Zealand. In Polynesia, for example, Western Samoa (now Samoa) was granted independence in 1962, and Tonga ceased to be a British protected state in 1970. Decolonization in island groups held by the United States and France (Micronesia and French Polynesia, respectively, in particular) was and still is a slower, more complex, and conflictual process. A notable factor in both cases is the use by both powers of islands for nuclear testing until well into the 1990s.

Today, France maintains a colonial presence in French Polynesia and Wallis and Futuna (both Polynesian groups), which is contested in the former but receives general local approbation in the latter. The United States signed Compacts of Free Association with the Federated States of Micronesia and the Marshall Islands in 1986, and with Palau in 1994, and since then these entities have been recognized as sovereign nations despite some continuing US security interests in the islands. American Samoa and Guam are unincorporated US territories in which the federal government continues to maintain control of many functions, in spite of some local opposition in the case of Guam. The Northern Mariana Islands is a Commonwealth with more control of local affairs. Rapanui is administered by Chile, despite some political tension, and tiny Pitcairn Island (Polynesian from a geographical point of view) by Britain. New Zealand holds special political ties with three now self-governing territories, namely Niue, Tokelau, and the Cooks. Hawaii, a state of the United States, and New Zealand are both postcolonial entities in which the politics of indigeneity are tense. These varied historical connections, as well as the different configurations in which domination, resistance, and everything in between are embedded, have contributed to the socio-political diversity of both regions.

The states and territories of Polynesia and Micronesia include some of the tiniest political entities of the world, such as Tuvalu (10,000 inhabitants, 26 km²). Outside of New Zealand, most are heavily dependent on world powers, relying on foreign aid, migrations, and access to preferential markets to ensure at least a semblance of economic viability and, in some cases, political stability. The notable exception is Nauru, which is one of the richest countries of the world because of decades of phosphate mining.

5. Political Re-emergence

In tune with the worldwide decolonizing trends of the second half of the twentieth century, island nations began obtaining their independence from world

6. Society and Culture

In precontact times, the societies of Polynesia and Micronesia displayed a certain degree of sociocultural commonality, as witnessed, for example, in a tendency to have stratified political systems and in the elaboration of certain symbolic complexes such as *tapu*

(roughly, 'religiously-based prohibition') and *mana* (roughly, 'efficacy of divine origin') in Polynesia. However, the recognition of patterns of commonality must always be qualified in at least two ways. First, one must be attentive to the dynamics through which certain characteristics have come to be identified as 'typically' Polynesian or Micronesian in spite of the fact that these characteristics are absent in some societies of the region. Second, 'precontact times' is a vague characterization at best, and all island societies experienced radical changes over the centuries, some of which can be identified archeologically, in the course of which 'typical' Polynesian or Micronesian characteristics appeared in and disappeared from particular societies.

A significant number of societies in both regions appear to have been stratified political entities, the more so in Polynesia than in Micronesia. Particularly on large islands and island groups, chiefdoms were organized around a leadership that derived power through a combination of genealogical ties to both sacred and profane entities that confirmed claims to power (ascription) and personal performance that hopefully confirmed these claims (achievement). In some of more stratified societies, persons were also ranked into categories ranging from the highest ranks, which were commonly sacralized, to the lowest ranks, whose members were often not considered human. Other societies, in contrast, displayed little stratification and emphasized egalitarianism and consensual decision-making. Political organization on some islands was centered on localized kinship units, particularly in Micronesia but also on the smaller islands of Polynesia. The rough correlation between the amount of resources to be produced and organized and the degree of social stratification, at least in Polynesia, led some early researchers to propose that one engenders the other: chiefs, as resource managers, increase in importance as resources increase in volume (Sahlins 1958). Few anthropologists today would give such determinative power to resource management (and indeed the empirical evidence does not support the proposal), although it certainly plays a role in the development and elaboration of social stratification.

Prevalent patterns throughout the area centralized the identification of a common founding family ancestor, creating in some societies a pyramid-shaped kinship structure. In Polynesia, the most important branch was the senior patrilineal branch, and members of other branches reckoned their relative status according to their relative distance from the main descent branch, measured through relative patrilineality and seniority. Micronesian societies are predominantly matrilineal. There, matrilineal clans have historic claims to particular pieces of land and are the basis for social organization. Rank is based on claims of founding settlement of particular pieces of land. Probably all Polynesian and Micronesian societies also offered the possibility of bilateral affiliation,

whereby kinship could be based on either patrilineal or matrilineal principles, thus providing room for maneuvering for individual advantage. In Polynesia, there emerges an east-west contrast between societies in which gender and its associations constitute a pivotal organizational principle for kinship organization (as in Tahiti and Hawaii), and societies in which seniority plays a greater role (as in Samoa and Tonga). Adoption in its various guises was and is also prevalent throughout Polynesia and Micronesia.

Many aspects of precontact (or early contact) society and culture have reproduced over time and continue to characterize contemporary circumstances. However, any statement about contemporary Polynesian and Micronesian societies must take into consideration the enormous transformations that these societies have undergone in both bygone days and more recent times, introducing dynamics and agents that have been variously resisted, localized, and transformed. Two examples will suffice. The first is the recognition that many contemporary Polynesian and Micronesian societies are vigorously diasporic. While strong sociopolitical forces continue to ground society and culture in the 'islands of origin,' these forces are increasingly subject to contestation as second- and third-generation expatriates constantly negotiate their place across different identities and allegiances. The second illustration is the fact that Christianity, which is two centuries old in some area of Polynesia and Micronesia and much more recent in others, is almost universal and highly visible in both regions. In some parts of Polynesia, it has become one of the main backbones of hierarchy, exchange systems, and kinship, and is viewed as one of the most fundamental tenets of 'tradition.' In short, like all social groupings around the world, Polynesian and Micronesian societies are dynamic and adaptable entities, whose boundaries, core cultural values, and principles of social organization are subject to change, reassessment, and potential contestation.

N. Besnier

Popper, Karl Raimund (1902–94)

1. Popper's Life

Karl Raimund Popper was born in Vienna, Austria, on July 28, 1902. His father, Simon [Siegmund Carl] Popper (1856–1932), who had come from Bohemia to Vienna, was a well-established lawyer with his offices and family residence in the center of Vienna. Karl Popper's mother, Jenny Popper (née Schiff) (1864–1938) came from a musical family and was a gifted pianist herself. Both Simon and Jenny Popper were Jews by origin, but converted later in their lives to Protestantism. Besides their son Karl, they had two older daughters, Dora (1893–1932) and Anna Lydia (1898–1975).

Karl Popper left high school (Franz Josef Gymnasium) at the age of 16 without a degree, moved out of his parents' home and attended lectures at the University of Vienna on various subjects, in particular mathematics, philosophy, physics, and psychology. Besides occasional jobs to earn his living (e.g., coaching American students), Popper was engaged in social activities. For some time, he worked as an assistant of Alfred Adler on neglected children. Hints in Popper's autobiography indicate that this connection (through which he got acquainted with Adler's 'individual psychology') contributed to Popper's later critique of psychoanalysis as a 'pseudoscience.' In his youth, Popper had a strong favor for democratic socialism. For a few months, he even considered himself a communist, from which he refrained, in 1919, after witnessing a shooting incident in which socialist workers were killed by police forces. This experience of a useless sacrifice of lives demonstrated to him the futility of ideologies. A second, more intellectual

experience in 1919 was his taking interest in Eddington's test of Einstein's eclipse predictions carried out at an expedition of the Royal Astronomical Society, whose results gained widespread publicity at the time. During a total solar eclipse which was observed from West Africa and Brazil, a shift of apparent position of stars in the presence of the sun's gravitational field could be established, as predicted by the general theory of relativity. This coined Popper's later insistence that scientific theories develop by exposing them to possibly falsifying experience. Around that time, Popper visited a lecture by Einstein in Vienna.

The young Popper also tried manual work. From 1922 to 1924 he was an apprentice to a cabinet maker. At the same time, he passed the high school exams ('Matura') as an external participant and formally enrolled as a student at the University of Vienna. He also considered becoming a musician. After being disappointed with the sort of music cultivated in the Schönberg circle, he enrolled as a student of Church Music at the Vienna Academy of Music ('Konservatorium') and stayed there for one year. He was admitted upon submission of a fugue for organ in F sharp minor. Besides his scientific studies at the University of Vienna, in 1924 he qualified as a primary school teacher. Since no appropriate teacher's post was available at the time, Popper worked as a social worker with neglected children.

In 1925 Popper became a student at the Pedagogic Institute of the City of Vienna, where he stayed until 1927. This institute, which Popper was admitted to due to his status of a social worker, had been newly founded. It was linked to the University, though formally independent. In today's terms, its purpose was to scientifically accompany and evaluate the school reform movement. This school reform movement had been politically supported by the Austrian social democrats since 1919 and was in 1925 still very strong in Vienna. It was characterized by ideas of abolishing school learning as an accumulation of facts in favor of developing a more autonomous and participating attitude. The influence of these ideas on Popper should not be underestimated. His later criticism of what he calls the 'bucket theory of knowledge,' i.e., the inductive generation of knowledge by collecting facts, is related to pedagogic proposals on how learning proceeds or should proceed. Actually, Popper's first published papers were in this field and appeared in journals belonging to the school reform movement. The very first one *Über die Stellung des Lehrers zu Schule und Schüler (On the teacher's attitude towards school and students, 1925)* is very significant in this respect.

At the pedagogic institute, Popper met Josefine Henninger (1906–85), who was training as a teacher and who was to become his wife in 1930. (They had no children.) He also met the psychologist Karl Bühler and the philosopher Heinrich Gomperz, both of them

professors at the University. They were of crucial importance to Popper's intellectual development. It was through discussions with Gomperz and reading his works that Popper shifted away from any psychological approach to the philosophy of science. From Bühler he adopted the distinction of expressive, signaling, and descriptive functions of language, which still figured prominently in Popper's late metaphysical writings.

In 1928 Popper completed his Ph.D. in Psychology with Karl Bühler and Moritz Schlick as examiners. The subject of the thesis was *Zur Methodenlehre der Denkpsychologie* (*On the Methodology of the Psychology of Thinking*, unpublished), a work which combined Popper's interest in psychology with his methodological bias that he had finally shifted to during his time at the Pedagogic Institute. In 1929 Popper qualified as a teacher for secondary schools ('Hauptschulen'), and in 1930 he became a teacher in Vienna.

Since 1922 Popper had been in contact with members of the Vienna circle, a group of philosophers around Moritz Schlick who propagated what they called 'logical positivism,' a version of empiricism which made strong use of modern mathematical logic as a tool of philosophical analysis. Mathematical logic had already been developed by Gottlob Frege (1848–1925) and Bertrand Russell (1872–1970) decades ago, but had not been appropriately appreciated within the established academic philosophy. Though never a member of the circle, Popper attended its sessions occasionally and was in contact with several of its members, in particular Rudolf Carnap, Victor Kraft, and Herbert Feigl. Although he shared certain basic attitudes of the Vienna Circle, in particular the plea for a scientifically oriented philosophy, he was highly critical of other tenets such as the theory of meaning and the form of empiricism propagated. Motivated by Feigl, he put this criticism into a large manuscript in two volumes *Die beiden Grundprobleme der Erkenntnistheorie* (*The Two Basic Problems of Epistemology*, published in 1979, the second volume only as a fragment). A shorter version of the second volume of this manuscript was published in 1934 as *Logik der Forschung* (*Logic of Scientific Discovery*), which was to become his main work.

The book was well received. Reviews appeared in many journals. Even Einstein wrote Popper a letter after the book was sent to him through intermediates. In 1935 and 1936 Popper received invitations to England, where he lectured at Bedford College and Imperial College, London, at the London School of Economics and at Cambridge. He made a lot of contacts. Of most importance for his later career were those with Ernst Gombrich and Fritz Hayek. However, attempts to find a position in England did not materialize, and in 1937 he emigrated with his wife to New Zealand, accepting an offer of a lectureship at Canterbury University College.

During the time in exile Popper intensified his interest in social and political philosophy and in the philosophy of history, besides continuing his research in logic and philosophy of science. From that time on, he published mainly in English. He wrote a series of articles *The Poverty of Historicism* (Popper 1957a originally 1944–5); and, more importantly, his two-volume classic *The Open Society and Its Enemies* (Popper 1945). For both works he had to struggle to find a publisher. Due to the *Open Society*, he acquired his initial postwar reputation and, in particular, his post, from which he carried out all subsequent work. Through the intervention of Hayek who, together with Gombrich, had made the publication of the *Open Society* with the publisher Routledge possible, he was offered a readership in 'Logic and Scientific Method' at the London School of Economics in 1945, which Popper took up early in 1946, shortly after publication of the *Open Society*. In 1949 he received a professorship of the same title at the London School of Economics, which he held until his retirement in 1969.

During the first five years of his stay in Britain, he was sort of a 'star.' The *Open Society* made him a quite popular theoretician of political liberalism. It has often been said that this book filled some intellectual vacuum in the postwar period. Popper was invited to many places and, at the same time, had a substantial audience at the London School of Economics. In the 1950s, he shifted more to working from home with less institutional involvement. At the same time, his research interests moved away from political and social philosophy and back towards the subject of the *Logik der Forschung*, i.e., the methodology of the natural sciences. However, the first English edition of this book appeared only in 1959, with a lot of material added compared with the German original. Many other books and plenty of papers followed. Up to his death, Popper produced an enormous scientific output and had a vast correspondence. From the mid-1960s on, Popper received a great number of prizes and honorary degrees in many countries, including Knighthood and Membership of the Royal Society in Britain. He died on 17 September 1994 in London. His ashes were buried in Vienna, where his wife had died in 1985.

2. Popper's Work

Popper's work covers nearly all areas of theoretical philosophy. His overall profile is that of a great philosophical classic. However, most important are his contributions to the methodology of science, where he established falsificationism as one of the basic orientations in the modern philosophy of science.

The basic claims of falsificationism are put forward in the *Logik der Forschung* (1934, official year given in

the book: 1935). Most of Popper's later methodological contributions can be viewed as elaborations or amendments of what was already stated in his first book. Even Popper himself treated the *Logik der Forschung* like a classical text, with all changes in the first English translation (*The Logic of Scientific Discovery* 1959) as well as in the later 10 German and 10 English editions, as a system of footnotes and appendices to the 1934 edition.

Falsificationism can be described as a 'why not' methodology in contradistinction to a 'why' methodology with respect to scientific theories. According to Popper, a scientific theory is posed without any prior justification. It gains its confirmation, or 'corroboration,' which is Popper's preferred term in later writings, not by experimental evidence demonstrating *why* it should hold, but by the fact that all attempts at showing *why* it does *not* hold have failed. The main activity of an experimental researcher is trying to refute or '*falsify*' a scientific theory, rather than to justify or '*verify*' it. Theoreticians who design theories should do this in such a way that they can be refuted most easily. In no case must a theory be immunized against possible falsification, e.g., by the introduction of *ad hoc* hypotheses. We rely on a theory only because we have not managed to falsify it (so far), not because we have any positive or direct reasons in its favor.

His own theorizing, and especially the idea of falsificationism, is considered by Popper as proposing 'methodological rules.' These methodological rules have to prove fruitful in the understanding of scientific research and, particularly, of scientific progress. The main argument in favor of his falsificationist proposal is that the converse proposal, which is called 'verificationist,' is bound to fail. Verificationism, which underlies the 'inductivist' methodology, claims that a scientific theory is supported by a collection of verifying instances. However, as has already been established by David Hume (1711–76), the inductive reasoning from a finite set of observations to a general statement is not logically valid if the domain of reasoning is infinite or at least indefinite. Furthermore, any attempt at creating a special nondeductive form of reasoning (an 'inductive logic') can only be justified by means of induction itself, thus ending up in a vicious circle. To quote Popper's famous example, no observation of white swans can verify the general statement that all swans are white.

Popper's falsificationist methodology rests on the assumption that unlike verification, falsification of a general statement by experimental or observational means is logically without any problem. The statement 'All swans are white' can be falsified by the observation of a single black swan. The logic involved here is just ordinary deductive logic, due to which the falsity of an instance derived from a general hypothesis falsifies the hypothesis itself. Seemingly singular statements such as 'The planet Pluto has a moon,' which at first glance seem to be verifiable but not falsifiable, are viewed by

Popper not in isolation but as embedded in a general theory and therefore are no counterexample to what he calls the 'asymmetry between verification and falsification.'

More complicated is the example of statistical theories where definite falsification is not possible. Here Popper applied as an additional methodological rule that what is extremely unlikely can be neglected as something which cannot be reproduced deliberately. This allows Popper to cope with the standard way of rejecting statistical theories by means of a critical test (usually defined by stipulating a level of significance).

In traditional methodology, particularly that of the Vienna Circle, inductivism was tied to empiricism and guaranteed the connection between theoretical statements and their empirical basis. In falsificationism, the empirical significance of theoretical statements is kept by relating them to basic statements which possibly falsify them. However, these basic statements are no longer purely observational in some epistemological sense, but are themselves theory-laden from the very beginning. Even elementary perceptual evidence has to rely on theoretical assumptions. Thus Popper rejects any semantic division between theoretical and observational statements and, especially, the claim that a particular sort of certainty comes with the latter. According to Popper, the validity of basic statements can only be fixed in the course of the testing of a theory, and, in the end, this fixing is a matter of convention. This variant of conventionalism, which enters Popper's approach in addition to the conventionalism inherent in the choice of methodological rules, has repeatedly been the subject of criticism.

For Popper the distinction between a theory which can be falsified by means of basic statements and one which is not falsifiable serves as a demarcation criterion for empirical science vs. metaphysics. However, metaphysics, though not falsifiable, is not meaningless. Metaphysical statements may serve useful purposes, even within science. For example, the principle of causality ('any event can be causally explained'), which cannot be falsified and is therefore metaphysical, can be viewed as the useful methodological rule never to abandon the search for laws which explain observed facts. This view of metaphysics is less rigid than that of the Vienna Circle, who considered metaphysics to be meaningless throughout. It allows Popper to sharply criticize certain nonfalsifiable theories as 'pseudosciences' (such as psychoanalysis) but nevertheless to make sense of certain traditional philosophical claims or to appreciate the fruitful role of metaphysical research programs in the history of physics ('A metaphysical epilogue,' in *Quantum Theory and the Schism in Physics* 1956, published 1982b).

In his later works, Popper extended the methodological approaches of the *Logik der Forschung* towards a general account of the dynamics of scientific theories ('Truth, rationality, and the growth of scientific knowledge,' in *Conjectures and Refutations* 1963).

According to this view, theoretical progress is made by successive critique and revision of existing theories, which is governed by the idea of objective truth. Scientific progress works by replacing a falsified theory with a new one which, in the ideal case, is more encompassing than the previous one in that, while coping with the new results, it also covers the unfalsified instances of the old theory. This appeared to be the case with classical and relativistic gravitational theories in the presence of the results of the 1919 solar eclipse observations, which were so impressive to the young Popper. His later claim is that the new and more encompassing theory is nearer to the truth than the older and more special one, even if it should at some point become falsified itself. Popper has tried to characterize the distance of a theory from truth, its 'truthlikeness' or 'verisimilitude,' in numeric terms. Considerable work has been carried out in recent decades to develop improved measures.

Within the revision of scientific theories, Popper strongly distinguishes between hypotheses being tested and background knowledge which, though testable in principle, is not being questioned at the same time. This distinction makes the falsification of parts of a theory possible, and not only the falsification of a theory as a whole. Therefore Popper pleads to formulate theories in a modular way such that its parts can be tested independently of each other. He is opposed to 'holistic' views of theories, according to which, in a single test, the whole theory (Pierre Duhem) or, even more radically, all our theoretical knowledge including logic and mathematics (W. V. O. Quine) is at stake. Popper defended his model of scientific progress as a change of scientific hypotheses by means of falsification against historic approaches which denied the rational character of scientific change. So he was strongly opposed to Thomas S. Kuhn's account of scientific revolutions as irrational changes without the concept of 'progress' being applicable. Similarly, he argued with Imre Lakatos (1922–74) and Paul K. Feyerabend (1924–94), who started as Popperians, but later on made changes in falsificationist methodology by weakening and relativizing Popper's strict idea of progress by critical testing.

In *Evolution and the Tree of Knowledge* (1961, published 1972 in *Objective Knowledge*), Popper embedded the idea of theory change by falsification and revision within a general theory of the evolution of knowledge. Here 'knowledge' is viewed as a form of adaptation of an organism to the environment. Popper's schema of progress from problems via falsification to new problems is interpreted as the evolutionary transition from organisms via natural selection to organisms which are better adapted. By viewing all life as problem solving (*All Life is Problem Solving* 1994c), Popper claimed to combine theories of biological evolution with theories of scientific progress, relating his approach to evolutionary epistemology in the sense of D. Campbell. However, it must be

emphasized that, unlike most evolutionary epistemologists, Popper was not a naturalist. He insisted that the cultural-scientific evolution is rational and based on conscious and deliberate criticism, not on natural selection governed by chance.

In his later work, Popper also replaced the narrow concept of 'falsification' with a broader concept of 'criticism' or 'critical examination.' This broader concept not only applies to scientific theories which are formulated in a logical language but to philosophical claims which are metaphysical. It involves tests of consistency and the investigation of how far the theory in question is able to solve particular problems. This orientation, with critical examination as its cornerstone, was called 'critical rationalism' by Popper and has since become the standard denomination of the Popper school. The main examples of Popper's dealings with metaphysical problems are his treatment of determinism and his philosophy of mind. Quite independent of problems of quantum mechanics, which often serve as arguments against determinism, in *The Open Universe: An Argument for Indeterminism* (1956, published 1982a), he developed an indeterministic world view. In 'Of clouds and clocks' (1966, reprinted in *Objective Knowledge* 1972), he extended this view with arguments for the openness of the future for free action. In the mind–body debate, Popper defended a mind–body dualism ('Language and the body–mind Problem,' 1953, reprinted in *Conjectures and Refutations* 1963), which he later extended to a model of three worlds of (a) physical entities, (b) mental states, and (c) objective contents of thought, which causally interact. This approach gained much attention through his discussions with J. R. Eccles which, together with their separate contributions, are presented in their joint book *The Self and its Brain* (1977).

Epistemologically, Popper was an outspoken objectivist and realist. On the Popperian view, our theories are not just methodological instruments or means of acquiring (some degree of) certainty about something, but attempts at explaining the real world. As reality is described by means of true sentences, this is another way of claiming that the goal of science is truth. Part of Popper's objectivism and realism is his rejection of any subjective interpretation of probability. In particular, he was strongly opposed to Bayesianism and its view that scientific progress is just changing the probabilistic degree of belief in certain propositions, which means that scientific dynamics is probability dynamics (*Probability Magic or Knowledge out of Ignorance* 1957b). Both the probability of hypotheses, for which Popper coined the term 'logical probability,' and statistical probability, which may be part of a hypothesis, are objective probabilities reflecting properties of what they are attributed to. Logical probabilities are inversely proportional to the content of a theory, the less probable theory having a higher content. Statistical probabilities which, in the *Logik*

der Forschung, were interpreted as relative frequencies, were later viewed as objective 'propensities' of experimental designs to develop certain outcomes (*Realism and the Aim of Science*, 1956, published 1983). This propensity interpretation of probability claims to be a solution of the problem of assigning probabilities to singular events, rather than only to events as members of a given sequence or set of related events.

Popper's attitude against probabilities as degrees of belief does not contradict the fact that he attempted to measure the degree of corroboration of a theory in probabilistic terms. However, first of all, Popper's degree of corroboration, though relying on probabilities, is not a probability itself, i.e., does not obey the laws of the calculus of probability. Second, the degree of corroboration is intended as a strictly objective measure which reflects the way the hypothesis in question was subjected to falsification, and is definitely not meant as a degree of rational belief in a hypothesis. According to Popper, epistemology is the methodological treatment of objective scientific contents and not a theory of the knowing subject ('Epistemology without a knowing subject,' 1967, reprinted in *Objective Knowledge* 1972).

Popper's social and political philosophy which was developed during his emigration in New Zealand and published in *The Poverty of Historicism* (1944–5) and *The Open Society and its Enemies* (1945) can, to some extent, be viewed as an application of falsificationism to the area of social interaction. By 'historicism' Popper denoted the claim that the methodology in the historical and social sciences differs fundamentally from those in the natural sciences but, nevertheless, allows one to formulate objective laws of historical development, which cannot be changed by subjective action. The standard example is Marxist philosophy of history (historical materialism). In contradistinction to that, Popper put forward the idea of 'piecemeal social engineering,' i.e., of a development of social institutions in small steps which can be revised and whose potential damage can be controlled. According to Popper, piecemeal social engineering can be combined with a falsificationist form of social research, which is based on trial and error as it generates models for social development. For areas of historical and sociological research which are interested in the explanation of single events rather than the testing of general laws, Popper proposed the procedure of a 'logic of the situation' which describes the acting of individuals under the hypothesis of rational purpose-oriented behavior within a certain social situation. In this context he defends the autonomy of sociology against psychologism, as this situation is described in objective terms by reference to social institutions, etc. Since 1961, Popper defended this account of social theorizing against representatives of the neo-Marxist Frankfurt school in Germany, in particular, Theodor W. Adorno and Jürgen Habermas, in a dispute which became known as the 'positivist dispute in German

sociology,' and which made Popper well known to a wider audience in the German-speaking countries.

The *Open Society* extends the critique of historicism to a critique of the philosophical theories of state and society by Plato, Hegel, and Marx, which Popper considers to be philosophical precursors of political totalitarianism. According to Popper, they advocate the idea of a closed society, which is a collectivistic and organismic whole, without the distinction between natural and cultural laws. In an open society, which Popper strongly favors, individuals are personally responsible for their decisions and can therefore be critical to social regulations. Popper argues that the traditional question 'who should rule' ought to be replaced by the question of how to minimize the risk of bad rulers and how to get rid of them once they are in power. For Popper, the long-standing philosophical discussion about the best rulers belongs to justificationist thinking that has to be abandoned in favor of critical thinking, just as in general methodology. The utilitarian principle of maximization of happiness should give way to the idea of minimizing suffering.

Although there appears to be a lot of moralizing both in the *Open Society* and in many short papers and interviews on questions of morals and politics given towards the end of his life, this should not be understood as fragments of an ethical theory. For Popper, there is no such thing as ethics, because ethical sentences are not propositions in the logical sense that one could argue for or that one could reject. However, there are moral actions. These are actions which are carried out by someone who is aware of their consequences. Since the consequences of actions can be critically examined in the sense of critical rationalism, moral decisions are not irrational.

3. Relevance and Impact of Popper's Philosophy

Popper's methodological program was revolutionary as it reverted the established conceptual order between certain fundamental notions. He put 'negative' concepts such as 'falsification' and 'rejection' first, and made 'positive' concepts such as 'acceptance' or 'corroboration' dependent on them. Whereas according to the traditional philosophical view of science established ever since Bacon, acceptance of a theory is based on the direct generalization from observation, according to Popper, it can only rely on failed rejection. It is therefore correct to speak of Popper's 'negative methodology.' As Popper tried to show in his later writings, this is not just a program for the natural sciences, but applies to any area of scientific reasoning and even to metaphysics, where negative concepts such as that of 'criticism' come first. The credit we give to a conjecture is based on the fact that refuting it by criticism has been unsuccessful. This program is even the basis of Popper's political phil-

osophy. The negative question of how to restrain political power and to remove bad rulers from power is of primary concern compared with the positive one of whom to give power. Popper's negative methodology is a unified view of rationality under the header 'critical rationalism.'

This comprehensive perspective of theoretical reasoning and social and political action makes Popper's philosophy comparable with that of great classics like Aristotle or Kant. It was also one of the sources of the great success which Popper enjoyed still during his lifetime. As a general and unifying view, 'critical rationalism' is, of course, liable to oversimplification and, among certain adherents of Popper there has, in fact, been a considerable amount of that. On the other hand, it was only critical rationalism as a general orientation that could publicly compete with the eloquence of hermeneutic or neo-Marxist approaches. Philosophical theories like logical empirism, though with respect to intellectual clarity and responsibility by no means behind Popper's, would have been too academic to develop any major public significance.

In fact, it is not very difficult to give an outline of the basic principles of critical rationalism to somebody who is not a trained philosopher. Critical rationalism is an approach which offers something at any depth of understanding. Popper's works both cover extremely intricate discussions, e.g., of the methodological role of probability, whose significance can only be judged by highly specialist researchers, and general questions of reasoning, society, and politics at a level accessible to anybody who is really interested. With the exception of the chapters on probability and on quantum mechanics and of the appendices, the *Logik der Forschung* can easily be studied without deep expertise in academic philosophy. Even from a first reading, the average student would gain a preliminary understanding of falsificationism. Matters of presentation are very important in philosophy, and Popper was a master in that. His language is extremely clear and nonpretentious, which distinguishes him from many other philosophers, particularly in the German tradition.

Popper made a strong impression on politicians of various directions, although he was himself never involved in party politics. Both conservative and social democratic or labor politicians have referred to Popper to justify their respective programs and proposals. The term 'open society,' which Popper coined, has become widely accepted as a designation of basic features of a democratic state.

Popper's lasting impact on the shape of philosophy of science was not only due to his methodology in the narrower sense, but also due to his drawing attention to the *dynamics* of science. It is significantly due to Popper's influence that the philosophical and logical reconstruction of scientific reasoning is not just a modeling of static theories in logical terms but, to a great extent, an account of theory dynamics, i.e., of

what it logically means that a theory is being given up or revised. The combination of philosophy of science with the history of science, which is reflected in many divisions of university departments, denominations of chairs, etc. emerged on this background, as philosophical theories of theory dynamics have to be tested against the historical development of theories, and, conversely, the proper understanding of historical developments requires appropriate methodological tools. Although today's theorizing differs in many respects from what Popper argued for and often contradicts his claims (i.e., Bayesian approaches in the field of belief revision), the research program of putting dynamics of theories first in the methodology of science is unthinkable without Popper's revival of the induction problem and his negative methodology as a proposed solution.

The influence of Popperian theories on the 'working scientist' should not be underestimated. If scientists have any interest in the methodology of science at all, they would know of Popper's approach. This is particularly true of the social and behavioral sciences. There, falsificationism figures prominently in textbook chapters dealing with methodological questions. One may speculate why falsificationism is so appealing to social scientists. A possible answer might be that statistical methodology, which lies at the heart of the social sciences, has a bias towards falsification. According to the most widespread statistical methodology, which is a combination of accounts by R. A. Fisher and by J. Neyman and E. Pearson, the rejection or falsification of a statistical null hypothesis at a certain level of significance is a direct and uncontroversial result, whereas the acceptance of a positively formulated statistical hypothesis is only indirect and preliminary (as it depends on features such as sample size) and, in any case, is technically more involved.

Certain results of modern computer science have challenged Popper's view on induction. His methodology comes along with the claim that we always start with theories or hypotheses which, in the course of time, are then revised to better hypotheses by trial and error. How a new hypothesis is formed was for Popper not the subject of rational investigation. In artificial intelligence and, in particular, in learning theory, algorithms have been developed to generate theories that fit given data. This does not contradict falsificationism, as these heuristically developed hypotheses would then have to be tested, just as falsificationism claims. However, the availability of such procedures destroy the myth that a theory is the extrarational product of a genius or some sort of accidental mutation, and lays the foundation for algorithmic inductive heuristics as a rational enterprise.

There are a lot of questions in the technical development of the Popperian approach, e.g., his treatment of probability and of logic, whose significance for future developments has still to be proven.

Something similar holds for Popper's metaphysical theories. However, these are less important details compared with his basic methodological claims, which will remain a standing challenge.

P. Schroeder-Heister

Popular Culture

For most of us, popular culture is a source of entertainment. It encapsulates mass media (such as film, television, print media), and includes sports events, advertisements, street fairs, and tourism. We engage with popular culture because we get pleasure from it; at the same time, we are also informed by it. We usually associate information with news rather than with entertainment. But other forms of popular culture that we often associate with 'mere entertainment'—for instance, tourist practices, popular music, films, sports, and television programs—also inform us in profound ways. For example, the US sitcom, the *Cosby Show*, may shape our ideas not just of what an ideal family is, but also about the relationship between race and upward mobility; a romance novel might instill in us expectations about intimacy as well as about gender and sexuality. Popular culture plays an important role in shaping our personal and collective identities. It also provides us with an analytic lens to understand sociohistorical processes such as class, gender and sexuality, nationalism, and transnationalism.

1. What is Popular Culture?

In the modern world, popular culture is available to what we may call 'the public' or to 'masses' of people. For this to happen, there have to be established means of production, distribution, and reception. For example, for a soap opera to exist there have to be a crew of script writers, actors, a director, a producer—in other words, a crew of people who work behind the scenes and in front of the camera. There also has to be a means to finance this production: in capitalist societies, soap operas are financed by sponsors who pay for the production and telecast of a soap in exchange for being able to advertise on it. This is how the term 'soap opera' originated: soap operas were sponsored originally by manufacturers of detergents. Even today, the manufacturers of detergents and other household goods like washing machines, kitchen appliances, and cleaning agents are key advertisers on soap operas. There also needs to be an infrastructure for its distribution. This is where television networks come in. Very often, television networks are part of larger media conglomerates or groups of companies. Television production is, therefore, part of a larger system of industrial production.

Popular culture presents us with a vantage point on the world: it is a domain that shapes our sense of self or our identity. Not only is it available generally to a large number of people, it also responds to and creates points of identification among large groups within a community or nation. Popular culture plays an important role in constituting and representing the public to itself. It is public in two senses: not only does it circulate widely and is often associated with public exhibition and display, it also configures 'the public,' 'the nation,' 'society,' 'culture,' 'family,' and other collectivities. From a sociological viewpoint, popular culture is probably the most important influence on the lives of millions. However, it is important to recognize that viewers are not just unthinking targets of popular culture. Rather, in order to understand the cultural significance of popular culture, we need to examine how its consumers respond to, reinterpret, and employ its messages.

Popular culture is a site of struggle between dominant discourses and forces of resistance. It contains 'points of resistance' as well as 'moments of super-session;' it forms a 'battlefield where no once-for-all victories are obtained but where there are always strategic positions to be won and lost' (Hall 1981, p. 233). Mass media may open up a 'zone of debate' about issues current in a given community (Gupta 1995). For instance, television shows like the US sitcom 'Ellen' enabled the rearticulation of debates around homosexuality. Popular culture, then, does not simply 'reflect' the lives and worlds of audiences; nor does it 'impact' these worlds or lives in a simple way. Instead, popular cultural texts are social formations in and of themselves.

Our subjectivities are constituted in the process of making sense of the world around us and in our interaction with others. In capitalist and postcapitalist societies, these processes are refracted by mass media. Film, television, popular music, and mass market fiction constitute and represent the public realm in cognitive, moral, and emotional terms. But these representations do not impact us as if we are blank screens—instead, 'they occupy and rework the interior contradictions of feeling and perception ... they do find or clear a space of recognition in those who respond to them' (Hall 1981, p. 232). Thus, although representations are neither all-powerful nor all-inclusive, they have material effects on how people see themselves and lead their lives.

2. Scholarly Perspectives on Popular Culture

Definitions of popular culture have shifted according to the disciplinary emphases of its students. Historians of early modern Europe (e.g., Peter Burke (1978) and Robert Darnton (1984)) stress how members of different classes created and participated in popular culture and, simultaneously, were shaped and constrained by it. These historians analyze the factors influencing the popular cultures of early modern Europe, chiefly, the rise of cities and the advent of printing. They supplement thematic analyses of books with information about audiences and, thus, aim at providing the context for the meaning and uses of books.

Some of the foundational work on the relationship between capitalism and mass media is Max Horkheimer and Theodor Adorno's *The Culture Industry: Enlightenment as Mass Deception* (1944). Horkheimer and Adorno focused on how culture and the individual are 'produced' by the culture industry. They claimed that the culture industry's power lies in its ability to disseminate ideas and beliefs on a mass scale. They were concerned about how the management and control of leisure time and the socialization of the ego by the culture industry leads to a 'mass' culture that undermines the private realm.

The relationship between modern forms of popular culture and the growth of capitalism is also examined by some cultural studies scholars. Some of the most influential work in this area was produced (and has been influenced by) the Centre for Contemporary Cultural Studies at the University of Birmingham, UK. These scholars are concerned with how mass media shape dominant ideologies and discourses. Their central project is to examine the relationship between the production and consumption of popular culture and social axes of inequality, such as class, race, and gender. Although cultural studies' earliest borrowings were from literary criticism, chiefly the work of Raymond Williams and Richard Hoggart, its primary focus has been on practices of everyday life.

The greatest debts of this genre of cultural studies are to Marxist theories of culture. Its basic premise is that cultural production often takes the form of commodities. Other important propositions are: (a) popular culture is inextricably tied up with social relations; (b) popular culture can both enable social groups to define and realize their needs and reproduce asymmetries; and (c) popular culture is a terrain where social differences and struggles are articulated. These concerns reflect the influence of Gramsci on the ideological and popular struggles involved in the construction of common sense. In addition, some cultural studies scholars influenced by Lacanian analyses of film and television reconceptualize ideology in terms of how texts construct subject positions. Others have rethought the role of ideology in popular culture in terms of Foucault's analyses of discursive practices. Finally, breaking with Horkheimer and Adorno's assumption of the audience as a passive and undifferentiated mass of receivers, many cultural studies scholars conceive of audiences or consumers who actively 'decode' and interpret popular culture texts.

In addition to studying everyday practices, some cultural studies scholars also use semiotic methods of textual analysis. They treat cultural products as 'texts' to be 'read' according to interpretive strategies, including the literary analysis of narrative, semiology, and deconstruction. These analytical strategies reveal that literary conventions and forms have greater social and cultural significance than we might first suspect. For example, feminists have pointed to the place of fictional representations of romantic love in cultural constructions of femininity. Far from being 'mere' literary constructions, these representations play a crucial role in the constitution of dominant practices of gender and sexuality.

Anthropologists bring important theoretical and methodological insights to the study of popular culture because of their commitment to ethnographically analyzing the relationship between popular culture and other social institutions. Initially, mass media was neglected by anthropologists (exceptions include Bateson 1943 and Powdermaker 1950) because it was deemed 'too redolent of western modernity and cultural imperialism for a field identified with tradition, the non-western and the vitality of the local' (Ginsburg 1999, p. 297). Since the 1980s, however, many anthropologists have analyzed popular culture by studying mass media. They have examined the cultural implications of popular culture through an ethnographic attention to the everyday practices and lives of producers and/or consumers of media, and have traced how popular culture participates in the formation of identities, collectivities, and imaginaries.

Anthropological perspectives underscore that popular culture cannot be generalized across different historical and cultural contexts simply on the basis of the mass media apparatuses. Producers and consumers of mass media are, fundamentally, social and historical

subjects and mass media are, primarily, cultural institutions that need to be studied in their concrete particularity. Hence, we cannot conceptualize relationships between popular culture and the social actors who engage its myriad texts in the abstract: neither can be studied outside their location in specific socio-historical contexts.

Several anthropologists have engaged in analyses of mass media texts. These scholars, together with those who study the reception of mass media, carefully situate popular culture in the discursive and historical contexts in which it is produced and consumed. These studies undermine unilinear models of 'communication flows,' and foreground the importance of examining the specific conditions in which popular culture circulates.

3. *Popular Culture as a Lens for Studying other Sociocultural Processes*

Popular culture is a terrain where class identities are articulated, negotiated, and consolidated. The production and consumption of popular culture is mediated by class. For example, class provides individuals with 'cultural constraints' and a common 'outer frame of meaning' (Darnton 1984, pp. 6–7). A mutually influencing relationship exists between elite culture and popular culture. Popular culture also provides a site for the negotiation and articulation of class identities and hegemonies. Thus, in nineteenth-century India, Bengali elites took upon themselves the task of 'purifying' popular culture produced by working-class women: while their objective was ostensibly to 'emancipate' women of their class, their efforts resulted in the consolidation of their own middle- and upper-class identities through the marginalization of working-class popular culture (Bannerjee 1989).

The role of popular culture in mediating discourses of gender and sexuality has long been acknowledged. Two pioneering works in this regard are Laura Mulvey's *Visual Pleasure and Narrative Cinema* (1975) and Janice Radway's *Reading the Romance* (1984). Laura Mulvey examined how the cinematic forms and narratives of classic Hollywood film 'suture' viewers into 'spectatorial positions' that reinscribe dominant ideas about gender and sexuality. Mulvey's work provided feminist critics of popular culture with a paradigm for examining the role of mass media in the constitution of discourses of gender and sexuality. Janice Radway's work laid the foundation for studying the role of a specific genre of texts, romance fiction, in the constitution of discourses of gender and sexuality. Radway situated women's reading practices in their social relationships and everyday lives, and studied their interpretations of different romances in order to analyze what the books mean to their readers.

Since the publication of these works by Mulvey and Radway, the relationship of popular culture to gender

and sexuality has been analyzed by scholars too numerous to cite. Some of the most noteworthy studies in this regard, however, come from scholars, chiefly anthropologists, who have examined media in non-Western contexts. These include the analysis of the relationship between popular culture, gender and sexuality in Japan (Allison 1996), and television and notions of modern womanhood in Egypt and India (Abu-Lughod 1993, Mankekar 1999, respectively). The significance of these studies lies in their decentering of Eurocentric perspectives dominant in cultural studies, media studies, and feminist studies.

Some scholars have argued that the conceptualization of popular culture was itself engendered by the emergence of nationalism (Burke 1978). Building on Benedict Anderson's insights about the role of print capitalism in the construction of nations as imagined communities (1983), several scholars have examined the role of popular culture in the formation of national identity. For instance, diverse forms of popular culture, including tourism, exhibitions, material culture and consumption, have enabled the constitution of the national imaginary in China (Anagnost 1997). In some parts of the developing world, television has been consciously deployed to construct a 'national community': in Mexico and Venezuela, indigenous soap operas called telenovelas have combined entertainment with 'social messages' about development. In India, state-owned television was harnessed to the explicitly nationalist goals of development and national integration (Mankekar 1999) and, furthermore, participated in the consolidation of an exclusionary and strident Hindu nationalism (Rajagopal 2000).

Yet, at the same time that popular culture enables the constitution of local and national communities, some of its forms are inherently transnational. Thus, the telenovelas described above circulated not only within but across national borders in Latin America, and were adopted as models for the television programs in India. In addition, the transnational circulation of popular culture has resulted in the creation of new forms of diasporic identities. The transnational circulation of newspapers, film, television programs relayed via satellite, advertisements, and mass market fiction have created, what anthropologist Arjun Appadurai terms, 'mediascapes' (1996). Mediascapes 'refer both to the distribution of the electronic capabilities to produce and disseminate information ... now available to a growing number of private and public interests throughout the world, and to the images of the world created by these media' (1996, p. 35).

The boundaries of cultures and nations have thus proved to be permeable to globalized and transnational forms of popular culture. Yet, globalization has not resulted in a homogenization of culture. At different historical moments, globalization has resulted in a recasting of 'tradition' and processes of

creolization (Hannerz 1996, pp. 67–77). Transnational popular culture thus forces us to revisit previously held notions of culture as bounded and systemic (Appadurai 1996, Gupta and Ferguson 1997).

Population Aging: Economic and Social Consequences

The notion of aging is quite natural for human beings: from the age of reason, we understand that with the passage of time, every living thing ages and finally dies. Young children experience this with their goldfish or dog, adults with their parents and old people with their friends. By analogy, we apply the notion of aging even to nonliving things: for example, as a car deteriorates, we say that it is getting old and eventually we relegate it to the scrap lot. Although a good wine may improve with age, in the end it becomes undrinkable.

From the individual, the notion of aging is extended to the group formed by the individuals: thus we speak of an aging fleet of cars or an aging population, meaning that the average length of life of the entire group of these individual units changes with the passage of time. However, unlike the case for the individuals making up the group, the group itself is able not to age, or even to get younger. This is the case for human populations. For them the aging process is strictly structural, not biological. The decay generally associated with the aging of individuals should not be assumed to apply to aging populations.

1. Population Aging: A Modern Demographic Phenomenon

A population changes through the interaction of the fertility, mortality, and migration of its members. In recent centuries, we have witnessed remarkable changes in human fertility and mortality, which, uncontrolled since time immemorial, had always been high. In the past, there was a 'natural' fertility and mortality, and population numbers throughout the world were relatively low. Eventually, people found ways to reduce first mortality and then fertility after a certain time lag. In theoretical terms, this historical process is known as the demographic transition (Chesnais 1986). During this process, the population grows at a higher or lower rate, depending on the extent of this time lag. At the end of the process, according to the theory, both fertility and mortality are low and the population stops growing. But an inescapable law of demography says that a population either grows or it ages (Coale 1987). As all populations around the world have reduced or stopped their

growth, they are all bound to age. In some countries the fertility level is well below the replacement level, and thus their populations will decrease unless they experience in-migration, a possibility not foreseen by classical transition theory.

There are several ways of measuring the aging of a population. Instinctively, one could say that a population is aging if the average—or median—age of its members as a group increases over time. Alternatively, one could look for an increase in the proportion of old people in the population. But at what age does a person become old? We do not want to enter into a debate over the exact threshold of old age or retirement, but for purposes of illustration we will use the percentage aged 65 and over in the population. To avoid delving too far into the past or future, we will restrict our discussion of demographic aging to the period from 1950 to 2050.

During the twentieth century, the growth in the number of people aged 65 and over was relatively small and there were roughly as many people old (according to this definition) in industrialized countries as in less developed countries. However, from now until 2050, this number will grow spectacularly, mainly because of the increase in less developed countries (Table 1a). But if we look at the proportion of people aged 65 and over in the population, as a measure of demographic aging between 1950 and 2050 (Table 1b), we see that the situation differs greatly from one continent to another. Africa will remain young while the more developed countries as a whole will have more than one-quarter of their populations in the 'old' category. Asia will age at an increasing rate: in 2050, it will have more than 900 million people aged 65 and over. This is two-thirds of the world's elderly population.

In the industrialized countries, the process of population aging is relatively slow, but in developing countries it will be more intense and rapid. This can be clearly shown by a comparison of Canada and China (Fig. 1). In 2050, China will be a world leader in demographic aging with almost 450 million people aged 60 and over. This is close to 30 percent of its total population.

In the face of globalization, the changes occurring over this century will give rise to a number of socioeconomic issues that would not have made themselves felt if population aging affected only the currently industrialized countries. There will be both demographic and economic and social consequences for our societies.

2. Demographic Consequences

As is easily demonstrated, in the early stages of the demographic transition aging is much more the result of a decline in fertility than in mortality. When mortality declines from a high level, it is primarily

Population aging in Canada and China, 1870–2050

early deaths that are eliminated, in particular deaths of children and young adults. The result is a younger (not older) population, as was seen in Africa in the 1950s and 1960s (Table 1b).

But when life expectancy is already very high, as is the case now in industrialized countries, mortality becomes an important factor in demographic aging. If mortality is low and decreasing, we get a double effect.

First, increasing numbers of people reach the old age threshold—because of lowered mortality before that age. Second, people live for increasing lengths of time beyond this threshold—owing to a continued decline of mortality at old age (Bourbeau et al. 1997). The main consequence of this development is that old people no longer form a homogenous group: we now have the young old, who generally are in quite good health, and the oldest old, who generally are more dependent for income security and health. Thus we have moved from having three main lifecycle stages to four. There is a new third age that extends from retirement to the oldest-old stage. This is an entity that never existed before in human history (Laslett 1989). Another important feature in mortality changes in many societies has been an increased mortality gap between men and women. Very frequently old people in these societies are and will continue to be primarily old women.

Like any other population, the elderly population is subject to a process of incessant inward and outward movement of cohorts. In most industrialized countries the incoming generations will be clearly differentiated with respect to their numbers and their characteristics. The generations now approaching retirement are the Baby Boomers born after World War II. They will be followed by the Baby Busters, who are far less numerous. These generations, particularly the women,

will have characteristics very different from those of today's old people (Marcil-Gratton and Légaré 1987), especially in terms of education.

The changes in the age structure of our societies will cause major realignments that affect not only the elderly but the entire population. In terms of health and financial security, will old people be more independent or more dependent than before? The increasing presence of very old people tends to suggest dependence, while the characteristics of the future younger elderly appear to suggest greater autonomy. Will the younger adults, who are far less numerous than the Baby Boomers, be willing to pay for a golden twilight for tomorrow's seniors? We now turn to these questions in the following sections.

3. Economic Consequences

3.1 The Aging Process and the Working-age Population

At the beginning of the population aging process, a standard age pyramid shows the population cohorts by age increasingly reduced by mortality. As the process gradually proceeds, positive impacts on the working-age population appear. The decline in mortality eliminates early deaths and increases population numbers. Then, as the effects of fertility decline come to the fore, cohort size is increasingly reduced. When mortality improvements lead to significant reductions in old-age deaths, the members of the retired cohorts become as numerous as, and sometimes more numerous than, those of working-age cohorts. The pyramid changes into a top and finally into a cylinder. This means that at the end of the aging process, all generations are of approximately the same size except for the very old. This process is reflected in the variations of what are commonly called the dependency ratios, one of which is the ratio of people aged 65 and over to those aged 19–64. Unfortunately, the use of the adjective 'dependency' may unduly give an impression of economic dependence. These indicators are merely indices of the age structure and it would be more appropriate to speak of demographic dependency ratios.

In studies of aging we frequently find the members of the working-age population equated to actual workers. While in the past this was true for men when their labor force participation rate was close to 100 percent, it is now less so, in particular for women. To assess the economic impacts of aging and our ways of dealing with them, we needed to take into account not only population numbers, but perhaps more importantly labor force participation rates and worker productivity (Fellegi 1988). If the shift from agricultural to industrial societies had great impacts on the world of work, the shift to aging post-industrial

societies will have an equally great impact. This is particularly true for the change in the rate of labor force participation by women and by older workers.

The radical decline in fertility and otherwise changing family arrangements has freed women from a myriad of family duties and made them available for increased participation in the paid labor market. The women's liberation movement also contributed to changes in attitudes and women are becoming increasingly independent, not only at working age, but also, and perhaps especially, during retirement.

One of the corollaries—and achievements—of the development of industrial societies has been the right to retirement and associated pensions. In this century we have witnessed a decline in the labor force participation rate of older workers, along with a systematic decline in the age of leaving the labor market. This ever-earlier retirement from the labor market is now increasingly being questioned. As life expectancy increases, especially at old age, and as the time spent taking education is extended, the life segment in retirement is growing longer and the segment in which one works is getting shorter. When a large and growing share of the costs of social security, including pensions and health insurance, is borne by those who work, some adjustments must be considered. It is not possible to maintain contribution and benefit levels and, simultaneously, to bring down, or even maintain, the age of access to benefits.

There is a need for greater flexibility, both in wages and responsibilities for the population approaching retirement. For older workers, one should consider a gradual progression from wages to pension income, perhaps following a normal rather than S-shaped curve. This may call for a change in attitudes, not only among the workers themselves but also among employers and trade unions.

Solidarity among generations presupposes a minimum of equity between groups. When social security programs in the industrialized countries were re-organized after World War II, both the population and the economy were growing: the populations were young. Pay-as-you-go financing did not create any visible problems and it eliminated some perverse effects of funded programs, many of which had collapsed in Europe during the Depression and the war. In aging societies—particularly those which have experienced a large baby boom followed by a baby bust—a hybrid system combining pay-as-you-go and funded elements is likely to be more equitable across generations.

At present, the labor market is undergoing major changes. Workers will no longer hold full-time jobs for life the way they did previously in industrial societies. New workers will enter the labor market later in life. They will hold part-time jobs with varying employers, more often and possibly for a significant part of their working life, or be self-employed. From time to time they will have periods of unemployment or of retrain-

ing. Moreover, such patterns, which formerly applied mainly to women, will now apply to men as well. Consequently, retirement systems based on previous labor market participation and involving individual employers will be subject to in-depth revision. In addition, one should take the value of unpaid work into account. In particular, work performed to raise children or to care for aging parents needs to be recognized.

3.2 An Aging Society: A Burden?

Because population aging is equated to individual aging all too often, one tends to highlight problems for aging societies, in particular problems related to the costs of health and pension programs for the elderly. On this subject some issues need to be clarified and some myths should be dispelled.

First, the situation of old people in most countries has improved greatly largely as a result of post-war social programs. There have even been hard economic times when their situation has deteriorated less than that of younger people.

Second, health and pension costs will certainly continue to increase in aging societies, but at what rate will this happen? With regard to health Zweifel et al. (1999) have shown that increases in medical costs are more closely linked to the number of old-age deaths than to the size of the elderly population, and the number of old-age deaths is increasing much less rapidly than the size of the elderly population. The same is not true for pensions, whose costs are linked directly to the number of old people. However, one should not forget that retired people also pay taxes, both on their income and on consumption. As people age, their material needs (other than those related to health) decrease, however, and this might be reflected in their pension requirements.

Third, although incomes are on average lower at old age than at other ages, the elderly often hold a large share of the collective wealth through their assets, in particular by owning of their dwellings.

In brief, far from being an impediment to economic development, elderly people in aging societies can sometimes serve as an important actor if not the engine of such development.

4. Social Consequences

Increasingly, the group of old people is not homogeneous with regard to health status and wealth, and this has numerous consequences for their life-style. First, let us recall that to a large extent the world of the elderly is a world of old widows. This feature has become increasingly prominent over the twentieth century, as excess male mortality has grown while the difference in age at marriage has remained stable. In

addition, this century has been characterized by the quest for greater independence at all ages. Old people in industrialized countries prefer to live alone if they do not live with their spouse, particularly when they are in good health. But this choice does not necessarily imply isolation. Alternatively, living together with people other than one's late spouse may become a strategy for dealing with financial or health problems, perhaps as a stage that precedes institutionalization.

Multigenerational households are much more common in less industrialized countries, mainly for cultural and economic reasons. We can only wonder what will happen in the future in these societies. In a context of rapid urbanization and scarcity of dwellings, there will be an acceleration in aging following the sharp decline in fertility. With its one-child policy, China is a particularly poignant case. Demographic constraints may become apparent as daughters and daughters-in-law become increasingly less numerous and less often available to take care of old parents.

In societies with low mortality (or equivalently, long life expectancy), early deaths are reduced to a minimum and are usually related to life-style rather than caused by exogenous diseases. This produces a great deal of interest in the population's health status, and public health policy objectives may concentrate on insuring quality of life for the aging population more than on preventing early adult deaths. The focus moves from mortality to morbidity, from life expectancy to healthy-life expectancy (Robine and Romieu 1998). By means such as surveys on seniors' functional capacities, it is possible to identify impediments to independent existence and to develop policies that will minimize the adverse effects of biological and social aging.

Such policies are centered on support networks. Assistance provided to old people may come from professionals hired by the state, the community, or private enterprise. Alternatively, they may be offered by the family, friends, or neighbors. The expanding need for services provided through such formal and informal networks is an increasing source of concern. For the informal networks, the many changes that have occurred in family structures leave future prospects unclear; for the formal networks, it is mainly the cost that worries public policy makers. In this picture one should not forget that seniors are not only receivers of assistance, but very often also providers.

5. Conclusion

Some believe that the twenty-first century will see the emergence of intergenerational conflicts similar to the gender conflicts of the twentieth century. Major transformations of the population age structure have altered the ratio between the retired and the working population and will continue to do so. In addition to solidarity among generations, any reforms to social

security programs taking account of the new demographic reality need to aim to promote inter-generational equity. For this purpose, we have seen the development of new measurement techniques, known as demographic accounting (Auerbach et al. 1999). By making use of individual-level data and by making adequate long-term projections we will be able to benefit from these new methodologies.

In conclusion, we observe that for centuries, life in all its forms was regulated by nature. Gradually, human societies became able to control their destiny by largely controlling their mortality and fertility. This resulted in great changes for the societies, and in particular it accelerated their aging. The fact that most now live to old age and that our populations progressively age can only be regarded as great cultural progress (Loriaux et al. 1990). However, like all progress, individual and societal aging must be managed skillfully. Moreover, we are in the midst of a process of shifting control from society to the citizen (Légaré and Marcil-Gratton 1990). Decisions concerning demographic behavior, like whether or not to get married, whether to have children, how many and when, whether to leave an existing marriage and contract another one, and so on, are now made on the individual level more than ever before. In a world where centenarians will become rather common, people will doubtless also want to have a say on the timing of their departure from life.

Population and Technological Change in Agriculture

Induced innovation refers to the process by which societies develop technologies that facilitate the substitution of relatively abundant (hence cheap) factors of production for relatively scarce (hence expensive) factors in the economy. For example, the choice between land saving vs. labor saving technological change has been largely determined by the relative scarcity of land and labor in a particular society (Hayami and Ruttan 1985). Population pressure has played a defining role in technology development and farmer choice of technologies. Ester Boserup (1965) argued that societies across the world have responded to increasing land scarcity in a strikingly similar and predictable manner, by increasing land productivity through agricultural intensification. The transition from low-yield, land-extensive cultivation systems to land intensive, double and triple crop systems has only been profitable in societies where the supply of uncultivated land has been exhausted (Boserup 1965, Hayami and Ruttan 1985, Pingali et al. 1987). The process of agricultural intensification has been observed in traditional as well as modern agricultural societies.

The movement from forest and bush fallow systems of cultivation to annual and multicrop cultivation systems, whereby plots of land are cultivated one or more times per year, has generally been influenced by rising population densities in traditional societies (Boserup 1965). It is no accident that the modern seed-fertilizer revolution has been most successful in densely populated areas of the world, where traditional mechanisms for enhancing yields per unit area have been exhausted.

Kikuchi and Hayami (1978) document the process of land augmentation as the cultivation frontier closes for Japan, Taiwan, Korea, and the Philippines. 'As population pressure pushes the cultivation frontier into marginal areas, we expect the marginal cost of agricultural production via expansion of cultivated area to rise relative to the marginal cost of production via intensification. Eventually the economy will reach a stage at which internal land augmentation becomes a less costly means of increasing agricultural output than external land augmentation' (Hayami and Ruttan 1985, p. 310).

In addition to high population densities, intensive cultivation will also be observed in areas with better access to markets, provided soil conditions are suitable. Intensification occurs in the less densely populated areas for two reasons: (a) higher prices and elastic demand for output imply that the marginal utility of effort increases, hence farmers in the region will begin cultivating larger areas; and (b) higher returns to labor encourage migration into well-connected areas from neighboring regions with higher

transport costs. In other words, where population densities are low, the returns to intensification are high only if markets, domestic and/or export, are easily accessible, such as the Central Plains of Thailand or parts of South America's Southern Cone. If these conditions are not present, labor and other costs associated with intensive agriculture are substantially higher than its incremental economic returns.

1. *Farmer-induced Technological Change in Traditional Farming Systems*

Pingali et al. (1987) documented, in the case of Africa, the movement from shifting cultivation to permanent agriculture with increases in population densities and improvements in market infrastructure. As land became scarce, traditional farming communities across sub-Saharan Africa extracted higher and higher levels of output from their land through investments in land improvements and soil fertility management. Erosion control, irrigation, and drainage are the most commonly made land investments for enhancing productivity. Tiffen et al. (1994) provided an excellent case study from the Machakos District of Kenya on the process of intensification and farmer investment in land improvements.

The extent of intensification is conditional on the relative responsiveness of the soils to inputs associated with intensive production such as land improvements, manure, and fertilizers. As population densities rise, one observes the cultivation of land that requires substantially higher labor input but that is also more responsive to the extra inputs. The responsiveness to intensification is generally higher on soils with higher water and nutrient holding capacity; these are usually the heavier, clayey soils, rather than the lighter sandy soils (Pingali et al. 1987). The movement from communal access, to individual property rights, with population growth induced increases in land values, provide individuals the incentive to invest in land improvements and other technologies necessary for intensive agricultural systems (Binswanger and Deininger 1997). Formal land ownership as characterized by the possession of a title also helps the farmer in acquiring credit for making the necessary investments in land and technology (Pingali 1990).

In using population densities as a basis for predicting the level of agricultural intensification, one ought to standardize arable land by soil quality and climate. Binswanger and Pingali (1988) provide a standardized population density measure: the number of people per million kilocalories of production potential. This measure is called the agroclimatic population density. When countries are ranked by agroclimatic population densities, Niger and Kenya turn out to be more densely populated than Bangladesh, and India ranks only twenty-ninth rather than seventh as in the traditional

population rankings. This explains why one observes intensive cultivation in some sparsely populated countries with poor market infrastructure—Niger and Botswana are examples.

2. Adoption of Modern Scientific Innovations

The intensification of traditional farming systems was a process that the more densely populated regions of Asia had been through several decades, and in some cases centuries, earlier. The application of modern scientific innovations in the form of high yielding seeds and fertilizer allowed the extremely land scarce regions of Asia achieve levels of land productivity that were not possible through the exclusive reliance on traditional farmer innovation systems.

A cross-sectional comparison across Asian countries shows that the proportion of irrigated area and the percentage of area under high yielding varieties of crops (HYVs) and fertilizer use is positively related to population densities (Pingali et al. 1997). It was not a historical accident that research for enhancing the yields of the two major food crops of Asia, rice and wheat, began in the 1950s. Research investments for enhancing yields were made in response to declining opportunities for area expansion, which was the main source of output growth in the pre-Green Revolution Asia. A comparison of sources of rice output growth during the early and late Green Revolution periods shows that the overall rate of growth was similar for the two time periods. In the early period, one-third of the growth came from an increase in cropped land, while in the latter period almost all of it was due to yield increases. The adoption of the Green Revolution technologies has been spotty in other parts of the world; this reflects in part the differences in land and labor endowments relative to Asia (Pingali and Heisey 1999). Research on induced intensification has not been restricted to the agricultural economics literature alone; a substantial number of comparative studies that look at the process of intensification, over time and over space, can be found in the geography–anthropology literature; see for example, Turner and Brush (1987) and Turner and Ali (1996).

3. Labor Use and Employment and Labor Saving Technologies

In both traditional and modern agricultural systems, intensification of agriculture leads to an increase in labor use per hectare, due to an increase in the number of tasks performed, such as irrigation, drainage, etc., and due to an increase in the intensity with which some tasks have to be performed, such as more intensive manure use and weeding (Pingali et al. 1987). Intensification therefore leads to an increase in agricultural employment as well as an increase in yields per hectare.

Labor productivity can only be sustained, as intensity rises, if labor saving technologies are available.

Pingali et al. (1997) have argued that the adoption of the plow in African agriculture has been closely associated with the level of intensification. Similarly, increases in labor productivity in Asia are associated with the increasing adoption of labor saving technologies, both as a means of saving on the higher labor needs due to intensification as well as a means of economizing on labor as its opportunity cost rises with economic growth. The movement from single-crop cultivation systems to a double- and triple-crop systems shifts out the demand for labor and also increases the demand for timely completion of operations. Initially, the switch to modern varieties was profitable, even with higher labor requirements per hectare, because the labor requirements per ton of paddy were lower compared with that of traditional varieties (Barker and Cordova 1978). Over time however, increasing labor demand for peak period operations led to a rise in real wages for these operations, even in densely-populated labor surplus countries such as India and Indonesia. The rise in wages was further exacerbated by the concurrent growth in the rural nonfarm sector and increasing employment opportunities in the urban sector, as has happened in Japan and Korea and now being witnessed in Southeast Asia.

Widespread adoption of labor-saving mechanical and chemical technologies has alleviated the growing labor constraints, and contributed substantially to overall productivity growth (Sidhu and Byerlee 1992). The most notable confirmation of this hypothesis comes from the now developed country, Japan, where graphs plotting the log of land productivity vs. the log of labor productivity show almost no increases in land productivity but substantial gains in labor productivity in the last 30 years (Hayami and Ruttan 1985, Craig et al. 1997).

4. Intensification and Degradation—When Does the System Break Down?

The process of population induced technological change is by no means automatic; there are several instances where societies faced with growing population pressure have not been able to achieve sustainable intensification. Failures in agricultural intensification can be attributed to one or more of the following reasons: persistence of uncertain long-term rights to land; encroachment of cultivation onto marginal lands; collective effort required for watershed-level protective investments; and an inappropriate policy environment.

Farmer incentives for regenerating soil fertility and for making erosion-prevention investments are high if secure long-term land rights exist, both to currently cultivated land and to fallow land. Where farmers do

not have long-term rights to land, the private rate of discount is higher than the social rate of discount, hence private investments in land productivity will be lower than the societal optimum. In societies with slowly and steadily growing populations, property rights to land evolved systematically, being induced by growing land scarcity. However, the evolution to secure land rights has not been successful in societies experiencing rapid population growth (through natural increase or through migration), nor in societies where this induced institutional change is circumvented by government policies (e.g., land expropriation by colonial authorities or socialist governments).

Given secure rights to land, the rate of return to land investments varies by agroclimatic zone and soil type: degradation problems are most severe where the returns to land investments are lowest. The arid fringe areas, upper slopes in the semi-arid and the humid zones, and shallow sandy soils exhibit the highest levels of erosion, other things being equal. Degradation problems are likely to be most severe in regions with relatively large endowments of marginal lands.

Degradation of marginal lands is also likely to be severe where institutional arrangements are not available for controlling access to grazing and forestry. Where privatization is infeasible or undesirable, community action or government intervention is required both for control of access and for investments in erosion control and forest replanting. Difficult dilemmas frequently arise as traditional users are threatened with a loss of their use rights. Societies are often incapable of solving these problems of ownership or controlled access before serious damage has occurred.

In several instances, inappropriate policies, both micro- and macroeconomic, have created disincentives for farmer investments in land productivity enhancing and/or resource conserving technologies (Heath and Binswanger 1996). Pingali et al. (1997) argue that even in the intensive lowland cereal production systems, where Green revolution technologies were most successfully adopted, price and trade policy distortions are leading to significant levels of environmental and ecological degradation.

The potential problems of declining labor productivity and environmental degradation are not problems of levels of population densities. Given sufficient time, it is likely that a combination of farmer innovations, savings, and the development of research facilities and institutions for dealing with soil degradation issues will be able to accommodate much more than the current population in most countries, especially in many of the less densely populated ones. However, if all these changes are required quickly and simultaneously because of high population growth rates, they may emerge at too slow a pace to prevent a decline in human welfare.

Population Composition by Race and Ethnicity: North America

In the three nations of North America—Canada, the United States, and Mexico—ethnicity has different connotations and is officially recorded using a variety of measures. Weber's (1978) definition of ethnic groups as those that share 'a subjective belief in their common descent because of similarities of physical type or of customs' permits various attributes to be used to characterize ethnic boundaries. Not only do these traits vary from place to place, but they change over time as well. In contemporary Mexico, the primary ethnic distinction is between the indigenous and non-indigenous populations. Statistics Canada records national origin, minority and aboriginal status, and religion. Finally, the US Census Bureau solicits race and Hispanic origin, and for a subset of the population, inquires about ethnic ancestry.

1. Historical Perspective of North America's Ethnic Composition

The peopling of North America has been shaped by the presence of indigenous Americans, European colonization, African slavery, voluntary immigration, and for Mexico, considerable emigration. Along with differential fertility and mortality rates, these factors have dramatically transformed the continent's ethnic landscape over time.

The size of the indigenous population of North America at the time of European colonization is unknown. Estimates for the pre-Contact population of Canada and the US range from 900,000 to 18 million (Snipp 1989), while similar estimates for Mexico range from 4.5 million to 25 million (Alba 1977). Despite the lack of consensus about fifteenth-century population levels, there is widespread agreement that in the wake of European colonization, indigenous depopulation was severe. Although 200,000 Native people were estimated to inhabit Canada when the French began settlement in the early seventeenth century, less than 100,000 remained by 1867 (Anderson and Frideres 1981). In 1548, 6 million indigenous people were estimated to inhabit Mexico, but by 1605, only 1 million remained (Alba 1977). Depopulation estimates for North America as a whole have been put at 1.75 million to 4.75 million between 1500 and 1890 (Snipp 1989).

As Native American population levels dropped, the arrival of Europeans, and to a lesser extent Africans, began a repopulation process that transformed the demography of North America. Until the twentieth century, Canadian immigration would be dominated by the arrival of English and French settlers, while in the US, English colonization followed by German, French, Dutch, Irish, and Scotch-Irish immigration

was accompanied by the coercive importation of African slaves. Although Africans were a feature of colonial Mexican society, their shares were extremely small and highly concentrated geographically.

Despite some similarities in their peopling processes, the three nations of North America have experienced distinct immigration trends following the European colonization. In 1870—soon after Confederation and almost 400 years after Christopher Columbus arrived in the Americas—Canada's population was overwhelmingly European-origin; 61 percent of approximately 3 million claimed roots in the British Isles and 31 percent reported French ancestry (Anderson and Frideres 1981). In contrast, the US population of over 38 million was more ethnically diverse: nearly 13 percent were 'colored' (i.e., black) (US Census Office 1883).

Three waves of immigrants diversified Canada's population during the twentieth century. Around the turn of the century, the European origins of Canadian immigrants changed, but remained overwhelmingly white. From 1896 to 1914, 3 million new immigrants responded to government incentives to settle the western prairie provinces, and the majority were German, Slavic, or Scandinavian. In a second wave from approximately 1946 to 1961, Canada absorbed 2 million newcomers, mainly Europeans who were fleeing the aftermath of World War II. Finally, in the wake of immigration reforms after 1970, the share of European immigrants dropped sharply from 76 percent in 1966 to 39 percent in 1973, while arrivals from Asia jumped from 6 percent to 23 percent (Anderson and Frideres 1981).

Like Canada, the volume and national origin composition of US immigration flows has varied over time. In the early years of the republic, the population was largely of English, German, Irish, and African origin. When the legal importation of slaves was halted in 1808, the black population stood at over 16 percent of the total (US Census Bureau 1976). Concurrent and continued immigration for Italians, Russians, Poles, and Scandinavians boosted the white population during the nineteenth and twentieth century. Following the 1965 Amendments to the Immigration and Nationalization Act, immigrants from Asia and Latin America have dominated flows. As a result, the US has become both less white and black than it was at its founding.

Mexico's demographic evolution has differed in several ways from its neighbors to the north. After the decline of the indigenous population that characterized the early colonization, and the subsequent period of Spanish settlement and African slavery, the Mexican population grew slowly by natural increase, as it was untouched by the large-scale immigration to the US and Canada. From the sixteenth through the seventeenth centuries, admixture between Europeans, Indians, and Africans produced the *mestizo* population that characterizes Mexico today. Both fertility

and mortality rates were high throughout this period, and remained so well into the twentieth century. At the beginning of the nineteenth century, when the colonial period came to a close, Mexico's total population stood at 6 million—roughly equivalent to the indigenous population prior to colonization (Alba 1977). Mexico's indigenous population rebounded following a decline between 1900 and 1920 (as did the national population in the wake of the Mexican Revolution, emigration, and an influenza epidemic).

2. Contemporary Population Composition in North America

Recent changes in the ethnic composition of North America derive from three processes, namely immigration, intermarriage across race and ethnic lines, and differential fertility rates of natural increase. Inconsistent reporting categories over time preclude precise estimates of the magnitude and components of change, but general inferences about the relative importance of each are possible. Accordingly, we discuss the contemporary ethnic landscape of Canada,

the US, and Mexico and conclude with a broad comparison of the primary axes of ethnoracial differentiation among the three countries.

2.1 Canada

Table 1, which displays Canada's population composition in 1961 and 1996, reveals both increasing ethnoracial diversification over the 35-year period and also persisting dominance of European ancestries. Despite comparability problems over time, the two most salient differences are the absence of 'Canadian' as an ethnic category in 1960, and the allowance for multiple ancestries. In 1996 nearly 18 percent of all residents identified as 'Canadian'; this figure approaches one in five if the aboriginal population is added. Between 1961 and 1996 the aboriginal population increased its share slightly, but remains a tiny share of the total population. In 1961, virtually all Canadians (97 percent) traced their origins to a European ancestry, and of these, nearly three in four identified as either British or French origin. As recently as 1996, the majority of ethnic Canadians identify with

Notes: a The estimate of the 1960 Hispanic population is from Cary Davis, Carl Haub, and JoAnne Willette, 1983. 'US Hispanics: Changing the Face of America.' *Population Bulletin*, Vol. 38, No. 3, p. 8, Table 2.

b For 1960, the Asian population comprises the categories 'Japanese,' and 'Chinese,' and 'Filipino' only. In subsequent years, Koreans, Vietnamese, Asian Indians, Samoans, Guamanians, and Hawaiians were also included.

European ancestries; nearly half (48 percent) of all single origin ancestries reported in 1996 were from Europe.

Among Canadians who report a single ancestry, the major change in ethnic composition derives from shifts in the source countries of immigrants. Prior to 1961, fewer than 1 percent of Canadian residents derived from the Middle East, Latin America, or Asia, compared to 19 percent by 1996. Canadian immigration from these regions is relatively recent, which explains their small population shares at the turn of the twenty-first century. Among the million foreign-born Canadian residents admitted before 1961, less than 5 percent were from Asia, Africa, or Latin America. But, as the volume of immigration to Canada increased, so too has the representation of these groups among new arrivals. Should current immigration trends continue, Canada's ethnic mosaic will be very different in the middle of the twenty-first century. However, the homogenization of Canadians through assimilation and intermarriage may also swell the numbers who identify in nonethnic terms as 'Canadian.'

2.2 United States

Table 2 presents the ethnoracial composition of the US in 1960 and 1990 based on the last two censuses, and for 1999 based on Current Population Survey estimates. The broad groups are the official categories approved by the Office of Management and Budget. Like Canada, the US racial classification scheme evolved to reflect the rapid growth of the Hispanic population and increasing diversification of Asian populations. Although Hispanics can be of any race,

the vast majority is considered white because *mestizo* has not been an acceptable racial category for administrative reporting purposes. In 1960, the Asian and Pacific Islander category included only Japanese, Chinese, and Filipinos, but when the racial classification was revised and expanded in 1980, Vietnamese, Asian Indians, Samoans, Guamanians, and Hawaiians were added as separate racial groups. In 1990, the US Census identified nearly 1,000 unique racial and ethnic codes, which included nearly 400 American-Indian tribes, hundreds of detailed Asian and Pacific Islander groups, and many more self-identified nationalities.

Changes in the US racial classification system notwithstanding, trends in ethnic composition are clear. The white share of the total population has been falling steadily, from 85 percent in 1960 to 76 percent in 1990 and 72 percent in 1999; the black share grew slowly from 10.5 percent in 1960 and remained stable around 12 percent during the 1990s, while Hispanics and Asians increased their population shares. Census projections indicate that the Hispanic population will surpass blacks by 2003 or sooner. Less than 1 percent of the 1960 US population was Asian, but by 1999 Asians comprised almost 4 percent of all US residents—a seven-fold increase since 1960. Although Asians are the fastest growing minority population in the US, their population share remains low for historical reasons, primarily due to laws restricting their admission as immigrants until 1968. Compared to blacks, Hispanics and Asians, the indigenous population of the US remains tiny. In 1960 less than 0.3 percent of the total population consisted of indigenous groups, and by 1990 this share had increased to 0.7 percent. Part of this increase is an artifact of changed reporting criteria that increased incentives and opportunities for individuals of mixed

Table 3
Ten most frequently cited ancestries, 1990

a The ancestry data includes multiple-ancestry reports. A person who described herself as 'French' and 'English' would be counted twice, once under each ancestry listing.

racial origin to self-identify as Native American (Snipp 1989).

Because the US reports race and ethnic origin separately, ancestry data are instructive about the impact of historical and recent immigration trends on the ethnic landscape. Table 3 reports the 10 most frequently reported ancestries in 1990. Multiple responses are double counted; therefore the white population is more heavily weighted because they tend to report more ancestries (resulting from intermarriage) and because inter-racial marriages are typically rare. Germans, Irish, and English are the top three most frequently reported ancestries, followed by African-Americans and Italians. Only 4.2 percent of the US population identified as 'American,' but this figure would be higher if multiple ancestries were not double

counted. The prominence of Mexicans among the top 10 ancestries reflects the dramatic growth of this population through immigration since 1960. Between 1970 and 1995, for example, the Mexico-born population of the US increased eight-fold, rising from 750 thousand to 6.2 million. Currently, Mexico is the largest single source of US immigrants.

Census Bureau projections using moderate assumptions about mortality, fertility and intermarriage patterns and current immigration levels indicate that by the year 2020, 65 percent of the US population will be white and 13 percent black. However, the two groups most affected by immigration, Hispanics and Asians, are projected to comprise 16 and 7 percent, respectively, of the total population. This is a marked change from 1960, when Hispanics and Asians combined made up less than 5 percent of the total. In recognition that intermarriage will continue to blur ethnic and racial boundaries, plans for the US Census 2000 will allow Americans to identify themselves using multiple races.

2.3 Mexico

Mexican ethnoracial categories are less differentiated than either Canada or the US mainly because it is a country of emigration rather than immigration. In Mexico the key racial division is between the indigenous and *mestizo* populations, and use of an indigenous language is the only measure the government now uses to draw this racial distinction. This is because designating members of indigenous groups hinges much more on sociocultural characteristics (like language) than phenotype or precise blood lineages, as practiced in the US.

Table 4
Mexico: indigenous language speakers, 1900–90 population aged 5 and above

Year	Spanish	Indigenous language*	Total population	Percentage indigenous language
1900*	11,528,345	2,078,914	13,607,259	15.3
1910**	13,200,063	1,960,306	15,160,369	12.9
1930	11,632,660	1,185,162	12,817,822	9.2
1940	18,410,534	1,237,018	19,647,552	6.3
1950	19,373,423	795,069	20,168,492	3.9
1960	33,818,174	1,104,955	34,923,129	3.2
1970	45,113,823	3,111,415	48,225,238	6.5
1980	61,665,795	5,181,038	66,846,833	7.8
1990	65,279,855	5,282,347	70,562,202	7.5
1995	74,735,782	5,483,555	80,219,337	6.8

* From 1950 forward, the 'indigenous language speakers' includes both those who do and do not speak Spanish. In earlier years, it is unclear if both groups are included.

** The 1900 and 1910 figures are for the entire population, not just those aged 5 and above.

Table 4 provides a glimpse of Mexico's indigenous population and its evolution since the turn of the twentieth century. The series reported in Table 4 is not totally consistent because the criteria used to enumerate the indigenous populations at times were restricted by age (5 years and over) and at times combined speakers of indigenous languages who did and did not speak Spanish. In 1990, the majority of the indigenous population spoke over 11 different languages, but Nahuatl, Maya, and Zapoteco were the three most commonly spoken. Mexico's indigenous population is concentrated in the southern and least developed states, with Quintana Roo, Yucatan, Campeche, Chiapas, Oaxaca, Guerrero, Puebla, Hidalgo, and Tlaxcala housing the vast majority of indigenous peoples.

Despite changes in enumeration criteria, the historical record shows a clear decline in the share of indigenous people in Mexico's population. The indigenous population has grown strongly in absolute terms, but this is due partly to improvements in enumeration and coverage over the period. At the turn of the century, 15 percent of Mexicans were indigenous language speakers but by 1995 this share had been halved. In relative terms, the indigenous population of Mexico is shrinking. Mexico's declining linguistic diversity is due to social and economic integration of indigenous minorities through internal migration, urbanization, and modernization processes. Further shrinkage of Mexico's indigenous population is likely in the future, but linguistic diversity is likely to persist much longer than in Canada and the US owing to the larger population base and the persisting rural isolation of many groups.

2.4 Comparative North American Perspective

Canada, the US, and Mexico have some similarities and many differences in the composition and evolution of their ethnoracial landscapes. First, despite rising immigration to Canada and the US from Asia, Africa, and Latin America, both countries have witnessed an increase in the population shares that do not self-identify in ethnic terms, but report themselves as Canadian or American. Second, by comparison to Mexico, Canada and the US have much smaller indigenous populations. Third, unlike the US, Canada and Mexico have negligible shares of residents who trace their ancestries to Africa; owing largely to the legacy of slavery, blacks comprise over 12 percent of US residents. Finally, immigration has diversified the ethnoracial landscape of Canada and the US since the 1960s, but Mexico has witnessed a negligible impact of foreign admissions. As an emigrant country, Mexico's population composition will be driven by the assimilation of indigenous populations into the national population, a process that is shaped largely by social and economic change, along with internal migration and intermarriage patterns.

Population Cycles and Demographic Behavior

1. Population Cycles in the Context of Intellectual History

Population studies and economic theory have been developed and discussed in conjunction with one another since the early nineteenth century. At this time Thomas Robert Malthus devised the ingenious theory, influenced by religion and controversial in its time, that bears his name. Ever since then it has been assumed within the social sciences almost as a matter of course that a strong linkage exists between demographic and economic factors. Malthus elaborated his classical theory around the year 1800. There were few new theoretical contributions for a long time afterwards, and those that came forth were not especially

significant. Until well into our own day, therefore, Malthus' basic ideas dominated the scene. According to his theory the causal relation between population and the economy goes chiefly in one direction—population changes play only a passive role and are determined by changes in the means of subsistence. Furthermore, in his system a single demographic variable, i.e., mortality, is mainly influenced by the economy. Although Malthus points out that moral restraint and the postponement of marriage may counteract excessively strong population growth, mortality is the dominant force adapting population size to the existing means of subsistence.

By contrast, theoretical developments have proliferated rapidly during recent decades. Entirely new models have emerged to elucidate the interaction between the population and the economy. This has given rise to population economics as a new and vigorously expanding field of scholarly endeavor. Its reasoning is usually strongly rooted in traditional economic theory and often bears the imprint of Malthusian thinking. These developments have meant that the shaping of theory has taken quite another turn and has also become more diversified, with much greater breadth and depth than before. The major characteristics of modern population economics are discussed below.

First, interest has shifted from one demographic variable to another. The strong link which Malthus believed to exist between changes in the economic environment and mortality has been called into question. Mortality variations are influenced by a number of other factors, the means of subsistence and standard of living forming only one of these, and not always the most important one. Fertility—along with the factors which determine it, of which particular mention may be made of varying age at marriage, the use of birth control, abortion, and nutrition—has been regarded instead as being determined by economic factors in a way quite different from that found in Malthus. This does not apply only to modern society. Several studies have shown that even in preindustrial society, the link between fertility and economic factors was often stronger than the relation between mortality and the economy, in both the short and the long term.

Second, population variables have been linked more closely to economic theory, especially neoclassical microtheory, and have then usually been analyzed in a more stringent manner than is the case with the Malthusian theory. Here we may point to the 'micro-economic theory of fertility' or, as it is sometimes termed, the 'new household economics' or 'new home economics.' In this theoretical construction, fertility is viewed as the result of economically rational decisions (the demand for children). Established economic methods and conceptual mechanisms are employed in order to explain variations in fertility. For example, models are devised in which fertility is regarded as a function of income and the 'price' of children in

relation to the price of other goods and services. In this reasoning children are regarded as ordinary goods, exchangeable in the choice situation for other goods and services. Fluctuations in fertility are explained using only prices and incomes. The pioneering theoretical work in this area was done by Gary Becker (1960) and was then elaborated, for example by Becker and Lewis (1973); it has often been cited as one of the basic explanations of fertility variations in the Western world since World War II. Models have also been formulated along highly neoclassical lines and have been based on a traditional investment approach: cost-benefit analysis. This method regards fertility as being determined by how costs and revenues associated with children change over time. From this standpoint, accordingly, the strong decline of Western fertility which set in at the end of the nineteenth century should be regarded as a consequence of the falling revenues and rising costs which having another child would entail for the parents.

Third, Malthus' view that there is a one-way causality between the population and the economy has been abandoned. What is now emphasized is that the interaction between the population and the economy is considerably more complex than Malthus believed. In many instances, demographic events can be one of the most important factors underlying the process of economic change. In other words, the population factor may also, in many cases, be the independent variable, which in its turn influences the economy and the means of subsistence. According to this approach, numerous other elements of social change must be viewed in the context of changing population size and composition (e.g., Boserup 1965, Simon 1977, Easterlin 1980).

Fourth, the various models which have been developed to represent the interaction between the population and the economy have become considerably more dynamic in character. One important element marking this trend has been the wide-ranging research conducted into the incidence and causes of various population cycles and into their effects on social change. Intensive discussions have been conducted concerning the extent to which population cycles with varying durations and strengths can be identified; what demographic or other factors can be cited as explanations of their genesis; and what effects the various population cycles have had on demographic behavior and on the national economy as a whole.

2. The Mechanisms of Population Cycles

The study of population cycles goes a long way back in time. Its origins can be traced back to the northern European countries in the nineteenth century. As early as in 1855 Ejler Sundt, a Norwegian embryonic sociologist and statistician, observed that a strong rise

and fall in a country's birthrate is repeated during the next generation, though in a less marked fashion. On reaching marriageable age an extraordinarily large birth cohort will bring into the world more children than an age group of normal size. The same law applies in reverse: after one generation an undersized cohort will produce a new undersized group. As a result, regularly recurring waves or 'echo effects' are generated in the size and age composition of the population.

Ten years later, in 1865, the Swedish demographer Fredrik Berg paid tribute to Sundt for the idea of cohort analysis, and emphasized the importance of keeping different birth cohorts apart and studying them separately. He also argued that it ought to be possible to use variations in birth cohort sizes to compute the future number of births. Berg foreshadowed modern population projection techniques.

The Swedish demographer Gustav Sundbärg was a pioneer in expressing the view that a substantial change in birthrates may have far-reaching repercussions, not only on the economy but also on institutional and social change for a long time ahead. He may also have been the first to point out that *the size of a cohort* can have an impact not only on individuals' demographic behavior, but also on their behavior in numerous other spheres. Sundbärg developed these ideas in his analysis of the strong rise in the number of births in Sweden between 1815 and 1830, and its after-effects. Little by little the rise in births transmitted itself to higher age levels and grew in strength compared with earlier cohorts because mortality was also falling dramatically. Sundbärg believed that this rise had a far-reaching influence in many areas of social and economic development in Sweden all through the nineteenth century. He wrote in 1903:

As they reached school age these cohorts filled up all the school rooms so that their education and upbringing became a burning issue. As they reached working age they shattered the guilds (in the 1840s) and compelled the introduction of a more liberal trade legislation, without which these masses of people would have been unable to survive. As they reached marriageable age their large numbers enforced delayed marriage, and in the end (though not until the second generation) the great emigration movement. The immense class of 'all others' who were excluded from democratic representation at the time destroyed the constitution based on the four estates (in the 1850s and 1860s). And in our own day, having reached old age they fill our poorhouses and make the problem of disability and old age a matter of topical concern.

In 1937, the German economist August Lösch noticed that sudden and dramatic changes in the population structure, caused by war for example, generated long waves in population growth, which in turn brought about far-reaching changes in the economy. Great wars are characterized by a deficit of births during the war and a surplus of births in the immediate postwar period. In a now-classical article in the

Quarterly Journal of Economics, 'Population Cycles as a Cause of Business Cycles,' Lösch described how these features caused a population cycle which in turn gave rise to strong fluctuations in German economic growth and in the business cycle.

This discussion of the origins of population cycles and their influence on demographic and economic factors transmitted itself to the American scholarly arena after World War II. American researchers had been able to identify long cycles in US economic activity since the middle of the nineteenth century. How these cycles were generated and propagated became the object of extensive empirical and theoretical studies by American scholars during the 1950s and 1960s. They found that rather than being a passive response to changes in the economy, population cycles played an active role in determining the long cycles that had been observed in US economic activity. These long cycles could be found not only in aggregate production growth but also in most of its sub-components. This made it possible to identify long cycles in the growth of the labor force, in capital formation, in productivity, and in utilization of capacity. In particular, there was an extensive discussion on the existence of, and mechanisms underlying, Kuznets cycles—named after Simon Kuznets—or 'long swings,' as they are often called. Models were devised to show how changes in the age structure and population growth over about 20 years generated long-term fluctuations in investment activity, mainly in building construction, and corresponding fluctuations in economic growth. In explanations of the underlying mechanisms the primary stress was laid on the interaction between demographic and economic factors. In this way long cycles in marriage frequency, birthrate, and immigration were seen to give rise to long cycles in both the growth and the utilization of resources through their effect on such factors as capital formation, housing construction, and labor supply. The causal relation in the reverse direction was also important. Through the link with unemployment and effective demand, changes in the utilization of resources intensified immigration and gave rise to long-term cycles in the pattern of immigration. In the same way, the variations in unemployment influenced job opportunities for the labor reserve (mainly married women, ethnic minorities, and older workers). In other words, there was a long-term cycle in the size of the labor supply. A side result of this wide-ranging discussion of the interaction between demographic and economic factors was that economists increasingly incorporated demographic variables into their reasoning.

After World War II the long-term cycles assumed a different character both in duration and strength. A number of the suppositions applied to earlier periods of history were changed. Some of the mechanisms which formerly generated Kuznets cycles changed character and others weakened or vanished. In par-

ticular, the great influence that immigration to the USA had exerted in the generation of Kuznets cycles after 1850 was modified. When immigration was restricted during the interwar period, its cycle-generating function vanished. Instead, this function was replaced by the marked rise in the number of births during the 1940s and 1950s and by an equally marked decline during the next two decades (e.g., Kuznets 1958, Abramovitz 1961, 1968, Easterlin 1968).

2.1 The Easterlin Hypothesis

One of the most prominent figures in this earlier research into the genesis of population cycles and their influence on demographic and economic phenomena was the American economic historian Richard Easterlin. It was also Easterlin who drew attention to the changed demographic conditions that applied to the Kuznets cycle after World War II. It therefore seems quite appropriate that it would be Easterlin who made the most trail-blazing analysis of the causes of the dramatic changes in births in the USA after World War II and their effects on the demographic and economic behavior of individuals. A number of other features of modern social change must also be viewed, he argued, in the context of demographic events.

A group of people born during a given period are marked by the same code of values and attitudes in many respects. Easterlin believes it possible to identify an important underlying reason why values and attitudes may vary from one cohort to another. Accordingly he asserts that an individual's behavior in a number of areas will be influenced by the size of the cohort to which he or she belongs, since it determines economic situation and future prospects to such a large extent. At this point Easterlin ties in with earlier thinking by Gustav Sundbärg and others, but he conducts the analysis with considerably greater precision and stringency (e.g., Easterlin 1968, 1978, 1981, Artzrouni and Easterlin 1982.)

For young individuals who belong to a large cohort, prospects for the future appear somber. Their incomes will be lower in general and the likelihood of becoming unemployed is higher than for individuals belonging to a small cohort. As a consequence they marry later and also divorce more frequently. Besides they have a greater propensity to commit suicide and to manifest higher frequency of criminality. Married women in a large cohort will participate in the labor force more often because of the family's difficult economic situation. Unmarried women have high nonmarital fertility, also resulting from social stress factors. Alcoholism is also regarded as more common in a large cohort. Values, too (political opinions, attitude to work, savings, etc.), depend on cohort size.

One key element of Easterlin's reasoning is the 'relative income hypothesis.' This holds that the individual's behavior is determined by the relation

between, on the one hand, the material standard and position in society which he or she has attained, and on the other hand, what he or she had expected. The expectations are in high degree determined by family background, i.e., by the parents' economic situation, while the possibilities of translating them into reality are dependent on the prevailing labor market situation and relative wages. In other words, it is not the absolute level of living standard that determines behavior, but the relative level, in which the crucial factor is the relation between expectations and the possibilities of realizing them (material aspirations). During a period when high aims are set but the possibilities of realizing them are low, as is the case with a large cohort, the social stress factors are magnified. The stresses and strains associated with large cohort size are likely to continue throughout the whole course of a cohort's life.

In a small cohort the reverse applies. Firms have to compete for the relatively few new entrants to the labor market, which means that starting wages become high and opportunities of advancement good. Social stress is reduced considerably, and divorce, suicide and criminal frequencies become low. Moreover, in a small cohort expectations are low, because they are determined by the parents' (the preceding large cohort's) economic situation. On the other hand the possibilities of realizing expectations—and even of surpassing them—are high. Here, too, it happens that these favorable circumstances follow the small cohort all through its life.

Easterlin makes a particular point of analyzing how cohort size influences childbearing. He observes that a large cohort will bear relatively few children per woman while a small cohort will give birth to many. The linkage between birthrates and adverse economic and social effects causes the emergence of 'crowding mechanisms' operating within three major social institutions: family, school, and labor market. The result of the 'crowding mechanisms' is that the appearance of social stress factors are quite different in large and small cohorts. A large cohort adapts in order to avoid deterioration of its living standard compared with that of its parents. One such adaptation is that family formation takes place later in life. Another is that a woman in such a situation finds herself compelled to combine labor force participation with childbearing, which reduces her natality. By means of such demographic adaptation the large cohort strives to maintain its economic status compared with that of its parents. For a small cohort the situation is again reversed. Its members have no need to make any demographic adaptation in order to preserve an economic status that is favorable from the outset.

These demographic mechanisms produce what is called the 'Easterlin effect,' and they have been used as an alternative to the explanation suggested by the 'microeconomic theory of fertility' for the large fertility variations observed in the USA and Western

Europe during the postwar period. The most essential difference between the two approaches is that, according to the Easterlin model, demographic behavior is determined by incomes and consumption relative to expectations, whereas in the neoclassical theory demographic behavior is determined by absolute incomes and actual levels of consumption. Where the neoclassical economists regard the cost of children as a response to exogenous changes in female wages, Easterlin regards tastes as response to exogenous changes in relative income status. Instead of assuming a constant preference structure as in Becker's theory, Easterlin introduces a shifting one; the shift being determined by incomes and prices. The Easterlin model is regarded by many as an attempt to introduce a sociological mode of thought into economic theory.

The observation that large cohorts would give birth to relatively few children and small cohorts to many children also creates the potential for continuing fluctuations in the relative size of birth cohorts. As a result there emerges a self-generating and to a certain extent self-correcting fertility cycle of around four to five decades in length and with associated changes in a wide range of social and economic phenomena induced by fluctuations in relative cohort size. Pre-World War II Kuznets cycles of 15–25 years caused by aggregate demand fluctuations would be replaced, according to Easterlin's argument, by post-World War II swings of double the length originating in fertility changes operating with a lagged effect on the age structure of labor supply. Some scholars have included such population cycles in mathematical models (e.g., Lee 1974, Samuelson 1976, Chu and Lu 1995). With the relative income hypothesis as a starting point, Easterlin describes *inter alia* important elements of social change in the USA during the postwar era, his main objective being to explain the baby boom of the 1940s and 1950s and the baby bust of the 1960s and 1970s. As a result of low birthrates during the interwar period—and of low immigration—relatively few young people entered the labor market during the 1940s and 1950s. Labor market conditions were favorable, since firms were competing fiercely for the limited numbers on the labor market by such means as increased starting wages. The future beckoned brightly too, for the prospects of advancement appeared good in the prevailing conditions of labor shortage. As a result of the fall in the proportion of young people in the total labor force during the 1940s and 1950s, the relative incomes of the young cohorts increased during this period at the same time as fertility was rising.

Conditions for the next generation were quite the opposite. Because of the high relative incomes of their parents and the subsequent rise in fertility, the new generation was comparatively large and at the same time entertained expectations of a high material standard. Thus, when the new generation emerged on the labor market during the 1960s and 1970s its expectations were high. Because of the cohort's size,

starting wages were low, the likelihood of becoming unemployed was high, and opportunities for advancement seemed rather limited. The chances of fulfilling their high expectations therefore appeared small. As a consequence, families were formed later, and childbearing was reduced. In other respects, too, as regards marriage and divorce patterns for example, female labor force participation rates, nonmarital fertility, suicide and criminal frequencies, and political alienation (students riots in the late 1960s, etc.), the 1960s and 1970s exhibited characteristics quite different from those of the previous two decades. Easterlin also predicted that a repetition of the baby boom would take place during the 1980s and early 1990s. In reality, however, fertility remained largely unchanged in these small cohorts.

2.2 Criticism of the Easterlin Hypothesis

Though much admired, the Easterlin hypothesis has not been exempt from criticism. Some scholars contend that the analysis is conducted at far too high a level of aggregation. They assert that the information available on the individual level concerning numbers of children and relative wages at a given time does not substantiate the Easterlin hypothesis, though there also are micro studies that report findings consistent with it. A number of scholars maintain that the theoretical ground for believing that changed relative incomes should influence fertility, labor force participation rate, and so on, are not particularly well developed either. Easterlin is also said to fail to take account of women's contribution to family income. If men's relative incomes are low at the same time as the labor force participation rate of women is high, it is fully conceivable that household incomes—which are the relevant factor at this point—are even higher than if the man had a relatively high income and the woman participated little in the labor force.

Other scholars argue that Easterlin's view of the modus operandi of the labor market is too simple and not rooted in any accepted labor market theory. In particular, one has criticized the idea that substitutability between older and younger workers is as limited as the Easterlin hypothesis holds. Easterlin is even accused of being careless with empirical data. He is said to pay too little attention to alternative explanations and to let his hypothesis rest on fragile empirical foundations, underpinning it only by *one* observed cyclical covariance between age structure relative incomes, and fertility.

Furthermore, the efforts made by Easterlin to link varying economic conditions to individual behavior in fields other than that of childbearing have not had any profound impact on current research. The studies which have been carried out give incomplete or conflicting results.

Nevertheless, the view that generation size significantly affects the attitudes and actions of individuals in a variety of areas, especially fertility behavior, has formed the basis of a number of international studies. As noted above, the relationships postulated by Easterlin seem to fit rather well for the USA. Some other countries (Australia, New Zealand, Norway, Canada) show similar patterns. In other countries there is a connection, but it is considerably weaker (Finland, France, The Netherlands, England and Wales, Sweden). For certain countries (Germany, Italy, Denmark) no such connection has been found at all. It should be observed, however, that usually it is only the reduced relation between age structure and fertility that has been studied, which is a 'second best' solution in this connection. Empirical studies have had to be based on age-specific incomes of different age groups to test the hypothesis properly. (For an overview of the 76 empirical analyses of the 'Easterlin hypothesis' that have been undertaken so far, and also of the criticism against the hypothesis, see Macunovich 1998.)

The first link of Easterlin's key relation between age structure relative incomes and fertility, has shown itself to be the more tenable and has inspired some scholars to develop the basic lines of thought both empirically and theoretically. In Easterlin's original analysis the relation is constructed on the basis of a relatively simple model of how the labor market functions. Thus, Easterlin does not pay much attention to possibilities for substitution between younger and older workers, nor does he differentiate between educational categories. An increased supply of younger labor will, therefore, result automatically in reduced relative incomes and increased unemployment for that younger element, all other things being equal. Later studies have shown with greater precision and detail how changes in the age structure have influenced relative incomes, and have established *inter alia* that cohort effects on incomes have been stronger for higher-educated categories than for lower. It has further been shown that the cohort effect on incomes has a tendency to wane over time, and that it is essentially absent for female workers. This suggests that the possibilities of substitution between younger and older women are large.

Easterlin's thesis that economic conditions can vary very widely between different demographic groups, and that a group's size influences its relative economic situation, has been clearly substantiated. But studies concerning the period after 1980 suggest that the effect applies only under special conditions. According to Easterlin, the relative income of the young ought to increase when the 'baby bust' cohorts entered the labor market in the late 1980s. Yet what one could observe was a continued decline in the relative wages of the young. It seems that changes in the supply of male workers may be able to explain the pattern of wages prior to 1980, but that a change in the structure

of labor demand—in particular an increase in the demand for more educated labor—offers a better explanation of wage patterns after 1980.

Easterlin himself has noted that the fortunes of a cohort depend on a number of other factors besides cohort size alone. One would therefore expect cohort size effects to dominate a cohort's experience only when other factors are relatively constant. This was the case in the period after World War II, when governmental monetary and fiscal policies stabilized growth of aggregate demand. In addition, the relative impact of immigration on the labor force was greatly reduced as a result of restrictive legislation adopted in the 1920s. In Easterlin's view the general slowdown of economic growth after 1973 and the widespread retreat from full employment as an objective of macro-economic policy are more important than changes in cohort size as factors explaining observed changes in fertility during the most recent decades. Furthermore, high immigration and the rise in female labor force participation also tend to limit the importance of birth cohort size, and so will government welfare programs that offer policies of full employment. According to Easterlin this is the reason why stronger cohort effects can be observed for the USA than for European nations, since the latter have more general welfare systems (see also Pampel and Peters 1995).

Just the same, it has proved possible to single out one factor—cohort size—that underlies variations in relative income and in fertility during certain periods and in some countries after World War II. This finding is moderate in scope, but solid and robust in its moderation. Only in exceptional cases can it be adduced as a dominant explanation of the variations observed. Nevertheless, the 'Easterlin hypothesis' and the many studies it has inspired, has given us new insights into the kinds of different connections and responses of economic, sociological, demographic, and psychological character which generate population cycles.

Population Cycles, Formal Theory of

A population cycle is a roughly periodic variation over time in the size or composition of a population. Here, composition refers to the component structure of the population, for example into distinct age classes. The formal theory of population cycles consists of mathematical tools that yield qualitative and quantitative information about the characteristics of cycles, such as their amplitude or period. There are three broad types of cycle: *transient* cycles are a response to a perturbation of finite duration such as a fertility transition, *externally driven* cycles are triggered and sustained by a persistent external perturbation such as an

economic cycle; *internally driven* cycles are maintained by interactions within the population such as a feedback between cohort size and cohort fertility. This article discusses the theory for these three types of cycles, dealing mainly with age-structured populations, although other aspects of population structure are considered briefly.

1. Mechanisms Driving Population Cycles

To explain the different mechanisms that drive cycles, and the kinds of formal theory that are required, it is useful to begin with Lotka's classical demographic equation which relates births $B(t)$ at the present time $t > 0$ to past births, by summing the reproductive contributions $\phi(a, t)$ made by individuals of all ages a , as

$$B(t) = \int_0^t da \phi(a, t) B(t-a) + H(t). \quad (1)$$

Here $H(t)$ specifies births to individuals who were present at $t = 0$, and immigration is ignored. The theory of this classical demographic model is discussed in *Population Dynamics: Theory of Stable Populations*; *Population Dynamics: Classical Applications of Stable Population Theory*; *Population Dynamics: Theory of Nonstable Populations*.

Transient cycles typically occur in a population whose vital rates, i.e., mortality and fertility, change over a time interval, say from $t = 0$ to $t = t_1$, and are constant thereafter. A practical example of such a perturbation is a decline from high fertility to replacement fertility that starts at $t = 0$ and is completed at $t = t_1$. After time t_1 , the population is described by classical demographic theory and undergoes damped oscillations towards the classical stationary state. But the dynamics during the transition are also oscillatory and require a different treatment.

Externally driven cycles result from a persistent perturbation of vital rates. One example is a periodic variation over time in fertility that is generated by an exogenous force, such as an economic cycle in wages. Another example is an irregular, stochastic variation in fertility or mortality that produces an ongoing stochastic response that has cyclical components. Formally, such perturbations are described by an appropriate time-dependence in the function $\phi(a, t)$.

Internally driven cycles result from changes in vital rates that are driven by changes in population size and composition. In such cases, the net reproduction $\phi(a, t)$ has a functional dependence on the past trajectory of births, or on past vital rates. One example is a relationship between the fertility of a cohort in its childbearing years with the size of the cohort: for a substantive discussion of such relationships, see *Ferti-*

lity Transition: Economic Explanations; Baby Booms and Baby Busts in the Twentieth Century; Population Cycles and Demographic Behavior. Another example is provided by inverse projection in historical demography (Lee 1977), in which observed counts of births and deaths over time are used in conjunction with the Lotka equation to estimate the time-variation in the level of mortality rates. Here, the constraint of matching observed counts results in a feedback between the level of mortality and population counts (Wachter 1986).

The formal theory of cycles driven by each of these mechanisms is discussed below, followed by a brief consideration of future directions.

2. Transient Cycles

A perturbation such as a fertility transition may take decades to complete, and a formal theory must provide formulas for the birth sequence $B(t)$ both during and after the perturbation. Li and Tuljapurkar (1999b) provide an explicit if cumbersome description of the decaying population cycles that result from a perturbation. This theory shows that the population undergoes damped cyclical changes during and after the transition. The characteristics of these cycles have not been explored except in particular cases; but this analysis makes possible the computation of population momentum for all gradual transitions (Li and Tuljapurkar 1999a). It is worth noting that the analytical results for this case rest on properties of the roots of Lotka's equation. The relationship between these roots and the age-pattern of reproduction has been studied by approximate (Keyfitz 1985) and exact (Wachter 1984) methods that are also useful in the analysis of externally and internally driven cycles.

3. Externally Driven Cycles

An illuminating treatment of population cycles driven by external periodic variation in reproduction was given by Coale (1972), who showed that the population responds with periodic variation in the numbers and relative sizes of its age components. The challenge for the theory lies in the nonlinearity of eqn. (1) when $\phi(a, t)$ contains a periodic component. To see this, suppose that $\phi(a, t) = \phi(a) + \psi(a, t)$ with ψ being periodic in time t , and suppose that the resulting birth sequence in eqn. (1) has the form $B(t) = B + b(t)$, with b also a periodic function. Substitution of these forms into eqn. (1) shows that the unknown $b(t)$ depends on a nonlinear product $\psi(a, t - a) b(t - a)$. General results for nonlinear renewal eqns. of this type are not known. There are analytical approximations which employ an expansion in the amplitude of the periodic perturbation ψ ; these describe the amplitude response of the

population and the phase difference between population cycles and the external driving cycle (Tuljapurkar 1985). An interesting class of periodically perturbed Lotka models has been described and analyzed exactly by Kim and Schoen (1997), Schoen and Kim (1994, 1997). The latter work demonstrates that it is sometimes possible to solve exactly the homogeneous form of equation (1), i.e., with $H = 0$, for an explicitly time-dependent $\phi(a, t)$. Such analytical examples can be valuable as a source of insight into the dynamics, and as a check on approximate theories intended for less tractable problems.

The analysis of periodic perturbations suggests that a persistent stochastic perturbation of vital rates will also generate a superposition of cycles of population change. The dynamics of a population subject to stochastic perturbation are also nonlinear, so again the theory has relied upon approximations. Lee (1975) pioneered the application of time-series methods to the linearized analysis of stochastic perturbations. To go beyond linearization, e.g., if the perturbations are large or have strong positive serial correlations, a higher order approximation may be used as discussed by Tuljapurkar (1990), Tuljapurkar and Lee (1997).

4. Internally Driven Cycles

The formal analysis of internally driven cycles is quite distinct from the analyses used in classical demography, and draws on developments in nonlinear dynamics (for a review of modern nonlinear techniques for dynamics, see Guckenheimer and Holmes (1983)). To start with, it is important to recognize that there are different forms of internal feedback. One class of feedback is exemplified by cohort size effects on fertility: large birth cohorts go on to have lower fertility than their parents and the opposite for small birth cohorts (Lee 1974, 1976, Wachter and Lee 1989). A second class of feedback is generated by social norms or expectations: for example, individual fertility is influenced by the average fertility in the population (Kohler 2000). A third class of feedback arises through an interaction between a population and external variables—for example, economic conditions, environmental conditions, or resources such as land holdings—and these external variables in turn influence fertility or mortality (Bonneuil 1990, 1992, 1997, Chu 1998, 1999, Feichtinger and Sorger 1990, Feichtinger and Dockner 1990, Lee 1987, Milik and Prskawetz 1996).

The formal theory of such feedbacks shares several elements that may be illustrated by considering a nonlinear version of Eqn. (1). Suppose that the net reproduction $\phi(a, t)$ in that equation changes with the population structure: for example, the fertility of individuals aged a at time t depends on the size of that cohort relative to the size of their parents' cohort.

Such feedbacks result in a functional relationship of the form

$$\phi(a, t) = \phi(a)h(g, a, \{B(t-s), 0 < s < S\}). \quad (2)$$

Here the function h on the right describes the effect of the other birth cohorts, born as long as $S > 0$ years ago, on the fertility of the cohort aged a . The parameter g controls the strength of the feedback, for example, by controlling the gradient of h . Lotka's equation is now a nonlinear renewal equation, which can be written in abstract form as

$$B = \mathcal{L}(\mu, B). \quad (3)$$

The nonlinear operator $\mathcal{L}$ maps past values of births into their current value. This verbal description can be formalized suitably; for an example of the mathematical details see, e.g., Cushing (1978).

In most applications the nonlinear eqn. (3) has a constant solution, $E(\mu)$. The dynamic stability of this solution is examined by studying small deviations $x(t) = \{B(t) - E(\mu)\}$: stability means that $x(t)$ should decrease over time. An expansion of the nonlinearity in eqn. (3) yields a series of terms of the form

$$x = \mathcal{H}(\mu, x) + \mathcal{G}(\mu, x, x) + \mathcal{R}. \quad (4)$$

The operator $\mathcal{H}$ is a linear operator, $\mathcal{G}$ is quadratically nonlinear, and $\mathcal{R}$ involves higher-order nonlinear terms. Local stability is determined by the eigenvalues of the linear operator $\mathcal{H}$, and these in turn depend on the elasticity of the linear response (Wachter 1991a). In typical examples, the equilibrium is locally stable when $g < g^*$, say, but becomes unstable when $g \geq g^*$. Local instability means that small deviations from the equilibrium births will change with time as $\exp\{(p+iq)t\}$ where $p > 0$ and q are given by eigenvalues of the linear operator $\mathcal{H}$. The local change in $x(t)$ follows a cycle of period $(2\pi/q)$. The central question now is: when such local instabilities grow and experience the nonlinear forces in equation (4), will they turn into sustained, stable cycles? If they do, increases in the parameter g past the threshold value g^* will generate a sustained population cycle, called a *limit cycle*. Since $E(\mu)$ is still a constant solution, eqn. (3) (or its solution) is said to have undergone a bifurcation at $g = g^*$.

For any value of g above but not far from the threshold g^* , the nonlinear limit cycle may be represented by a superposition of periodic solutions to the linear part of eqn. (3). Numerical illustrations of such limit cycles are given by Frauenthal and Swick (1983). A systematic procedure for computing the amplitude, period, and stability properties of this limit cycle beyond the bifurcation point is described by Tuljapurkar (1987), and substantive applications that illustrate these computations are given by Wachter

(1991b) and Chu (1998). These procedures may be extended to many other models with feedback, and provide an important part of the theory of population cycles. Other feedback mechanisms may result in a different approach to bifurcation (e.g., bifurcation in fertility level, Kohler 2000).

5. New Directions

The formal theory of cycles has moved considerably beyond classical demographic theory. The nonlinear bifurcation analysis discussed above can be considerably extended. Wachter (1994) has explored global properties of feedback models, addressing the behavior of cycles far above a bifurcation threshold. Bonneuil (1992), Prskawetz and Feichtinger (1995), and Tuljapurkar et al. (1994) show that increasing feedback can lead to more complex types of population cycles including aperiodicity and chaos. Purely internal feedbacks may not be strong enough to generate demographic cycles in human populations, but feedbacks mediated by social or external interactions may well be strong enough. The challenges that face the theory now lie in two areas: confrontation with data to test and modify theories, and the development of new models that incorporate a wider range of demographic dynamics and interaction. As yet, nonlinear cycles in human populations have not been examined in the realistic and rich way that biologists have explored cycles in the structure of laboratory populations (de Roos 1997, Cushing 1997).

Population Dynamics: Classical Applications of Stable Population Theory

1. Introduction

The theory of stable populations is presented in both continuous and discrete form in the article *Population Dynamics: Theory of Stable Populations*. Virtually any real population, whether contemporary or historical, deviates from stability, but the stable model produces a standard for comparison based on simplifying assumptions that allow us to handle data limitations. Some applications of the theory appear in the introductory article just mentioned and in other articles, including *Demographic Techniques: Indirect Estimation*; *Population Dynamics: Momentum of Population Growth*. The present article will review several applications within a structure that specifies the amount of information that is required. The applications are ‘classical’ in the sense that they are relatively well known.

It is helpful first to distinguish between two classes of models that are widely used: survival processes and renewal processes. The prototypical example of a survival process is the single-sex, single-decrement life table, described in the article *Life Table*. A survival process describes a cohort, real or synthetic, from age 0 until some terminal age ω . The main concepts are (a) the survival function, $l(x)$, namely the proportion of the cohort that survives to each age x , and (b) the mean waiting time or remaining life expectancy, e_x^o , at any specific age x .

A renewal process, by contrast, is a survival process with reproduction. With this component, the process generates successive cohorts that are (in general) larger than necessary simply to replace the persons who have died. The cohort interpretation is supplemented with the asymptotic implications of fixed and stable overall rates (of growth, mortality, and fertility), and a fixed and stable age distribution, none of which depends on initial conditions.

If a renewal process is in equilibrium—that is, if reproduction is exactly at replacement value, then the stable population is stationary. It has an intrinsic growth rate of zero, and one does not need explicit

age-specific birth rates to analyze it, for its overall birth rate is identical to the overall death rate. There are several classical applications and generalizations of this scenario, all of which can be regarded as applications of stable population theory because a survival process is a special stable renewal process.

A stable population is typically motivated as the asymptotic consequence of projecting the population indefinitely with fixed age-specific rates. Its overall rates and age distribution converge to functions that do not depend on the initial conditions. However, unless the intrinsic growth rate is zero, there is a fundamental implausibility in this asymptotic interpretation. If the intrinsic growth rate is positive, then the overall population size will increase exponentially, an outcome that cannot be sustained indefinitely in a real population. If the intrinsic growth rate is negative, then the overall population size will *decrease* exponentially until eventual extinction. In probabilistic terms, the fixed-rates assumption implies almost certain ultimate extinction or explosion (see *Population Dynamics: Probabilistic Extinction, Stability, and Explosion Theorems*). It is probably more useful to regard the stable population parameters simply as a synthesis of the underlying age-specific probabilities or rates.

2. Applications Not Requiring Schedules of Rates

Applications of stable population assumptions can be organized according to the amount of information they utilize. Probably the simplest possible applications occur when the only parameter utilized is the intrinsic growth rate, r . If we assume stability between two times t_1 and t_2 , and that the population size at those two times is n_1 and n_2 , then

$$n_2/n_1 = e^{r(t_2-t_1)}$$

Solving for r , we get

$$r = (\ln n_2 - \ln n_1)/(t_2 - t_1)$$

We can then estimate the population size at an intermediate time, $t_1 \leq t \leq t_2$, to be $n_t = n_1 e^{r(t-t_1)}$. This formula, or variations upon it, is often used when the population is not stable, in the absence of better information. Another simple and well-known application is to determine the doubling time associated with a given value of r . Setting $n_2 = 2n_1$ and letting T be the time required for the population to double, we obtain $2n_1 = n_1 e^{rT}$, leading to $T = (\ln 2)/r = 0.6931/r$. For example, if the annual growth rate is 0.01, or 1 percent, a stable population will double in 69.31 years, or approximately seventy years. These and related applications are discussed by Hinde (1998, pp. 154–8), for example.

Suppose that in addition to the intrinsic growth rate, r , we also know the intrinsic birth rate, b (and hence the intrinsic death rate $d = b - r$). Keyfitz (1977, pp. 12–14) uses such information to estimate the

number of persons who have ever lived on Earth, which is the same as the number of persons ever born. His strategy is to piece together long intervals of time within which stability (at different levels) is assumed. If the population is stable between t_1 and t_2 , then the number of person-years lived in that time interval will be

$$PY = \int_{t_1}^{t_2} n_1 e^{r(t-t_1)} dt = (n_2 - n_1)/r$$

PY can be converted to the corresponding number of births by multiplying by b :

$$B = bPY = b(n_2 - n_1)/r$$

(If $r = 0$, then $n_1 = n_2 = n$, $PY = n(t_2 - t_1)$, and $B = bn(t_2 - t_1)$.)

3. Applications that Assume Schedules of Rates

Another class of applications arises if we know r , b , and d , and do not know the survival and fertility schedules but are willing to make some assumptions about them. Coale and Demeny (1983) blended empirical life tables into four sets of so-called regional model life tables (north, south, east, and west) for males and females, keyed to the life expectancy e_0^m at birth and e_{10}^f at age 10 (see *Demographic Models*). They also developed plausible fertility schedules, varying according to the mean age of childbearing but adding up to one child, so that the entire schedule could be multiplied by a hypothetical total fertility rate (TFR). With this information, much of it hypothetical, they were able to generate sets of stable age distributions. It is then possible to estimate a wide range of population characteristics, using only a few pieces of summary information (along with a specification of region and sex). The summary information typically includes certain combinations of the following: a measure of growth, such as r ; a measure of fertility, such as b , the gross reproduction rate (GRR), or the TFR; a measure of mortality, such as d or the average age at death; or a measure of the age distribution, such as the proportion of persons below age 20. Stable age distributions generated in this way can also be used to approximate real age distributions in settings of deficient data. Some methods for the computation of population parameters using the stable population model are described in *Demographic Techniques: Indirect Estimation*.

4. Applications that Require Schedules of Rates

A number of analyses of population dynamics have resulted from examining the sensitivity of population characteristics to disturbances of a stable population. These applications require knowledge of the age-specific schedules for mortality (say m_x for each age x),

of fertility (say f_x for each x), and for any other transitions in the model. For example, Preston (1974) took partial derivatives of the basic stable population formulas to estimate the effect of various age-specific mortality changes upon the intrinsic growth rate, birth rate, and age composition. He found that the effects could be represented as simple functions of the age pattern of the cumulative changes in the mortality rates. Probably the best known of these sensitivity analyses has been on the topic of population momentum, which in its simplest form measures the eventual effect on population growth of an immediate shift to replacement fertility (see *Population Dynamics: Momentum of Population Growth*).

The classical stable population model has no in- or out-migration, but several authors have used the model in innovative ways to evaluate the impact of emigration (Keyfitz 1971) or immigration (Lesthaeghe et al. 1988). Mitra (1990) considered how a population could maintain stationarity through a combination of below-replacement fertility and a steady stream of immigration. With assumptions about the ages and fertility of the immigrants, it is possible to determine the necessary size of the stream of immigration. This model is relevant, at least as a first approximation, to the current mix of below-replacement fertility and immigration in Europe and North America.

The classical formulation of stable population theory only allows individuals to be born, procreate, and die, but later developments permit individuals to move between several statuses or states during their lifetime, as in multistate models (see *Multi-state Transition Models in Demography*). In one obvious application the states represent regions of a territory (Feeney 1970). In another, Keyfitz developed a linkage between aging and career mobility in stable populations (1973; the title of this paper is misleading because he included stable as well as stationary populations). He supposed that advancement in status across a set of discrete categories is essentially based on the steepness of the age distribution. In a setting of high growth, age (as a proxy for experience) tends to produce earlier advancement because there are relatively few people at higher levels. In a setting of low growth, seniority is less valued, because there are relatively many people at higher levels, and promotion will take longer. The approach is again a type of sensitivity analysis, in which the age at reaching a sequence of discrete gateways is expressed as a function of stable population parameters (in particular, the intrinsic growth rate).

5. Applications that Link Individuals to One Another: Kinship

Assume now that we have access to complete schedules of survival and fertility. In continuous form, say that $l(x)$ is the probability that a woman will survive to age

x and $m(x) dx$ is the probability that a woman will have a daughter between ages x and $x+dx$ (with $m(x) > 0$ for x in the reproductive age range $\alpha < x < \beta$ within the full range of ages $0 < x < \omega$).

Single-sex kinship provides a structure by which individuals are linked through lines of descent or ancestry. Two specific models for kinship structures will be described here. In the context of kinship, reference individuals (ego) are linked to their direct descendants, such as daughters; to progenitors, such as mothers; or to their lateral kin, such as sisters. Two-sex approximations are possible. The main outputs are the probability that a specific progenitor is still alive when ego is age a , and the expected number of descendants and lateral kin (in a specific category) who are still alive, or were ever born, when ego is age a . These are obtained from various convolutions of the survival and fertility functions.

The first kinship model to be described was developed by Goodman et al. (1974, 1975). The following exposition will be limited to surviving kin when ego is age a . It can be modified to refer to kin ever born simply by deletion of the outermost survival function (that is, setting it equal to 1).

Each kinship role is expressed with a different formula, but the strategy for generating these formulas is the same for all roles. The steps to link ego with a consanguineal relative are to identify the relevant sequence of births, and the ages of the respective mothers at those dates; to incorporate the fertility rates for those ages, the probability of surviving to those ages, and, for the final link, the probability of surviving to the time when ego is age a ; and integrating over all allowable combinations of ages of the linked kin. Note that the birth of ego herself, and her survival to age a , are assumed.

For example, to link ego with her daughter, the relevant birth is that of the daughter, which occurred when ego was some previous age x . If the daughter is still alive when ego is age a , then the daughter's age is $a-x$. Thus ego experienced the fertility rate for age x , and the daughter survived to age $a-x$. Multiplying in reverse order and integrating over allowable ages x , the expected number of surviving daughters for a woman age a is

$$D(a) = \int_{\alpha}^a l(a-x)m(x) dx$$

(If $a < \alpha$ then $D(a) = 0$ and if $a > \beta$ then $D(a) = D(\beta)$.)

The stable population probability that ego's mother is alive when ego is age a was originally calculated by Lotka (1931), and is useful for estimating adult mortality when some empirical information about the incidence of orphanhood is available. If the mother was age x when ego was born, then the probability that she is still alive a years later is the probability of surviving to age $a+x$, $l(a+x)/l(x)$. Obviously this

depends on the value of x , as well as a , and these survival ratios must be weighted by the probability that the mother was age x to age $x + dx$ when ego was born. In a stable population these weights will be given by $W(x)dx = e^{-rx}l(x)m(x)dx$ (from the characteristic equation, this is the density function for mothers' ages and integrates to 1). Therefore,

$$\begin{aligned} M_1(a) &= \int_{\alpha}^{\beta} [l(a+x)/l(x)]W(x)dx \\ &= \int_{\alpha}^{\beta} e^{-rx}l(a+x)m(x)dx \end{aligned}$$

is the probability that ego's mother is alive when ego is age a .

The expected number of surviving sisters when ego is age a involves a similar logic but will not be given here. Ego is linked to her sisters through their mother. It is necessary to distinguish between older and younger sisters because the survivorship of the mother is problematic after, although not before, the birth of ego. The formulas can be extended to aunts, nieces, first cousins (mother's sister's daughters), and indeed any category of kin.

A noteworthy feature of this application of the basic model of a stable population is that it requires only the basic survival function and maternity function, and a structure to link individuals. As an alternative to linkage by kinship, it should be possible to substitute an organizational structure or some form of vertical and horizontal connections, but we are not aware of any analogous applications.

The formulas are deterministic, rather than stochastic, and will not produce distributions. They assume that the birth of a child is independent of the number of children a woman has already had, that survivorship is independent of biological relationship, and that the population is homogeneous. Although these limitations are severe, it would be difficult to find data corresponding to more realistic assumptions. Calculations using these multiple integrals require some form of quadrature.

In a second application of kinship (Pullum 1982), counts are not conditional upon the survival of ego or any other kin, but are defined as 'eventual expected' numbers of kin. For example, the net reproduction rate

$$N = \int_{\alpha}^{\beta} l(x)m(x)dx$$

is the average number of female births that will be produced, a generation later, from a single female birth. This is equivalent to the eventual expected number of daughters that a woman (ego) will have, defined at the point of ego's birth and the daughters' births.

The eventual expected number of sisters, defined at the point of ego's births and the daughters' births, can be referred to with the symbol S . N is not equivalent to any of the functions defined by Goodman et al. (1974) but S does appear within their scheme as the (expected) number of sisters (older and younger added together) ever born by the time ego has reached age $\beta - \alpha$, the maximum age at which a sister can be born. This formula superfluously conditions on the survival of ego, but allows for all sisters to be born.

It can be shown that N and S are sufficient to obtain the eventual expected numbers of any other types of kin. For example, an average of N^2 granddaughters (daughters of daughters) will be born, SN first cousins (daughters of sisters of the mother), SN nieces (daughters of sisters), and so on. The sex ratio at birth will also be constant in a stable population, and by including it one can easily extend to a two-sex kinship structure. For example, define s to be the ratio of males to females at birth, so that for every female birth there will be $1+s$ births of males and females. This implies that for every female child there will be $1+s$ children, so N is replaced by $(1+s)N$; for every sister there will be $1+s$ siblings, so S is replaced by $(1+s)S$. (Note that instead of one mother there will be exactly two parents.) The number of grandchildren (sons and daughters of sons and daughters) will be $(1+s)^2N^2$; the number of first cousins (sons and daughters of brothers and sisters of the mother or father) will be $2(1+s)^2SN$; the number of nieces/nephews (sons and daughters of brothers and sisters) will be $(1+s)^2SN$; and so on.

Like the applications given in Sect. 3 above, this second model of kinship only requires summary measures of the stable population (in this case S and N), and does not require any schedules of rates.

6. Conclusion

These applications have been presented largely at a conceptual level, without the specific data or numerical conclusions that might help to demonstrate their value (the bibliography and other entries in this encyclopedia describe several further examples). In each case, however, the original goal was to utilize stable population theory to draw approximate conclusions about real populations in situations where data are scarce. The model approximation has certain elegant formal properties and in effect permits the simulation of data that are generally not available for real populations. Indeed, significant improvement in the availability of demographic data is a likely reason why there have been relatively few new applications of the theory in recent decades.

Population Dynamics: Mathematic Models of Population, Development, and Natural Resources

Although the importance of the links between population and environment is widely appreciated, there is little agreement in the literature about the nature of these links.

The dynamic link between population and natural resources—influences are never entirely unidirectional or constant over time—constitutes the main difficulty in assessing formal models and unified theories. To

complicate matters further, this interrelationship depends on the level and type of economic activities, technological development, institutional settings and cultural systems. Even the variables themselves are not uniquely defined, but depend rather on the level and purpose of the analysis.

This article does not survey numerical simulation models of demographic/economic/environmental interactions (see Sanderson 1994 for a review), of which the World 3 Model (Meadows et al. 1972) is the most popular. Instead, it looks at some simple mathematical models that capture stylized facts of the link between population and natural resource dynamics. Such 'mathematical cartoons' help us to explain and understand how various population and environmental characteristics might affect each other, and they can teach us how to respond most effectively to various demographic and environmental developments.

Although it was exhaustible resources that first received theoretical attention, this article concentrates on renewable resources since these are the most interesting and least understood as regards changes in population structures and dynamics. In contrast to nonrenewable resources, the use of which is controlled largely by market prices, renewable ones are very often open-access resources. The overuse of resources if property rights are absent or poorly defined is called the 'first tragedy of the commons' (Hardin 1968) and can be corrected by restricting access to the resource. But as emphasized by Lee (1990), if the population is not fixed—as is presupposed in the models presented in this article—free access through reproduction constitutes the 'second tragedy of the commons.'

1. Malthusian Population Dynamics and Natural Resources

The study of interactions between population and resources has a long history. According to Malthus, population growth reduces material welfare due to diminishing returns to labor on a fixed supply of land. On the other hand the higher the level of material welfare the higher the population growth rate will be. The Malthusian model predicts that 'population will equilibrate with resources at some level mediated by technology and a conventional standard of living' (Lee 1986). Improvements in technology will be offset in the long run by increases in the size of the population, but the standard of living will not be related to the level of technology. As such, the Malthusian model provides a description of a rather primitive society with incomes not too far above the subsistence level and where local renewable resources are an important part of the economic production process.

Renewable resources (agricultural land, forests, lakes, etc.) are not in fixed supply as Malthus assumed. Renewable resources regenerate, but if the rate of

utilization (harvest) exceeds the rate of regeneration, a renewable resource will be depleted or, in the extreme case, irretrievably exhausted. By adding the dynamics of renewable resource growth to the dynamics of population growth, the Malthusian model is capable of explaining patterns of population growth and resource degradation that do not necessarily end up in a single equilibrium (Malthusian trap) (see Brander and Taylor 1998 and Prskawetz et al. 1994).

The structure of these models can best be described in terms of prey–predator dynamics, with the resources, R , being the prey and the population, P , acting as the predator. The dynamics of renewable resources (Eqn. (1)) are commonly described by the standard model of mathematical bioeconomics, where the net growth of the renewable resource, $dR(t)/dt$, is affected by two counteracting factors: indigenous biological growth, $g(R(t))$, and the harvest, $H(R(t), P(t))$, which depends on the stock of resources available to be harvested and the number of people who are harvesting. Indigenous resource growth is modeled by the logistic growth function $g(R(t)) = aR(t)(K - R(t))$, where the coefficient K determines the saturation level (carrying capacity) of the resource stock (i.e., K is the stationary solution of R if the resource is not degraded) and parameter a determines the speed at which the resource regenerates. The functional form of the harvest function is determined by the prevailing economic structure, and it establishes the link between the stock of resources and population. The population growth rate, $(dP(t)/dt)/P(t)$ (Eqn. (2)), is modeled as an increasing function of material welfare $y(t) = y(P(t), H(t))$, which is determined by the level of the harvest and will be reduced by population growth. Whenever material welfare falls below the subsistence level, the population will decline. These Malthusian population dynamics imply that population growth may well adapt to resource constraints in contrast to models with exogenous positive population growth, where the economy collapses if resources do not regenerate quickly enough.

$$\frac{dR(t)}{dt} = g(R(t)) - H(R(t), P(t)) \quad (1)$$

$$\frac{dP(t)}{dt} = n(y(t))P(t). \quad (2)$$

Within this class of models it is possible to investigate how the equilibrium between resources and population stock changes, dependent on the functional relations that govern the dynamics of population and resources. For instance, the efficiency of harvest technology, the degree of substitution between labor and resources, the indigenous rate of resource growth and the carrying capacity of the resource stock will have an effect on material welfare and hence on population growth. In turn, fertility and mortality will affect the resource dynamics via the input of changing

labor stocks in the harvest. An empirical calibration of the model for the case of the small Pacific Easter Island characterized by pronounced population fluctuations was carried out by Brander and Taylor (1998).

Contrary to the Malthusian predictions, increasing population densities might be beneficial, as argued by Boserup (1981), and could well increase the human carrying capacity of the earth. Higher population densities will initiate technological innovations in agriculture, thereby increasing the yields so that the natural environment can support a larger population without reducing the level of welfare. Similar positive feedback mechanisms are captured in a simple mathematical cartoon of the interdependence between the growth in population $P(t)$ and carrying capacity $K(t)$ (expressed in numbers of individuals) by Cohen (1995) as

$$\frac{dP(t)}{dt} = rP(t)[K(t) - P(t)] \quad (3)$$

$$\frac{dK(t)}{dt} = c \left[\frac{dP(t)}{dt} \right] \quad (4)$$

with $r > 0$ and c either negative, zero, or positive. The parameter c , which captures the effect of an increment of population on the carrying capacity, determines the long-term population dynamics, and it can represent technological innovation. When $c = 1$ population size grows exponentially (Euler, eighteenth century); when $c < 1$ population grows logistically (Verhulst, nineteenth century); and when $c > 1$ population grows faster than exponentially (Forester and co-workers, twentieth century).

Malthusian results (in the sense that population will grow to the point where material welfare matches subsistence demand) can be further undermined by allowing population growth to be a choice variable. Zero population growth may well be the optimal choice for individuals in the economy. Since environmental changes are often slow over the course of an individual life span, and since environmental damage may outlive its perpetrators, overlapping generation models (Eckstein et al. (1988)) provide an appropriate demographic structure. Intra- as well as intergenerational conflicts can be modeled in such a framework, taking account of the effects of increases in population and resource exploitation on the future population's quality.

The models presented so far represent traditional societies in which populations derive their living from primary occupations (agriculture, hunting, fishing, etc.) which depend on the availability of resources. But as societies become less bound to the land, more urbanized and more technological, they not only use the environment as a source of natural resources but also as a dump for waste products arising from human activity. Furthermore, an economy's production possibilities are no longer determined by the maximum

sustainable yield of renewable resources. Improvements in technology can increase the sustainable yields or reduce the resource stock required for production, and economic growth will allow for the use of man-made capital in place of natural resources. In open economies with trade, technological change, and economic growth, there is no simple and direct relationship between population growth on the one hand and the environment on the other hand.

Resources might still be at risk, albeit no longer by positive population growth alone. The risk can stem from the environmental costs of consumption and production. It is therefore of great importance to understand how these environmental impacts depend on different population structures.

2. *The Impact of Population on the Environment*

In a seminal paper, Ehrlich and Holdren (1971) express the impact on the environment, I , (e.g., the value of some pollutant) as the product of population, P , and per capita impact, $F(P)$:

$$I = PF(P) \quad (5)$$

Depending on whether diminishing returns or economies of scale are dominant, per capita impact can be increasing or decreasing in the total population. The most familiar form of such a demographic impact model is the so called I-PAT identity, which divides per capita impact $F(P)$ into affluence A , and technology T . Affluence can be measured as GNP per capita, and technology represents the mean impact of an extra dollar of production (impact/GNP). The latter variable encompasses the cleanliness of technology, the effects of institutions, and other factors which can alter the impact efficiency of production.

Demographic impact models (Wexler 1996) constitute multiplicative identities aimed at decomposing the effect on the environment of population on the one hand and that of consumption and technology on the other. The number of variables on the right-hand side of Eqn. (5) can be any number greater than two. Although these models are commonly used, they face several criticisms. They suppress any feedback relation between the variables on the right-hand side; their implications are highly sensitive to the choice of decomposition variables; and the method of decomposition and the role of institutions and culture are ignored. Recent research on the I-PAT identity has dealt with some of these problems. Expressing the identity in terms of variances rather than means (Preston 1996) allows one to incorporate the links between the decomposition variables. Considering households instead of individuals as the unit of consumption (MacKellar et al. 1995) highlights the effect of economies of scale as household size increases. Typical results of such analyses are that the population

has a much stronger impact on the environment in developing countries than in developed countries. In the case of environmental hazards produced by industrial processes, population growth plays a minor role both in developing and in developed countries.

Milik et al. (1996) embed the I-PAT identity into a dynamic model where population P , affluence A , and technology T influence each other and vary over time. Pollution I reduces the regenerative capacity of natural resources, which in turn influences the dynamics of population and affluence. The model highlights the fact that understanding and monitoring the impact of pollution on the environment is important even when outward signs of damage (as a reduction in the resource stock) are not yet visible. Ecosystems often absorb stresses over long periods of time and then eventually reach a disruption level at which the cumulative consequences of stress appear in critical proportions. A policy of waiting until the first signs of environmental deterioration are observed before actions are taken to reduce the impact on the environment may well prove to be disastrous. When action is initiated, the impact on the environment might already be irreversible. Mathematically, these systems can best be described in terms of 'slow-fast' dynamics, where during certain periods some variables vary much more rapidly than others. While population and economic variables can be regarded as slow moving variables, the environment changes much rapidly once the system has absorbed too much stress. For instance, the emission of carbon dioxide occurred almost unobserved for several decades before any attention was paid to the impact of greenhouse gases on global warming.

It becomes difficult to quantify the impact of population on the environment if the demand for local resources is not related to local population growth and if institutional environments are not stable. In fact, 'commercialisation by converting a limited and inelastic subsistence demand to a limitless and elastic export demand (from the standpoint of the region, at least) can lead to much more rapid rates of exploitation than would be implied by population growth alone.' (Repetto and Holmes 1983).

3. *Modeling Environmental Influences on Population Dynamics*

Existing models of environmental influences on population exhibit two shortcomings. First, they generally do not distinguish between the separate effects the environment may have on fertility and mortality. Second, the environmental impact on population growth is commonly modeled to work only through the economic and social variables of the model. There are only two examples in the literature that model the direct effect of environmental stress on fertility and mortality.

The first example (Nerlove 1991) is based on the vicious circle of poverty, population growth, and environmental degradation as evidenced in small rural communities of sub-Saharan Africa. In these economies simple tasks like fetching water and collecting fodder and wood are mostly carried out by children. This means that children are not only valuable to parents for future income but also as a source of current income. Higher population growth leads to more resource depletion, which reduces the marginal productivity of the resource. To offset this effect families have more children, thus depleting the resource even more. In a short parable Nerlove demonstrates that increasing the birthrate when the environment deteriorates will be the optimal choice for a household that maximizes per capita harvest when 'the perceived marginal product of an additional child increases as environment deteriorates.' In addition, in a system in which land rights are acquired through cultivation, a large number of children can imply increased claim to land ownership. This positive feedback between fertility and environmental degradation is in stark contrast to Malthusian dynamics, where population equilibrates with resources. Since the marginal private and social costs of reproduction are not the same, Nerlove then shows how social interventions in the form of taxes or subsidies can be used to induce a specific birthrate corresponding to a socially desirable stationary state.

The underlying mechanism of the above-mentioned vicious circle is neither population growth nor environmental degradation but poverty, which prevents the substitution of alternative fuel sources, and the low status of women and girls, which devalues the large amount of time and effort that they must devote to daily gathering activities. To escape this vicious circle one needs to alleviate poverty and to educate women.

As suggested by Chu (1998), the increasing specialization and level of economic activity typical of advanced societies may also imply a substantial dependency of population dynamics on the state of the environment. Increasing the level of human activities destroys the earth's biodiversity, so that the ability of the environment to absorb negative shocks will decline, while increased specialization makes people less adaptive to environmental shocks. Chu suggests a simple mathematical model of the survival probability $f(\cdot, \cdot)$ to capture both effects:

$$f(m_t, x_t) < f(m'_t, x_t) \quad \text{if } x_t > 0 \quad (6)$$

$$f(m_t, x_t) \geq f(m'_t, x_t) \quad \text{if } x_t \leq 0 \quad (7)$$

where m_t denotes the logarithm of the number of intermediate goods (a measure of the division of labor) with $m_t < m'_t$ and x_t is a realization of the environment value X_t with the critical state $x_t = 0$. The mean and the variance of the random variable X_t will be increasing functions of m_t . By reducing the ability to adapt, increased specialization m'_t will decrease the

survival probability if the environment is already in a disastrous state $x_t < 0$, while the opposite relation will hold if the environmental state is favorable $x_t > 0$.

4. Concluding Assessment of the Literature

Although there is a growing awareness of the population/environment linkage, as evidenced by the increasing number of empirical (case) studies, research has not progressed much in the Malthusian spirit of modeling the complex interaction in simple mathematical cartoons. Even worse, dynamic interactions between population and environment are often neglected—or increasingly complex simulation models are set up where anything can happen.

Further research on this topic is urgently needed. The concern should be shifted away from physical limits to growth towards the ability of social units to respond to environment/population linkages. Although they are more difficult to formalize, such models should also include organizational and institutional issues. The study by Angelsen (1999) provides a first step in this direction.

Population Dynamics: Momentum of Population Growth

The momentum of population growth refers to the tendency of continued growth of a population with a history of high fertility after its fertility has fallen to replacement level. A population with sustained high fertility is growing in size and has a ‘young’ age distribution, that is it has a high proportion of young people. If such a population adopts replacement-level fertility, the population continues to grow before its size stabilizes. The eventual population is a stationary population, i.e., one whose size and age distribution remain constant over time. This ultimate stationary population has an older age distribution than the initial population, and its size is larger. The ratio of the eventual population to the pretransition population size is defined as the momentum of population growth.

1. Momentum Under Specific Assumptions

In a seminal paper, Keyfitz (1971) presented a simple mathematical expression for the population momentum under specific assumptions. Keyfitz assumed that the initial population has a stable age distribution, and that its fertility falls instantaneously to replacement-level fertility. The drop in fertility level is assumed to occur proportionately at all ages

so that the age pattern of fertility remains unchanged. Mortality is assumed to be constant at all times. Under these assumptions, the population momentum M can be expressed as

$$M = \frac{be_0}{r\mu} \frac{R_0 - 1}{R_0} \quad (1)$$

where R_0 is the net reproduction rate (NRR), b is the birth rate, and r is the growth rate, all of the initial stable population, e_0 is the expectation of life at birth and μ is the mean age at childbearing in the stationary population, i.e., the mean of the net maternity function. Equation (1) provides a simple, closed-form expression that permits calculation of an exact population momentum from a few known summary measures of the initial stable population. This avoids the need to project the initial population for a long time until it stabilizes at zero growth as was done by Frejka (1973).

In observed populations, each of the four assumptions is rarely satisfied, and the resultant momentum will be larger, due mainly to delayed fertility transition and to decline in mortality. The Keyfitz momentum M in Eqn. (1) can then be considered as a lower bound of the extent of future population growth. The formula has been used widely, and it has been shown that initial populations with high growth rates produce a substantial population momentum, frequently around 1.6. That is, the initial population grows by 60 percent before its size stabilizes at a constant value even when the most optimistic fertility reduction scenario is assumed.

2. The Anatomy of Population Momentum

The continuation of population growth after an instantaneous drop in fertility to replacement level is due to the large number of women at childbearing ages in the initial population. To understand what ‘causes’ the growth of a population after a fertility drop, the population momentum can be written as a product of two ratios: (a) the ratio of the numbers of births in the ultimate to the initial population, and (b) the ratio of ultimate to initial population size when both have the same number of births. The first factor is the stable-equivalent number of births, and its value is approximately equal to $1/\sqrt{R_0}$, a value less than one for an initially growing population. The second factor is given by be_0 , and is approximately equal to R_0 . Since the product of the two ratios yields the population momentum, the population grows approximately by a factor of $\sqrt{R_0}$ if the pretransition population had an NRR of R_0 (Frauenthal 1975, Kim et al. 1991). Thus the growth of the population is due entirely to the eventual old age distribution relative to the initial young age distribution, but is *not* due to the larger number of births after the fertility drop. The number of births drops when fertility rates drop in spite of the large number of young people in the initial population.

Preston (1986) showed that when fertility drops to replacement level, the population segment below some age near the mean age at childbearing remains virtually constant, so that all of the growth is confined to the population segment above that age, typically around 28. Inspired by this insight, Kim et al. (1991) examined the anatomy of the population momentum in detail. It was shown that the momentum of *any* observed population is given as the ratio of the *proportion* of the observed population under the mean age at childbearing to the *proportion* of its life table population under that age. Thus, the younger the initial population, the larger is the momentum.

The age-specific momentum for broad segments of a population was also presented. Approximately, (a) the momentum for the segment of a population below age 30 is 1, that is the under-30 population size remains constant, confirming Preston's (1986) result; (b) the momentum for age group 30 to 60 is R_0 ; and (c) the momentum for the group above age 60 is R_0^2 . The exact age below which the population size remains constant can be determined exactly (Kim et al. 1991, Kim and Schoen 1993), but age 30 works well for all practical purposes. To illustrate the age-

specific momentum graphically, the trajectory of population segments in five-year age groups after the immediate fertility drop is shown in Fig. 1a (initial $R_0 = 2.9$ in this example). The number of births (here represented by the population size of ages under five) initially drops when fertility falls, then recovers somewhat before it stabilizes at a new level, which is lower than the original level. In this process, the population segment under age 30 (below the lower solid line) remains virtually constant except for a small fluctuation around time 30, which is when the smaller birth cohorts born right after the fertility drop reach that age. The total population growth of some 60 percent after the fertility drop is due entirely to the increase in the population segment above age 30.

Because the total population growth was contributed solely by the population above age 30 while the population under age 30 remains fixed in size, the population momentum and population aging occur simultaneously. The aging process of the population is shown clearly in the percent age distribution of Fig. 1b. The proportion under age 30 makes up 70 percent of the initial population but it decreases to a little over 40 percent in the eventual population, while the population above age 60 increases from a mere 4 percent to almost 20 percent, showing a substantial degree of aging of the population. The results described here hold for any initial population that is not stable, as well as for initially stable populations.

3. Population Momentum and Population Aging

Population momentum and population aging during the transition to stationarity are two aspects of the same phenomenon. The population momentum expresses population aging, and vice versa. The two quantities are separate aspects of the long-term change in size and age structure that results from a reduction in fertility to replacement level.

To make the relationship between the dual consequences of fertility decline—population momentum and population aging—more specific, three measures of aging were considered (Kim and Schoen 1997). They are: (a) the increase in the mean age of population (ΔA), (b) the relative size of the proportion under age 30 (F_{30}), and (c) the relative size of the proportion above age 65 (F_{65+}). The first measure, ΔA , is defined as the increase in mean age of the eventual stationary population from that of the initial population. The second measure, F_{30} , is defined as the ratio of the population under age 30 in the initial population to that in the ultimate stationary population, and the third measure, F_{65+} , is defined as the ratio of the proportion over age 65 in the initial population to that in the ultimate stationary population.

The three measures of aging are highly correlated with each other and with the population momentum, for these four quantities are linear functions of the

Figure 1

Age distributions and the momentum of the observed population of Singapore (1957): $R_0 = 2.9$. (a) Evolution of population segments from 0 to 90, in five-year age groups. Solid lines represent ages 30, 60, and 90. (b) Population segments from 0 to 90, in five-year age groups as percentages of total population. Solid lines represent ages 30, 60, and 90. *One time unit is five (5) years

intrinsic growth rate, r , of the initial population. The theoretical linear relationships as well as some empirical results are presented in Kim and Schoen (1997). For empirical relationships, two data sets are used. The first is a set of Coale-Demeny West model stable populations (see *Demographic Models*) that includes 39 stable populations with the intrinsic growth rate r ranging from -0.01 to 0.05 in increments of 0.005 at three mortality levels (e_0 values of 60, 70, and 80). The second data set is comprised of 41 observed populations in 1985 (Keyfitz and Flieger 1990).

Figure 2 presents the empirical two-way scatterplots for the momentum, M , and each of the three aging measures generated by the first data set. The first plot (from left to right) shows the relationship between M and ΔA , the second M 's relationship with F_{30} , and the third with F_{65+} . The momentum-mean age linear fit is quite good, and the estimated slope (as well as the theoretical value) suggests that the mean age of the population increases by a little more than two years for every 10 percent increase in population momentum. The middle plot shows that the relative size of the proportions under age 30 is not only linear, but is *identical* to the momentum. This is a direct consequence of the fact that the population size under age 30 remains constant before and after the transition, as discussed in Sect. 2. The third plot presents the relationship between the momentum and the relative size of the proportion above age 65. The fit is not as good as with the other two measures. The theoretical exposition reveals that, for this measure, the contribution from the quadratic term is not negligible, and that the coefficient of the linear term is affected by mortality levels, especially at the high end of the initial growth rate.

Thus, although the proportion over age 65 has great appeal as a conventional index of aging, it performs the poorest among the three measures of aging considered. The increase in the mean age of the population is simple and performs well, both theoretically and empirically. However, the ratio of the proportion under age 30 in the initial population to that in the ultimate population gives the population momentum *directly*.

As Fig. 2 illustrates, these linear relationships hold for *negative* momentum of population decline as well as for positive momentum of population growth. An initial stationary population with $r=0$ bridges the negative and positive momentum seamlessly.

4. Momentum Under Gradual Decline of Fertility

A population's growth potential is significantly underestimated when fertility is assumed to drop instantaneously to replacement level because no population can achieve such an abrupt fertility reduction. If fertility declines gradually over time, the resultant momentum is larger.

If an immediate fertility reduction is adopted by cohorts, the period NRR declines gradually (Frauenthal 1975). Suppose that cohorts born before time 0 maintain the old fertility level at a NRR of R_0 , while all cohorts born after time 0 reproduce at replacement-level fertility. Then the time trajectory of the period NRR resembles a declining logistic curve that begins to decline at time 15 (the beginning age of childbearing), and decreases to 1 at time 45 (the maximum age at childbearing). The *extra* momentum generated by this delayed fertility transition is R_0 . Thus the eventual population momentum under the assumption of a sudden drop in *cohort* fertility is given by $M_c = M \cdot R_0$.

Gradual fertility declines in period fertility have also been examined. Schoen and Kim (1998) consider a linear decline in the growth rate of births to 0 in a given period, during which the number of births grows to a higher level. In this case, NRR reaches replacement level a generation *after* the number of births stabilizes, and the time path of NRR decline is a smooth curve also resembling a declining logistic function. Li and Tuljapourkar (1999) consider a linear path of NRR decline, and derive the exact momentum when the duration of fertility transition is short (e.g., less than 15 years), then show numerically that it is a good approximation for as long as 40 years.

The two formulations give consistent results. The extra momentum increases exponentially as the duration of the fertility transition increases. More specifically, if the *period* NRR declines monotonically to replacement level over a duration, D , the *extra* momentum is larger by a factor $e^{Dr/2} \approx (\sqrt{R_0})^{D/\mu}$ (Schoen and Kim 1998). This is consistent with intuition: it can be interpreted as the growth at half the original growth rate during the given period, or as the growth at the original growth rate for half the duration. Therefore the eventual population

Figure 2

Scatterplots and coefficients of determination (R^2) for M , ΔA , F_{30} , and F_{65+} , coale-demeny female stable population

Thus the momentum generated by a gradual period fertility transition over 30 years is approximately equal to R_0 , equally contributed (multiplicatively) by the age distribution and the delayed fertility transition. The momentum under the sudden *cohort* fertility transition can also be explained in this vein. The extra population momentum, shown to be R_0 , is contributed equally by the growth during the first 15 years at the original growth rate, and during the next 30 years with declining *period* fertility. The growth generated by a *sudden cohort* fertility transition that takes 45 years is equivalent to that of a *gradual period* fertility transition over 60 years.

The extra momentum generated by delayed transition is not sensitive to variations in the time path of fertility decline. A comparison of the momentum generated by a linear decline in the period NRR and that generated by the logistically declining paths (produced by the scenarios of Frauenthal 1975 and of Schoen and Kim 1998) shows that the difference is small (Li and Tuljapurkar 1999). The extra momentum is determined mainly by the number of years a population needs to complete a smooth fertility transition.

5. Future Population Growth

In practice, future population growth is determined by improvements in mortality and the pattern and extent of migration, as well as by the future trends in fertility decline and by the current age distribution. The population growth that results from urbanization of a highly rural population in which the rural sector has higher fertility than in the urban sector is called spatial momentum (Rogers and Willekens 1978, Schoen and Kim 1993). Modern projection/prediction studies show that as the world's populations complete demographic transitions, the momentum inherent in the current young age distribution is the major component of future population growth in most developing countries (Bongaarts and Bulatao 1999). The other components of population growth—the spatial momentum, and the growth due to changes in fertility and mortality—under realistic assumptions is shown to be less than the age momentum (Bongaarts and Bulatao 1999, Brockerhoff 1999). Thus the growth associated with the young current age distribution in developing countries will be the major contributor to the future growth of the world population.

Population Dynamics: Probabilistic Extinction, Stability, and Explosion Theorems

1. Extinction, Stable Size, or Explosion?

Historically, probabilistic population theories originate from the *extinction problem*: suppose you know the probabilities of begetting 0, 1, 2, 3,... children. Now determine the probability that a population of a known number of individuals will eventually die out. Already Malthus had noted that a rapid increase of the whole population could occur together with frequent extinction of the separate families constituting the population. Rephrased in the terminology of evolutionary biology, frequent extinction of species does not contradict a rapid growth of the biomass of the world.

The mathematical explanation of this apparent paradox is due to Bienaymé (1845) and independently,

thirty years later and only in parts correctly, to Galton and Watson, who were later to lend their names to the simplest, generation-counting version of the so called branching processes that provide the mathematical structure underlying most stochastic population dynamics. Indeed, if p_k denotes the probability of giving birth to k children, $k = 0, 1, 2, 3, \dots$ then the extinction probability of a population stemming from one ancestor will be the smallest nonnegative solution q of the equation

$$\sum_k p_k q^k = q.$$

If we disregard the trivial case $p_1 = 1$, q will equal 1 if and only if the mean number of children

$$m = \sum_k p_k k \leq 1.$$

If $m > 1$, then the population growth rate per generation will be m , and even though q must be < 1 it can still be pretty large: it is easy to formulate demographically or biologically plausible cases where, say, m exceeds 2 and q is still around 0.8.

If a stochastic population does not die out, it can be proved very generally that it must grow beyond all limits (see Jagers 1991). This is a consequence of stochasticity and the asymmetry between extinction and big sizes: however big the population, there remains an albeit small but still positive risk of extinction, whereas an extinct population cannot be resurrected. This is in contradiction to deterministic population theories which allow population sizes to be stable, cf. Keyfitz 1968.

A finite world can certainly not sustain infinite growth. One can therefore argue that probabilistic population dynamics show that all real populations will die out sooner or later. But before that happens there may be a long period of growth.

2. Population Growth

To describe population growth in real time rather than generation-wise, a more sophisticated description of individual life and reproduction is needed. Probabilistic population dynamics is *individual based* in the sense that it starts from such a description. Deterministic theories, on the other hand, often start directly from an assumed behavior of the population as a whole. Demographic theory is often *pseudoprobabilistic* in that it uses probabilistic notions but makes conclusions only about the expected behavior of the population as a whole. (This is the reason why there exist deterministic populations with stationary sizes: if the underlying stochastic population is critical in the sense that on average each individual is replaced by one child, then the expected total population size will

be stationary, whereas the population itself will die out sooner or later.)

The most general probabilistic formulation of individual life goes as follows: at birth an individual inherits a *type* from her mother. The type determines her survival distribution as well as the distribution of age at childbearing. It also determines the types of the children she will give birth to in her turn. (Think of the type as a genotype, or a genotype combined with the social and biological conditions of life.)

In the *supercritical* case, where there is a positive chance of nonextinction, the probability laws of survival and childbearing determine a positive *Malthusian* parameter, which gives the rate of exponential growth. In the theory of branching processes this rate is usually denoted by α , so that the population will grow like $e^{\alpha t}$, as time t passes. In deterministic theory the conventional notation is often r instead.

Even though exponential growth appears to be a consequence of the independence assumed (tacitly or explicitly) between the reproduction of different individuals, it is interesting to note that such growth has recently been proved also to occur in many cases where individual reproduction depends upon the population as a whole, e.g., its size. For such results in the case of simple Galton-Watson branching processes see Klebaner (1984).

In cases where the reproduction approaches criticality as the population grows, non-Malthusian growth can occur nevertheless, e.g., in the form of linear growth (Klebaner 1994).

3. Stable Population Theory

In contrast to population size, the composition of growing populations tends to stabilize. The description of this composition, or rather the various stable compositions pertaining to different reproduction and survival laws, is the object of stable population theory.

The most well known aspect of stable population composition is the stable age distribution, first described by Euler in 1760 and since then rediscovered repeatedly: if the Malthusian parameter is $\alpha > 0$ and all individuals have the same survival function ℓ , then the age of an individual sampled at random in an old population will have the density

$$\frac{e^{-\alpha a} \ell(a)}{\int_0^\infty e^{-\alpha u} \ell(u) du}$$

at age a , exactly as in deterministic theory. This is, of course, a law-of-large-numbers effect; we are considering ever larger populations.

If, as in the general setup mentioned above, there are several types of individuals, each with its own life span distribution, then the situation will be more

complex. First of all, the type distribution will converge to a stable type law, determined by an eigenmeasure property. Then the survival function ℓ above will have to be replaced by an average of all the different survival functions weighted by the stable type distribution.

But the stable composition describes many other aspects of a balanced growing population besides ages. For example the probability of being first-born can be calculated as well as other aspects of family structure. In modern evolutionary biology the genealogy of individuals and, say, the mutational history plays an important role. In an old population this is described by a stable, typical ancestry, which can be used to determine time back to some event like divergence between species.

Population Dynamics: Theory of Nonstable Populations

1. Background

To introduce the theory of nonstable population dynamics, we start by presenting a Malthusian model studied by Lee (1974). Consider an overlapping-generation framework in which each individual lives

one or two periods. The first period is childhood and the second is adulthood, and all surviving adults will be in the labor force. The Malthusian model can be characterized by the following two equations: $W_t = f(N_t)$, $b_t = g(W_t)$, where W_t is the wage rate (at time t), N is the size of the adult group, b is the crude birth rate, and $f(\cdot)$ and $g(\cdot)$ are two functions. The $f(\cdot)$ function characterizes the wage/employment relationship in the labor market, and the $g(\cdot)$ function specifies the influence of the labor market reward on fertility.

Suppose the number of children born in period t is B_t , and the child survival rate is l , then $N_t = l \cdot B_{t-1}$. The above two equations can be combined in the following reduced form: $B_t = h(B_{t-1})$, where $h(B_t) \equiv g(f(l \cdot B_{t-1})) \cdot l \cdot B_{t-1}$. The above expression is a recursive equation of B_t , from which the dynamic pattern can be analyzed, and the possible existence of cyclicity can be studied. Here the Malthusian model is interpreted as a model of density dependency, where the density is characterized by the birth size of the previous period. It turns out that the Malthusian model described above may not converge to a ‘dismal’ steady state, as Malthus suggested. Mathematically, the B_t series may converge, diverge, or be cyclic, and the volatility of the birth series B_t crucially hinges on the feedback elasticity of $h(\cdot)$ with respect to B_{t-1} . When this elasticity is sufficiently large, the B_t series can easily have cycles. This is the classical case of nonstable population. Modern versions of nonstable population will be discussed below, after we introduce the general population structure.

2. The General Population Structure

Let $N_t \equiv (N_{t,1}, \dots, N_{t,n})$ be an n -type population vector at period t , where $N_{t,i}$, $i = 1, \dots, n$ indicates the size of type- i population at period t . The type here may refer to any criterion that is used to classify the population, such as age, sex, and occupation. A general formulation of population dynamics can be written as follows:

$$N_{t+1} = Q(N_t)N_t, \quad (1)$$

where $Q(N_t)$ is the transition matrix. The simplest case is when $Q(N_t) = Q$, a time-independent matrix. In this situation, the above equation reduces to a time-invariant Markov chain: $N_{t+1} = QN_t$. It is a well-known implication of the Frobenius–Perron theorem that if Q is positively regular, meaning that there is flexible cross-period mobility across types, then the population vector N_t will converge to a steady state, in which all elements of the N_t vector grow at the same exponential rate, thereby the population composition is also time-invariant. It has been shown by Chu (1998) that, for most population models with time-

independent Q , this positive regularity condition is likely to be satisfied, therefore any nonstable behavior of the population would appear only when $Q(N_t)$ is not a constant matrix, or equivalently when the relationship between N_{t+1} and N_t in Eqn. (1) has some nonlinearity. Below we shall introduce several special cases of the generic setting in Eqn. (1), and discuss their empirical relevance. The reader can see that each model corresponds to a special interpretation of the generic setting in Eqn. (1).

3. Easterlin Cycles

For demographers, the most familiar version of the dynamic models in Eqn. (1) is the Lotka–Leslie age-specific models, where the type criterion is age. Let $N_{t,i}$ be the number of population aged i at period t , B_{t-i} be the birth size at period $t-i$, and l_i be the probability that a person can survive to age i , then the following relationship must hold: $N_{t,i} = B_{t-i} l_i$. The transformed dynamics in terms of B_t is the well-known Lotka's equation:

$$B(t) = \sum_i B_{t-i} \cdot l_i \cdot m_{t,i} = \sum_i B_{t-i} \cdot \phi_{t,i} \quad (2)$$

where $m_{t,i}$ is the average number of births per surviving member aged i at period t , and $\phi_{t,i} \equiv l_i \cdot m_{t,i}$ is the net maternity function. Evidently, the Malthusian model presented in the previous section is a special case of Eqn. (2a) with two age types. As we mentioned, when the fertility function $m_{t,i}$ is independent of t , then the process of B_t follows a time-invariant Markov chain, and the usual convergence result applies. But if $m(t,i)$ is time dependent, then cycles or more volatile behavior may appear. One typical case of such time dependency is when the age-specific fertility rates are functions of previous birth sizes: $m_{t,i} = m_i(B_t)$, where $B_t \equiv (B_{t-1}, B_{t-2}, \dots)$.

Suppose the birth series corresponding to Eqn. (2a) has a steady state. Taking a Taylor expansion around this steady state, Lee (1974) showed that the volatility of the birth series characterized by Eqn. (2a) hinges upon the elasticities of the net maternity function with respect to B_t . When previous birth sizes are larger, usually the density pressure is larger. Intuitively, larger feedback elasticities imply that present reproduction would be more sensitive to previous birth shocks, hence the birth series would be more volatile. Easterlin (1961) argued that the baby-boom/baby-bust cycles observed in the United States are typical examples of a feedback cycle.

How large the feedback elasticities are is an empirical question. In order to estimate such elasticities, two models have been proposed: the first is to assume that $\phi_{t,i}$ is only a function of the cohort size aged i : $\phi_{t,i} = \phi_i(B_{t-i})$, and the second is to assume that $\phi_{t,i}$ is a function of the weighted average of birth sizes of different ages: $\phi_{t,i} = \phi_i(\sum_j w_j \cdot B_{t-j})$. The former is

referred to as the cohort model, and the latter as the period model. However, empirical evidence has so far failed to back up either of these two models in producing persistent birth cycles that fit all characteristics (such as amplitude and period). Moreover, even if there does exist a cyclic solution to Eqn. (2a), the information concerning feedback elasticity is not sufficient for us to tell whether the cyclical solution in question is stable. Related analysis is rather technical, and the reader is referred to Tuljapurkar (1987) for details.

4. Predator–Prey Cycles

The predator–prey model describes a two-type population structure, where the types are prey and predator, respectively, referred to as type-1 and type-2. The simplest formulation of the predator–prey model is characterized by the following difference equations:

$$\begin{aligned} \Delta N_{t+1,1} &\equiv N_{t+1,1} - N_{t,1} \\ &= aN_{t,1} - bN_{t,1}N_{t,2} \end{aligned} \quad (3a)$$

$$\begin{aligned} \Delta N_{t+1,2} &\equiv N_{t+1,2} - N_{t,2} \\ &= -cN_{t,2} + dN_{t,1}N_{t,2}, \\ a, b, c, d &> 0. \end{aligned} \quad (3b)$$

Equation (3) is obviously a special case of Eqn. (1). The prey are considered the only food resource available to the predator. Thus, if $N_{t,1} = 0$, the predator population decreases exponentially at the rate c . With the nonexistence of predators, the prey population grows exponentially at the rate a .

In the steady state of Eqn. (3), $\Delta N_{t,1} = \Delta N_{t,2} = 0$, there is only one nontrivial solution: $(N_1^*, N_2^*) = (c/d, a/b)$. Let the Jacobian matrix of Eqn. (3) around the nontrivial solution be denoted J . It turns out that the determinant of J is

$$J = \begin{pmatrix} a - bN_2^* & -bN_1^* \\ dN_2^* & -c + dN_1^* \end{pmatrix} = \begin{pmatrix} 0 & -bc/d \\ ad/b & 0 \end{pmatrix}$$

$|J| = ac > 0$ and the trace of J is zero.

Thus, we know that the eigenvalues of J are purely imaginary, meaning that besides the equilibrium point $(c/d, a/b)$ itself, the solution trajectories of Eqn. (3) are cyclic and nonstable. But it was also pointed out that when the predator–prey model embodies the concerns of diminishing or increasing returns, then the solution becomes locally stable or divergent.

5. Dynastic Cycles

Based on stylized facts found in Chinese history, Chu and Lee (1994) proposed an occupation-specific population model, in which the population is separated into

three occupations: bandits, peasants, and soldiers. Peasants grow crops and pay taxes, soldiers (rulers) collect taxes and hunt for bandits, and bandits rob food and clash with peasants and soldiers. It is assumed that soldiers are drafted by the government, and all other civilians can choose to become peasants or bandits. Their occupation choice is made depending on which occupation is expected to generate a higher utility. When the bandit/soldier ratio is relatively high, it is likely that the incumbent power regime will be overthrown by the bandit group, and the dynasty switches. It turns out that this pattern of population dynamics characterizes the dynamic evolution of dynasties in Chinese history, and the cycles were called dynastic cycles by historians.

In terms of demography, the occupation switches mentioned above are merely changes in population composition. But there is a unique feature associated with the above-mentioned occupation switching, which we shall explain below. For most animals, it is believed that when density pressure occurs, the environment becomes less favorable, and the reproduction rate of animals is reduced. One might expect that rational human decisions may be able to weaken the outside density pressure through institutional and rational regulation. But the scenario of dynastic cycles seems to be a counterexample. As noted by historians, clashes between soldiers and rebellious peasants in human history were often initiated by famine or density pressure. The higher the bandit ratio, the less likely a peasant can safely keep a good proportion of his crop, and hence the greater attraction for the peasant to join the bandit group and seize other people's crops. Thus, human beings' occupational choice between peasants and bandits has a 'demonstration effect,' which tends to magnify the originally weak density pressure and 'destablize' the dynamics of the population compositional structure.

The cyclical pattern of population composition mentioned above is not the only case we find in human history. Some researchers have considered a neo-classical economic growth model, and focused on the two economic classes in the economy: the laborers and the capitalists. Let u_t be the income share attributed to labor, and v_t be the employment rate of labor. Under some reasonable assumptions, Goodwin (1967) has shown that the dynamics of u_t and v_t mimic that of Eqn. (3). Thus, the conclusion that the capitalists' economy appears to be 'permanently oscillating' was reached. But just as the original predator-prey model is sensitive to variations in institutional specifications, Goodwin's model after some minor modification also generates qualitatively different results. Definite evidence of the nonstability of human population has yet to be found.

Population Dynamics: Theory of Stable Populations

A population with an age distribution which remains constant over time is referred to as 'stable.' A stable population of constant size is said to be 'stationary.' These concepts are of considerable antiquity. Euler, for example, knew in 1760 the stable age distribution a population needed to have if it were to have a given growth rate. Compilers of some of the early life tables such as Graunt in 1662 appear to have assumed populations which were stationary, and nineteenth-century actuaries certainly made use of the stationary population concept (King 1902).

Subject to age-specific mortality and fertility rates which remain unchanged over time a population will eventually develop a stable age distribution which depends on those mortality and fertility rates but is independent of the initial age distribution of the population. This result, due to Sharpe and Lotka (1911) caused renewed interest in stable populations among demographers. Although demographers usually think of a stable population as one with an age distribution which is unchanging, such a definition is restrictive, because populations can also exhibit stability in respect of other characteristics as well as age and in more general situations.

1. The Population Model of Sharpe and Lotka

Sharpe and Lotka considered the male population alone and assumed that the growth of the female population would be such as to justify assumptions of

constant age-specific fertility and mortality for the males. Subsequent writers have usually applied the model to the female component of the population because of its shorter reproductive age span and the fact that the number of females in the reproductive age range plays a more significant role in determining the number of births than the number of males (Pollard 1973).

Applied to the female population, the model assumes $F(x, t)dx$ females in the age range $(x, x + dx)$ at time t and $B(t)dt$ female births between times t and $t + dt$. Then, if the average number of daughters born per female aged exactly x in time element dt is $\lambda(x)dt$ and the probability that a female survives from age u to age $u + v$ is ${}_v p_u$, the following relationship is immediately apparent:

$$B(t) = \int_0^{\infty} F(x, t) \lambda(x) dx \quad (1)$$

Noting that those alive and aged x at time t , enumerated in $F(x, t)dx$, must either have been born at time $t - x$ ($x < t$) or else have been aged $x - t$ at time 0 ($x > t$), Eqn. (1) may be rewritten as

$$B(t) = \int_0^t B(t-x) {}_x p_0 \lambda(x) dx + G(t) \quad (2)$$

with

$$G(t) = \int_0^{\infty} F(x, 0) {}_t p_x \lambda(x+t) dx \quad (3)$$

The solution to the integral equation (2) reveals that for large values of t , under quite general assumptions

$$B(t) \cong C e^{rt} \quad (4)$$

where the constant r (the *intrinsic growth rate* of the population) is the unique real solution to the integral equation

$$\int_0^{\infty} e^{-rx} {}_x p_0 \lambda(x) dx = 1 \quad (5)$$

and the constant C depends on the initial age distribution of the population as well as the age-specific mortality and fertility rates (Keyfitz 1968, Pollard 1973).

Since the females aged between x and $x + dx$ at time t are the survivors of those born x years earlier between times $t - x$ and $t - x + dx$, it follows from Eqn. (4) that

$$F(x, t) \cong C e^{r(t-x)} {}_x p_0 = (C e^{rt}) (e^{-rx} {}_x p_0) \quad (6)$$

The first factor in the right-hand side of Eqn. (6) indicates that the population grows exponentially asymptotically at rate r , while the second reveals that the age distribution is asymptotically independent of t . In other words, a *stable age distribution* is reached.

2. The Discrete Time Model of Bernardelli, Leslie, and Lewis

Whilst the continuous time model of Sharpe and Lotka is elegant and predicts a stable population asymptotically under conditions of constant age specific mortality and fertility, the discrete time formulation of Bernardelli (1941), Lewis (1942) and Leslie (1945), which makes similar assumptions, is more readily adapted to analyze stability in more complicated situations.

The number of females aged x last birthday at time t is represented by $n_{x,t}$. There is no migration, and no one can live beyond age k last birthday. The average number of daughters born to a female while she is aged x last birthday, those daughters surviving to be enumerated as being aged zero at the next point of time, is F_x , and the proportion of females aged x last birthday surviving to be aged $x + 1$ last birthday a year later is P_x . Under these assumptions, the following matrix recurrence equation must apply to the numbers of females in successive years:

$$\begin{pmatrix} n_{0,t+1} \\ n_{1,t+1} \\ n_{2,t+1} \\ n_{3,t+1} \\ \dots \\ n_{k,t+1} \end{pmatrix} = \begin{pmatrix} F_0 F_1 & F_2 \dots & F_{k-1} F_k \\ P_0 & & \\ & P_1 & \\ & & P_2 \\ & & & \ddots \\ & & & & P_{k-1} \end{pmatrix} \begin{pmatrix} n_{0,t} \\ n_{1,t} \\ n_{2,t} \\ n_{3,t} \\ \dots \\ n_{k,t} \end{pmatrix} \quad (7)$$

This equation may be written more concisely as

$$\mathbf{n}_{t+1} = \mathbf{A} \mathbf{n}_t \quad (8)$$

so that

$$\mathbf{n}_t = \mathbf{A}^t \mathbf{n}_0 \quad (9)$$

Under fairly general conditions, matrix $\mathbf{A}$ is positive regular, in which case it has a dominant eigenvalue α which is positive, of multiplicity one, and greater in absolute size than any other eigenvalue. It follows from Eqn. (9) therefore that for large t ,

$$\mathbf{n}_t \cong C \alpha^t \mathbf{z} \quad (10)$$

where C is a constant which depends on the initial age distribution of the population, and $\mathbf{z}$ is the column eigenvector corresponding to the eigenvalue α . If Π_s is written instead of the product $P_0 P_1 \dots P_s$, the elements of $\mathbf{z}$ are $\Pi_0 \alpha^{-0}, \Pi_1 \alpha^{-1}, \dots, \Pi_k \alpha^{-k}$. It follows, therefore that the number of females aged x last birthday at time t is

$$n_{x,t} \cong (C \alpha^t) (\alpha^{-x} \Pi_x) \quad (11)$$

This is the discrete analogue of the Sharpe and Lotka formula, Eqn. (6). The second factor defines the asymptotic stable age distribution; the first shows the exponential growth of the population (Keyfitz 1968, Pollard 1973).

3. Stability with Migration

The most appropriate model for a population subject to significant migration must depend on the pattern that migration takes. In the case of a country accepting a constant number of immigrants each year with a constant age pattern, for example, the discrete time recurrence of Eqn. (8) needs to be modified as follows:

$$\mathbf{n}_{t+1} = \mathbf{A} \mathbf{n}_t + \mathbf{b} \quad (12)$$

where $\mathbf{b}$ is a constant vector of immigrants. Under this model, immigrants are assumed to adopt immediately the mortality and fertility patterns of their new homeland (see *Immigrant Fertility*). Repeated application of Eqn. (12) for $t = 0, 1, 2, \dots$ reveals that, provided the dominant eigenvalue of $\mathbf{A}$ is not equal to one,

$$\mathbf{n}_t = \mathbf{A}^t \mathbf{n}_0 + (\mathbf{I} - \mathbf{A}^t) (\mathbf{I} - \mathbf{A})^{-1} \mathbf{b} \quad (13)$$

If the rate of natural increase of the population is less than zero, α will be less than one, and for very large t

$$\mathbf{n}_t \cong (\mathbf{I} - \mathbf{A})^{-1} \mathbf{b} \quad (14)$$

The population will become stationary with its age structure determined by the ages of the immigrants (vector $\mathbf{b}$), as well as the mortality and fertility of the host country (matrix $\mathbf{A}$). Where the fertility of the host country is greater than replacement level, α will be greater than one, and the following asymptotic formula follows from Eqn. (13) for very large t :

$$\mathbf{n}_t \cong C' \alpha^t \mathbf{z} \quad (15)$$

In this case, the population grows asymptotically with the same exponential growth rate as it did in the discrete nonimmigration case of Sect. 2. The asymptotic stable age distribution (vector $\mathbf{z}$) is also the same. The constant C' , however, is different, depending on

the initial age structure, the vector of immigrants $\mathbf{b}$, and the mortality and fertility of the population.

In the pathological case where the levels of mortality and fertility in the population correspond exactly to replacement, α is equal to one, and a different algebraic approach is necessary to the solution of Eqn. (12), which yields, for very large t , the following asymptotic result:

$$\mathbf{n}_t \cong C'' t \mathbf{z} \quad (16)$$

The population grows linearly asymptotically and the asymptotic age distribution is the same as in the previous case. The constant C'' depends on the immigration vector, as well as the fertility and mortality rates of the population.

For a population experiencing net emigration with a proportion β_x of females aged x departing each year, the matrix model of Sect. 2 can be utilized with each of the P_x in matrix $\mathbf{A}$ replaced by $P_x - \beta_x$. The mathematical theory can then be applied in the same manner as before, and an asymptotic stable population emerges. The dominant eigenvalue and eigenvector will of course be different from those in Sect. 2. Depending on whether the dominant eigenvalue of the modified matrix $\mathbf{A}$ is less than, equal to, or greater than one, the population will ultimately decline, become stationary or grow in size.

The above models are only two of a very wide range of possible migration models appropriate in different circumstances. They demonstrate how the discrete time model of Sect. 2 may be readily modified to take account of migration and the fact that population stability will usually emerge in the presence of migration when the migration parameters, mortality, and fertility remain unchanged over time.

4. Generalizations

The discrete time models of the earlier sections are readily adapted to study populations partitioned according to other characteristics as well as age. Multiregional demography is the best known example (Rogers 1966, 1975). Females of a population are characterized by age and geographical region in an extended column vector $\mathbf{n}_t$ of dimension mk , where k is the maximum age last birthday attainable and m is the number of regions in the country. As well as surviving and reproducing in the manner of Sect. 2 with rates that may differ from region to region, females can move from one region to another with transition rates which depend on the regions involved and may also depend on age. The matrix recurrence equation is again Eqn. (8), but with $\mathbf{n}_t$ of dimension mk and $\mathbf{A}$ of dimension $mk \times mk$. Conditions for a unique dominant eigenvector are readily determined, and asymp-

totic stability for the population by age and geographic region is predicted.

Another partition characteristic sometimes proposed is the *parity* of woman. Females at time t are enumerated in a vector $\mathbf{n}_t$ with elements $\{n_{x,y,t}\}$ which record the numbers aged x last birthday who already have y children. The only possible transitions for a female aged x and parity y remaining within the system are to age $x+1$ and parity y or to age $x+1$ and parity $y+1$ (ignoring the small possibility of multiple births). Where there is a change in parity, a new female will be introduced into the population aged 0 last birthday and parity 0 if the mother's change in parity corresponds to a female birth. Recurrence matrix $\mathbf{A}$ contains these transition rates. The fundamental recurrence equation is again Eqn. (8). For all realistic populations, the enlarged matrix $\mathbf{A}$ will have a unique dominant eigenvector, and the population enumerated by age and parity will approach stability (Keyfitz 1968).

The discrete-time models of Sects. 2 and 3 have also been applied to workforce planning (Bartholomew 1973, Pollard 1967), membership of learned societies (where Fellows are elected on merit and there is a danger of the society becoming a rapidly aging institution), and membership of other groups including pension schemes (Sherris and Pollard 1980). A learned society, for example, might have a policy of electing five new Fellows each year. The membership of the society at time t can be summarized by a vector $\mathbf{n}_t$ with elements $\{n_{x,t}\}$ representing the numbers at the various ages at that time. The number of new members (five) and their age distribution can be summarized in a vector $\mathbf{b}$. The transition rates in the recurrence matrix are simply the proportions $\{P_x\}$ surviving from age x last birthday to age $x+1$ last birthday a year later, for all relevant ages. Assuming that the ages are listed in their natural increasing order, the transition matrix $\mathbf{A}$ is particularly simple in this case: all its elements are zero, except those immediately below the main diagonal which comprise the survival proportions $\{P_x\}$. With $\mathbf{n}_t$, $\mathbf{b}$, and $\mathbf{A}$ defined in this manner, the recurrence equation for the society is Eqn. (12). All the eigenvalues of $\mathbf{A}$ are zero, and for t greater than the number of ages involved, $\mathbf{A}^t = \mathbf{O}$. The society will approach a stationary state given by Eqn. (14).

All such linear models with realistic assumptions concerning transition between states, entry and reproduction can be shown to predict stable populations asymptotically.

5. Applications

No observed population experiences constant levels of mortality and fertility. Nevertheless the concept of a stable population finds frequent application. Keyfitz's elegant formula for the effect of population momen-

tum (see *Population Dynamics: Momentum of Population Growth*) assumes that the population is stable immediately prior to fertility falling to replacement level. Yet the formula works remarkably well for observed populations which are not stable. Stable population theory may be helpful in deducing results in respect of populations with unreliable and/or limited demographic data. Equation (4), for example, can be used to infer an approximate value for the crude birth rate of a population where contraception is not widely practiced, using only a reliable census of the population and a more or less appropriate life table (Bourgeois-Pichat 1957). Many of the applications of model life tables rely on stable population theory (see also *Population Dynamics: Classical Applications of Stable Population Theory*).

6. Limitations

The discrete time model of Bernardelli, Leslie, and Lewis, like the continuous (female) formulation of Sharpe and Lotka, assumes that the development of the male component of the population is such as to justify the assumption of unchanging female age-specific mortality and fertility. Linear models which include the male component of the population alongside the females have also been proposed, and mathematical analysis analogous to that presented in Sect. 2 predicts a stable age-gender composition for the whole population. Nonlinear models have also been proposed to accommodate the 'two-sex problem' (see *Population Dynamics: Two-sex Demographic Models*). Many of these nonlinear models would also seem to predict populations which are asymptotically stable under conditions of unchanging rates of mortality, fertility and nuptiality.

For many developing countries, for which stable population theory had been an extremely helpful tool, mortality began to decline in the second half of the twentieth century, but fertility remained essentially unchanged from previous levels. To accommodate the improvements in mortality, the concept of a quasi-stable population was introduced: one with improving mortality but constant fertility (Coale 1963).

Population Dynamics: Two-sex Demographic Models

1. Classical Stable Population Theory

A population is in ‘demographic equilibrium’ if the fraction of individuals in each age-sex category remains constant over time and the population is growing (or declining) at a constant rate. Demographers call a population that is in demographic equilibrium a ‘stable population.’ This use of the phrase stable population blurs the distinction between questions involving the existence of a demographic equilibrium and those involving its dynamic stability; hence, I depart from standard demographic terminology and in its place use the phrase ‘demographic equilibrium.’ In deference to traditional usage, however, I refer to demography’s standard model as ‘classical stable population theory.’

Nondemographers are often surprised to learn that the classical stable population theory operates with a one-sex model. The theory postulates an age-specific fertility schedule for women and an age-specific mortality schedule for women. These two schedules, in conjunction with the very strong assumptions that both of these schedules remain constant over time, imply an equilibrium growth rate and an equilibrium age distribution for the female population.

Demography’s two-sex problem is the problem of integrating men into this one-sex, female-based model. The two-sex problem is often motivated by discussing the effect on fertility of a ‘marriage squeeze.’ A marriage squeeze is an imbalance between the female and male populations of marriageable age brought

about, for example, by wars that disproportionately reduce the number of marriageable men. A marriage squeeze can also result from a baby boom: because women typically marry older men, a baby boom increases the number of marriageable women many years before it increases the number of marriageable men. Common sense suggests that a marriage squeeze is likely to reduce age-specific fertility rates for women, but the classical stable population theory, because it assumes that age-specific fertility rates remain constant, cannot accommodate this common sense conclusion.

2. The Birth Matrix-mating Rule Model

Demography’s two-sex problem is solved, in a formal sense, by the ‘birth matrix-mating rule’ (BMMR) model introduced in Pollak (1986). (Feeney (1972), in an unpublished doctoral dissertation, presents a two-sex model with the same basic structure, but without a satisfactory proof of the existence of equilibrium.) The BMMR model has three primitives (i.e., components not derived from more fundamental components):

- (a) a birth matrix, which indicates the number of offspring born to each possible type of union (e.g., the union of a female of age i and a male of age j);
- (b) a mating rule, which indicates the number of unions of each type as a function of the number of females in each age category and the number of males in each age category; and
- (c) age-specific mortality schedules for males and females.

Under relatively weak assumptions, the BMMR model determines equilibrium growth rates and equilibrium age distributions for the female and male populations. It also determines who marries whom or, more precisely, the age pattern of assortative mating. The BMMR model assumes that all fertility is marital fertility and all unions are monogamous, although both of these assumptions are easy to relax. Because the BMMR model allows changes in the age structure of the population (e.g., shortages of marriageable men relative to marriageable women) to change the number of unions, it accommodates our common sense conclusion about the effect of a marriage squeeze. Throughout a marriage squeeze, the birth matrix (i.e., the number of births to each type of union) remains constant, but the number of unions changes, and these changes in the number of unions imply changes in the number of births and, hence, changes in the implied age-specific female fertility rates.

2.1 Linear and Nonlinear Models

Because the classical stable population theory utilizes a linear model, the mathematics is straightforward. The age-specific fertility and mortality schedules for the female population together define a mapping of the female population vector (by age) in period t

into the female population vector in $t + 1$. Because the implied mapping is linear, demographers use the simple and powerful tools of linear algebra to investigate the existence, uniqueness, and dynamic stability of the equilibrium. The matrix corresponding to the mapping of the population vector in period t into the population vector in period $t + 1$ is called the Leslie matrix. The equilibrium age distribution is an eigenvector of the Leslie matrix; the equilibrium growth rate is obtained by subtracting 1 from the corresponding eigenvalue. In linear demographic models, cases in which an equilibrium fails to exist, cases of multiple equilibria, and cases in which the dynamics do not exhibit global stability are generally regarded as pathological.

The BMMR model, like the classical stable population theory, defines a mapping of the population vector in period t into the population vector in period $t + 1$. The initial population vector, together with the mating rule, determines the number of unions of each type; the number of unions of each type, together with the birth matrix, determines the number of newborns in the next period. The initial population vector, together with the mortality schedules, determines the number of individuals in each of the other age-sex categories, just as in the classical stable population theory.

Nonlinearity is a necessary feature of any two-sex demographic model. The two-sex problem arises precisely because the classical stable population theory fails to recognize that the effect on population in period $t + 1$ of adding a female of age i to the population in period t depends on the number of males. In the BMMR model, this dependence is captured by the mating rule. Any mating rule for monogamous unions must satisfy two accounting requirements: a nonnegativity condition ensuring that the number of unions of each type is positive or zero, and an adding-up or balance condition ensuring that the number of mated females of each age does not exceed the total number of females of that age, with a similar requirement holding for males. This adding-up requirement is the fundamental source of nonlinearity in the BMMR model.

Because the BMMR model is inherently nonlinear, establishing the existence of equilibrium and analyzing dynamic behavior in the BMMR model is more complex than in the classical stable population theory. A 'natural' but unsuccessful strategy for establishing the existence of equilibrium is to apply a fixed-point theorem to the mapping of the population vector in period t into a suitably normalized population vector in period $t + 1$; a fixed point of such a mapping—a population vector that maps into itself—is an equilibrium of the BMMR model. The difficulty with this strategy is that the mapping defined by the BMMR model carries some population vectors into the 0 vector and, hence, this strategy fails to establish the existence of a nontrivial equilibrium. An alternative

proof strategy, followed in Pollak (1986), avoids this difficulty by drastically limiting the domain of the mapping and reducing the problem to a single dimension.

2.2 Uniqueness and Dynamic Stability

Multiple nontrivial equilibria are not pathological in nonlinear models, and Pollak (1990a) demonstrates by example that the BMMR model can have multiple nontrivial equilibria. An overly strong apparently innocuous sufficient condition for the BMMR model to have a unique nontrivial equilibrium is that at every population vector an increase in the number of individuals in each age-sex category does not decrease the number of newborns in the next period.

Uniqueness and dynamic stability are intimately related. In a model with multiple equilibria, initial conditions determine which, if any, of several equilibria will be realized, and small differences in initial conditions can lead to large differences in long-run behavior. Pollak (1990a) discusses four sets of demographically meaningful conditions that imply local stability. Local stability rather than global stability is the relevant issue because, *inter alia*, some initial population vectors must lead to the trivial equilibrium. Further work—both theoretical and empirical—is required to determine whether any of the sufficient conditions for uniqueness and dynamic stability are satisfied and whether multiple equilibria or dynamic instability are realistic possibilities in two-sex demographic models.

Simulation is a possible approach to investigating these issues, but simulation techniques are much less informative in models that lack parametric specifications. In linear models, parametric specification is a feature of the model itself, but to simulate the BMMR model, we must first specify a functional form for the mating rule, and then specify the appropriate parameter values. Explicit functional forms for mating rules are discussed in Pollak (1990b).

3. Behavioral Models

Further work is also required to transform the BMMR model from a formal into a substantive model of population age structure and growth. The transformation requires importing behavioral theories from social science into the BMMR model to explain its three primitives—the birth matrix, the mating rule, and the mortality schedules. (In the generalized version of the model in which unions can persist for more than one period, there is a fourth primitive requiring a behavioral explanation: the schedule specifying the probabilities that unions of each type will end in desertion or divorce: see Pollak 1987.) From the

standpoint of social science, however, these three primitives are different kinds of analytical constructs. The mortality schedule is often regarded as a biological datum, although there is ample precedent (from Malthus to recent concern about excess female infant mortality rates in India) for regarding mortality as endogenous. The elements of the birth matrix reflect the decisions of individuals or of families facing economic and biological constraints. The analysis of these decisions is the subject matter of economic and sociological theories of fertility.

Whether we interpret 'unions' narrowly or broadly, the mating rule of the BMMR model is more complex analytically than the mortality schedules or the birth matrix because it reflects not only individual behavior but also the interactions of individuals in the 'marriage market.' The marriage market metaphor is useful because it suggests notions of choice, competition, and equilibrium. That is, the mating rule is not a full-blown theory of marriage or union formation but a reduced form, presumably reflecting the requirements of equilibrium in the marriage market.

There are two approaches to modeling competition and equilibrium in marriage markets, one based on matching and the other based on search. Mortensen (1988) and Weiss (1997) provide accessible introductions to both matching and search approaches; Roth and Sotomayor (1990) provide the definitive treatment of matching models. Both matching and search models begin with the preferences of individuals and analyze their implications for marriage-market equilibrium. They differ, however, in their assumptions about the information available to and the alternatives faced by marriage-market participants. Matching models are nonstochastic and timeless; they implicitly assume that complete and accurate information about potential spouses is instantaneously and costlessly available to all marriage-market participants. Search models, in contrast, are stochastic and dynamic; they recognize explicitly that individuals have less than complete and accurate information about potential spouses, and that acquiring more and better information takes time and, in some search models, requires resources. In a search model, when two individuals meet in the marriage market, they must decide whether to marry or to continue searching, balancing the attractiveness of marriage now to a particular individual against the expected value of remaining unmarried and continuing to search. Because search models do not assume that individuals have complete and accurate information, they may appear to be more 'realistic' than matching models. The price that search models pay for added realism is their sensitivity to specific assumptions about the rate at which potential spouses meet in the marriage market, the impatience or time preference of individuals, and individuals' beliefs about the characteristics and beliefs of other marriage market participants.

Ecologists may find models that allow the possibility of a positive equilibrium rate of population growth unsatisfactory because such models fail to recognize density dependence and other factors that prevent population growth from continuing indefinitely.

4. Summary

To summarize: classical stable population theory is parsimonious both because it allows us to use well-known, powerful mathematical techniques to investigate existence and dynamic stability, and because it allows us to infer a population's equilibrium age structure, growth rate, and dynamic behavior from very little data. The birth matrix-mating rule model, which allows fertility rates to depend on the population's age-sex structure, is more complex analytically and more demanding in its data requirements. In return for these extravagances, the BMMR model solves demography's two-sex problem and provides a framework for addressing the marriage squeeze and other important issues in demography that require a two-sex model.

Population Ecology

One part of this research program examines the demography of organizations. It finds that organizational mortality processes depend upon the age and size of the organization, as well as on characteristics of populations and environments. Moreover, there is evidence of an imprinting process, meaning that environmental conditions at certain early phases in an organization's development have long-term consequences. In particular, organizations subject to intense competition have elevated mortality hazards at all ages.

A central theme is structural inertia, the tendency for organizations to respond slowly relative to the speed of environmental change. A central argument holds that inertia derives from the very characteristics that make organizations favored kinds of actors in modern society: reliability and (formal) accountability. It follows that changes in an organization's core features are disruptive and increase mortality hazards, at least in the short-run. Research on this subject tends to support this view.

The concept of niche provides a framework for relating environmental variations and competition to population dynamics and segmentation. Much empirical work examines the niches of organizational populations in terms of dimensions of social, political, and economic environments.

Most research in this field builds on theories of resource partition and of density dependence. Resource-partitioning theory concerns the relationship between increasing market concentration and increasing proliferation of specialists in mature industries. The key implication of this theory concerns the effects of concentration on the viability of specialist organizations (those that seek to exploit a narrow range of resources). The theory of density-dependent organizational evolution synthesizes ecological and institutional processes. It holds that growth in the number of organizations in a population (density) drives processes of social legitimation and competition that, in turn, shape the vital rates. This argument implies certain nonmonotonic relationships between density and rates of founding and mortality. Both theories

have been subject to empirical test in diverse populations of organizations; the preponderance of evidence supports both.

Current research emphasizes formalization (often using tools of formal logic), integration of methods of social network analysis and ecological analysis, and developing implications of organizational ecology for other aspects of social structure.

The population ecology of organizations, commonly called organizational ecology (OE) examines interactions within and between populations of organizations. This approach differs from other sociological research by focusing on the population level, relying on selection logic, and studying the life histories of all organizations in populations studied over their full histories.

This approach built initially on neo-classical population bioecology, which analyzes numerical aspects of population interactions from an evolutionary perspective. In a paraphrase of bioecologist G. E. Hutchinson, Hannan and Freeman (1977) posed the following orienting question of OE: Why are there so many kinds of organizations? They suggested that the social science literature lacked good answers to this question and that seeking answers would clarify the dynamics of the organizational world. Subsequent research has shown that organizational diversity has important consequences for individuals and social structures (Carroll and Hannan 2000).

OE sought initially to resolve a tension in the human ecology concerning what Hawley (1968) termed the principle of isomorphism, 'Units subjected to the same environmental conditions or to environmental conditions as mediated through a given key unit, acquire a similar form of organization.' Hannan and Freeman (1977) argued that Hawley's principle, like other adaptationist premises, does not apply straightforwardly in uncertain, heterogeneous environments. Extending the received wisdom about adaptation requires specification of the underlying dynamic processes and attention to processes of selection and segmentation.

1. The Basic Demography of Organizations

With its concentration on the vital rates of founding and mortality, OE has a strong demographic character. Key structuring processes are specified at the population level. Although mortality histories can always be associated with individual organizations, histories of foundings cannot because the absence of foundings in some period or place must be considered.

Populations must have unit character to serve as useful objects of analysis (Hawley 1968). Researchers generally regard populations as spatial-temporal instantiations of organizational forms, templates for organizing. Several conceptions of the basis of form

have guided these efforts: common resource dependence, structural equivalence in network position, and identities coded in cultural rules.

Constructing organizational demography and ecology requires attention to differences between organizations and organisms. In particular, organizations experience more varied 'birth' and 'death' events, typically lack clear parents, have multilayered, partly decomposable structures, and can transform themselves. The major methodological project has involved dealing with these complexities (Carroll and Hannan 2000).

The resulting strategy examines the full histories of organizational populations, because experience shows that early events can have lasting consequences for population dynamics. It gathers life history data on all organizations in the population(s), including the large and famous as well as the small and insignificant—this is crucial for avoiding problems of selectivity bias. It records detailed information about type of entry (new founding, entry from another industry, merger, etc.) and exit (disbanding, acquisition, transformation, etc.). Finally, it uses event-history methods to estimate the effects on vital rates of characteristics of organization, population, and environment. This research strategy has diffused widely to areas of organizational research that do not necessarily share theoretical commitments.

Ecological research finds that many more organizations have operated in well-studied industries than is usually assumed. Careful archival searches usually find information on hundreds of organizations that get overlooked in published counts. They also reveal that organizational life expectancies are generally an order of magnitude smaller than for individuals.

Much attention has been paid to organizational aging. Stinchcombe (1965) observed that organizations (and organizational populations) experience a liability of newness. Efficient organization requires trust among members, which takes time to build. Creating roles and routines, learning about the environment, and developing relationships with other organizations also take time. Once established, these patterns of relationships enhance survival chances. Much early research found this pattern. Some later research found a variation, a liability of adolescence: the hazard rises during the early lifespan—while initial stocks of endowments get exhausted—before declining. Recent research, using designs that measure (age-varying) organizational size, has produced (mixed) evidence in favor of positive age-dependence (Carroll and Hannan 2000). Two interpretations for this pattern have been proposed. If inertial forces are strong, then the possibilities of adapting to changing environments are limited and older cohorts of organizations have lower fitness—there is a liability of obsolescence. Alternatively, the accumulation of rules and routines impedes adjustment to environmental change—the liability is one of senescence. Current

research seeks to clarify the conditions under which the various patterns arise—see later.

2. *Inertia and Selection*

Stinchcombe's (1965) insight that new organizations get imprinted by their environments provided inspiration for developing the ecological approach. According to Stinchcombe's argument, new organizations get tested against assumptions that are taken for granted but change over time. Hence, the characteristics of organizations that pass such tests and emerge reflect the social structure of the time. Imprinting requires both a mapping of environmental conditions onto the organization and inertia in the imprinted characteristics. Absent the second condition, later adjustments will erode the association between founding conditions and those features.

OE has built on this image of inertia (relative to the speed of environmental change). According to Hannan and Freeman (1989), inertia prevails as an inadvertent by-product of a selection process favoring the properties of reliability (low variance in the quality of performance) and accountability (the ability to construct rational accounts for actions). Achieving these properties depends on structures being reproduced faithfully over time. Yet, high reproducibility means that structures resist transformation. Therefore, this selection process inadvertently favors corporate actors with strong inertial tendencies.

Fundamental change presumably diminishes reliability and accountability. Old learning loses value, and new processes must be learned. Vestiges of the old system conflict with the new one emerging. Thus, even if fundamental change has long-term benefits (the new form might be better aligned with environments and internal processes), change might increase mortality hazards in the short-run. If so, then reorganization-prone organizations have a lower probability of representation in future populations.

Much research has tested the implications of this argument. Most well designed studies reveal that changing core structures does increase the hazard of mortality in the short-run, often substantially (Carroll and Hannan 2000). Moreover, the magnitude of this effect increases with organizational age.

A different way of viewing imprinting yielded one of OE's most robust empirical findings: density delay. Organizations subject to intense competition at founding (as evidenced by a high density of organizations in the population—see later) have elevated mortality hazards at all ages. In other words, density at founding has a (partially) delayed effect on mortality processes. This relationship has been interpreted as reflecting enduring effects either of building structures under scarcity or of positioning at the margins of resource distributions.

3. Organizational Niches

The concept of niche provides a framework for relating environmental variations and competition to population dynamics and segmentation. A population's fundamental niche consists of the combinations of environmental parameters for which its growth rate (fitness) is non-negative in the absence of competition. Much empirical work in OE examines the niches of organizational populations in terms of dimensions of social, political, and economic environments (e.g., Dobrev 1999). Even when such issues do not stand in the forefront, ecologists routinely control statistically for the effects of such dimensions in examining dynamic processes.

Niche theory has also been central to research on competition (Hannan and Freeman 1977, 1989, McPherson 1983). Populations compete if the presence of each reduces the spaces in which the others can sustain themselves (their realized niches). By this reasoning, populations compete if and only if their fundamental niches intersect. The assumed equivalence of niche overlap and competition has played a crucial role in allowing organizational ecologists to relate empirical observations on realized niches to models of population dynamics.

Niche width concerns the variance of resource utilization. Does evolution favor populations of Jacks-of-all-trades and masters of none (generalists) or specialists at a few tasks? Research shows that the organizational world tends toward segmentation into specialist populations (each highly isomorphic) when relevant environmental variations are uncertain, large in magnitude, and long in duration (Hannan and Freeman 1989, Péli 1997).

4. Resource Partitioning

Resource-partitioning theory, OE's best-developed theory of segmentation, concerns the relationship between increasing market concentration and increasing proliferation of specialists in mature industries. The theoretical imagery concerns crowding in a heterogeneous market. Organizations initially target resource segments. Specialists choose narrow, homogeneous targets; generalists choose broad, heterogeneous ones.

The theory assumes an advantage of scale (in production, marketing, or distribution). Because organizations targeting narrow segments cannot grow very large, they have higher (per unit) costs. Organizations with scale advantages expand products to broaden their appeal without losing established domains. Small organizations then face formidable invaders, and many fail. Competition is most intense in resource-dense centers, resulting in dominance by large generalists. Failures of smaller generalists cause some resources to become free. Because larger genera-

lists can best secure these resources, the surviving generalists become larger and more general. However, generalists can rarely secure all of the newly freed resources. As the struggle among generalists proceeds to its monopoly equilibrium, the surviving generalists grow and broaden, but the set of resources they hold collectively actually declines. In other words, more resources become available for specialists as the market concentrates. Therefore, as concentration rises, the viability of specialist organizations increases as well: founding rates rise and mortality rates fall.

The empirical implications of this argument involve an interaction effect between organizational form (specialism-generalism) and concentration in affecting each vital rate. Empirical studies on diverse populations support this hypothesis (Carroll and Hannan 2000). Populations studied include American airlines, brewers, investment banks, microprocessor manufacturers, newspaper publishers, telephone companies, and wineries, as well as British automobile manufacturers and Italian cooperative banks (full citations can be found in Carroll and Hannan 2000).

5. Density Dependence

The theory of density-dependent organizational evolution synthesizes ecological and institutional processes. It holds that growth in the number of organizations in a population (density) drives processes of social legitimation and competition that, in turn, shape the vital rates (Hannan and Carroll 1992). An organizational form gains (constitutive) legitimation when it becomes taken-for-granted (Meyer and Rowan 1977). New organizational forms generally lack such legitimation, which makes organizing difficult. If the form gets promulgated, legitimation increases. Initially, when there are few organizations in a population and the form lacks legitimacy, the returns to legitimation of adding another organization are great. However, when the population contains many organizations, constitutive legitimation increases little—if at all—as density rises further. In other words, a population's legitimation increases with density at a decreasing rate and approaches a ceiling.

Competition refers to the consequences of efforts by multiple agents to acquire the same limited resources. Density-dependence theorists focus on diffuse competition because it has a clear relationship with density as the intensity of diffuse competition within an organizational population rises as a function of the number of potential bilateral competitors. As density increases linearly, the number of possible competitive relations increases geometrically. Thus diffuse competition rises with density at an increasing rate. The theory posits that founding rates are directly proportional to legitimation and inversely proportional to the intensity of diffuse competition and that these relationships are inverted for mortality hazards.

This theory (formalized appropriately) yields two theorems. First, as density increases, founding rates rise initially, reach a peak, and then decline. Second, the relationship for mortality is the mirror image. These theorems, expressed in parametric forms, can be falsified empirically. They have been tested for diverse populations, including automobile manufacturers in Europe and the USA, brewers in Germany and the USA, banks in Denmark, Japan, Singapore, and the USA, and American labor unions, life insurers, newspapers, and social movements of women and ethnic groups. These studies have supported the theory in most cases (full citations can be found in Carroll and Hannan 2000).

6. Emerging Trends

Current research seeks to sort out these varied arguments, learn about conditions of applicability, and (when possible) unify them. One strand begins by reconstructing the fragments in formal languages. In the case of age dependence, a partial integration has been achieved in a formulation in first-order logic (Carroll and Hannan 2000). The next steps require use of nonmonotonic logic, which allows premises to be overridden by more specific ones so that the conclusions of an argument can change as more knowledge about specifics becomes available (Pólos et al. 1999).

Efforts are underway to rebuild the foundations of the research program on an improved formal representation of organizational forms, with forms based on culturally coded and enforced identities (by Pólos et al. 2002). In this construction, density dependence plays a role in the cultural coding process, as do social movements. Processes of enforcement of identities generate inertial mechanisms as well as punishments for fundamental changes (those that violate codes).

Basing forms on identities helps clarify issues in resource partitioning. Specialization based on claims to authentic identity (as in the case of the rise of specialist producers of microbrewed beer in the USA and 'real ale' in the UK) can prevent large generalists from gaining complete control of concentrated markets. Other research seeks better representations of dynamics and segmentation. The formal model of density-dependence serves as the foundation for many of these efforts. One approach rescales the effects of density using a specification of subniches to weight density. Some research weights densities according to an organization's position within a broad technology class or by licensing restrictions, location, and price (Baum and Singh 1994). Alternatively, the weightings are set to reflect the strength of competitors (Barnett 1997). These specifications generate refined understandings of dynamics (at the cost of considerable complexity).

A second variation envisions competition as more localized than legitimation, because political author-

ities can better impede flows of products than ideas. For instance, research on the European automobile industry shows competition operating primarily within national markets but legitimation operating throughout Europe (Carroll and Hannan 2000). The third has shown the effects of density change systematically over a population's history, either directly as a function of population age, reflecting the growing importance of identities, statuses, and reputations in affecting life chances in mature populations or as a function of industry concentration (Barron 1999), in the spirit of resource-partitioning.

The empirical scope of OE also continues to expand. Current research focuses on a diverse set of industries. In addition to those already mentioned, these include: accountancies, bicycle manufacturers, computer manufacturers, disk-drive producers, footwear manufacturers, hotels, law firms, magazine publishers, paper manufacturers, sex shops, and television stations. A major thrust of current work is collecting data on life histories of organizations and on connections among the organizations (including flows of personnel among them). These studies highlight the value of social network analysis for understanding the ecology of organizations.

New processes are also being brought into the picture. Organizational status has been shown to affect life chances, with the impact increasing with the uncertainty in evaluations of quality (Podolny et al. 1996). Social movement research relies increasing on OE as a guide to modeling dynamics (Minkoff 1997); ecologists, in turn, increasingly view social movements as pivotal in the emergence of forms (Wade et al. 1998). Studies of careers find that organizational demography induces considerable job mobility (Haveman and Cohen 1994); at the same time, careers of managers shape strategies and thereby influence life events for organizations (Sørensen 1999).

M. T. Hannan

Population, Economic Development, and Poverty

1. Introduction

Assessing the consequences of population on the pace and process of economic growth is one of the oldest themes in the literature on economics. These assessments have varied enormously over time, spanning the highly pessimistic to the outright optimistic. A systematic review of the major studies in this literature represents a useful way to organize a survey of the

consequences of demographic change. Such an approach places the population debates in perspective, and it infuses a healthy dose of caution in appraising current debates. Specifically, how have the ‘bottom-line’ appraisals of the consequences of demographic change on development changed over time; why have they changed; and what are the most recent contributions to this literature?

2. The Beginnings: Malthus (1798)

The debate began with two propositions by the Reverend Thomas Malthus in 1798 (*First Essay on Population*) that population would grow at a geometric rate (e.g., 1, 2, 4, ...) due mainly to a lack of conscious restraints on fertility, and that food would grow at an arithmetic rate (e.g., 1, 2, 3, ...) due substantially to diminishing returns to increasingly scarce land. The resulting outcome would be food shortages, starvation, and deaths. In the long run, population size would be held in check by food availability and mortality. Population pressures would constrain income per capita to a low level of subsistence—a ‘Malthusian trap,’ as it has been termed. These images caused economics, unfairly, to be dubbed the dismal science.

Fortunately Malthus’ predictions were not sustained by the preponderance of experience over the next two centuries. Couples did not breed without restraint, but rather by consciously managing fertility in response to changing conditions. Food was not unduly constrained by land availability. Instead, technology blossomed and food expanded apace in the very geographic regions where Malthus focused his empirical studies. Ironically, food *surpluses* turned out to be a ‘problem’ confronting many nations, and governments implemented policies designed to curtail farm production.

Clearly the Malthusian ideas regarding population–economic linkages were incomplete, and richer analytical and empirical foundations were needed. The urgency for such a framework was made apparent by demographic events. By the mid-twentieth century, it was recognized that the simultaneous occurrence of declining mortality and exceptionally high and sustained fertility in scores of developing countries was resulting in high population growth rates. A concern emerged that these rates could not be sustained over long periods of time. While, as in the past, fertility would predictably decline (*a la* the Demographic Transition), it was unclear whether such a decline would be soon or rapid enough to avoid potentially deleterious effects on welfare, economic progress, and the environment. Thus, while the ‘Malthusian Problem’ reappeared, approaches to assessing population consequences assumed quite different tacks. It was time for a fresh reassessment.

3. Expanded Elaborations: 1950s, 1960s, 1970s

3.1 The United Nations (1953)

The first major installment that exposed economic-demographic interactions in detail was provided in a seminal study by the United Nations in 1953, *The Determinants and Consequences of Population Trends*. This study was both balanced and comprehensive. Twenty-one economic-demographic linkages were taken up. The impact of population on some factors was judged to be positive (economies due to scale and organization), on some negative (diminishing returns), and on some neutral (technology and social progress). Overall, a net negative impact of undetermined size was considered most likely in much of the developing world, although this conclusion was guarded, and the UN predicted a wide diversity of effects according to country-specific conditions.

3.2 Coale and Hoover (1958)

A second major installment in the evolution of demographic assessments appeared in 1958 in an influential book by Ansley J. Coale and Edgar Hoover (C/H) entitled *Population Growth and Economic Development in Low-Income Countries*. Based on the simulation results of a mathematical model calibrated by Indian data, C/H concluded that India's development would be substantially enhanced by lower rates of population growth. Their analysis rested on two premises. First, household and economy-wide saving would be diminished by large families; it certainly would not be stimulated enough in response to demographic changes to provide the increased capital required by an enlarged population. Second, economy-wide investments would be skewed away from relatively productive activities since funds would be shifted toward so-called unproductive population-sensitive social expenditures (e.g., health and education). This crowding out of productive investment was linked mainly to the youthful age composition of the high-fertility population, and not population size, density, or growth, *per se*.

The C/H study had a profound impact on US population policy. It also attracted the attention of academic scholars given its focus on physical capital (as distinct from the Malthusian focus on land), then considered by many to be a (the?) key to economic development.

The C/H study was not without challenge. Over time its impact waned, in part due to the appearance of empirical studies that failed to unearth empirically strong and consistent impacts of population pressures on Third World saving. This is not surprising. At the household level, such saving impacts are fundamentally based on a life-cycle conceptualization of be-

havior. This requires a lengthy forward looking planning horizon. It also requires an institutional structure (e.g., developed capital markets and/or government social security options) to implement lifetime plans. These conditions do not describe the day-to-day survival mode of most residents of the Third World. Indeed, spending on children represents a form of saving (e.g., parents may expect transfers from their children in old age); and moreover, children can be quite productive both in the household and on the farm.

A second challenge to the C/H framework was the appearance of empirical studies that downplayed the role of country-wide age structures as a determinant of spending on education. Even in the face of population pressures, school enrollments and attainments advanced at historically unprecedented rates in many developing countries. This surprisingly occurred without substantial realignments in social budgets. Nations found ways to economize on education resources, and tradeoffs within education budgets were more pervasive than was assumed in the simple C/H model. In short, the empirical underpinnings of the C/H framework were questioned by an increasing body of evidence. Additionally, over time economic theory itself was in flux, highlighting both the *productivity* of human capital (considered economically unproductive in the C/H model), and the importance of technical change (also absent in C/H). While these limitations do not diminish the importance of C/H's pioneering work, they served to shift the population debates in the ensuing decades.

3.3 National Academy of Sciences (1971)

The most pessimistic assessment of population consequences since Malthus appeared in a study organized by the National Academy of Sciences. The findings, *Rapid Population Growth: Consequences and Policy Implications*, appeared in two parts: Volume I, a short Executive Summary, and Volume II, a large set of papers compiled by a panel of distinguished scholars. The study's findings, as summarized by the Executive Summary, are baffling and difficult to interpret. They must be handled with care.

On the one hand, the Executive Summary conveyed a highly negative, indeed an outright alarmist, assessment of the impact of rapid population growth. Twenty-five separate adverse impacts were listed and assessed; no notable positive effects of demographic change were identified. Moreover, there was a substantial disconnection between the Executive Summary and the findings of the key scholars participating in the study, as documented by the papers found in Volume II. The Executive Summary, whose pessimistic conclusions obtained wide publicity in the 1970s, was demonstrably unfaithful to the scholarly studies in

Volume II. The Summary was not vetted with the scholars who participated in the study, and indeed its authorship is unknown to this day, in spite of extensive attempts to clarify the historical record (an exhaustive historical assessment of this episode is provided in Kelley 2001). Clearly the assessment of the Executive Summary must be strongly discounted. In spite of this, however, a careful reading of the papers and supporting components of the Report do reveal an important insight that assists in illuminating the ebb and flow of population assessments over time.

Specifically, the Executive Summary was by admission based mainly on 'direct,' *shorter-run* impacts of demographic change. ('We have limited ourselves to relative short-term ... issues,' p. vi). In contrast, the major research papers supporting that study in Volume II, which were much less pessimistic, were based on a *longer-run* focus. More than any other factor, the outcomes of the population debates from the 1970s to the present day would turn on this difference in time perspective. *Direct, shorter-run impacts of demographic change are almost always attenuated (and sometimes even offset) by feedbacks that occur only over longer periods of time.*

3.4 United Nations (1973)

In 1973 the United Nations updated its early assessment. This revision arrived at a less eclectic, and a somewhat more pessimistic (but by no means alarmist) evaluation of the various impacts of population growth. This is particularly true of anticipated difficulties of feeding the expanding populations (reverting to traditional Malthusianism), and of pressures on capital formation (reverting to the concerns of Coale and Hoover). In both cases, short-run, direct impacts were highlighted. The report downplays some indirect, longer-run feedbacks that will likely occur due to price responses, and induced innovation and institutional change.

The most important new contribution to the population debate deriving from the 1973 study was a finding by Simon Kuznets that, based on simple correlations, a net negative impact of population growth on per capita output was not obvious in the data. While his work was based on *longer-run* assessments, and while they were appropriately qualified, they were important to conditioning the bottom-line UN assessment. Given the strong priors of demographers and policy makers that the negative impacts of population growth on development were large, the inability to easily confirm this hypothesis through simple, albeit inconclusive, correlations more than any other factor kept the population debate alive during the ensuing decades. The stage was set for a new round of debate.

4. Revisionism: The 1980s

4.1 Julian L. Simon (1981)

This debate was initiated in 1981 with the publication of Julian L. Simon's *The Ultimate Resource*, which challenged the pessimistic views of economic-demographic interactions. The significant impact of Simon's book is explained by several factors. First, it concluded that population growth was likely to exert a *positive* net impact on economic development in many Third World countries *in the intermediate run*—a startling assertion that attracted extensive attention. Second, it illustrated that the outcome of population impacts on the economy are likely to hinge both on the *time* dimension of the assessments, and whether *feedbacks* are included in the analysis. Third, it reintroduced to the debates the roles of alternative demographic impacts, specifically those of density and size, to add to the popular focus on population growth and age structure. Fourth, and importantly, the book elevated the role of *technology* as a (the?) driving force of economic growth. Simon asserted that demographic pressures would favorably influence the nature and pace of technological change. Finally, it was written in a highly accessible, confrontational debating style that goaded and infuriated his skeptics and amused and emboldened his supporters.

These various attributes of Simon's framework are best illustrated by his analysis of the likelihood that demographic pressures would ultimately cause natural resource exhaustion. He illustrated with numerous graphs that over longer periods most natural-resource prices actually declined, even in the face of rising demands stimulated in part by expanding populations. Price-induced substitutions in production and consumption of natural resources, and an expansion of supply through discovery and technical advance, are offered to explain this result. Most importantly, these 'adjustments' or 'feedbacks' were in part *caused by* population pressures, a reality that could be exposed only by extending the analysis over several decades. It is this longer-run perspective, and the *feedbacks* in markets and other institutions, that account for Simon's findings.

Similarly, Simon hypothesized and attempted to document that the pace of technical change, and its bias, were actually stimulated by population pressures, particularly in agriculture where Ester Boserup's (1965) model, first expounded in *The Conditions of Agricultural Growth*, was advanced. She proposed that increasingly productive agricultural technologies are made economically feasible only at higher land densities, and therefore population pressures against increasingly scarce land could have a powerful positive effect on agricultural output growth. Simon extended this notion to observe that major social overhead projects (roads, communications, irrigation) benefited from expanded populations and scale.

While Simon's book was highly influential in its own right, arguably its greatest impact was as a catalyst in setting the stage for reassessing the basic propositions of the population debates. The 1980s witnessed a flurry of major reassessments.

4.2 National Research Council (1986)

The most important and influential reassessment was compiled by a Working Group on Population Growth and Economic Development under the auspices of the National Research Council (NRC). The bottom-line assessment by this group was eclectic, balanced, and nonalarmist:

On balance, we reach the qualitative conclusion that slower population growth would be beneficial to economic development of most developing countries (p. 90).

This carefully worded statement illustrates well the central elements of all of the major population assessments in the 1980s: (a) there are both important positive and negative impacts of population growth (thus, 'on balance'); (b) the actual size of the net impact—and even whether it is strong or weak—cannot be determined given current evidence (thus 'qualitative'); (c) only the direction of the impact from high current growth rates can be discerned (thus 'slower,' and not 'slow'); and (d) the net impact varies from country to country—in most cases it will be negative, in some it will be positive, and in others it will have little impact one way or the other (thus, 'most developing countries').

It is interesting to speculate on factors that account for the guarded and qualified assessment of the NRC group. Three factors can be singled out.

First, the Summary Report highlights *individual and institutional responses* to initial impacts of population change—conservation in response to scarcity, substitution of abundant for scarce factors of production, innovation and adoption of technologies to exploit profitable opportunities, and the like.

Second, the study was compiled almost exclusively by economists, whose faith in the potential for market-induced responses to modify initial direct impacts of population change is greater than that possessed by other social and biological scientists.

Third, research which had been accumulating over the past 10 to 15 years downplayed many of the previous concerns voiced on the impacts of rapid population growth. For example, as noted by Simon and others, the concern that population growth results in the exhaustion of non-renewable natural resources is misplaced. The relationship between population growth and global resource use is not as strong as had been assumed.

Similarly, the concern about a substantial reduction of saving due to rapid population growth is not

confirmed by the data. While some capital shallowing occurs, the impact of this on economic growth is not particularly strong. Finally, the concern that population growth will significantly shift resources from productive physical capital formation into alleged 'less-productive' areas was not sustained by the data. The financing of educational enrollments, which expanded significantly even in the face of population pressures, came from some combination of increases in public (sometimes deficit) spending, reduction in per pupil expenditures, and efficiency gains.

Interestingly, a new concern was elevated in importance by the 1986 Report in the area of renewable resource degradation. Unlike non-renewable resources, property rights are difficult to assign or maintain for renewable resources like fishing areas and rain forests. Overuse can result. The problem is not population growth *per se*, but rather institutional failure. Cutting population growth in half would not solve the problem; it would only postpone the deleterious outcome of resource degradation. The solution requires policies to focus on the *causes* of failure (the need for more effective property rights, market responses, and government policies to correct externalities) rather than a focus on population pressures, which mainly exacerbate the environmental responses.

4.3 Other Studies in the 1980s

The bottom-line assessments of five other studies in the 1980s merit citing. All reflect the balanced, longer-run methodological perspective of the 1986 National Research Council report. Specifically, all highlight direct and indirect responses to population pressures. The resulting bottom-lines, while assigning a negative net impact of rapid population growth are, on average, both qualified and guarded.

The World Bank's *World Development Report* 1984 is concerned most about countries that exhibit exceptionally rapid growth rates: '...population growth—at rates above 2 percent ...—acts as a brake on development' (p. 79), although, 'Up to a point, population growth can be accommodated ...' (p. 79).

An overall appraisal of both the *World Development Report* 1984, and the National Research Council report two years later, is offered by Dr. Nancy Birdsall, who headed the World Bank study and was also a member of the NRC Working Group. She concluded that 'Rapid population growth can slow development, but only under specific circumstances and generally with limited or weak effects' (Birdsall 1988, p. 529).

Allen C. Kelley's 1988 survey for the *Journal of Economic Literature* concludes that '...economic growth...would have been more rapid in an environment of slower population growth, although in a number of countries the impact was probably negligible and in some it may have been positive' (p.

1715). Adverse impacts are most likely to occur where (a) water and arable land are scarce, (b) property rights are poorly defined, and (c) government policies are ineffective and biased against labor.

T. N. Srinivasan's 1988 survey parallels the conclusion of the NRC Report. He emphasizes caution in the formulation of population policies, noting that 'many of the alleged deleterious consequences [of population growth] result more from inappropriate policies and institutions than from rapid population growth. Thus policy reform and institutional change are called for, rather than policy interventions in private fertility decisions to counter these effects' (p. 7).

It appears that in the 1980s a broad consensus was struck on the net assessments of demographic change. Most analysts held that while slower population growth would indeed advance the economic progress of most developing countries, the size of the net impacts would not likely be especially remarkable by comparison with numerous other determinants of economic growth. The shift of the research emphasis during the decade to highlight the importance of (a) *time* in the analysis (modifying shorter-run direct impacts of demography with feedbacks occurring over the longer run), and (b) the need to account for the separate components of demographic change (births, deaths, age, size, density), combined to put the research programs on solid footing. While these revisionist renderings and methodologies were widely embraced, uncertainties still remained, most importantly the need to obtain more precise *quantitative* assessments, especially those that accounted both for the components of demographic change and the timing of their impacts.

5. New Paradigms: The 1990s and Beyond

While most of the 1990s was preoccupied with digesting the revisionist results of the 1980s, population research did advance in several areas.

First, the findings from simple correlations between the rate of population and per capita economic growth appeared to have changed. While a general *lack* of correlation was the widely obtained statistical result for the 1960s and 1970s, in the 1980s the correlation turned negative (see Kelley and Schmidt 1994). On the one hand, most analysts agreed that such simple correlations are difficult to interpret, plagued as they are by failure to adequately account for reverse causation, excessive reliance on cross-section data, sensitivity to the selection of countries, the complexity of demographic linkages that are poorly modeled, spurious correlation, econometric pitfalls, and data of dubious quality. On the other hand, the previous finding of *no* correlation for the 1960s and 1970s in the face of strongly held priors of a negative correlation literally kept the population debate alive. Now, a

change in this relationship from one of no correlation to one of a negative correlation for the 1980s required an explanation. New questions appeared: what accounts for the changed correlations; are the new results robust; are they quantitatively important?

The ability to address these issues coincided with the emergence in the 1990s of empirical 'convergence' models of economic growth. Pioneered by Robert Barro, these empirical paradigms distinguish between factors (economic, political, social, institutional, geographic) that determine each country's *long-run* level of per capita output, and the shorter-to-intermediate-run *transition* of countries to this longer-run state. These models lent themselves to investigating the impacts of demography since they exposed both short- and long-run impacts.

Efforts to model demography using the new convergence models have varied notably. Barro (1997), for example, looked primarily on the longer-run impacts of demography, and found that reductions in the total fertility rate increased the potential for economic growth.

In yet an earlier study, Kelley and Schmidt (1995), building on the Barro core variables, distinguished between several alternative demographic influences on the economy's potential output in the long-run, (e.g., the impacts of population size and density), and timing of demographic impacts (e.g., the timing of reductions in birth and death rates) which influence both the short and long run. These timing specifications highlighted the reality that birth-rate reductions have an immediate positive impact on growth by economizing on child-rearing expenses while, in fifteen or so years, the impacts will be reversed, since there will be fewer persons entering their productive work force years. Death rate reductions, especially infant/child mortality, can have similar timing impacts. Kelley and Schmidt found that these timing/transitional features were empirically important, and the long-run impacts of both density and size added modestly to growth as well.

Bloom and Williamson (1998), also building on Barro's empirical framework (although with different core variables highlighting policy and geography), modified the demographic modeling to break out an accounting reckoning of age-compositional impacts. While explicit modeling of longer-run demographic impacts is absent in their framework, their clean accounting framework clearly exposes the impacts of changing age structures, driven by changes in fertility and mortality. These are quantitatively important impacts on the *transition* to long-run output per capita. Their results focused on East Asia where declines in fertility were rapid and shorter-run transition effects are predictably large.

Finally, Kelley and Schmidt (2001) compared the above (and other) modeling efforts in a single empirical investigation, and came up with a somewhat surprising result: demography accounts for around 20 percent of

changes in output per capita growth from 1960–95 across a wide collection of countries. While for several reasons they consider their findings qualified, it is interesting that these findings are broadly consistent with those of the 1980s. Population *does* matter: its impact is likely adverse over the period 1960–95; this impact varies from decade to decade; components of demographic change exert both positive and negative impacts; these impacts vary notably from place to place; and, as a determining variable of long-run economic prosperity, population's impact is notable, but not remarkable. In the shorter-to-intermediate run, during periods of transition (both demographic, and economic), populations impact can be elevated or diminished, depending on the pace of demographic change and especially on the country's specific institutions (government policy, efficacy of markets, definition of property rights).

Population Forecasts

Population forecasts summarize existing knowledge about the change in the size and structure of populations. They support decision making by providing broad perspectives for future development. In other cases they may provide detailed estimates for specific planning tasks. The methods that are currently in use were mostly developed in the 1920s, 1930s, and 1940s, before modern computers were available. Although the forecasts provide us with important insight into the possible future development of the populations, a major deficiency in those methods is that they provide the forecast users with inadequate assessment of the uncertainty to be expected. The reasons for the unpredictability of demographic processes are only poorly understood. However, the development of new statistical models and the availability of fast computing allows a realistic description of forecast uncertainty in terms that are understandable to nonspecialist users.

1. Development of the Cohort-component Method

1.1 Curve Fitting Approach

Early calculations concerning the renewal of populations were based on simple mathematical models.

Define $V(t)$ as the total population at time t . If the rate of growth is constant, or $V'(t)/V(t) = r$, then the population grows exponentially, $V(t) = V(0)e^{rt}$, from the starting or *jump-off* population $V(0)$. If the rate of growth decreases with increasing population according to $V'(t)/V(t) = r(M - V(t))/M$ where M is a limiting population size, then the growth is *logistic*, $V(t) = Me^{rt}/(1 + e^{rt})$. A discrete time version of the exponential model was used, for example, by T. Malthus in his *Essay on the Principle of Population* in 1798. The logistic model was introduced by F. Verhulst in 1838.

Such models were widely criticized because (a) they do not give age detail; (b) they do not allow a change from increase to decrease; (c) they are too mechanistic for human populations; (d) even though the exponential and logistic models are empirically indistinguishable when $V(t)$ is small relative to M , they give completely different long-term forecasts.

1.2 Incorporation of Age Structure

Methods for describing age-structured populations were developed around the turn of the nineteenth century in many countries, first in England by E. Cannan in 1895. By the end of the 1920s, forecasts by age and sex had also been made for the Soviet Union, The Netherlands, Sweden, Italy, Germany, France, and the United States (de Gans 1999).

Define $V(x, t)$ as the size of the female population at age x at the beginning of year t . Then, for ages $x > 0$, we have the bookkeeping equation $V(x + 1, t + 1) = V(x, t)p(x, t) + N(x + 1, t + 1)$, where $p(x, t)$ is the probability of surviving from age x to age $x + 1$ during year t , and $N(x + 1, t + 1)$ is the net number of migrants during year t who are at age $x + 1$ at the beginning of year $t + 1$. For age $x = 0$ we have $V(0, t + 1) = \sum_x f(x, t)V(x, t) + N(0, t + 1)$, where the summation is over the childbearing ages (often $x = 15, \dots, 49$), and $f(x, t)$ is the expected number of children at age 0 at the beginning of year $t + 1$ that were borne by women at age x one year earlier. Corresponding formulas can be written for the male population, and they can be extended to comprise several regions. This system of calculation is called the *cohort-component* (c-c) method.

1.3 Advantages of the Cohort-component Method

The c-c method can be viewed as a response to the criticisms of Sect. 1.1 in the following sense. (a) Since the c-c method treats the population by age groups, it provides direct estimates of the future population by age and sex. That this is useful for the planning of housing, schools, hospitals etc., was understood from the beginning. (b) The c-c method makes no as-

sumption about the growth rate. It shows that, other things being equal, the growth rate increases with the proportion of women of childbearing ages. In 1925 L. Dublin and A. Lotka introduced the concept of intrinsic rate of growth. For a closed population with unchanging fertility and mortality, it gives the asymptotic rate of growth. As such it provides important insight into the renewal of populations that cannot be detected from current growth rates. Many of the early cohort-component forecasts assumed unchanging fertility and mortality, and no migration, and showed that the size of the childbearing population, and with it the total population, would cease to grow, even though the populations had been growing fast during the early 1900s. This contradicted the forecasts by exponential and logistic models. (c) The reason why the c-c forecasts are less mechanistic than those based on exponential or logistic curves is that they utilize the available information or assumptions about the change of the *vital rates* (of fertility, mortality, and migration). The forecasters of the 1920s knew that fertility and mortality had been declining for decades. How far down would they go and how fast? Examples from other countries or from privileged social groups were used as leading indicators for future mortality. The spreading of the urban lifestyle was seen to lead to a decrease in fertility. Opinion surveys were developed around 1940 to collect data on desired family size (Whelpton et al. 1947). (d) The early forecasters knew that the exponential, logistic, and other curves often gave similar fits to past data, but led to very different forecasts. Since statistical *model choice* depended on judgment but had a drastic effect on the results, why could one not use judgment in other ways as well? The solution by Whelpton to this problem was to set up targets for future vital rates, and to connect the most recently observed rates to the targets by suitable mathematical curves. Dutch forecasters had also used similar methods. This practice has been widely followed, and most national population forecasts use judgmental methods for specifying future vital rates, often via explicit targets (e.g., Andrews and Beekman 1987).

Although the c-c method was an improvement over the curve fitting methods, it was soon understood that it is really a bookkeeping framework, and without an accurate specification of the future change in the vital rates improvements in forecast accuracy would not materialize.

As an example we may consider a forecast of Sweden that was crafted by S. Wicksell in 1926. The forecast had 1920 as the jump-off year with a population of 5.90 million. It had five fertility variants. For 1940 the most likely forecast was 6.53 million inhabitants. The high forecast was 6.87 and the low forecast was 6.28. The actual population size was 6.37 so the error was 2.5 percent. For 1970 the most likely value was given as 6.67 and the high-low interval was [6.26, 8.44]. The true value was 8.08 so the error was -17.5 percent.

Even though many of the errors were large, the high–low intervals were wide and they gave a realistic indication of the uncertainty of the forecast.

2. Foundational Aspects in the Forecasting of the Vital Rates

Most national forecasts of the vital rates are purely demographic, i.e., they do not explicitly incorporate social or economic factors. Only rarely do they take into account the fact that the forecast itself might influence the future development. Partly because of these factors, and partly because of the poor accuracy of past forecasts, there has been a lengthy debate about whether the results of the calculations would be better interpreted as mere ‘projections’ rather than ‘forecasts.’

2.1 The Difficulty with Explanatory Models

Refinement in demographic analysis often refers to the partitioning of the population at risk into more meaningful subgroups. For example, instead of relating births and deaths to the total population (which gives the crude birth and death rates), one may relate births to age of mother and consider deaths by age and sex (which gives the age-specific fertility and mortality rates) (see *Demographic Measurement: General Issues and Measures of Fertility; Demographic Measurement: Nuptiality, Mortality, Migration, and Growth; Demographic Techniques: LEXIS Diagram*). The use of crude rates in exponential or logistic models can imply growth forever, whereas the use of the age-specific rates in a c-c model may imply a future decrease of the same population.

The analysis can be further refined. Age-specific rates may be analyzed for birth cohorts and by parity; marital and nonmarital fertility may be considered separately; or one may consider fertility by race, for example. Empirical evidence of whether this improves accuracy is mixed.

However, the more fundamental social or economic factors that determine the fertility, mortality, and migration of population subgroups are rarely used explicitly in forecasting. This is because future changes in such factors can be harder to forecast than the vital processes themselves. Keyfitz (1982) reviews many of the difficulties.

One attempt at solving the problem has been *conditioning*. By making detailed assumptions about the future course of relevant social and economic factors, forecasters have sought to formulate conditional forecasts, or *scenarios*, in which the evolution of the vital processes would follow assumed relationships with their determinants. A drawback of such an approach is that the manner in which the conditioning is done can have a major effect on the results. A

sensitivity analysis that systematically varies some of the assumptions may then be helpful.

2.2 Self-fulfilling or Self-negating Prophecies

In some countries such as Germany and France the early population forecasts were motivated by the fear of population decline and loss of political power. In The Netherlands overpopulation was the concern. In both cases the forecasts were seen as a means of influencing social policies (de Gans 1999). Inasmuch as the forecasts were influential, they were self-negating.

In other cases such as regional forecasting, a forecast of population growth may cause the local society to develop the infrastructure of an area to allow for future growth. The favorable circumstances created may then turn the forecast into a self-fulfilling prophecy.

Although examples of both types of ‘prophecies’ exist, it has been difficult to demonstrate the causality in a historical context. Deliberate government attempts at lowering (or increasing) fertility, or lowering mortality, have seldom had long-lasting effects that could be attributed to the policies as opposed to other concurrent factors.

2.3 Debate on Terminology

From the very start forecasters have been aware that the future vital rates cannot be known with certainty. Evaluations of past forecasts have vividly demonstrated the unpredictability of demographic change. For example, the post-World War II baby boom was missed by all national forecasters. Mortality has similarly declined faster in the industrialized countries than the forecasters anticipated.

To safeguard their reputation some forecasters have occasionally tried to communicate the uncertainty by using the terms ‘projection,’ ‘illustrative projection,’ or even ‘horoscope’ for the results of their calculations. This is a reasonable practice, e.g., if the calculation consists of a c-c forecast with constant vital rates, when no one expects the rates to remain constant. However, as pointed out by H. Dorn in 1950, the producers of official forecasts typically publish calculations that are based on what they consider as the most likely future vital rates, and users also interpret the results in this way. Indeed, we may define a calculation based on what is regarded as the most likely assumptions as a *forecast*.

3. Statistical Uncertainty in Forecasting

Although probabilistic terminology is used in many branches of demography (e.g., probability of death in

life tables) (see *Life Table*), and experience has shown that forecasts of the future population have been highly uncertain, the forecasting models considered so far have all been deterministic. The recognition of the uncertainties in probabilistic terms opens up new possibilities to enhance the usability of the forecasts.

3.1 Uncertainty in the Events and in the Rates

Consider a child-bearing population of size V . Suppose the number of births during a year is B . We can think of B as a sum of V random experiments with an average probability f of a birth. The expected number of births is $E = fV$. Based on a Poisson approximation one can estimate that in a sequence of B values the relative variability (coefficient of variation) is $E^{-1/2}$. In a small regional population we may have $E = 100$, for example. Then, the births vary by about 10 percent each year due to random variation alone. However, if $E = 10,000$, they only vary by about 1 percent, and if $E = 1,000,000$ they vary by 0.1 percent each year. It was pointed out by J. Pollard in 1973 that much larger relative variations are observed in the numbers of births in different countries, so this type of Poisson variation does not account for the variability of the observed birth processes.

The situation changes if we allow f to change from year to year with a coefficient of variation c (or by 100c percent). Then the relative variation is at least c irrespective of the expectation E . The conclusion is that for forecasting large populations, the uncertainty lies in the randomness of the rates rather than in the Poisson type variation in the events themselves.

3.2 Logical Flaws in the High and Low Variants

Over the years it became customary to produce high and low variants, in addition to the most likely medium variant, to give the forecast users an indication of the plausible range of the future developments. Users have typically ignored the high and low variants. One reason has been the added complexity of having more than one number in a planning context. More fundamentally, an additional reason may have been that the high and low variants have not had a logically coherent interpretation. There are two reasons for this. First, suppose $[B_L, B_H]$ and $[D_L, D_H]$ are high–low intervals for births B and deaths D , respectively. In general, there is no guarantee that the two intervals cover an equal range, because no probability content for the intervals has traditionally been given. Any calculation based on intervals with unequal ranges is difficult to interpret. Second, suppose that the intervals are given a probabilistic interpretation, so that the probability is, e.g., 80 percent that each one of them contains the true value. This was first suggested by L. Törnqvist in 1949.

Suppose there is no migration. Then the increase of the population is $I = B - D$. One can show that the usual high–low interval $[B_L - D_H, B_H - D_L]$ for I has a *higher* probability than 80 percent to cover the increase. Only if the number of births and deaths have correlation -1 does the high–low interval have probability content 80 percent. But the assumption of perfect negative correlation is known empirically to be false.

In a traditional c-c forecast a very large number of vital rates are given high–low variants, and these are combined in complex ways to produce high–low intervals for population sizes at different ages. No uniform interpretation can be given to the latter intervals. For example, a United Nations forecast of the total world population published in 1998 gives a high–low interval of [7.4, 8.8] billions for the year 2030 and [7.3, 10.7] for 2050. Since it is not known what probability contents these intervals are intended to have, it is not clear how they should be interpreted.

3.3 Expressing Uncertainty Probabilistically

Modern probability theory provides a language that can be used to describe the uncertainty of the future vital rates and vital events. This leads to a *predictive distribution* of the future population given what we have observed in the past.

The availability of fast computing allows the use of stochastic simulation to describe numerically the predictive distribution. In practice this is done so that a set of age-specific vital rates is sampled from their respective predictive distributions. A c-c calculation is then made based on the sampled values to produce a possible *sample path* of the population in each age and sex group. This is repeated thousands of times and the results are stored. For any age–sex group, or for any larger population aggregate, one can represent the uncertainty of the forecast in terms of graphics (histograms, boxplots, etc.), or in terms of statistical summaries (means, medians, standard deviations, etc.). Such techniques are available for single region populations, and they are being developed for multi-regional (or multistate) populations, household forecasts, and other functional forecasts.

The key element in such calculations is the formulation of the predictive distributions of the vital rates based on statistical analysis of past data. This can be based on formal time series methods, the analysis of the accuracy of the past forecasts, and judgment.

Predictive distributions provide the forecast users with a richer view of the possible future developments than the traditional population forecasts. For users needing a point forecast only, one would typically offer the median of the predictive distribution. At the other end, a complete predictive distribution is available to a sophisticated user who wants to use formal *loss functions* in *risk analyses*. Stochastic forecasts are

well suited to the analysis of the financial stability of pension funds and other social security systems, for example.

Population Policies, Politics of

Population policy has a long history of engendering political controversy that promises to persist as it is fueled by divergent views of the Good Society. The deeply held beliefs that make population policy an object of intense dispute have their roots in such issues as political and economic ideologies, religion, morality, nationalism, and ethnicity. The impetus for governmental intervention into demographic processes grows out of the realization that births, deaths, and migration are not merely a question of numbers, but

are critical to the social, economic, and political character of a nation. As Kingsley Davis has pointed out, 'Never, apparently, is a demographic goal sufficient by itself to justify a population policy. People judge a population trend to be good or bad only in the light of its presumed social and economic consequences' (Davis 1971, p. 6). Although Western nations have been deeply involved in the effort to curtail fertility in the Third World beginning in the 1960s, the West's experience with population policy has been mainly to encourage higher fertility in their own countries. This article will discuss the difficulties faced by governments that adopt policies to either lower or increase birthrates.

1. The Definition of Population Policy

The controversial nature of population policy extends to the definition of the term itself. There has been a tendency among scholars as well as government officials to abuse and misuse the definition. Population policy has often been defined in terms designed to advance a particular social or demographic agenda rather than to provide a rigorous structure for understanding and analysis. Many writers, including population professionals and students of demography, define population policy as any action of government that directly or indirectly influences population size, distribution, or composition (Eldridge 1954). Other writers go so far as to treat population policy as any government action that directly or indirectly exerts an effect on health, well being, status, or quality of life. These definitions are broad and encompass almost everything a government does. However, this is also the weakness of these definitions as almost every government policy, from the construction of roads to the provision of health services, has demographic implications.

For those interested in the formulation, content, or outcomes of population policy, a more exacting definition is required such as that found in the United Nations volume, *The Determinants and Consequences of Population* (1973). This definition, based on statements by Spengler and Duncan, states that population policy consists of 'a specific set of governmental objectives relative to the population magnitude and/or composition together with the instruments by which it may be possible to achieve them' (United Nations 1973, p. 632). Implicit in this definition is the expectation that government will establish an agency or organization to advance these goals, and will also provide resources to enable that agency to succeed. While the Spengler–Duncan definition provides a rigor that is missing in most definitions of population policy, it may at the same time not allow sufficient latitude for the give and take, negotiation, and compromise that characterize the policy process.

2. Structure Of Population Debate

The structure of the population debate was formed when Karl Marx bitterly attacked and condemned Malthus and his ideas more than a half a century after Malthus published his famous *Essay on Population* in 1798. Although Marx never formulated a 'theory of population,' he adamantly maintained that 'over population' was a consequence of the economic system, and would be remedied once the goal of socialism had been achieved. Marx recognized that if Malthus were correct to say that human poverty is anchored in human nature, then the intellectual edifice of Marxism was threatened. While the Marx–Malthus dispute provides a backdrop to the entire controversy over population policy, neither Marx nor Malthus had a profound affect on policies governments adopted until well into the twentieth century, when governments began to decide that their birth rates were either too high or too low to achieve national goals.

3. Population Policies in the Premodern Era

From earliest times, rulers and governors have attempted to increase the size and growth of their populations, which were periodically ravaged by famine, epidemic disease, and warfare. A large and growing population was universally regarded as a sign of a healthy and vital society while small or decreasing numbers signified weakness and decay. In classical Greece, the most martial city-state, Sparta, enacted laws that made marriage compulsory and imposed special taxes, civil indignities, and political disadvantage on celibates. Procreation was similarly encouraged in Rome when that city was still a city-state intent on conquest. Later, the famous population laws of Augustus, elaborated between 18BC and AD9, tried to address the low fertility of the senatorial class, on which the empire relied for the administration of its colonies (Hutchinson 1967). During this period pro-natalist policy had its origins in nationalism or imperialism, sentiments that would motivate pro-natalism through the mid-twentieth century. Before the modern era, however, the government lacked the means to reach into the hinterland, and it did not command the technologies required to enforce the law. Thus, it is doubtful that these policies were effective.

A second rationale for pro-natalist policy emerged in the Mercantilist states of Europe during the sixteenth to eighteenth centuries. To the Mercantilist rulers, a large and growing population was equated with a rich and prospering nation; therefore, the more people the better. While Mercantilist theorists disagreed over many points, most regarded labor as the most important factor of production. They also observed that high production density fostered industry and commerce and provided the basis for the establishment of colonies that would further enrich the

nation. Mercantilist policies thus encouraged marriage and procreation, severely limited emigration, and encouraged immigration, especially of skilled tradesmen. Once again, effective techniques for implementation were lacking and it is unlikely that the laws had much effect (Spengler 1960).

4. Population Policies in Developed Countries

In the belief that population size and national power were closely related, political leaders in the late 1920s and 1930s saw a low birth rate and population decline as nothing less than a threat to national survival (Tietlebaum and Winter 1985). Concerned by the phenomenon of below replacement fertility, several governments adopted policies to raise their birthrates in an effort to alleviate severe economic depression and assure that the state would not decline in its relative power status in the future.

Mainly in the 1930s, several European governments formulated policy responses to declining fertility, utilizing both repressive and social welfare measures (Glass 1940). The first moves were to re-activate abortion legislation already inscribed in the criminal codes, which imposed Draconian penalties for convicted abortionists and forbade advice on birth control and the advertising and sale of contraceptives—except for condoms which were regarded as prophylactics. On the welfare side, child and family allowances, marriage and housing loans to subsidize maternity leave, benefits to reduce infant mortality, the establishment of nurseries and day care centers, and campaigns of pro-natalist propaganda were among the most significant measures introduced.

While France, Sweden, and other European nations relied mainly on welfare measures to encourage higher fertility, Nazi Germany initiated a vigorous pro-natalist policy for those thought to be of Aryan stock while simultaneously pursuing a policy of sterilizing the 'hereditarily unfit' and 'racially impure.' At the same time that Germany was urging its women to bear more children for the Fatherland, it invaded neighboring countries on the ground that it needed additional space, *Lebensraum*, for its people. Germany also utilized the power of the state and its extensive control apparatus to enforce its prohibition against abortion (Harmsen 1950). However, other than in Nazi Germany the restrictive legislation on abortion in other European nations had only a small effect, as judges and juries were loathe to convict because of the severity of the penalty and their own lack of commitment to the abortion law (Glass 1940).

Despite the anxiety over 'depopulation,' the liberal democracies of Europe could not achieve national consensus over the adoption of coherent pro-natalist policies until the late 1930s. By this time, however, birth rates were already starting to rise as preparations for war contributed to the end of the Depression and

the return of full employment. Pro-natalist measures were introduced in the Soviet Union immediately prior to World War II and spread to Eastern Europe after the war. Moreover, pro-natalism in the Soviet Union was buttressed by Marxist ideology that held that 'overpopulation' was only a problem under capitalism.

Fertility started to fall in Communist bloc states in the mid-1950s, soon after abortion was liberalized in these countries. Eastern Europe responded quickly by placing restrictions on abortion, with the most severe in Romania. Though legal, contraceptives were to all intents and purposes difficult to obtain or unavailable. Child allowances were increased and long-term maternity leave of one to three years was introduced (McIntyre 1975). A benefit was provided that varied between the minimum and average wage and re-employment was assured in the same or a similar job. These policies largely succeeded in maintaining fertility above the replacement level.

In Western Europe, by contrast, fertility fell below replacement level, and governments once again adopted pro-natalist policies. Recognizing that in the contemporary world national power no longer depended on numbers alone, policy makers gave increased emphasis to enhancing the quality of the population, that is, the health, education, and other factors that contribute to what has been called 'the effective population' (Organiski et al. 1972). Equally important as a gauge of national power was economic and technological superiority, as well as a nation's structure of alliances. For those nations intent upon encouraging couples to have at least an additional child, the most effective approach seemed to be a policy that lessened the difficulties of balancing paid work and motherhood (McIntosh 1983). Pro-natalism proved to be less than a successful undertaking for Western democracies as they were constrained by their own liberal democratic politics from implementing the multifaceted measures required for an effective policy aimed at increasing the birth rate.

5. Population Policies in Developing Countries

Although population had been a subject of philosophical speculation and debate since ancient times, it was not until the middle of the twentieth century that it became a cause inciting intense political controversy. There were several developments that moved population from speculation and theory to the policy arena. Of singular importance were demographic trends in less developed and colonial countries that challenged leaders of these nations, especially after they had achieved independence. Earlier, both fertility and mortality rates were high. After World War II the introduction of improved public health measures, especially clean water and improved sanitation, as well as the new availability of antibiotics, led to a decline in

infant and child mortality and an unprecedented increase in the rate of population growth.

Beginning in the 1950s, leaders in developing nations came to regard rapid population growth as an obstacle to their country's economic development, a view that was reinforced by census results which showed that population size and growth exceeded earlier expectations. Four years after gaining its independence from the UK, India adopted a population policy as part of its initial five-year plan in 1951. In roughly the same time period, Pakistan and Sri Lanka instituted population policies. There were also leaders and political elites in many developing countries who, while they recognized the burden of rapid population growth, were nevertheless reluctant to adopt population control policies, partly because of the 'distrust the leaders had of the former metropolitan powers' projection of population as the greatest threat to national development.' (Made with reference to Sub-Saharan Africa in UNECA Population Policy Overview Report 2000).

Meanwhile China, the world's most populous nation, captured the imagination of many Third World countries at the Bucharest Conference in 1974, by proudly proclaiming that socialist China could accommodate increasing numbers of people. Significantly, within five years China implemented the most vigorous population control program in modern history. The sharp changes in China's population policy were not merely a response to demographic conditions but were closely linked to the revolutionary fervor of China's leadership and their economic goals.

The One Child Per Family policy, adopted by the People's Republic of China in 1979, imposed penalties—at times severe—on those who abrogated the law. The policy succeeded and China achieved the sharpest fertility decline that any country had ever experienced. In achieving this goal, many women either sought or were compelled to undergo abortions in order to avoid a second child and avoid the possible legal consequences. A better understanding of demographic processes by Chinese officials combined with resistance to the one child policy within China and criticism from abroad, contributed to a *de facto* modification of the policy (Banister and Harbaugh 1994). Chinese officials realized that their population goals could be achieved, albeit more slowly, and with less public resentment, by implementing the one child policy less strictly.

Population policy came to be recognized internationally as emblematic of a nation's commitment to modernization. This trend was abetted and encouraged by the rich industrial nations, especially the USA, as well as by the United Nations, most particularly the United Nations Population Fund (UNFPA) and the World Bank. Industrial nations of the West felt that high fertility in poor countries would keep them poor forever. Consistent with this attitude, the USA, Canada, European nations, Japan, and

indeed all donor nations began to support efforts to limit population growth.

In 1967, partly as a result of a financial contribution from the USA, the UN began to address the issue of population growth. The Secretary General created a trust fund which eventually became the UN Fund for Population Activities (UNFPA), whose purpose was to encourage countries to identify their population problems and to attempt, with international assistance, to cope with them. Although many branches and organs of the UN would eventually be involved in curtailing rapid population growth, the creation of UNFPA was critical to the entire multilateral effort.

A point that is often neglected is that 'overpopulation' was attractive to both industrial societies as well as to developing countries as an explanation for the poverty of much of the Third World. It was much easier to attribute 'underdevelopment' to excessive population than to confront social and economic inequality, culture, religion, female subordination, or other plausible contributing factors. In the same spirit that western industrial nations found population control an appealing remedy for Third World poverty—for population control did not demand radical changes in the social and economic structure—scholars, intellectuals, and political leaders in developing countries also embraced population control as it did not require them to question fundamental attitudes and beliefs of their society. Thus, poor countries felt they could address their problems of development without first coming to grips with the social costs imposed by established structures of their societies. The discourse on the relationship between development and population has flowed from country to country and in the process has become universal rather than contained by national boundaries. The centrality of population to society assures that population issues will not be confined to any subsector of society but will become an issue that demands the attention of the polity. This has been the case in the past, and there is no reason to question its continuation.

6. The US Influence in Population Policies

The USA played a particularly significant role in shaping world population policy starting in the 1960s and in framing the modern debate over the politics of population. Until the 1960s, the USA was firmly opposed to playing any role, except a negative one, in the incipient population control movement. In words that he later came to publicly regret, President Dwight D. Eisenhower said, 'I cannot imagine anything more emphatically a subject that is not a proper political or governmental activity or function or responsibility' (Critchlow 1999, p. 44). Under Eisenhower's successors the American government became steadily more supportive of family planning at home and abroad.

Once the USA decided to assist poor nations to curtail their population growth, it became an American 'cause.' The USA soon became the world's largest donor to population assistance and used its political influence and financial resources to motivate the United Nations system to support family planning efforts in developing countries. Although the UK, Scandinavia, and other northern European states were important in the spread of the population movement, it was once again the political and economic influence of the USA that played a dominant role in persuading Third World countries that family planning programs were essential to their social and economic development. Equally important, the USA developed a strong professional cadre of population specialists covering every aspect of population and family planning from medicine to demography to management and communications, to assist family planning programs in almost every country in the developing world.

Perhaps of even greater importance in shaping population policy as well as in creating an international community of population experts was the investment made by the USA in training large numbers of men and women from the Third World at American universities. Upon returning home, graduates of these educational programs often filled critical positions in development programs and family planning. The USA also invested heavily in applied research designed to enhance the effectiveness of family planning programs as well as to provide an empirical base for health policy. One early research effort, the surveys of family planning and contraceptive knowledge, attitudes, and practice (KAP), demonstrated in country after country that women were having more children than they desired. The scientific contribution of KAP surveys was limited; however, they were believed to be politically valuable in persuading leaders to adopt national population policies.

As the USA exported its expertise and beliefs in voluntary family planning, so too did it export its profound political problems centering on the population issue. In the USA, the population dispute was entangled with such issues as foreign aid, state intervention in fertility decisions, sex education, contraception as a source of immorality, and, most serious of all, the abortion controversy, the most divisive issue in American society since the Civil War.

Family planners hold that abortion is a necessary backup procedure in the event of contraceptive failure. Other supporters of abortion argued that it is an essential component of any successful effort to limit population growth. A third group, led by but not limited to feminists, held that it is simply a woman's right to choose whether or not to have an abortion. Thus, while family planning and abortion are analytically distinct, there is a general tendency for family planning proponents to be pro-choice. Conversely, anti-abortion or pro-life advocates were prone to broaden their target to include opposition to family

planning. Both pro-life and pro-choice advocacy groups created international linkages whereby they have attempted to replicate the Western abortion controversy in developing countries as well as in the international arena.

7. Population Policies and International Conferences

United Nations conferences reflect the highly political and ideological quality of population policy at the international as well as the national level. Since the Stockholm Conference on Environment in June 1972—a conference generally regarded as highly successful—the United Nations has increasingly relied on the mechanism of international conferences to shape global policy on a variety of social and economic issues ranging from women, children, and human rights to population and development. In contrast to regular UN proceedings, these conferences have been more open to the inclusion and participation of nongovernmental organizations representing a broad spectrum of interest groups. To the extent that the policy process becomes more open and diverse groups acquire access to power, it is almost inevitable that political considerations are likely to play an important, if not a dominant, role in formulating policy at UN population conferences.

United Nations sponsorship of international population conferences actually began with gatherings in Rome in 1954 and Belgrade in 1965. The United Nations jointly sponsored these conferences and the International Union for the Scientific Study of Population (IUSSP), a highly respected international nongovernmental organization (NGO) with a comparatively small but influential worldwide membership of population professionals. The UN and IUSSP invited population experts to participate in the Rome and Belgrade conferences. These meetings, while of some intellectual significance, had only a modest impact on national population policies. Conference participants were invited as 'experts' rather than as representatives of government. Concerned about the lack of policy impact, the United Nations, as well as some of its more powerful members, changed the structure and composition of these early conferences. Their intent was to move the population debate out of the hands of scholars and experts and into the domain of government where population policy is made.

Under the leadership of the United Nations Population Fund (UNFPA), and with the strong support of the USA and other Western donor nations, the UN convened its first of a series of decennial population conferences in which governments rather than individual experts were represented. In contrast to the earlier World Population Conferences in Rome and Belgrade where participants were invited in their individual capacities as experts, delegates to the UN

population conferences in Bucharest in 1974, Mexico City in 1984 and Cairo in 1994, were representatives of their government. Members of national delegations were not exclusively government officials and political leaders; governments also chose to select physicians, family planning activists, social workers, as well as feminists to represent their countries.

Contrary to expectations, these changes did not result in a stronger commitment by governments to population policy. Instead, they opened the door to a variety of interest groups to advance their own agendas and redefine population policy in terms that were more congenial to their interests. Governments also found these intergovernmental conferences a convenient host to their efforts to promote their own ideological and political agendas in collaboration with other friendly governments. Population conferences became far more controversial, interesting, and perhaps even more significant. For example, at Bucharest the Population Plan of Action, the consensus statement of the conference, urged a new and more equitable international economic order. In language that resembles a Marxist critique of development theory, the Background section of the Plan held that population problems are really symptoms of imbalances in the development process and a faulty international economic system. Twenty years later at Cairo, the new definition of population was one that gave primacy to women's reproductive health and the status of women. Nongovernmental organizations were far more prominent at Cairo than at either Bucharest or Mexico City, a move intended to gain the support of the growing universe of nongovernmental organizations. This too resulted in further politicization of the conference proceedings as NGOs at Cairo were articulate, well organized, and embraced an agenda that paid little attention to demographics.

8. The Future of Population Policies

Notwithstanding the near universality of fertility limitation programs in developing nations, world population reached 6.1 billion in mid-2000 and, according to UN estimates, was growing at an annual rate of 1.2 percent or 77 million people per year (United Nations Population Division 2001). According to the United Nations 'medium' projections, by 2050 world population will reach 9.3 billion. This growth is not evenly distributed throughout the world: almost all of it is taking place in developing countries. Clearly, on a global basis, the total fertility rate is above replacement level. Population growth will continue, if for no other reason than the momentum inherent in the age structure, that is, the large numbers of young people who have yet to complete their reproductive years (Bongaarts 1994). Thus, if world population is moving toward stabilization, it is moving at a much slower pace than the population community

predicted or desired. To the extent that societies and political leaders are dissatisfied with demographic conditions in their own countries, there remains little question that they will introduce population policies in an attempt to ameliorate these conditions. Whether they will set clear goals, create an organization to implement these goals, and provide sufficient resources to successfully carry out their policy remains, as in the past, a matter of political commitment.

Population Policy: International

There are two distinct but highly interrelated elements within international population policy. The policy set of goals and activities by states or international entities intended to influence and shape population outcomes in countries beyond their own national boundaries finds expression in both *bilateral* relationships and in *multilateral* activity. Bilateral activities seek to change population outcomes in specific countries. The collectivity of policies of the international community, expressed in multiparty international agreements, charters, covenants, and—most important for the population field—in international conferences and conference resolutions are *multilateral*. This activity is designed to standardize views and practices, and to

form a world-view of desirable goals and outcomes. The two are linked. Countries with active national or bilateral programs also seek to influence the direction of multilateral, international population policy.

1. The Unique Context of the Twentieth Century

Humans have probably always tried to manage fertility at the level of the individual and family. Rites and rituals to encourage fertility are time honored. There are also specific hieroglyphs in Egyptian antiquities citing herbal methods of contraception or abortion. More than a century before Christ, Polybius deplored both the tendency of comfortable urban Greeks to delay marriage and sharply reduce family size, and the resultant decline in population.

National concern and international preoccupation with population issues is very much a phenomenon of the last half of the twentieth century. While anxiety for the health impact on women of large families and unwanted pregnancy has been of long standing concern to health care providers, the major upsurge in interest in population issues originated in concern for the impact of rapidly accelerating global population numbers. Some appreciation of the remarkable quality of twentieth century demographic developments is therefore essential to understanding this policy evolution.

Never before the twentieth century did a human being live through a doubling of population; indeed the global population quadrupled between 1900 and 2000. The population increase in the 1990s alone was the equal of all of those who lived in the seventeenth century. In the preceding millennia, a good century for the human race was one in which the population grew at all. Plagues and normal high death rates in most societies ensured that this was not always the case.

Although everyone dies eventually, human death or mortality at an early age is what keeps population levels low. Absent high levels of mortality, migration, or decreasing fertility, population levels will increase. With the relative decline of famines and epidemics and increases in transport, communication, public health, and control of infectious diseases, nineteenth century Europe grew rapidly. About one-third of this increase was exported to colonies and overseas, a series of deliberate but minimally enunciated international population policies. The same spurt happened in post-W.W. II in the nonindustrialized countries emerging from colonialism, or 'developing world.' The increases in numbers were bigger, and the pressure valve of migration was no longer available. The world was regarded as settled by the major players who controlled immigration flows.

When the global population numbers really began to grow, when the ability to count them improved markedly, and when attitudes regarding sexuality and

family issues began to change in the industrialized world, population issues arrived on the global scene and international population policy began.

Twentieth century population growth changed the shape and weight of international relationships. Over 95 percent of the population increase of the last decades took place in the developing world. At the beginning of the century, almost one person in five was European; at the end, less than one-tenth of the world lived in Europe. The six billionth child was born in the last year of the century. That child will very likely live long enough to see the peak of human population and the stabilization of population numbers. The trends that will cause the decline of high fertility are well begun. Although another huge population increase will take place in the first two decades of the twenty-first century, the end of the high fertility period is in most places now in sight. International population policy in the twenty-first century will likely focus on different issues, already emerging.

2. The Content of Population Policy: Sensitive, Fragmented, Confrontational

There has never been policy consensus on the nature, importance, or remedies in this field. The first stage of policy making revolved around the question of whether rapid population growth and high levels of fertility were in fact a threat, and what to do about them if they were. Many continued to insist that high levels of population growth were a transitory factor that would decrease with development and progress. The answer was seen to be investment in accelerated general development, not specifically targeted programs, i.e., 'development is the best contraceptive.'

Those on the other side of the issue used phrases such as 'population bomb' to describe what Malthus in the late eighteenth century foresaw as predictable crisis deriving from the geometric nature of human growth expansion, not sustainable by the foreseen linear growth of agricultural production. Concerns about the real and also postulated but never provable impacts of population growth expanded beyond food production.

Early advocates for international fertility reduction efforts voiced fears that such growth would lead to mass starvation, perpetual economic underdevelopment, internal conflict, and external wars to expand boundaries. In late 1960s there were confident assertions from certain US thinkers that the battle to feed humanity was over and that widespread famine would shortly begin. In later years, the list of concerns expanded to include the impact on the environment, climate change, and the battle to preserve biodiversity.

On the other side of the ledger, concern for the human rights implications of family planning programs and the emergence of feminist concerns in their

turn significantly reshaped the content of international debate and many population programs. Family planning and contraception services began in the industrialized world with Margaret Sanger and Marie Stopes in the USA and UK, respectively. These programs were delivered through the medical model of a doctor–patient relationship. What developed in the 1960s and 1970s was the novel idea that the state, or a public health service provider, should provide these services on a mass basis in order to bring down the number of births. Thus was born the idea of officially endorsed (or at least tolerated) family planning programs. Begun in Southeast Asia in the 1960s, family planning programs spread throughout the developing world in the subsequent 20–30 years. Internationalization occurred as foreign states and international actors intervened in such domestic programs, sometimes providing the impetus for their creation. The full impact on policy of the multilateralization efforts came somewhat later, with the creation of an international network, influenced by and influencing the existing programs.

The tools of the family planning part of population policy were largely unavailable until the 1960s. Such contraceptives as existed in the first half of the twentieth century were unwieldy, unmentionable, and often illegal. The advent of the contraceptive pill in 1960 provoked a revolution in behavior in the industrialized world. With it grew the conviction that new contraceptives, especially those which could be injected, implanted, inserted, or swallowed as opposed to being applied at the time of sexual relations, had the potential to stop or slow the rising levels of population in the developing world.

Yet another part of debate centered on the degree of importance that should be accorded to these tools and to the provision of contraception services vis-à-vis other fertility-influencing interventions such as girls education. This issue was characterized as the ‘beyond family planning’ debate. Later, with feminism came a strong concern that women’s health issues must override concern for demographic increase in the population agenda. Included were preoccupations related to both the mechanism of program delivery, particularly targets, and several of the recently developed contraceptives. This discernibly altered and shaped population policy programs from the 1990s onward. The emergence of AIDS similarly pulled new elements related to the reproductive health of individuals into the population policy ambit.

These debates and uncertainties and the transitory coalitions that have endorsed particular actions at specific times have given changing goals and forms to international population policy.

While demographic trends can be discussed in statistical and abstract terms, and contraceptive techniques discussed in terms of their mechanisms of action, the reality of population change is grounded in the most personal human relationships, in human

sexuality, and in highly sensitive social issues. These include the nature and power relationships that establish marriage, the role and status of women, the behavior of adolescents, definitions of morality and immorality, the ethical judgments related to sexual activity, and to the very value attached to life at various stages.

For this reason, the myriad of social institutions that define different societies, including organized religions and political forces, have strong interests in most population issues. The major religious have been supportive with the notable exclusion of official Roman Catholic policy and the orthodox elements of many established churches. The moral and ethical issues are complex and the introduction of state activity in these areas therefore often highly contentious. That foreign states might have an interest in the decision of a man and woman in another country to have or not have more children could not but raise very complicated issues indeed.

3. Population Issues Enter Foreign Policy

For most of human history, countries did not have population policies, domestic or international. There was a long tradition of hope for population increase as a sign that prosperity was edging out pestilence and disease. The 1901 Census reports for India expressed the cautious hope that population would increase in the decades ahead. Nongovernmental activity preceded both governmental and intergovernmental activities in the national and international spheres. A major step forward was the formation of the International Planned Parenthood Federation (IPPF) in 1952, which grew by the end of the twentieth century to be a federation of advocacy and service providing organizations in over 150 countries, supported by another 20. The Indian Family planning program began the same year, as did several US nongovernmental organizations (NGOs).

There was a major upsurge in population activities in the late 1960s. Governments became less timorous and more active. Several dozen heads of government agreed to come out in favor of moderating global population growth, and agreed to be featured with photos and quotations in a widely used poster campaign. The World Health Organization (WHO) began population activities. The UN Secretary General established in 1967 a Trust Fund which later became the UN Population Fund or UNFPA. The World Bank adopted a policy to lend for population activities after President Robert McNamara declared that population growth constituted a threat second only to the prospect of nuclear war. (Continuing ambivalence within the Bank about the actual impact of population growth on development has, however, meant that while loans are available in aid of Health Ministry programs, Finance and Planning ministries were never

pressed by bank officials to support or give any special priority to population programs. Many other aspects of national management have been subject to such suasion over the years.)

3.1 The International Community Response: A Wide Spectrum of Policy Perspectives, and Some Domestic Determinants

As foreign policy is the pursuit abroad of domestic policy goals, it could be postulated that even though the desired impact of bilateral population programs was to change outcomes abroad, donor countries would normally not have international population policies until they began to have domestic population policies. This was by and large the case. Most states approached the issue of their domestic population issues with a great deal of diffidence. President Eisenhower is widely quoted as saying that he could imagine 'no subject less fit for government activity' than family planning. The United States became the unquestioned global leader in this field (see Sect. 3.2), while a variety of stances characterized the roles and programs of other countries.

Sweden and the other Nordics countries were early financial supporters of family planning in developing countries, reflecting their relative lack of embarrassment in dealing with these issues domestically. In the later decades, as the influence of women's health advocates grew at home and abroad, Sweden in particular disclaimed linkage between providing contraceptives to women to support them in their own family size decisions and any demographically related outcome.

Successive French governments pursued strong pronatalist policies at home in France and perceived that strong support for family planning programs abroad could well be seen as somewhat racist. There has never been major French support. The UK bilateral programs in many areas included a vigorous population component. Italian governments were widely believed to have exchanged peace with the Vatican on the domestic contraception/abortion front in Italy, in exchange for Italian inactivity abroad. Canada was at one time the third largest supporter of population programs. Interest and support declined rapidly in the 1990s, probably reflecting aid officials' desires to distance themselves from US programs, and some political level wish to avoid exacerbating deemed Quebec sensitivities. Both are longstanding elements of Canadian domestic policy.

The Netherlands from the mid-1990s dedicated a full 4 percent of their aid programs to population and reproductive health. They often played the role of coordinator and host to conferences and meetings on a variety of population-related issues. Their domestic belief in frank discussion and the provision of open explicit information starting at an early age has translated into an active international program.

Japan, under heavy US pressure, dedicated fairly large amounts of funding to population programs, very broadly defined. Once again, the impact of domestic constraints for a long time meant that the nonavailability of hormonal contraceptives to Japanese women precluded their inclusion in the aid package.

The developing world presented a mixed picture. Thinkers in Mexico, Egypt, and India before independence worried about population gains destroying the positive impacts of their own development efforts. India's 1951 five-year plan had population program expenditures. The Southeast Asian countries were early and enthusiastic advocates with national programs established in Thailand, Taiwan, Singapore, and Korea. Over a two-decade period, most southern countries adopted some form of population policy, after a period of initial resistance on the part of many. Virtually all countries eventually formulated population policies, influenced by their own cultural and religious backgrounds, and development aspirations. Until the advent of the international conferences described below, only industrialized countries had international dimensions to their population policies. The advent of the conferences gave developing countries the opportunity to express views on population issues on the world stage.

Bilaterally, the Vatican has acted not as a state but as religious advisor to governments. It has been especially powerful in keeping official support away from these services in Latin America, and to some extent in Africa. This reluctance to endorse any form of contraceptive device continued to include proscriptions against condom use, even as the AIDS epidemic affected millions.

The Marxist countries during the Cold War period had an avowedly antifamily planning stance. The states of the former Soviet Union accorded little or no importance to the provision of contraception with subsequent high reliance on abortion. Population levels dropped sharply in many socialist countries and desperate, coercive measures were adopted by several. The pronatalist policies of Ceausescu in Romania provided the sharpest example. The Marxian view was that difficulties caused by population growth really reflected maladjustment in wealth distribution. Although they did not proselytize to any major extent, this view was very strongly echoed by many developing countries in the early years. Particularly since it fit well with other themes of the New International Economic Order, the 'development is the best contraceptive' theme became the most commonly used rhetorical position in opposition to the new enthusiasm.

3.2 Global Leadership—the United States Role

Unquestionably, the global leader in this field has been the United States. American activity began in the 1960s and the US quickly became the most enthusiastic

proponent of population programs. A bipartisan, centrist coalition in Congress maintained support for international family planning programs, even in the Reagan years. Domestic NGOs appeared in the US for the express purpose of lobbying for greater global attention to this issue. The early name of one such group—ZPG or Zero Population Growth—indicates the intensity of public policy concern that underlay US policy aimed stabilization of global population levels.

Later with the resurgence of the religious right and the 1990s shift to political conservatism, the abortion issue re-emerged to cause violent schisms in US society. It defined presidential campaigns, filled the courts, and provoked violence against domestic abortion providers. The bipartisan consensus that had supported the family planning programs shattered. Republicans' public policy stance became the equation of family planning with abortion, and therefore opposition to all forms of public involvement in it. Democrats remained the champions of such programs.

The international policy reflection of this schism caused sharp reductions and severe restrictions on US support. Migration for economic improvement and to escape unfavorable political and social situations around the world will continue to be a growing population issue.

Specific measures of censure for China's one-child policy were included in funding conditions. Multilateral organizations were cut off from funding. A so-called gag rule was enacted. It prohibited the release of US family planning funds to international or foreign NGOs which use their own funds to provide abortion services or participate in policy debates on abortion outside the United States. This measure, which would be unconstitutional in the USA itself, was put into effect once by administrative decree in the Reagan years, and again by law in the final Clinton years.

The US flag has flown higher over population assistance in most countries than anyone else's. One of the advantages was the creation of unparalleled expertise in American government, nongovernmental, academic, and program delivery circles. The visibility was also a liability, especially in the early years when sensitivities were high about western enthusiasm for reducing southern births. Because of the intensity of US internal debate, and the rapidity of policy shifts, the US has often been at odds with the rest of the world. It was far out in front on global targets and Malthusian rhetoric in 1974, then pulled back a decade later when just about everyone else was finally coming to some policy consensus in favor of attenuating population growth.

3.3 The Tools of Population Policy: Aid Programs

The tools of bilateral population programming have included policy statements, speeches, persuasion,

advertising, and funding. Assistance has included policy-influencing computer simulations, assistance to demographic and census departments, soap opera presentations, and research on a wide variety of reproductive health elements. Much program activity focused very directly on the provision of family planning services. Funds have been provided for contraceptive development, dissemination, and for the creation of national family programs.

Family planning programs had no real counterpart in developed countries, and were often 'vertical' or stand-alone programs, like some immunization campaigns. They occasionally became the focus of religious, traditional, and xenophobic criticism. These clinics often provided the only services available or available to poor women. In terms of impact on fertility, family planning programs were deemed to have succeeded; they probably accounted for about 40 percent of the decline in otherwise anticipated births that characterized the world as the demographic transition progressed in the countries of Asia and Latin America.

Because of the sensitivity of population and reproductive health issues, many donor countries directed a substantial percentage of their assistance through multilateral and international delivery mechanisms. Almost US\$500 million flowed through multilateral agencies two years after the 1994 Cairo Conference. The programs of the primary multilateral agency, the UN Population Fund, reached \$320 million in its high water years, usually providing a channel for about 25 percent of available donor funding. World Bank lending at one point reached \$500 but declined at the end of the century. The regional banks have not been major players, with some exception for the Asian Development Bank. An increasingly important element of support was the assistance provided by (largely US) foundations to the population field, reaching as high as \$150 million just after the 1994 Cairo Conference.

Aid or official development assistance to population/family planning was never large in relation to overall expenditures in the field or to overall levels of overseas development assistance. By the end of the twentieth century, developing countries were paying three-quarters of the costs of their own reproductive health and population programs.

Nor have population programs dominated the overall aid programs. Even within the US program, population assistance only ever represented about 7 percent of all US aid. Australia, Denmark, Finland, The Netherlands, Norway, and UK the population comprised about 3 percent and in France and Italy only 1 percent of their respective ODA programs. In dollar terms, when the totality of all countries' official development assistance was running around US \$60 billion per year, population assistance (mostly family planning) never got above \$2.0 billion in total. Eight countries almost always supplied 90 percent of all

population assistance. The US gave the biggest amount, usually about half of all bilateral aid to population. Denmark, Norway, Sweden, and The Netherlands gave higher percentages, relative to their own economic weight.

If not significant as a percentage of overall aid, or as a proportion of each country's aid program, foreign aid to population has often been *very* significant in relation to the total health budget of many developing countries. It has had a catalytic impact in determining the scope, content, impact, and in some places existence of programs across the world.

4. Multilateral Policy Making

The second zone of international population policy activity is multilateral or many sided in nature. It is important for two reasons. As just noted, multilateral organizations have been important sources of technical and capital assistance, and vital to program delivery. The second key multilateral activity relates to international population policy making within the international community. Here, all countries have roles; the multilateral organizations provide the venue and organization for this policy-making activity.

4.1 The Population Conferences—Policy Tracers Par Excellence

It is through the phenomenon of the international population conferences that the changes and shifts of international policy in this area can be traced. Margaret Sanger organized an international population conference in Geneva in 1920. It resulted in the formation of the first international nongovernmental population organization, the International Union for the Scientific Study of Population (IUSSP), mostly but not exclusively demographic in purview.

Modern population conferences are not like those of the World International Trade Organization where treaties are negotiated and monitored. Unlike conferences such as the 1948 Universal Declaration of Human Rights, they do not require countries to take legal steps to bring domestic activity into line with new policy norms. They are rather international conclaves of policy expression, where undertakings of good faith are made by all, and statements are made and resolutions drafted which together give a comprehensive picture of how the world's thinking has evolved on an issue. They also give the world the opportunity to comment on individual programs: the one-child policy of China and the specific programs of Indonesia and India have from time to time drawn attention.

The preparatory work preceding such conferences is key, often including the collation of detailed country statements which can include reviews and revisions of laws, budgets, policies, and program descriptions.

Most important, the preconference activity occasions consultation and negotiation on the domestic front in most countries. As the issue has internationalized, comparable activity takes place on a regional basis, and globally among NGOs. As NGOs and women's groups have become more important players, both the openness of the preparatory process and the difficulty in reaching consensus have grown. At the conferences themselves, NGO representatives have come to take part in the delegations and to play a role in formulating the consensus documents. Generally, countries reflect at these conferences the positions they have adopted domestically. The Vatican chooses on this issue to behave as a State in terms of attendance at international conferences. It works through lobbying, diplomatic demarches, and public diplomacy.

Population conferences as international policy making occasions therefore provide highly visible venues for intense debate about sensitive reproductive health issues of safe abortion, genital cutting, violence against women, and services for adolescents. These continue to provoke confrontation and contention.

4.1.1 Bucharest—1974. By the end of the 1960s, there was considerable enthusiasm—in the industrialized world—for serious attention to be given to population levels in the developing world. Serious attention in this era really meant a focus on family planning. In Bucharest, the developing countries both contested the view that population growth was deleterious, and asked to be paid more for going along with the industrialized country view. The socialist states and developing countries successfully insisted on bringing development, broadly and loosely defined, into the equation. The industrialized world did not disagree—John D. Rockefeller stated that ‘... the only viable course is to place population policy solidly within the context of general economic and social development in such a manner that it will be accepted at the highest levels of government and adequately supported.’

Post-Bucharest, program content did not change appreciably, concentrating primarily on family planning with some maternal and child health elements.

4.1.2 Mexico—1984. Many countries in the developing world, notwithstanding enunciated public positions, implemented population-limiting policies and programs in the largest growth period in family planning program activity, from 1974 to 1994. The last region to adopt population policies was Africa, following the landmark African regional conference in 1984, part of the lead-up to the Mexico City Conference. The 1984 world, except for the Vatican and allies, was reasonably united behind these programs, and was demanding more support for them. The US administration was by that time in full retreat from

former enthusiasm. 'Population growth is neither positive nor negative; it is a neutral phenomenon' became the leitmotif of the American administration position. Despite this policy level coolness, US budgetary and program support for continued growth in these programs were maintained.

4.1.3 Cairo—1994: a near universal consensus on a 20-year program of action. The preparatory sessions for Cairo were extremely contentious with severe criticisms of the existing approach to population programs coming from both conservative forces and from the new strong feminist voices. The pre-conference work was arduous, and the result was a complex, far reaching program of action that scarcely touched demographic forecasts and forces, but acknowledged at great length the complex context within which decisions about childbearing are made. The conference and action plan focused on health services, education, economic development, and livelihoods for women.

There was general acceptance that family planning must be voluntary and available, something never before achieved in conference documentation. The programs were to be centered on the needs of the individual and provided in a context which would take the client's entire reproductive health into account, particularly exposure to sexually transmitted diseases and AIDS. Targeted development interventions such as female education, credit for women, gender equity in inheritance and land ownership, infant and maternal mortality reduction, became explicit components of population policy.

Ninety percent of the 180 governments representing about 95 percent of the world's population approved the action plan in totality; a few conservative countries and the Vatican approved it in part. A price tag of \$17 billion was established for achieving the program.

There is fairly general agreement that the Cairo Conference made an appreciable difference to the field. Five years after Cairo, progress under the Action Plan was reviewed. Although the same issues provoked the same dissent from many of the same sources, there was consensus that considerable progress has been made in policy, program redesign, increased partnership, and collaboration directed toward implementation of the action plan. International aid fell away from rather than toward the \$7.5 billion target collectively undertaken in Cairo, but many developing countries were found to have made policy legislative and/or institutional changes in the area of population and development and reproductive health and rights. Improved transparency in governance, expanded activity of voluntary associations, improvements in communications, and legal and policy modifications were found to have advanced the prospects for the participatory approach seen to be at the center of successful implementation of reproductive health and

rights programs. Much of course remained to be done: enormous problems of maternal mortality, violence against women, and unmet need for contraceptive services all persisted, and at the end of century, two-thirds of the world's illiterates were girls and women.

5. *The Future of International Population Policy*

Is international attention to population growth finished? One of the results of the Cairo Conference was a sharp refocusing of debate away from demographic concerns toward reproductive health issues. Analysis has continued but with a sharp diminution on discussion of several former key elements. In terms of program content, many now realized to be most important in addressing high levels of fertility, especially girls education, are being addressed for their own importance. As the world continues to urbanize, and as the situation of women improves in many areas, fertility levels will continue to decline, and with them, demographic growth. It is indeed possible that countries and groups will begin to discuss policy measures that have succeeded in *raising* family fertility intentions.

Judging from declining flows of development assistance, and of international attention, there will probably be relatively less attention paid to assisting with service provision. Some continuing attention will be given to the high levels of maternal mortality. Violence against women will continue to be addressed both nationally and internationally. The same levels of international assistance and interest do not, however, seem to be available in the service of reproductive rights, as could be mobilized to slow population growth, before it became politically incorrect to speak of doing so.

This is the case despite very high levels of measurable unmet need for contraceptive services and even though an additional two billion will be added to the global population before stability is reached, with most of that two billion added in areas where food and water are critical now. These pressing global issues will be addressed primarily by applying resources to freshwater availability, food production and availability, etc., and rather less to addressing the numbers of people in need of them.

There are three main issues that will likely form the core of international population policy in the future: reproductive health issues touching infectious disease, and the linked issues of migration and aging.

Reproductive health issues will occupy an expanding place in the global agenda, particularly those related to the spread of AIDS and other sexually transmitted diseases. The realization of the security threat posed by these diseases began to accelerate with the turn of the century.

Migration for economic improvement and to escape unfavorable political and social situations around the world will continue to be a growing population issue.

A different set of international institutions and government departments from those concerned with fertility are the central actors on this issue.

While the dramatic nature of fertility increase in the twentieth century is widely known, there is considerably less appreciation of the fact that the equally dramatic decline in fertility has radically changed the number of people within age groups in many countries. Aging may well be the dominant policy issue of the twenty-first century. The spread of aging populations is uneven. While there are more Europeans moving into the over-65 year old category than the under 16 year old group, at the turn of the century there was still a 26:1 ratio in the other direction in the totality of the developing world. In developing countries that initiated rapid declines of fertility in the 1960s, such as Taiwan, Korea, China, Thailand, Mexico, and Brazil, issues connected with aging are now rising on the agenda. This issue will internationalize primarily because of the impact on migration created by declining labor force size, and the worries that this creates vis-à-vis social security pressures and health system financing.

Population Pressure, Resources, and the Environment: Industrialized World

1. Introduction

Few issues have attracted as much ink, and as much intellectual passion, as have debates about population, resources, and the environment. It is important to understand that many discussions of 'environment' have foundered due to at least four different uses of the term:

(a) As in 'the global environment' or the 'global ecosystem.' Explanations at this high level of abstraction often are so general as to defy contradiction or verification.

(b) As a shorthand reference for all natural resources, especially all sources of raw materials, energy, and food. Less general than the first use, but still combines very different settings and industries under one rubric.

(c) To connote the purity of air and water, especially as affected by urbanization and industrialization and their impacts on rural or 'natural' landscapes.

(d) As an antonym of 'heredity.' This is a quite different and often confusing meaning in which 'environmental' effects are those determined by social rather than biological processes, along with interaction between the two.

The disputes, which go back at least two centuries, touch upon theories and evidence central to much of modern intellectual history. Moreover, the participants in the debates have included many of the giants of Western scholarly and political thought, from Smith, Ricardo, and Malthus, to Marx and Engels, to Keynes and the Myrdals.

2. Two Fundamental Phases of Western Political Thought, 1750–1940

We can identify two fundamental phases of the developing debate on population, resources, and environment in the West. The first extends from 1750–

1880, the central period of industrialization in Western Europe and North America. The second covers the period 1880–1940, a period when industrial growth rates in Western Europe first peaked and then plateaued, Western imperial power peaked and then declined, and Western political instability and collective violence reached unprecedented levels. These two phases of ascending European political and economic power, followed by its slow decline, are reflected in the attendant debates about the balance among demographic growth, resources, and the environment.

During the expansionary phase, optimists from Godwin to Condorcet to Marx foresaw essentially unlimited expansion of material resources to support a growing population. What had to be changed was not the resource base, but rather the power of landowner and/or capitalist classes to place their demands above the needs of the majority. While Marx and his followers demanded revolutionary transformation of urban, industrial society, utopians sought to escape from its corruptions and create a new kind of society remote both physically and morally from the old. With the 20/20 vision of hindsight, we now can say that these utopian and Marxian views have not proven to be sustainable in the real world.

Meanwhile, pessimists of the period such as Malthus and his followers saw utopians as innocents unaware of the impossibility of human perfectibility. Malthus held that the human sexual instinct was a constant that would produce population growth ultimately leading to disaster. Idealistic efforts to reduce poverty (via ‘transfer payments’ in modern terminology) would prove self-defeating, he argued, because higher incomes would in turn lead to higher fertility and lower infant and child mortality. Hence, policies intended to relieve poverty would worsen the environment by putting additional pressure on the food supply through encouraging demographic increase. For Malthus, the only morally acceptable escape was by individuals exercising ‘prudential restraint’ of their fertility, by which he meant avoidance of marriage unless and until the couple had sufficient resources to support a family, accompanied by abstinence outside of marriage. Failing this, balance between population and resources would be imposed via the dreadful ‘positive checks’ of famine, plague, and war.

In similar hindsight we can say that Malthus’s forecasts were mistaken too. He underestimated how fast food production and economic activity would increase, and dismissed as infeasible the conscious control of fertility within marriage that later came to be the norm in urban/industrial societies. His provocative arguments did, however, stimulate a passionate debate on population and the environment. In particular, his views were assaulted vigorously by Marx, thereby establishing a destructive ‘right-left’ dimension to more than a century of population/resource/environment debates that ensued.

Other conservative writers of the nineteenth century focused less on population issues and more on the ‘destruction’ of the ‘natural environment’ produced by capitalist industrial development and urbanization. In response to such claims, Marx and his followers acknowledged the validity of their criticisms, but argued that these developments were a function of capitalism, and hence transitional.

The second phase of the population/environment debate began toward the end of the nineteenth century, when the use of ‘environmental’ as an antonym to ‘genetic’ emerged in discussions of human decadence and perfectibility. Such arguments derived from enthusiasm about Darwinian arguments, though many of their ‘eugenicist’ proponents were far from well informed of the scientific evidence involved.

In general, they argued that the human gene pool was deteriorating, with powerful detrimental impacts on society and its betterment. The urban environment was itself genetically damaging, producing a cycle of residents who bore large numbers of stunted offspring who in turn raised large families of equally unhealthy children. Meanwhile, social elites were controlling their own family size, resulting in a collective ‘enfeeblement.’ For these proponents, this posed profound dangers to state and empire by reducing military and international power, while the increasing fertility differentials between social classes foretold the prosperous being swamped by a flood of urban disability. What was essential, they argued, was intervention to reverse the rot.

While many eugenicists were politically conservative, others were liberals or socialists. Though relatively few were fascists, the eugenics movement ultimately was compromised fatally when its notions of biological decadence were co-opted by the Nazis.

3. Complex Phenomena, Simpler Analyses

Any intersection among three forces as multifaceted as population, resources, and the environment—each of which is itself a subject of convoluted debate—is bound to be one of challenging complexity, required balanced and nuanced analyses. Yet, unhappily, there is an enduring tendency for arguments that anoint one of the three forces as dominant. Proponents on all sides tend toward single-cause explanations of complex social processes. Some emphasize the biological, others the economic, still others the ecological. Each group embraces one unifying theme to the exclusion of insights from other perspectives, and produce pronounced polemics of denunciation and retort.

Malthus’s celebrated essay on the principle of population was itself such a response to earlier arguments from utopians (including his father). It in turn provoked passionate denunciations by utopian socialists and Marxists, some of whom argued that there were no natural limits on population growth.

Similarly, eugenicists of the early twentieth century exaggerated the importance of biological and genetic elements for social issues such as fertility, poverty, and illiteracy, and such arguments in turn led social scientists to exclude biological elements entirely from their discussion of the 'demographic transition.'

In short, there has been a mentality of the adversary underlying much of the discussion about population, resources, and the environment, redolent of the style of political, religious, and legal advocates who ignore the similarities of their approaches to those they condemn.

Another source of dissonance during the nineteenth and twentieth centuries was the tendency to search for or assert 'scientific laws' of population, resources, and/or environment. Marx and Engels claimed the mantle of science for their analyses of capitalism while attacking utopians seeing the world not as it was but as they wished it to be. Malthus too criticized utopians such as Godwin and Condorcet in the same way. The fact that Marx's arguments did not explain social conditions within his own lifetime, and that Malthus's distinction between geometric and arithmetic progressions of population and food was contradicted by trends underway as he wrote, failed to dissuade either from his claims of scientific validity.

Similarly, the near-appropriation of Darwinian theory by political proponents of social Darwinism, and later of then-modern genetics by those promoting eugenics as social policies, illustrates the deep mystique of science in political arguments of this period. Invoking 'scientific' evidence of biological limits to human progress, eugenicists derided moderate and revolutionary reformers' assurances that environmental or political change could ameliorate the lot of the poor. Such excessive arguments from eugenics then led social scientists from the 1930s onward to formulate a theory of the demographic transition that excluded biology.

Meanwhile, in the Soviet Union Lysenko and his associates developed a Soviet 'scientific' response to eugenics that asserted that environmental factors trumped genetic forces, and more specifically that hereditary characteristics could be acquired rapidly from the environment and subsequently transmitted reliably to later generations. This 'scientific' perspective offered Soviet officials the opportunity to use 'environmental' (i.e., social, economic, political) policies to manipulate the gene pool—an opportunity that produced devastating famines as a consequence.

4. Economists and Demographers

Economists and demographers of the twentieth century also tended to unduly limit the horizons of their analyses and data. Neo-classical economics flowered at a time when economic growth was so rapid that it was easy to ignore resource and environmental issues.

Natural resources must have appeared unlimited to those at the center of expanding global empires, while the bulk transport allowed by steam power, railroads, and refrigeration rendered moot early concerns about limited agricultural land.

The emerging field of demography had multidisciplinary roots in economics, biology, mathematics, statistics, and epidemiology. Yet leaders of the nascent field were offended by the excesses of some biologists and others who sought to explain Western fertility declines in exclusively biological terms, and by the conservative political views that increasingly were associated with such explanations. The emergence of fascism exacerbated their concerns, leading them to relocate their 1936 scientific meeting from Rome to London and to boycott another meeting in Berlin.

At this moment in the intellectual history of demography a social and economic explanation of Western fertility coalesced into the 'theory of the demographic transition.' Though not really a theory in the sense of offering testable predictive hypotheses, the demographic transition provided a grand historical generalization that fertility declines could be wholly attributed to economic and social forces of the industrial revolution. In so doing, it ignored biological explanations then in vogue of the same phenomenon, as well as elements of culture, language, and religion unless these were driven by socioeconomic change (e.g., the effect of urban and industrial development in weakening the hold of the extended family on fertility behavior.)

The thinking of both economists and demographers was affected deeply by the Great Depression of the 1930s. To some degree they interpreted it as a consequence of 'underutilization,' both of capital and human resources in the economy and of the ability to bear children. Gunnar and Alva Myrdal in Sweden and Enid Charles in England produced gloomy, sometimes apocalyptic writings anticipating the terrible consequences of continuing low fertility. The Myrdals' prescription for dealing with 'the population crisis' was social legislation that evolved into the Swedish welfare state.

World War II focused concerns in different directions, but the war was followed by a long period of buoyant economic growth accompanied by much higher fertility levels. Expectations of unlimited economic growth replaced the gloom of the 1930s. Fertility trends ranged from powerful and sustained baby booms in the United States, Canada, Australia, and New Zealand to smaller and shorter-term 'boomlets' in most of Western Europe.

By the early 1960s, concerns about the negative environmental consequences of economic growth began, accompanied by worries about accelerating demographic increase both due to the Western baby booms and to rapid mortality declines with sustained high fertility rates in formerly colonial developing countries. Both concerns contributed to growing

awareness and activism about environmental problems, enhanced further during the 1970s by the oil crisis, the accident at the Three Mile Island nuclear plant, and the appearance of economic 'stagflation' that had no explanation in the canon of Keynesian economics. These events suggested there might, after all, be limits to natural resources, technological advance, and economic prosperity. In the United States and Western Europe, a new kind of political environmentalism emerged, including a direct electoral form in the German 'Green' party.

During the 1980s, and partially in reaction to environmental politics, there emerged in the United States an odd amalgam of earlier utopian, Marxian, and *laissez-faire* thought, deploying apparently scientific data and economic analysis, in what came to be called libertarianism or 'cornucopianism.' In its most enthusiastic variants, cornucopians argue that there are no natural limits to economic and population growth, and that the availability of natural resources is rising rather than declining. Some asserted that the 'ultimate resource' is human intellectual power to innovate technologically and create new resources, and hence the more humans on earth, the more resources there would be, *ad infinitum*.

Many of those who embraced such arguments did not seem to appreciate their intellectual origins, especially their Marxian pedigree. They were promoted strongly by opinion organs of American new right groups (the Heritage Foundation, Cato Institute, and the editorial board of the *Wall Street Journal*).

5. *Environmental and Ecological Approaches*

While many biologists, economists, demographers, and politicians have tended toward simple arguments about population, resource, and environmental issues, environmental scientists have emphasized the place of the human species in a complex ecological web of biological systems in constant interaction with the physical environment. In so doing, they have pointed appropriately to its vulnerability to the external insults of human technologies. However, there has also been a tendency to minimize or ignore the potentially positive environmental impacts that can also be produced by human technologies.

Consider for example the 'epidemiological transition' (see *Mortality, Epidemiological, and Health Transitions*). The triumph of human knowledge over food shortages and many endemic infectious diseases has produced dramatic improvement in human mortality since the eighteenth century. This was, of course, the primary reason for the acceleration of rapid human demographic growth since 1750, but it may also be seen as a fundamental technological transformation of the ecological systems involving humans, their food supply, and their 'predators.' Though environmental writers generally do not describe these particular

technological achievements in negative terms, some prominent writers have expressed skeptical views of their long-term implications for the global ecosystem.

In general, environmental and ecological writers frequently have emphasized the negative effects of other elements of science and technology, such as those surrounding energy consumption and production and modern agriculture, and paid rather less attention to the potential of new technologies for expanding natural resources or ameliorating environmental damage from other human activities. Of course sophisticated ecologists take such potentials fully into account, but there remains among some elements of the environmental movement a tendency to de-emphasize the potential environmental positives of technological innovation—in some sense a polar extreme from the technological enthusiasms of some economists. To many ecologists, the technological optimism of much modern economics, and of both Marxists and the new right, ignores the laws and complexities of nature.

To some degree we have come full circle. When environmentalists denounce the rape of the rain forest or the despoliation of freshwater streams and lakes, they echo older and eloquent laments such as those of D. H. Lawrence at the ruination of the English countryside or Dickens's portrayal of the industrial wasteland in *Hard Times*. Concerns about the environment, like those about population and resources, have deep intellectual roots in Western intellectual traditions.

6. *Conclusion*

Given this rich but often contentious intellectual history, what might be expected of future discussions of population, resources, and environment? During the nineteenth century, most of the major political thinkers were forced by the powerful changes all around them to analyze population change and its interaction with resources and the environment. Typically they sought single (or at least simple) explanations of the complex transformations they could see, leading inevitably to an intensely ideological debate. Instead of building upon the work of earlier writers, they sought to refute their adversaries' errors. First the utopians, Malthus, Marx, and their allies clashed over the potential for demographic and economic growth with prosperity. Later biologists, eugenicists, and social scientists contested about the biological vs. environmental causes of declining fertility rates and increasingly 'enfeebled' urban populations.

These classical debates about population/resources/environment are a polemicists' dream: sweeping generalizations, exaggerated rhetoric, and emotional accusations. Those in the Marxian, socialist, and liberal-Christian traditions were certain

that when the majority took power from the reactionary elite, they would build a more humane environment unconstrained by demographic issues. Those following Malthus, and later the eugenicists, argued to the contrary that human progress is constrained by the laws of biology and demography.

The political and economic crises following World War I tended to mute these earlier debates about population growth, resource scarcity, and environmental degradation. After World War II, it was relief at the end of global war and the reappearance of prosperity that further eclipsed environmental and demographic questions. Only since the 1960s have these issues re-emerged, after decades of inattention.

There is good reason to fear that future debates may echo those of the past: ideological blinders, harsh rhetoric, narrow analytic perspectives. But there are also signs of hope. Resource economists have shown that it is possible to combine the power of economic theory and analysis with those of ecology and environmental perspectives. Demographers too have broadened their dependency upon purely socio-economic analyses to embrace insights from biology, ecology, political science, and other relevant disciplines. The hope is that these more ecumenical trends will persist and flower, so that our collective understanding of population, resources, and the environment may someday be as subtle and complex as the phenomena themselves.

Population Size Estimation and Capture–Recapture Methods

How many people were missed by the US census? How many injecting drug users are there in Glasgow? Homeless in Scotland? Industrial accidents in Maryland? Bugs in a computer program? How many words did Shakespeare know?

How do we estimate the sizes of such populations? If the population includes a subgroup of identifiable individuals and if their number is known, a simple approach is available. If a random sample can be taken from the whole population and the proportion of the subgroup that occur in the sample is calculated, that proportion can be used to scale up the sample size to provide an estimate of the unknown size of the population. Three important ‘ifs’ occur in the last two sentences that cause problems for this dual-system estimation (DSE) procedure, also known as capture–(or mark–) recapture (CR) from its widespread use in the study of wildlife populations by means of animals caught, given marks, released and subsequently recaptured.

Both in this simplest form, and in the many extensions proposed to overcome the problems posed by these ‘ifs’ in the real world, this CR method has many relationships with other statistical methods. The problem is one of sampling from a finite population. If an indicator variable y is defined to be 1 for an individual in that population, 0 otherwise, the unknown size of that unique population is the population total Y of y . The CR estimate is the classical ratio estimate based on the auxiliary indicator variable x which is 1 for an individual in the subgroup, 0 otherwise. Laplace’s (1786) estimation of the population of France, with subgroup those registered as born in the previous three years and a cluster sample of over two million, can be regarded as the first use of CR as well as the first use of a superpopulation model (Pearson 1928, Cochran 1978). Two books discuss CR as sampling theory—by Thompson (1992) and Skalski and Robson (1992).

1. Statistical Theory

Early discussion, summarized in e.g. Seber (1982) or Cormack (1968), focused on distributions for the observations—hypergeometric, multinomial etc.—under different rules for defining the subgroup and stopping the sampling. Practical differences are minor. The distribution of the estimate, especially for small subgroups or samples, is more important. If the population size is N , the size of the known subgroup X , and the sample size n contains x from the subgroup, then the intuitive, also the maximum likelihood,

estimate of N is $[nX/x]$, known as the Petersen estimate after the Danish fisheries biologist who first proposed its use in biology. This is the observed number of different individuals $[X+n-x]$ plus the estimate $[(X-x)(n-x)/x]$ of the number U of unobserved individuals. As a ratio estimate this is biased: the recommended correction (Chapman 1951) adds 1 to the denominator of the estimate of U . The distribution of the estimate of U is skew, and if U is small, or based on small observed numbers, then a confidence interval based on assumed normality can cause embarrassment by including negative values for U . Likelihood can be used directly (Cormack 1992) to avoid this. Other approaches have been proposed, with different loss functions and/or Bayesian methods. The latter are discussed below.

The known subgroup often comprises individuals identifiable because they occur in another list or sample. In wildlife applications, in which the next developments took place, the two samples were often obtained by the same protocol at different occasions, with a long enough period between for thorough mixing of the mobile animals to be (questionably) assumed. Generalizations of this two-sample case were made, to more samples (Darroch 1958) and, as time periods extended, to allow for the population to change through birth, death, or migration between samples. In open populations, survival estimation from recapture data on marked animals is more reliable than estimation of population size. Open population models were applied to historical lists by James and Price (1976): the willingness of residents of a medieval town to contribute to the town's defense, and their ability to avoid paying a tax to the king, are clearly displayed, together with evidence of unsuspected epidemics.

The natural statistical way of representing counts in a number of categories, formed by the presence in or absence from a number s of lists, is as the cells in a 2^s contingency table. Models and analytical techniques are summarized in books such as Bishop et al. (1975). In CR one cell is not observed, a structural zero, and the aim is, by formulating a series of models for the observed categories in the table, to estimate the missing number by extension of these models. When additional information on individuals is available in the form of quantitative covariates, such as age or severity of disease, the use of logistic models at the individual level was suggested independently by Alho (1990) and by Huggins (1989). The Horvitz–Thompson estimator is used, with inclusion probabilities, of being in each list, estimated from the model, a procedure developed differently by Pollock and Otto (1983). With no covariate information, or with categorical information only—e.g., gender, ethnicity, geographical region—log linear models form the current standard approach. Maximum likelihood estimates (MLE), perhaps bias corrected, are then derived. In this framework it is natural to examine the data for interactions between

categories, evidence that the samples were not random. Birth and death, unequal availability of different individuals, and behavioral change consequent on physical capture of animals, have all been expressed as interactions within the log linear framework.

Even thus far, numerous quirks arise whereby the corresponding statistical theory does not quite apply to the CR problem. Estimation from a log linear model does not maximize the complete likelihood: nuisance parameters of sampling probabilities are estimated from the observed cells, and N estimated conditionally on them. Normally such multinomial models for complete tables are fitted assuming a Poisson model, giving the estimates various desirable properties of the exponential family. With N unknown, the distributions of the estimate of N are different under multinomial and Poisson models though the point estimate is the same and estimates of nuisance parameters have the same properties. Regularity conditions for desirable properties of MLE do not hold in the multinomial model, but do in the Poisson. The Horvitz–Thompson correspondence shows that the estimate of N is calculated via estimates of $1/(\text{inclusion probabilities})$. Why then seek unbiased estimates of these probabilities? It is their inverses that are of interest.

2. Health and Social Studies

One widespread application in the social sciences is to ascertain how many individuals have some health or social problem, numbers needed for policy and budgetary decisions. Data are pre-existing lists from different agencies, each attempting to cover the whole population. Such lists have no or little random element in their formation. They will not, in general, be statistically independent. Individuals are referred from one agency to another. Conversely, two agencies may overlap, or be perceived to overlap, in their function so that an individual attending one may choose not to attend the other. Agencies primarily serving different sections of the population, geographically, by age, severity of problem, or whatever, will also be negatively dependent. Such correlation bias results in the standard estimate being an underestimate if lists are positively dependent, an overestimate if negatively dependent.

With two lists dependence is not identifiable: independence must be taken on trust. With more than two, log linear models can be used to elucidate the pattern of dependence. With three lists, eight models with different combinations of pairwise dependences are available. Extrapolation to the missing cell to estimate U and thus N requires the three-factor interaction to be zero or else expressible, from a model at the individual level, as a function of lower-order interactions. Most studies use some form of model selection to determine which dependencies must be

allowed for, usually based on log likelihood ratio statistics from the analysis of deviance—the residual deviance and the difference between deviances from nested models. The complexity of a model is balanced against its badness of fit. Many authors have advocated parsimony: others argue that a parsimonious model with independence between lists is difficult to believe *a priori*. With the latter attitude, it might seem best to always fit the saturated model, including all identifiable interactions. There are two objections to this. The first is that if all lower-order interactions are nonzero, considerable doubt is cast on the necessary act of faith that the highest-order interaction is exactly zero. The other is that the estimate is very sensitive to any small cell count, and gives either a zero or infinite estimate for the missing cell if any cell count is zero, an event which becomes more likely the more lists are included in the study.

Certain patterns of cells with small numbers cause problems for all analyses, in that they reveal that the data contain very little information about some dependencies, either having few overlaps between lists or, perhaps surprisingly, when one list has a very high coverage. Asymptotic distributions of criteria used for model selection no longer hold, and should be replaced by bootstrap resampling of data predicted by different models.

More than three lists can be analyzed similarly except that, with more than five or six, the small number problem usually dominates and routine application of a program to analyze log linear models becomes impossible. One approach to model selection is then to start with the model including all pairwise dependencies, perhaps use backward elimination to simplify, and add higher-order terms by forward selection. However, making inferences conditional on the truth of a model selected from the data has been recognized as the Achilles heel of statistical inference. The alternative of averaging over all models has been applied to CR by several authors (see Sect. 5).

In the study design a list should be sought which is likely to be independent of the others. In studies on drug abuse, lists from police arrests have sometimes appeared to fulfil this condition relative to lists from social and health agencies. Questions of commonality of definition do arise. Moreover, patterns of interactions have to allow for individual heterogeneity as well as direct dependence between lists. The resulting confounding is discussed below.

3. Heterogeneity

Animals, particularly humans, are not the exchangeable colored balls required by ideal mathematical theory. There are reasons why individual i is not observed in list j . To estimate the numbers missing from all lists requires exploration of these reasons.

Exploration and thought are crucial to give even a qualitative impression of the effect of such individual heterogeneity on the estimate. To quantify it needs modeling of p^{ij} , the probability that individual i is observed in list j . An early attempt by Cormack (1966) considered $p^{ij} = \theta_i * \beta_j$, but this is superseded by the logit model: $\log \{p^{ij}/(1-p^{ij})\} = \theta_i + \beta_j$ introduced by Rasch (1960) for educational test scores. In the context of repeated samples with the same protocol and same effort, so that β_j may be assumed constant, Burnham and Overton (1978) introduced the idea of the individual effects θ_i being a random sample from some distribution. Some workers have developed the consequences of assuming a beta distribution, but, if no specific form is assumed, the set of capture frequencies—numbers of individuals seen k times—are jointly sufficient statistics for N after integration over the distribution.

Without θ_i these models represent independent lists: differences between individuals necessarily cause dependence between lists. The Rasch model for individual behavior corresponds to a log linear model for cell counts with quasisymmetry, all interaction terms of the same order having the same value (Fienberg et al. 1999). Assuming a random model for an individual contribution's to his probability of being in a list, and integrating over that distribution, creates a superpopulation model for a sample survey. With nonrandom lists, any inference must be model-based, and estimates from superpopulation models are standard in survey sampling. However, while it is easy to accept that an estimate of, say, mean income in a superpopulation gives a reasonable inference for the one finite population of interest, doubts surface when the parameter of interest is the size of that one finite population. Unfortunately, allowing direct dependence between lists in a Rasch model for an individual is not the same as a log linear model with only that one extra dependence term. CR has also been expressed as a latent class problem by Agresti (1994).

Heterogeneity can be reduced by analyzing subpopulations as separate strata. Differences in models selected and in estimated inclusion probabilities can be studied. Samples from some strata may however be too small to permit effective model selection.

4. Coverage

Closely related to CR is the classical species problem. How many are there in the world? As a specific example, how many words did Shakespeare know? Concordances list all occurrences of any word in each play. Some words are used in only one play. There must be many he knew, but never used, just as there are many undiscovered species of beetle. Some words occur much more frequently than others, stark evidence of heterogeneity between individuals (words).

Apart from elegant models for specific applications, debate about sampling distributions and behavior of estimates has paralleled, and often predated, that about CR. A good review has been provided by Bunge and Fitzpatrick (1993). A key concept is that of coverage, the proportion of individuals of species represented in existing lists, perhaps easier to estimate than N , the unknown number of species. Chao and colleagues (e.g., Chao and Lee 1992) have developed various nonparametric estimates of N via coverage. These can be linked to martingale approaches to CR by Yip (1991).

5. Bayesian Methods

Bayesian methods have a long history in mark-recapture, even if Laplace's inverse probability argument is not considered pure Bayes. Early formulations make the point that independence of population size N and capture probabilities may not be appropriate *a priori*. Not only prior beliefs about N but also model uncertainty can be built smoothly into the analysis. Madigan and York (1997) develop models, with some analytical tractability, for decomposable graphical models with hyper-Dirichlet priors for cell probabilities, respecting the model's pattern of conditional independence, and allowing informative priors for N . Bayesian analysis of hierarchical log linear models has also been developed, an approach linked to the Rasch model by Fienberg et al. (1999).

6. Census Undercount

Recent national censuses show nontrivial undercounts. The possibility of adjustment has been widely explored and debated, in the US courts as well as the scientific and social literature. Because of the scale and expense, there are at least four major differences from applications discussed above. One is that matching and other nonsampling errors, present in other applications, gain prominence. Another is that the second list, from follow-up field survey, is necessarily performed only on a sample of the population. A third is that only two lists are the norm. The fourth is that estimates are required not only for the population as a whole, but for particular minority groups in relatively small geographical areas. Statistical summaries of the US debate have appeared in special sections or issues of the *Journal of the American Statistical Association* (1993) and of *Statistical Science* (1994), and in Anderson and Fienberg (1999).

Matching errors tend to identify two records of the same individual as different rather than vice versa. With two lists this leads to overestimation of N . Attempts to correct this, by algorithms which declare individuals identical, even when differing in some

identifiers, can give false positive matches, and hence underestimation. Probabilistic record linkage is discussed by Jaro (1995) and models for its effect on CR estimates by Ding and Fienberg (1996).

In recent usage, the second list comes from a postenumeration survey (PES), an intensive field survey of small geographical areas, defined slightly differently in different countries, in a complex randomized sample plan, typically with strata and clusters at two or more levels. The relationship between CR and ratio estimators allows CR models to be combined formally with the sample design, though sampling theory suggests other ways of using auxiliary variables.

With two lists, the required independence must be built into the design. Sampling units must be defined, small enough, to minimize heterogeneity. Small numbers cause instability, and attempts are made to correct this by spatial smoothing over neighboring areas. The multiplicity of ways in which sample-based inference can be integrated with model-based inference from multilevel data with CR models is a topic of much current debate.

7. Summary

The first difficulty with the use of CR is the definition of the population. If in a study of diabetes all observed individuals can be stratified by the medical care prescribed, then the missing numbers are not of undiagnosed diabetics, but of diabetics who have been diagnosed, but whose records have been lost. If different agencies have different definitions of homelessness, or cover different geographical areas, then which population is it hoped to estimate? No statistical analysis of the observed data resolves these problems. Second, there is the problem of matching individuals, a problem which grows with the size of the study, and the separation of the analyst from the data collection. The more sensitive the subject of the study, the more prevalent will be deliberate misinformation from an individual. Matching problems will vary between countries that have differing levels of confidentiality and anonymity. Third, there are the analytic problems caused by the unreality, in many cases, of the assumption of random sampling. Lists are not independent, individuals are not behavioral clones, and the two aspects of dependence and heterogeneity may be at least partially confounded unless care is taken to obtain data which allows disentanglement. Finally, there is the problem of the variety of analytical approaches—which to believe? With several lists, some models can be rejected because of lack of fit to the observed counts. However, failure to reject a model is not positive proof of its truth. Estimation of population size still requires extrapolation to the unobserved, the validity of which is untestable without randomness in the sampling.

Although absolute estimates of population size are often unjustifiable, it may be possible, by repeating the same protocol for list-formation at different times or places, to obtain reliable assessments of population change or geographical variation in incidence of a disease or social phenomenon.

R. Cormack

Populism

Populism is a form of mass politics. The core idea, as the etymology would suggest, rests with the claim to represent or act in the name of the people, understood as ordinary or common people, the majority, or the masses, as opposed to elites, privileged or special-interest groups, the establishment, or the power bloc. It is generally distinguished from two other forms of mass politics: class politics (based on class organizations of unions and social democratic parties) and pluralism (based on multiple, shifting, overlapping interest groups and a rejection of the populist dualism that stresses the representation of the general will of the people vs. some minority). 'Populism' has been used as a term of approbation by movements themselves and as a term of opprobrium by critics. Analysts have also used the term, applying it to diverse phenomena.

1. Empirical and Conceptual Variation

With origins in ancient Rome, where the *Populares* opposed the aristocratic *Optimates*, the first modern usage is probably the Russian *Narodnik* movement of the 1860s–70s, which never achieved mass adherents but represented a radical articulation of the idea that wisdom resides with the common people and that socialism could be based on the traditional peasant commune. American populism, beginning in the 1880s

and continuing particularly in the South through the twentieth century, has received much attention, as has Latin American populism of the mid-twentieth century. Currently there is a resurgence throughout the world of movements and leaders that have been dubbed populist: in Latin America (Collor, Fujimori, Chavez, Menem), in Western Europe (Haider, Le Pen), in the United States (Buchanan), and in post-Communist states (Meciar, Milosevic, Lukashenko). Many other movements have also been considered populist by at least some analysts, including those led by Nasser, Nyerere, Mao, Hitler, Father Coughlin, Gandhi, Chartists, and even Jimmy Carter.

The populist label has been attached to such a wide variety of political movements (right and left, from above and from below) that it is hard to stabilize any core meaning that can work rigorously as an analytical concept. Some analysts propose conceptualizations that are compilations of traits of specific movements, providing no basis for abstracting out a more parsimonious conceptualization that serves for broader, comparative analysis (Pipes 1964, Goodwyn 1976, Hicks 1955). Others, engaged in a more comparative quest, have highlighted a particular trait or subset of traits (Germani 1962, Di Tella 1965, Ionescu and Gellner 1969, Laclau 1977, Conniff 1999, Taggart 1995).

These approaches typically emphasize some components of the following.

(a) *Mobilization* or collective action from below, with deep roots in local communities.

(b) A *reform* or anti-status quo movement.

(c) A *support base* constructed by a discourse that attempts to promote an identity as the 'people' rather than a class, and sometimes aimed at neutralizing class identities. The political group constructed in this way is embedded in a particular adversarial juxtaposition to a vague 'other': elite (economic and/or political), alien, special interest, or minority group, often corrupt or conspiratorial. At the same time that a mass discourse seeks to construct an inclusionary base, populist movements in fact may be quite specifically supported by a particular class or classes.

(d) A multiclass or nonclass-based *coalition*.

(e) A *heteronomous* or politically subordinated, masssupport base, lacking autonomous power and subordinated to the leader and/or the interests of another class in the coalition.

(f) A particular *leadership style*, specifically strong, personalized, sometimes charismatic leadership.

(g) A leader-mass *linkage* that is direct, rather than mediated through organizations.

(h) Use of *rhetoric* and *oratory* that is anti-theoretical and anti-intellectual rather than coolly analytic, expository, explanatory, or abstractly elaborated in theory or ideology.

(i) An '*irrational*' form of politics in the sense that it attracts support on an emotive or moralistic rather than an interest or programmatic basis: sometimes

identified as a politics of status-anxiety rather than economic demands.

(j) A set of *economic policies* or an economic model that emphasizes growth, distribution, and demand-side stimulation, and deemphasizes fiscal and market constraints. In this way it is seen as an economic policy that is undisciplined, inefficient, and distorted or contaminated by the goal of winning political support.

Confronted with the great number and diversity of both movements and traits, Tindall (1972) proclaimed a 'semantic identity crisis.' Some analysts have responded with an attempt to construct subtypes. Canovan adopted a 'phenomenological' and 'naturalist' approach—an admittedly atheoretical exercise that yields seven types. These accommodate diversity but 'do not really look like seven varieties of the same thing; on the contrary, some of them seem quite unconnected with others' (Canovan 1982, p. 551). Roberts (1995) attempted to retain a conceptual core or commonality while accommodating diversity by proposing a 'radial' conceptualization. Here the aim is to delineate a set of traits that defines a 'pure' populism, and to recognize that subtypes (or actually existing populisms) may not in fact have all the traits in the definition. The diversity of populist movements is thus accommodated by constructing a typology of 'diminished' subtypes—types differentiated in terms of traits in the core definition which they lack.

2. Family Resemblance and Analytical Dimensions

The important point about 'populism' as it has been used is not just that types of populism lack the full set of traits. Taken as a whole, conceptualizations of populism share a family resemblance. However, different combinations of traits describe a diverse set of cases (or types) that may share few, if any, traits. Thus, 'populism' can encompass quite incongruous, even 'opposite' or inverse movements.

In the above list of traits, each seems to follow the other unproblematically. However, as one moves from the beginning toward the end of the list, one travels from authentic reform movements from below toward demagoguery—from programmatic movements based in grass-roots collective action and/or organization to instrumental top-down mobilizations of support by political leaders to facilitate their own political ambitions, or, in a Marxist framework, to promote the interests of a superordinate class. In between, populism has been associated with quite standard electoral politics and the pragmatic strategies of political leaders, particularly in catch-all parties, in order to achieve electoral victory, strategies which can be presented positively, as rational politicians instrumentally adjusting positions to conform to the median voter, and negatively, as pandering or the marketing of

candidates. (Canovan (1982) includes politicians in catch-all parties as populists.)

More important than trying to define some common core of populism is delineating some dimensions for comparing very different forms of mass politics. The different traits printed in italics in the above list point to distinct 'domains' which can be treated as dimensions on which movements analyzed as populist vary. The range of variation is evident from a description of three of the most successful sets of populist mass movements: the historical, 'classical' cases of populism in the United States and Latin America, which have received the most attention in the literature, and the recent cases emerging in diverse settings throughout the world. These cases differ dramatically with respect to, for example, leader-follower linkage, composition and heteronomy of support base, class/mass discourse, programmatic/interest vs. 'irrational' orientation, and economic policy.

3. Concrete Examples

American populism of the 1880s and 1890s arose out of the economic distress of farmers and was based in a web of thousands of independent organizations formed to address grievances at a local level. In 1892 the two regional alliances which these organizations had formed founded the Populist Party to contest national elections. The Populist Party thus emerged from the autonomous mobilization and organization of farmers. Its platform is interesting for its programmatic nature and its class discourse. Though free silver was one of the most important and well-known demands, the platform included many other economic and political planks: government distribution of credit; nationalization of railroads; graduated income tax; direct election of president, vice-president, and senators; initiatives and referenda; and a number of demands of interest to urban labor and unions. The Populists saw themselves as embodying the will of all the 'toiler classes' against the 'criminal classes.'

After a poor showing, the party retreated and in 1896 backed the candidate of the Democratic Party, William Jennings Bryan, who adopted many Populist planks and whose campaign reached oratorical heights. Those (Hicks 1955, Goodwyn 1976) who see populism as a grass-roots agrarian movement identify 1892 as its peak, after which it was coopted by the Democrats under Bryan. To the extent they see an ongoing populist thread, the analysts who identify populism with agrarian radicalism trace it forward to other progressive movements.

The conceptual confusion about populism is reflected in the fact that those who identify populism with an unmediated, oratorical leadership style see Bryan not as the coopter but as the prototype (Hofstadter 1955). Emphasizing majoritarian and crusading traits that imply intolerance and express the

irrationality of status anxiety, they trace American populism to the mobilization of an unorganized support base by paternalistic, demagogic Southern governors (e.g., Huey Long and George Wallace) and to McCarthyism, in which economic interests were even more distant, with the primary targeting of a foreign enemy and conspiracy against the nation. This alternative conception obviously involves very different sets of attributes.

'Classical' Latin American populism (of Cardenas in Mexico, Peron in Argentina, Betancourt in Venezuela, Haya de la Torre in Peru) emerged in the 1930s-40s as a strategy to win political support among the unionized proletariat in the context of the struggle by rising urban elites to attain or consolidate power. These movements consisted of urban, multiclass coalitions. It was a coalition between unequal partners, with the autonomy of workers limited to varying degrees, but generally workers had some bargaining power and political weight. The discourse was notably classist, and support mobilization occurred on the basis of real material and organizational concessions, not simply rhetorical appeal or charismatic leadership. Far from involving direct, unmediated leader-follower linkages, these were organizing periods when unions were strengthened, political parties were founded, and unions became affiliated to these parties. Union and party organizations played a central role in mobilizing support (Collier and Collier 1991).

If the first phase of early US populism is the autonomous expression and demands of farmer organizations and classical Latin American populism is the strategy of political leaders to construct an alliance with the unionized proletariat, contemporary populism is quite different. Like some US strands, contemporary populism ('neopopulism' in Latin America) generally consists of electoral support mobilization by leaders who make strong direct, rhetorical appeals to the 'people' unmediated by organizations. Yet unlike the 'classical' cases, contemporary populism occurs in the context not of a state interventionist economic model consistent with demand-side (re)distributive policies, but of the global move to marketizing policies, which are often unpopular. These policies have led to social-institutional change involving the growth of the informal sector and contingent workforce and the defensive position of organized labor. Politicians find fertile ground in the actual or threatened grievances and social dislocation resulting from new economic models, but once in office often adopt marketizing policies. Nonprogrammatic, nonclassist, noninterest-based appeals for support are thus a rational approach for sustaining governments pursuing marketizing policies.

The contrast of populisms is particularly evident in Latin America. There, classical populism represented a certain kind of inclusion and controlled mobilization of the new proletariat; neopopulism represents exclusion and demobilization. The one organizes classes;

the other disorganizes them or disarticulates their organizations. One is an alliance and bargains with the organized working class with broad payoffs (e.g., wage policy, food subsidies); the other is a rhetorical appeal to the unorganized masses (and particularly targets the growing informal sector) with selective, paternalistic distributions (e.g., local infrastructure). Postcommunist populism is a parallel form of 'post-organized' mass appeal when class solidarities and organizations have weakened or disappeared. In advanced countries, populist appeals have similarly targeted those threatened by the prospect or reality of the global relocation of production and labor, economic insecurity, and the pressure to flexibilize or liberalize labor regimes.

These examples suggest the diversity of 'populist' movements. The minimal commonality they share—that they seek to 'represent' or appeal to ordinary people in one way or another—is not very interesting; their differences are more important for elucidating the who, what, why, or how questions one might ask about them, and fitting them into larger theoretical and explanatory frameworks. If one is to use the term as more than political discourse or as a broad label, if the term is to do analytical work, it will be most helpful to delineate a common set of dimensions for scoring cases. Analysis of the resulting subtypes, with their distinct logics and dynamics, may be more useful than an ultimately elusive effort to achieve a common overall conceptualization of populism.

R. B. Collier

Pornography

The topic of pornography has been discussed from many vantage points and often hotly debated by scholars and researchers. Some have focused on the functions and effects of pornographic mass media as they pertain to understanding the impact of pornography on individual consumers. For example, some theorists have argued that the particular type of pornography an individual is attracted to may serve as a 'window to the mind,' revealing core developmental conflicts of the psyche (Stoller 1976). Others have considered the beneficial and/or negative effects of pornography on individuals in the realms of fantasy, sex education, esthetic/artistic expression, sexual addiction, etc. (Gagnon 1977, Gordon 1980). Yet other scholars have approached the topic at a broader level, exploring such topics as the relevance of pornography to group relations, social institutions, and the role of government regulation (e.g., Strossen 1995, Weinstein 1999). Assertions have been made that pornography use contributes to unequal power relations between dominant and subordinate classes, particularly male subjugation of women (Itzin 1992). Others have claimed that pornography is a degrading threat to social institutions and values, such as the traditional family structure (Wojtyla 1981); and that it has functioned as an agent of social change (Sorokin 1956), even as a contributing factor to major social revolutions (Hunt 1993).

It is beyond the scope of this article to consider all of these diverse approaches to the topic of pornography. Instead, the focus here may be described as a 'social science-centered' approach revolving around two central questions: First, what are the findings of social scientific studies on the effects of pornography on men (who are much more likely than women to be the consumers of such media) in the areas of aggressive attitudes and behavior? Second, how can we under-

stand this major asymmetry in male vs. female consumption of pornography?

An extremely large media industry has existed for many years that sells sexually explicit material, including movies, magazines, books, videos, and, increasingly, Internet-based media. This 'pornography industry' was recently described by *Forbes* magazine as a \$56 billion global industry that has become much more mainstream in recent years. Some companies marketing very explicit portrayals on the Internet are now listed on the Nasdaq stock exchange (Morais 1999).

1. Defining Pornography

Pornography refers to sexually explicit media that are primarily intended to sexually arouse the audience. Typical content consists of nudity and/or various sexual acts (e.g., intercourse, fellatio, etc.). Hunt (1993) notes that the production of media for this purpose is a relatively modern phenomenon, beginning toward the latter part of the nineteenth century. O'Toole (1999, p. 1) similarly argues that earlier in European history the use of sexually explicit depictions was primarily for political purposes, '... to satirise, criticise, to tilt at the Church, the state, the monarchy. ... Porn was controlled during this period not because it was obscene but because it was seditious, blasphemous, or defamatory.'

Pornography does not include sexual content that is 'embedded' or interwoven with much nonsexual content (e.g., a movie that primarily includes nonsexual content but also has one or a few sexual scenes). The research literature in that area has been recently summarized by Malamuth and Impett (2000). Sometimes the distinction between 'embedded' and explicit sexual content is not so clear. For example, *Playboy* magazine regularly includes considerable nonsexual content (e.g., interviews with politicians and jazz artists) as well as nude portrayals; the Starr Report, an official state document focusing on President Bill Clinton, included much sexually explicit content. Nevertheless, the focus here is on content that is primarily designed to sexually arouse the consumer.

In terms of legal definitions, the terms 'pornography' and 'obscenity' need to be distinguished. Obscenity refers to pornographic content that has been judged by the legal system to be illegal. In the USA, most states use the 1973 Supreme Court decision in *Miller vs. California* as the legal definition of 'obscene.' To be judged obscene under this case the material must satisfy three conditions: (a) The average person, applying contemporary community standards, would find that the work, taken as a whole, appeals to the prurient interest; (b) the work depicts sexual conduct in a patently offensive way; and (c) the work, taken as a whole, lacks serious literary, artistic, political, or scientific value.

With increasing use of new types of media such as the Internet, there may be changes in the content of pornography and the feasibility that governments can restrict access to content considered by some as offensive or harmful. For example, Barron and Kimmel (2000) recently measured the levels of sexually violent content in representative samples of sexual magazine, video, and Internet sex stories sites. They found that the Internet content was significantly higher in violence than the videos or magazines. This difference was particularly high when considering 'extreme' forms of violence (e.g., use of weapon on a victim, torture, mutilation) where 17 percent of the Internet sites contained such material as contrasted with only 2 percent in the other media. Furthermore, the Internet content depicted men in dominant positions, as victimizer and not victim, in far greater proportion than magazines and videos. The authors note that the Internet is more 'democratic' than the other media, which are constrained by dependence on commercial advertisers. The researchers suggest the Internet content is '... as close as one can get to men's direct expressions of their own fantasies, unconstrained by the demands of the marketplace or the high costs of producing and distributing those fantasies to others' (p. 166). It should be noted, however, that the men who currently use such Internet sex sites may not be representative of the larger population and may have particular attraction to more aggressive content.

2. Research on the Effects of Sexually Explicit Media

2.1 Differences Among Studies

Varied methodologies and dependent measures have been used to study the effects of pornography. Much research has centered on the potential link between pornography exposure and aggression, particularly sexual aggression. Most of the studies conducted within North America, may be described along two orthogonal dimensions based on whether they used experimental (random assignment to conditions) or correlational methodology, and whether the dependent variable they assessed was a response presumably affecting sexual aggression (e.g., attitudes supporting such aggression) or some measure of actual aggression. Such studies may therefore be organized into four categories: (a) experiments manipulating exposure to pornography and examining the effect upon attitudes as the dependent measure; (b) experiments manipulating exposure to pornography and assessing the impact on aggressive behavior as the dependent measure (in laboratory settings); (c) studies of the correlations between individual differences in pornography exposure in naturalistic settings and men's attitudes supporting aggression; and (d) two

types of studies examining the correlations between pornography exposure and aggressive behavior in naturalistic settings, those comparing criminals vs. noncriminals on pornography use, and within samples of noncriminals, those comparing different levels of reported past sexual aggression and individual variability in use of pornography.

Several meta-analyses of pornography systematically synthesize the research literature in three of the four categories and partly in the fourth category of study. Research correlating pornography use and sexual aggression within the noncriminal population has not yet been synthesized by a metanalytic review. Here, fortunately, a recent publication using a national representative sample of all men in some form of posthigh school education is available to help fill this void

Below is a summary of the findings of the various meta-analyses and the findings of the national study.

2.1.1 Experiments on the effects of pornography on attitudes. Allen et al. (1995a, 1995b) conducted a meta-analysis of experiments, both laboratory and field studies, on the effects of pornography exposure on attitudes. The meta-analysis revealed that across the various studies conducted, there was a significant though modest effect, with violent pornography resulting in significantly greater increase in attitudes supporting aggression than exposure to nonviolent pornography (although there was also some effect for both types of pornography exposure). Therefore, the overall data showed that exposure to pornography, under controlled conditions, does cause an increase in attitudes supporting sexual aggression.

2.1.2 Experiments on the effects of pornography on laboratory aggression. The meta-analysis of Allen et al. (1995a) concluded that men exposed to non-violent or violent pornography portraying sexual acts were more aggressive than those exposed to neutral content, in the laboratory research reviewed. In contrast, exposure to portrayals of nudity alone (without any sexual acts) resulted in reduced aggression in comparison to exposure to neutral content.

2.1.3 Pornography and attitudes favoring sexual aggression in naturalistic settings. Although correlational studies do not enable cause and effect conclusions, they often have the advantage of assessing responses occurring in naturalistic settings. Allen et al.'s (1995b) meta-analysis examined these studies. They found that there was a weak positive correlation that was judged not to be statistically significant between amount of exposure to pornography and atti-

tudes favoring sexual aggression. Therefore, the correlational data for attitudes in naturalistic settings did not yield supportive data for the conclusions emerging from the experimental studies conducted in controlled settings.

2.1.4 Pornography and aggression in naturalistic settings. Allen et al. (2000) conducted a meta-analysis focusing on the pornography use of convicted sex offenders as compared to those of men from the non-criminal general population. They examined several types of dependent measures: (a) frequency of pornography use; (b) age of first exposure; (c) the degree to which pornography was a direct prelude to some sexual act (masturbation, consensual sex, or forced sex); (d) and degree of sexual arousal, measured by direct genital measures of such arousal. The findings across all of the studies and measures combined did not show that criminality was associated with frequency of pornography exposure nor with age of first exposure. After viewing pornography, criminals were more likely than noncriminals to engage in some sexual acts such as masturbation, consensual, or criminal sex.

Finally, these investigators conducted a related meta-analysis examining the degree to which different types of stimuli affect people in laboratory settings. They focused on studies of physiological sexual arousal (assessed by direct genital measures) to various types of content. The researchers concluded that sexual criminals were generally more sexually aroused than noncriminals in laboratory studies examining physiological arousal to sexual stimuli. However, studies which separated portrayals of consenting and nonconsenting sex found that in comparison to non-criminals, sex criminals were more aroused by violent sex. By contrast, the difference was in the opposite direction with consenting sexual portrayals, with nonrapists showing relatively more sexual arousal. It should be noted that although criminals may be less aroused sexually by consenting depictions than non-criminals, the data on 'sexual acting out' (see above) suggest that they may still be more likely than noncriminals to engage in some sexual activity following exposure to either types of pornography exposure.

Although a meta-analysis has not been conducted on the few available studies examining among non-criminals the potential relationship in naturalistic settings between use of pornography and individual differences in self-reported sexual aggression, these few studies do point to a significant association (for a review see Malamuth et al. 2000). However, these few studies have some methodological limitations, which were rectified in a national probability study recently reported by Malamuth et al. (2000). This study found that for the majority of men, high

pornography use is not indicative of high risk for sexual aggression: Among those classified as being at relatively low risk for committing sexually aggressive acts (based on various measures previously found to predict such risk), there was only a small difference in sexually aggressive behavior between those who reported different levels of pornography use.

In contrast, pornography use was indeed a very good 'marker' of higher sexual aggression levels when these researchers considered a particular group of men: those who, based on the other measures of risk for sexual aggression, were previously determined to be at high risk. It was found that among these high-risk individuals, those who additionally were very frequent users of pornography were much more likely to have engaged in sexual aggression than their counterparts who consumed pornography less frequently. The researchers cautioned, however, that such data alone cannot be used to infer cause and effect conclusions, even if they are useful for risk assessment. They did speculate that:

associations between pornography consumption and aggressiveness toward women could be explained by a circular relationship between high coercive tendencies and interest in certain content in pornography, whereby aggressive men are drawn to the images in pornography that reinforce and thereby increase the likelihood of their controlling, impersonal, and hostile orientation to sexuality. The way relatively aggressive men interpret and react to the same pornography may differ from that of nonaggressive men. (Malamuth et al. 2000, p. 85)

2.2 Cross-cultural Comparisons

One of the most glaring apparent contradictions in the literature on pornography results from research conducted in different cultures (as well as using different methodologies). In research conducted primarily in Denmark (Kutchinsky 1970, 1991) and in Japan (Diamond and Uchiyama 1999) there has not been evidence of increased criminal sexual acts as a function of the wider availability of pornography. In commenting on such findings, Malamuth and Donnerstein (1984, p. 141) suggested some time ago that '... there may be considerable variations among individuals within a culture in susceptibility to media influences. Similarly, cultural factors may create major individual differences in the role and impact of media stimuli on members of differing societies.'

A similar point was also aptly made by Giglio (1985, pp. 289–90):

The cultural environment in each country is a factor to consider in understanding the prevailing public attitudes towards pornography. The Danes appear to enjoy a more natural approach to sex in general. Public nudity, for example, is more acceptable in Denmark than in the United States ... In a society where it is possible on a warm summer

Sunday to visit the Rosenborg Palace in the heart of Copenhagen and see dozens of partially nude women in the surrounding gardens, usually accompanied by family or friends, without the slightest public disturbance, lends credibility to Kutchinsky's theory that the Danes lack the sustaining desire for pornography to make it a profitable domestic business.

In keeping with the position that aggressive-sexual predispositions may moderate the impact of exposure to certain types of pornography, it would be expected that within countries such as Denmark, fewer men than in the USA are at high risk for sexual aggression. If this is correct, then the lack of an association between pornography use and sexual aggression would map nicely on to the findings we have obtained. Although we do not have direct evidence bearing on this issue, there are some potentially relevant data. Zak and Knack (in press) compared the levels of trust that people had for each other in various countries throughout the world. They found strong differences, with countries such as Denmark being at the very highest levels of trust between people, and these levels were considerably higher than in the USA. To the extent that such general levels of trust may also be associated with trusting between men and women (an important component of the measures used to assess risk for sexual aggression), men may be at relatively low levels of risk for sexual aggression in a society such as Denmark. Therefore, when considering the possible impact of pornography on individuals within a cultural context, it may be essential to take into account the larger context within which such exposure is embedded.

3. Gender Differences in Pornography Consumption

What is clear is that across all of the cultures that have been studied, substantial differences exist in the type of sexually explicit media men and women are more likely to be attracted to (for a review, see Malamuth 1996, Oliver 2000). Many studies provide evidence that large gender differences exist in the consumption of and gratification derived from sexually explicit media. For example, in comparison to women, men consume more regularly, are more sexually aroused by, have more favorable attitudes to, and react with less negative affect to, portrayals featuring nudity of the opposite sex and/or sexual acts devoid of relationship context (e.g., Bryant and Brown 1989, Laumann et al. 1994, Mosher and Maclan 1994, Stauffer and Frost 1976). In contrast, men are less likely than women to consume sexually explicit media that emphasize 'sexual communion' (e.g., sex accompanied by emotional closeness) and romance (e.g., Faust 1980, Krentz 1992, Lawrence and Herold 1988, Perse 1994). Various other related gender differences found in pornography research are summarized by Malamuth (1996).

3.1 Adaptive Problems and Sexual Media

These differences can be discussed using the theoretical framework of evolutionary psychology, which predicts when gender differences are or are not expected, their direction, and why they occur (Buss 1999). Generally, males and females are expected to have the same psychological mechanisms in domains where natural selection has favored a universal human adaptive solution. However, different mechanisms are expected to exist in domains in which males and females have recurrently encountered different evolutionary problems and/or where the 'optimal solutions' differed for the genders. Evolutionary theory predicts that sexuality is one of these domains. Somewhat different mating strategies probably evolved for males and females due to differences in maximum reproductive capability and parental investment. The consumption of sexually explicit media might be the result of differing evolved psychological mechanisms interacting with environmental factors.

As Malamuth (1996) discusses in some detail, there appears to be a high correspondence between the adaptive problems that evolutionary psychologists have argued underlies a 'short-term' mating strategy and the recurrent content of sexually explicit media primarily consumed by men. According to evolutionary psychologists, males who engaged in ancestral environment in a short-term sexual strategy faced problems about how to get access to as many fertile females as possible while minimizing the commitment and investment to any one woman. Pornography marketed towards males primarily portrays casual sex with numerous, accessible women who display fertility cues through age and body shape. There is similarly a high level of correspondence between female-oriented sexual media (e.g., romance novels, portrayals of sex within a relationship context) and the adaptive problems that led females to evolve a long-term sexual strategy. These problems included identifying and securing commitment from a man who had the ability (e.g., high status) and willingness to invest heavily in her and her offspring. Additionally, due to the increased vulnerability associated with pregnancy and childbirth, females preferred to mate with men who could offer physical protection. Finally, women attempted to identify men who were kind and sensitive, responses that may be strong cues of parenting skills. Romance novels, one of the most popular forms of sexually explicit media for women, frequently portray a woman securing a relationship with a high status, physically protective male who also possesses parenting skills and the willingness to invest time and resources in a single female and her offspring.

In contrast, some researchers have argued that the gender differences described above can be explained exclusively as a product of the differing socialization of males' and females' cultural roles. While this process of socialization is probably relevant to these and many

other gender differences, such a model needs to consider why such norms and rules of socialization emerged in the first place as well as to account for a large number of other related gender differences in the area of sexuality (Buss and Schmitt 1993).

4. Concluding Comments

Pornography research has often been influenced by ideological/political perspectives with vested interests in particular conclusions. This may have led to framing of research questions and design of some studies in ways that encourages simple conclusions, while not readily accommodating more nuanced conclusions (Linz and Malamuth 1993). Nevertheless, research in this area has progressed considerably. In future work, it is essential not to use an 'either-or' lens in which research is cast simply into questions such as whether pornography exposure is generally harmful or not. As suggested in the research summarized here, depending on such factors as the cultural milieu, the individual's background, the particular content of the stimuli, the type of responses focused on, the content of exposure, the consumer's environmental circumstances, and the way 'harm' is defined, differing conclusions may result. Some may wish for a 'one handed' set of conclusions, but the research more accurately justifies a 'multihanded' perspective that reveals the richness and complexity of the issues related to the study of pornography.

N. M. Malamuth

Positivism, History of

Positivism is the name of a social and intellectual movement that tried to learn from the mistakes of the Enlightenment project that eventuated, first, in the Reign of Terror following the French Revolution of 1789, and second, in the irrationalism of the Weimar Republic following Germany's defeat in World War I. While it has been customary to distinguish between the quasipolitical movement called 'positivism' originated by Auguste Comte in the 1830s and the more strictly philosophical movement called 'logical positivism' associated with the Vienna Circle of the 1930s, both shared a common sensibility, namely, that the unchecked exercise of reason can have disastrous practical consequences. Thus, both held that reason needs 'foundations' to structure its subsequent development so as not to fall prey to a self-destructive scepticism. In this respect, positivism incorporates a heretofore absent empiricist dimension to the risk-averse orientation to the world historically associated with Platonism.

1. Positivism's Platonic Political Roots

In terms of Western intellectual history, positivism inflects Plato's original philosophical motivation through a secularized version of the Christian salvation story, in which Newton functions as the Christ figure. This captures both the spirit of Auguste Comte's original project and its residual effects in twentieth century logical positivism, which dropped the overt historicism of Comte's project, while retaining the fixation on Newton as the model for what it means to express oneself scientifically and a vague belief that greater scientific knowledge will deliver salvation. Indeed, positivism's core conceptual problem has been to define a scientific vanguard capable of both offering guidance to the unenlightened and itself

changing in light of further evidence and reflection. Its Platonic roots are worth recalling.

Plato was affected deeply by the volatile political environment created by the public dialectical encounters of Socrates and the other Sophists who mentored the leaders of his Athenian youth. Thus, after the fall of Athens, Plato was keen to restrict the dialectic to a cloistered setting, only to be unleashed to the larger society once initiates were sufficiently secure in their own knowledge and judgement that they would not be unduly swayed by popular demands. Where Plato had hoped to produce implacable philosopher-kings who would rule as absolute monarchs, positivists typically have envisaged a more differentiated but no less authoritative (authoritarian?) rule by experts, each an oligarch over their domain of knowledge. In this respect, positivism is bureaucracy's philosophical fellow traveler.

Not surprisingly, positivism's relationship to democracy has been chequered. Like Plato, positivists have feared protracted public disagreement most of all and hence have tended to demonize it as 'irrational' and 'noncognitive.' Their image of 'plural' authority presumes nonoverlapping competences, such that legislative questions are reduced to judicial ones concerning the expertise to which one should defer. This is in sharp contrast to most republican conceptions of democracy, which base representation on interest groups, each invested with a competence appropriate to the promotion of its interests but typically about matters in which other interest groups might also have competence. Since matters of public policy typically affect several such groups at once, collective decisions do not turn on identifying the right group whose judgement should hold sway. Rather, it is expected that public debate will issue in a solution that transcends all the groups' starting points but nevertheless manages to serve their respective interests.

Thus, there is a fundamental ambiguity in positivism's appeal to organized reason, or 'science,' in the public sphere. Sometimes this ambiguity is finessed by saying that positivists regard science as the main source of political unity. At the very least, this implies that it is in the interest of all members of society to pursue their ends by scientific means, as that may enable them to economize on effort and hence allow more time for the fruits of their labour to be enjoyed. Ernst Mach (discussed in Sect. 3) comes closest to defending this position in its pure form. It fits comfortably with the libertarian idea that democratic regimes should enable maximum self-empowerment.

However, many positivists have drawn a further conclusion that can thwart this libertarian impulse. From Comte onward, it has been common to argue that science can unify the polity by resolving, containing, or circumventing social conflict. Here a well-established procedure or a decisive set of facts is supposed to replace more 'primitive' and volatile forms of conflict resolution such as warfare and

sometimes even open debate—all of which supposedly compromise the integrity of opposing viewpoints in the spirit of expedience. Accordingly, a scientific politics should not merely satisfy the parties concerned: it should arrive at the 'correct' solution.

To be sure, even this mentality admits of a democratic interpretation, as positivist social researchers have been in the forefront of presenting 'data' from parties whose voices are unlikely to be heard in an open assembly. Typically, this has occurred in surveys designed to represent the full empirical range of a target population. Nevertheless, the question remains of exactly who reaps the political benefits of these newly articulated voices: the people under investigation, the investigators themselves, or the investigators' clients? Moreover, once a target population has been registered empirically, do its members remain 'objects of inquiry' or are they promoted to full-fledged inquirers capable of challenging the original investigators' findings and methods? Probably the most sophisticated treatment of these questions in the context of positivistically inspired US social policy research is to be found in Campbell (1988).

These delicate questions arise because ultimately positivism turns Plato on his side by converting a static hierarchy into a temporal order. Where Plato imagined that authority flowed downward from the philosopher-king in a caste-based social structure, positivists have envisaged that all of humanity may pass (at a variable rate) through a sequence of stages that retrace the socioepistemic journey from captivity to autonomy. In the positivist utopia, it is possible for everyone to be an expert over their own domain. Moreover, there is a recipe for the conversion of Platonism to positivism. It proceeds by isolating a domain of inquiry from the contingencies surrounding its manifestations so that its essential nature may be fathomed. Whereas Plato reserved such inquiry to philosopher-kings, positivists have more often turned to state-licensed professional bodies. And instead of Plato's intellectual intuition (*nous*), positivists attempt to gain epistemic access by comparative historical and experimental methods.

This recipe can be illustrated in the work of Otto Neurath, an organizer of the Vienna Circle. He wanted to isolate the essence of the 'war economy' so that its efficient central planning mechanism can be transferred to environments where it would have more socially salutary consequences. Here Neurath anticipated what Alvin Gouldner would call the Janus-faced character of the 'welfare-warfare state,' whereby the same organizational structure (in this case, a concentration of resources in the nation-state) can have radically different consequences, depending on the supporting political environment. Nevertheless, as Neurath's many critics pointed out, positivism seems to have inherited Platonism's political naivete, which confuses the fact that, say, the 'war economy' can be identified analytically as a feature of many societies

and the analyst's ability to transfer it to new social environments—bar ring the imposition of sufficient force to hold all other environmental factors constant. If anything deserves the name of the 'positivist fallacy' it is this too easy assimilation of the forum to the laboratory. The history of positivism can be neatly captured as a Hegelian dialectic, the three moments of which are epitomized by the work of Auguste Comte (thesis), Ernst Mach (antithesis), and the Vienna Circle (synthesis). However, these moments have historically overlapped, occasionally coming together in figures such as Neurath. The career trajectories of positivism's standard bearers help explain the direction taken by their thought.

Comte was an early graduate of the *Ecole Polytechnique* who believed that its Napoleonic mission of rendering research a vehicle for societal transformation had been betrayed, once he himself failed to achieve a permanent academic post. Mach was a politically active physicist on the losing side of so many of the leading scientific debates of his day that his famous chair in Vienna, from which the logical positivists sprang, was awarded on the strength of his critical-historical studies, not his experimental work. Finally, the intellectual leader of the Vienna Circle, Rudolf Carnap, had to abandon physics for philosophy because his doctoral dissertation topic was seen as too 'metatheoretical' for a properly empirical discipline. For Carnap and others who came of age in World War I, physics had devolved into another specialized field of study, rather than—as it had still been for Einstein—natural philosophy pursued by more exact means.

2. Thesis: Comtean Positivism

Auguste Comte coined the word 'positivism' to refer to the positive side of the Enlightenment's essentially destructive approach to traditional social and intellectual orders. Comte agreed with the Enlightenment wits that scientific rationality is the model of social rationality, the exemplar of which is Newtonian mechanics. However, according to Comte, the French Revolution had refuted the wits' belief that people's 'natural reason' would come to light once they were freed from their captivity to religion and other traditional forms of authority. Comte thus designed positivism to replace both the church and the sovereign with scientific experts who together would function as a secular priesthood for modern society. 'Sociology,' another of Comte's coinages, referred at once to this political vision and the scientific project that would render it a legitimate form of authority.

Positivism in this basic sense has remained the philosophy underwriting science as a specialized profession of 'scientists' with an identifiable order of merit and career structure. Ironically, none of the movement's first phase protagonists—including Comte

himself, John Stuart Mill, and Herbert Spencer—ever called a university home. Nevertheless, they all earned their living from producing knowledge (some would call it 'ideology'), unlike those for whom the pursuit of knowledge was a refined way of consuming wealth. In this important respect, positivism was aligned with the ascendant bourgeoisie and hostile to such aristocratic forms of learning as the gentleman-scientist and the academic humanist. Comte arrived at this position from his mentorship under Count Henri de Saint-Simon, a spiritual godfather of today's management gurus, who at the dawn of the industrial age anticipated that organized knowledge would be the principal factor of economic production and political control in what Daniel Bell would call, 150 years later, 'post-industrial society.'

Given its explicitly anticlerical posture, positivism was more often found in medical schools and polytechnic institutes than traditional universities. (French universities did not become fully secular institutions until the Third Republic in 1870.) The medical interest is noteworthy because, in the nineteenth century, positivism was used to legitimize everything from phrenological and psychosomatic research to the experimental approach to medicine championed by Claude Bernard. What they all shared was the recognition that physical constitution plays a significant role in defining psychic, or spiritual, life. This basic assumption was sufficient to challenge religion's ministerial monopoly.

More generally, positivism's anticlericalism has been among its most powerful export values, especially in Latin America (where Comte's motto 'Order and Progress' remains emblazoned on the Brazilian flag). Without a thoroughgoing Protestant Reformation, Latin Americans found Comte's secularized version of Catholicism much less utopian than did their European counterparts. To be sure, background cultural allegiances divided positivist loyalties, with Francophile Latin Americans (e.g., Brazil) preferring Comte and Anglophile ones (e.g., Argentina) Spencer. In either case, though, positivism was equally likely to justify authoritarian and democratic regimes. Perhaps the most lasting intellectual residue of positivism's Comtean origins has been the default association that social scientists make between reliable knowledge and statistically significant empirical correlations. Hempel (1942), the canonical positivist account of historical explanation, placed the Vienna Circle's distinctive stamp on this point. Nowadays, its import is easily lost in methodological discussions that trivialize correlations as deficient accounts of causation, proof that positivism owes too much to Francis Bacon. However, following Karl Pearson, perhaps the first self-declared positivist to hold a professorship in Britain, the appeal to correlations served at least four distinct functions.

First, correlations enabled an economy of thought by summarizing observations already made. This would decrease the likelihood of 're-inventing the

wheel,' thereby expediting overall human progress. Second, correlations forced investigators to look beyond the singular striking success to more generalizable, albeit mundane, tendencies. Here the positivism helped moderate the hype surrounding new inventions and discoveries. Third, the focus on correlations implied that scientific work could be mechanized by treating individual experiences as instances of more general types. This helped dispel the idea that scientists must have a special 'genius' for finding hidden causes beneath the welter of data. Fourth and probably most significant in Pearson's own turn-of-the-century context, the appeal to correlations echoed the 'uniformitarian' approach to natural history championed by Darwin, whose theory of evolution presupposed that all biological change has occurred by principles that remain in effect today. Thus, there was no need for either a divine creator behind the scenes whose actions transcend observed correlations or a mystification of statistically extraordinary events as 'miracles.'

3. *Antithesis: Machian Positivism*

Ernst Mach symbolized the second moment of positivism's dialectic: he gave the movement a dose of its own medicine, namely, a scientific sense of science's own limitations. Mach's counsel emerged in the midst of the ironic, perhaps perversely self-defeating, character of *fin de siècle* Viennese culture, whereby Karl Kraus's quip that psychoanalysis is the disease for which its cure was eventually incorporated into positivistic lore as Ludwig Wittgenstein's dark saying that philosophy is the ladder that must be climbed in order to be discarded (Janik and Toulmin 1973).

In the long term, this sense of scientific self-restraint has made its strongest impression in the dual doctrines of 'value neutrality' and 'academic freedom,' which are most closely associated in the social sciences with Max Weber. Although these doctrines normally are treated as separate, it is difficult to motivate either without examining their historical interconnection. The missing link is the idea that, absent further empirical demonstration, the value of theoretical discourse—the most obvious epistemic marker distinguishing experts from the lay public—is purely heuristic. Theory enables those who already know something to know much more; however, it obscures the vision of those who have yet to know anything.

Thus, the various Mach-inspired positivist projects of 'reducing' theoretical discourse to its empirical bases have been motivated by a keen sense of the contingency of when and where new scientific insights arise. The distinction that Hans Reichenbach and Karl Popper drew between the contexts of discovery and justification canonized this point for contemporary philosophy of science. The unique means by which a discovery is made is neither necessary nor sufficient for demonstrating its validity. Elementary logic textbooks

demonize the failure to abide by this point as the 'genetic fallacy.' For Mach, the contingent nature of discovery places a special burden on scientists to render their insights as widely as possible, without denying themselves the right to follow it up in their own way. The Vienna Circle positivists may be seen as having compromised this legacy by limiting the context of justification to the received canons of inductive and deductive reasoning. But perhaps they had good reason.

Mach may have been too keen to let the lay public draw whatever conclusions they wished from their studies of science. The second moment of positivism enabled the conversion of scientific knowledge into a pure instrument detached from any prior theoretical or normative commitment. In practice, this 'neutral' stance made science available to the highest bidder, who in turn could hold a monopoly over its use (or nonuse). Consider the fate of the law of diminishing marginal utility (LDMU), which states that if there is enough of a good to satisfy a basic level of need, then each additional increment of the good satisfies the need less than the previous increment. LDMU first appeared in John Stuart Mill's normative political economy, the source of modern welfare economics. The German translation of Mill's *System of Logic* in 1849 had introduced the first phase of positivism to Mach and such contemporaries as Wilhelm Wundt and Wilhelm Dilthey, initiating the long-standing debates over the reducibility of the methods of the *Geisteswissenschaften* (Dilthey's rendering of Mill's 'moral sciences') to those of the *Naturwissenschaften*. While Mill's later work, *On Liberty*, would inspire Mach's own views linking academic freedom to the right of dissent, Mach refused to follow Mill in drawing normative conclusions from putatively scientific facts, even though Mill's aim of removing the accumulated advantage of the rich was close to Mach's own heart.

Mill treated LDMU as a scientific basis for redistributionist social policies. He inferred that each additional increment of income earned by the rich would improve their lives less than the same increment transferred to the poor. Mill presumed a common standard of interpersonal utility and the idea that different interpersonal endowments could be explained as reversible historical accidents. Moreover, he modeled LDMU on a certain interpretation of Newton's laws, which holds them to be true in an ideal physical medium but not in actual physical reality. Thus, Mill made the ideality of the scientific laboratory stand for the normative basis of social reform. What is now called the 'marginalist revolution' in economics reinterpreted the Newtonian precedent for LDMU in the value-neutral terms that captured the social situation of Mach and other second generation positivists who called a university home.

In the 1870s, Mill's academic nemesis, William Stanley Jevons, had begun interpreting LDMU as the

emergent product of interactions between agents whose respective utilities are in principle incalculable, that is, an empirically stable resolution of unknowable constitutive forces. Today we would say that LDMU is a macrolevel market effect, in which the parameters of the relevant market are left unspecified. Thus, cases that fail to conform to LDMU do not force a difficult normative judgement about whether the law or the case is at fault; rather, one casts around for an appropriately defined market to which LDMU might apply, since one may not have considered all the effects over a large enough scale, over a long enough period.

Second generation positivists came to regard LDMU as holding no clear implications for social policy. This opened the door to the curious twentieth century 'noninterventionist' policies that Milton Friedman and others have used to oppose scientific justifications of the welfare state. Here positivism's antitheoretical and antinormative stance is explicitly identified with the inductively self-organizing order of the so-called invisible hand. The shift from Jevons to Friedman is indicative of what logicians call the 'modal fallacy': The denial that X implies Y is interpreted to mean that X implies not Y , where X = LDMU; Y = State-managed redistribution of income. Thus, an economic principle that was seen originally as not necessarily licensing a particular policy intervention came to be seen as an outcome that obviates the need for any policy intervention whatsoever.

Nevertheless, the transition between the first two moments of positivism was neither smooth nor clearly separated from the third. Free market liberals continued to invoke Comte's original sense of positivism to stigmatize large-scale, usually Marx-inspired, social planning of the economy (e.g., Hayek 1952). A target of these studies was Vienna Circle organizer, Otto Neurath, who supposed that a specialist understanding of the persistent underlying structures of political economy provides a better handle on social policy than the spontaneously aggregated experiences of individual producers and consumers. While Neurath's Marxist orientation to social planning was close to Comte's privileging of expert over lay judgement, he also accepted the Machian view that useful knowledge should be spread as widely as possible. In that sense, Neurath's interest in designing an ideographic language ('Isotype') to enable the populace to understand capitalism's inequities was born of the same impulse as his debates with Rudolf Carnap over the construction of the 'protocol statements' that constitute the fundamental language of science. Here the second moment of positivism naturally shades into the third.

4. *Synthesis: The Vienna Circle*

The Vienna Circle was started by Moritz Schlick, another physics-trained philosopher who succeeded Mach to the chair of the history of inductive sciences

at the University of Vienna. Much has been made of the Vienna Circle's preoccupations with the conceptual and empirical foundations of science, the demarcation of science from nonscience, and the unification of the special sciences under a single metaphysical and/or methodological rubric. Less has been said to explain the Circle's partial return to positivism's communitarian and authoritarian origins, especially after Mach had made positivism virtually synonymous with the liberalization of epistemic authority. Nevertheless, there were few true liberals in the Vienna Circle: Schlick and Wittgenstein were conservatives, Carnap and Neurath socialists. Popper, the Circle associate closest to Mach's own politics, was not easily accepted into the fold.

This antiliberal turn can be explained by changes in science's social relations in the German-speaking world over the first quarter of the twentieth century. Seen against this background alone, the Vienna Circle appears utopian and even prone to nostalgia; but with Nazism's ascendancy in the 1930s, the 'logical positivist' movement quickly acquired a defiant and progressive cast. At first, the Circle recoiled from Machian positivism because of the ease with which Mach's neutral instrumentalism allowed scientists, especially chemists, to harness their knowledge for aggressive military-industrial ends. Consequently, Germany's humiliating defeat in World War I paved the way for the antiscientific backlash of Weimar culture that formed the backdrop to the Circle's meetings. In recognizably Platonic fashion, the Circle forged a philosophy that protected science from this backlash, while divesting it of any potentially corrupting links to technology. The key was the idea that a genuine science must satisfy certain logical and empirical criteria relating to the public testability of knowledge claims. The model for this requirement was ongoing debates over the foundations of mathematics, which Carnap and Reichenbach had already transferred to debates over the presuppositions of relativity and quantum theory.

However, one decidedly anti-Platonic insight that the Vienna Circle retained from Mach, which increased in importance over the years, was that esoteric forms of knowledge must be 'reducible' to their core 'cognitive' components so as to facilitate both their evaluation and utilization. Specifically, the Vienna Circle aimed to demystify 'metaphysical' jargon that encoded prejudice without extending insight. (Carnap famously cited Heidegger in this respect.) At the peak of its popularity in the 1940s, logical positivism was linked with such American best sellers of the 'general semantics movement' as Hayakawa (1978). Here the foe had shifted from Heidegger to Hitler, with the positivists arguing against the irrationalism of mass propaganda. Perhaps the most famous single work of the positivist movement, Ayer (1936), written by the British observer at the Vienna Circle, can be seen as a transitional work between these two phases.

Given this history, logical positivism appears in a rather ironic light in the highly publicized *Positivismusstreit* that transpired in 1961–8 between Karl Popper and Frankfurt School doyen, Theodor Adorno. It turns out that both Popper and Adorno demonized ‘positivism’ in social science for the exact same ills as the logical positivists had demonized Heidegger and Hitler a quarter-century earlier, namely, a ‘jargon of authenticity’ and its contribution to an ‘authoritarian personality’ (two relevant Adornian phrases). Moreover, the two antagonists presupposed the logical positivists’ ideal of unified inquiry and the inadequacy of defining society as simply the totality of ‘social facts.’ Where Popper and Adorno clearly differed from the positivists was over the latter’s promotion of a sharp fact-value distinction, whereby the presumed unity of factual knowledge offsets the irreducible plurality of value orientations. Here positivism courted a ‘relativism’ that both antagonists strongly opposed. Nevertheless, the ascendancy of relativism, in the guise of ‘postmodernism,’ would render Popper and Adorno’s wranglings over ‘critical reason’ beside the point by the 1980s.

In detecting positivism’s latent relativism, Popper and Adorno not only anticipated the future; they also recalled the ‘value neutrality’ that had originally turned Machian positivism into a vehicle of power politics. In the social sciences, Max Weber’s distinction between charisma and bureaucracy as modes of legitimation enabled both politicians and scientists to turn a blind eye to each other’s activities, as the two groups were supposedly driven by radically different normative orientations: the politician acts, while the scientist provides reasons. Similar criticisms have been made of other movements in the social sciences affiliated with positivism, most notably Hans Kelsen’s legal positivism and B. F. Skinner’s radical behaviorism. Yet, even Neurath was happy to call his project ‘neutral Marxism.’

These cases are united by a refusal to blur the boundary between science and politics, which in practice has meant a rejection of social democratic, welfare-state policies in favor of more extreme political stances: either complete withdrawal or outright authoritarianism. Once again, positivism would seem to have fallen victim to the modal fallacy: because politics and science can contaminate each other, therefore they inevitably will, and hence each must be left to its own devices.

5. Final Assessment: Does Positivism Have a Future?

After the leading members of the Vienna Circle migrated to the US in the 1930s, logical positivism seeded that country’s analytic philosophy establishment for the second half of the twentieth century. However, this is the only context in which positivism

possibly dominated an established discipline. For the most part, positivism has been embraced by disciplines that have yet to achieve academic respectability, even in the natural sciences, where Mach found his strongest support among chemists, biomedical scientists, and psychologists—not physicists. (It is often overlooked that positivism’s reliance on Newtonian mechanics as the model for all science generally was not appreciated by a physics community jealous to guard its guild privileges.) Unsurprisingly, positivism’s most ardent supporters have been social scientists, not for the Comtean reason that sociology is the pinnacle of all science but for the more mundane reason that positivism seemed to offer a strategy for rendering one’s activities ‘scientific.’

These matters came to a head with the publication of Kuhn (1970), which Carnap enthusiastically endorsed as the final instalment of the logical positivists’ *International Encyclopedia of Unified Science*. It provided an account of scientific change based largely on the history of physics that was quickly embraced by social scientists, as Kuhn stressed science’s self-organization over its larger societal impact. However, unlike previous positivist accounts, Kuhn’s explicitly fixated on particular scientific disciplines (or ‘paradigms’) without presuming that science as a whole is heading toward a unified understanding of reality. By implication, then, all scientific standards are discipline-relative. Kuhn’s approach suited what is now called the ‘postmodern condition,’ which the *Positivismusstreit* had desperately tried to stave off.

In retrospect, the popularity of Kuhn (1970) is better understood as signifying positivism’s decadent phase than, as it was originally seen, a fundamental challenge to positivism. The decadent state of contemporary positivism can be gleaned from the ongoing debates over the scientific status of ‘sociobiology.’ Each side of the debate captures part of the positivist legacy: proponents like E. O. Wilson hark back to positivism’s Comtean vision of unified knowledge in aid of societal transformation, while opponents like Richard Lewontin draw on positivism’s more recent restriction of the bounds of science to discipline-specific criteria.

If positivism has a future, it lies in rekindling a sense of ‘Science’ that transcends the boundaries of particular scientific disciplines. This is how Comte originally thought about the discipline he called ‘sociology.’ He claimed that it was the last to develop, not simply because of the complexity of its human subject matter, but more importantly, sociology had to reconstitute the (natural) sciences that historically preceded it. Too often the history of positivism’s quest for unified science has been interpreted as exclusively a matter of applying the methods of physics to less developed sciences. The reciprocal movement is really more important, namely, the application of sociological findings to the future direction of science as a whole. Such interdisciplinary projects as ‘social epis-

temology' and the 'science of science' have tried to fulfill this side of the Comtean promise, which may be redeemed once the present intellectual climate changes.

Positivism: Sociological

Positivism arose in the social sciences in an effort to legitimate sociology as a scientific discipline. In essence, positivism asserts that the social sciences, and sociology in particular, are natural sciences in

which abstract laws of human organization can be formulated to explain the operative dynamics of the social universe. The plausibility of these laws are then to be assessed against systematically collected empirical data.

1. The Rise of Positivism

Advocacy for a positivistic social science began with Auguste Comte's (1830–42) *Course of Positive Philosophy*. Comte was, no doubt, influenced by Montesquieu's ([1748] 1900) *The Spirit of Laws*, where the notion of formulating laws about the operation of human society was first suggested, and by both Turgot and Condorcet, from whom Comte received, via his mentor, Saint-Simon, the notion of the three stages in the evolution of idea systems. For Comte, the various sciences developed at different rates, with sociology (and by implication the other social sciences as well) emerging last. As each science develops it goes through three stages—theological, metaphysical, and eventually, positivistic. By the early 1800s, the idea that sociology and other social sciences could take their place at the table of science was widespread, but it was Comte who forged the various lines of argument into a forceful advocacy for a science of society. Comte's preferred name for sociology was *social physics*, and this name demonstrates his desire to develop a sociology organized around basic laws of the social universe.

In *Course of Positive Philosophy*, Comte posits a view of sociology as a theory-driven enterprise. As a descendant of the French Enlightenment, and as one who admired greatly what Newton had done for astrophysics, Comte argued for a sociology in which abstract laws of human organization would explain the dynamics of the social universe. His exemplar was Newton's law of gravity, and yet he never developed any such law—although he saw the 'law of the three stages' as something like Newton's law of gravity. Still, from the opening pages of *Positive Philosophy*, a clear message is sent: 'The first characteristic of Positive Philosophy is that it regards all phenomena as subject to invariable natural Laws' (1830, pp. 5–6, emphasis in original). In this same passage, Comte argues against a search for 'Causes, whether first or final'; rather the goal of positivism is the 'discovery of laws, with a view to reducing them to the smallest possible number.' In later portions of *Positive Philosophy*, Comte (1830–42) buttressed this emphasis on abstract laws by criticizing raw empiricism, for 'the next great hindrance to the use of observation is the empiricism which is introduced by those who, in the name of impartiality, would interdict the use of any theory whatsoever.' Comte concludes this passage with an even stronger statement: 'No real observation of any kind of phenomena is possible, except in as far

as it is first directed, and finally, interpreted, by some theory.'

Thus, in Comte's view, all observation is mediated through a theory, and the goal of positivism is to make the theories explicit and formal, while employing systematic methods to gather data on the plausibility of a theory. He advocated four basic methods: observation, experimentation, comparison, and historical analysis in order to collect the broadest array of data possible to assess the validity of laws that are presumed to explain the operation of the social universe in all times and places.

By 1830, then, Comte had laid out in bold and incisive fashion the basic tenets of positivism. As Comte's mental instability caused his star to fade, positivism was carried forward by Herbert Spencer in England and Emile Durkheim in France. The titles of almost all of Spencer's important works indicate the positivistic slant of his work in both the natural and social sciences: *First Principles*, and *The Principles of* (sequentially) *Psychology*, *Biology*, and *Sociology*. But nowhere was Spencer's advocacy more powerful than in his first published sociological work, *The Study of Sociology* (1873), where he not only reaffirms his commitment to seeing the universe as guided by forces whose dynamics can be captured by abstract principles, but also articulates in a systematic manner the sources of bias that can distort the formulation of these principles and their systematic assessment by data. Twenty-two years later, Emile Durkheim ([1895] 1938) made a similar plea in his *The Rules of Sociological Method* for a sociology based upon laws about 'social facts.' Both Spencer and Durkheim personified how positivistic sociology could be conducted, mixing sophisticated functional theory with presentations of data. Indeed, from Comte's early analogies to organisms, positivism was associated initially with functional sociology, a theoretical point of view that was to flower in the middle of the twentieth century, and then to die on the vine in the latter part of the century. And as functionalism faded, so did positivism as a coherent point of advocacy. Yet, much of the fate of positivism in the twentieth century is associated with intellectual ferment in Europe around what was to become known as the Vienna Circle.

2. The Vienna Circle and the Transformation of Positivism

During the first half of the twentieth century, a group of intellectuals located mostly in and around Vienna debated issues of thought and reasoning as well as connections between the empirical world and modes of representing this world (Johnson 1983). Two outside and somewhat marginal figures of the Vienna Circle—Ernst Mach (1893) and Karl Popper (1959, 1969)—are critical to the debate that raged within the

Circle for the first half of the twentieth century. Mach had proposed a radical empiricism in which all conceptions of the universe as guided by natural laws were rejected in favor of mathematical descriptions of relations among empirically observable variables. This extreme position called for a radical empiricism, emphasizing that formal thought must always be tied to, and inducted from, observable empirical facts. At the other pole were those concerned with the structure and logic of formal thinking to either the exclusion or subordination of empirical observations to rules of logic. Karl Popper's famous solution to this impasse was to emphasize that theories can never be proven by empirical facts, only disproven. The goal of science is, therefore, to assess the empirical plausibility of hypotheses deduced formally from abstract principles by repeated assaults from empirical observations. For many decades, this argument became the new standard way to assert the viability of positivism; and it led to the notion of 'logical positivism' in which emphasis is on the logic of deduction from abstract principles to testable hypotheses. Comte had never conceptualized how one makes abstract laws available for empirical assessment, and so this point of emphasis was perhaps required in a more complete formulation of positivistic science.

3. Vienna Circle Debates and US Sociology

The Vienna Circle had much more influence on US social science than on disciplines in Europe where scholars were, in general, more philosophically sophisticated than their US counterparts. But much more was involved; US social science adopted Popper's argument because these Vienna-inspired arguments were compatible with the new social science emerging in the USA.

If we look at US sociology of the 1920s and 1930s, there was a vacuum of theory. Spencer's star had faded, and other figures in sociology's European pantheon—Weber, Durkheim, Simmel, and Pareto—remained largely untranslated and, hence, unknown to many US sociologists. And yet, US sociology had been very much committed to Comte's view of science, and many early texts refer to 'principles' of various subjects in a manner reminiscent of Spencer. At the same time, quantitative statistical methods were being adopted by US sociologists under the influence of Franklin Giddings (1901), and later his students and followers. Sociologists were thus very much interested in finding a legitimating mantra for statistical analysis of data that could make claims to being scientific (Turner and Turner 1990). One mantra was quantification, *per se*, but many early sociologists had a more Comtean–Spencerian view of science as a search for laws. Popper's solution provided the reconciliation of the debate within not

only the Vienna Circle but also within conflicting camps of US sociology as well: theories were to be tested against quantitatively arrayed data using new statistical techniques borrowed from the European agronomist, Karl Pearson. Through much of the mid-century, the theory part of this reconciliation took a back seat to quantification. And, not surprisingly, it is from this period that the misperception of positivism as 'raw empiricism' becomes prominent, despite the fact that this label is wholly inappropriate to positivist epistemology.

The radical empiricism of the Vienna Circle found a comfortable home in American quantitative research in the last quarter of the century, and for a brief time, the logical part of positivism was trumpeted through the effort to 'build' and 'construct' theories. A host of books on 'theory building' and 'theory construction' emerged in the late 1960s, beginning with Hans Zetterberg's (1965) *On Theory and Verification in Sociology*, and continuing through the 1960s and 1970s (e.g., Blalock 1969, Dubin 1969, Gibbs 1972, Hage 1972, Reynolds 1971). These books attracted great interest in an effort to overcome the radical empiricism of quantitative research, since they tried to reconnect methods and theory along the lines suggested by Popper. The problem was that these books had a cookbook and mechanical character, in essence trying to do for theorizing what standardized quantitative protocols had done for quantitative methods. As a result, they soon fell into disuse—at about the same time that functionalism, which had been allied with positivism since its origins, was also going out of style. The result was that as functionalism faded and as the rather mechanical and restrictive character of theory construction books was exposed, positivism as Comte had conceived of it also declined. Indeed, the very term 'positivism' is now seen as anachronistic or as an epithet for raw empiricism.

4. The Critics of Positivism

Beyond inviting the label of 'raw empiricist,' proclaiming oneself a positivist in the contemporary era is to invite an additional series of attacks on scientific sociology in general and, more specifically, on the prospects for formulating universal laws on the dynamics of the social universe. Some of the most common lines of criticism are enumerated below (Turner 1992).

4.1 The Phenomenological Critique

The world 'out there' can only be known through human consciousness, and so the nature of reality is ultimately filtered through the human mind. Hence, laws of human organization cannot be formulated without a prior understanding of the dynamics of the human mind.

4.2 Hermeneutics

The fundamental nature of the social world can be changed by human agency. Hence, since the nature of social organization is subject to change in its most fundamental character, universal laws about generic processes are, at best, time bound and, at worst, the illusions of social theorists. Moreover, even if a law of social organization is articulated, it soon becomes a tool for changing the fundamental processes described by the law, thereby obviating the validity of the law.

4.3 Critical Discourse

Any set of laws describing the social universe operates as a legitimating umbrella for current social arrangements, many of which are oppressive. Thus, science legitimates the status quo and closes off discourse on less oppressive alternatives.

4.4 Historical Particularism

Social reality is historically specific, reflecting particular confluences of events at a particular moment in time. Hence, any effort to generalize beyond a given historical epoch is doomed to failure, since history constantly remakes the very nature of social reality. The most recent version of this kind of argument can be found in postmodernism, where it is postulated that a fundamentally new reality has emerged, obviating the laws of modernist social organization.

4.5 Scientific Politics

Since science is an organized activity, the knowledge produced by scientists reflects organizational, professional, and political processes as much as reality 'out there.' Thomas Kuhn's (1970) famous work reinvigorated what had previously been known as 'the sociology of knowledge'—an approach revolving around analyses of the social context of knowledge production. Scientific knowledge is, therefore, distorted by the very social processes that organize scientists.

5. The Defense of Positivism

The five lines of criticism listed above make interesting points, and then take them to the extreme. But they represent an *ad hoc* coalition of positions that oppose positivism, seeing positivism as a 'failed epistemology' in the social sciences. Others (e.g., Turner 1985) have sought to defend positivism, addressing the specifics of these points of critique, while trying to re-establish the search of universal and abstract laws about generic social process.

The phenomenological and scientific politics critiques are undone by the fact that the same problems exist for the physical and biological sciences; and yet scientists in these areas still manage to generate verifiable knowledge. The hermeneutical critique poses a unique challenge to scientific positivism in the social sciences, but it is merely assumed by those making this critique that the universe is constantly changing its fundamental character. To make their point stick, critics have to demonstrate that the fundamental forces governing the social world have changed; to assert this to be the case without demonstration with data makes the critique less convincing. The historical particularism critique encounters similar problems, for while it is true that specific events and processes are the product of a particular configuration of events, the underlying dynamics of specific historical conditions may still be generic processes of the social universe. Every specific event is the product of a causally unique historical chain of causes—such is the case in both social and physical universes—but this fact does not mean that the forces that move this chain of causes along are unique historically. Indeed, positivists would argue that these forces are universal, operating in all times and places.

The critical discourse critique is perhaps the most important because, to the extent that generalizations from current empirical reality are viewed as ‘laws’ of how things are, these statements summarizing current empirical reality will assert implicitly that the status quo is the way things *must* be. But the critical theorists run into the opposite problem of postulating ideal states that must be pursued, even if they violate basic laws of human organization and, as a consequence, positively harm people. If ideology were informed by scientific laws, then it is the theory more than the ideology that is useful in reconstructing the social universe in humane ways.

6. The Prospects of Positivism

Positivism will perhaps never be accepted uncritically in sociology, and perhaps not in anthropology and even some branches of psychology and political science. In other social sciences, especially economics, the basic arguments of positivists are not even subject to debate. Positivism was a unique advocacy created by Comte to legitimate the scientific study of human organization by a discipline reluctantly labeled ‘sociology,’ but his advocacy was never accepted by all in the nineteenth or twentieth centuries, and it is unlikely to be accepted in the twenty-first century. Indeed, the term positivism might be best phased out, since it appears to raise such a bright red flag to an *ad hoc* coalition of positions critical of the scientific pretensions of some social sciences. In a sense, theoretical

and empirical work dedicated to discovering and assessing general laws has been relegated to the status of yet another specialty in some social sciences, although one still can find positivistic elements within virtually all specialties of social science. Thus, there is some hope that science will persist in those disciplines, particularly sociology and anthropology, where doubts about science are greatest, but positivism in any guise will never be the only epistemology within sociology and anthropology.

Possession (Linguistic)

In linguistics, possession is conceived as a relationship of appurtenance between a possessor (P'or) and a possessed (P'ed, possessum, possessee) for which there are specific paradigms of expression in languages of the world. On the conceptual side, this relationship of appurtenance ranges from material possession via kinship and body-part relationships to the domain of abstract relations (someone's ideas, someone's activities, etc.). On the formal side, one distinguishes mainly between attributive possession (e.g., 'my house,' 'the man's house') and predicative possession ('the house is mine,' 'the house belongs to me,' 'I have a house'). However, it is not always easy to distinguish the conceptual domain of possession from other cognitive domains, and also on the formal side there is a continuum of expression rather than some strictly defined set of constructions. For instance, in many languages (e.g., in English or Icelandic) constructions like 'I have ploughed an acre' (expressing an event in time) historically go back to possessive expressions whose literal meaning was 'I have an acre as something ploughed,' and there are also numerous ways of crossing the boundary between attributive and predicative sentential constructions. For instance, many languages many alternate between attributive constructions like German *der Sohn des Mannes* (ART:NOM son:NOM ART:GEN man:GEN, 'the man's son'; where ART = article, GEN = genitive, NOM = nominative) and *dem Mann sein Sohn* (ART:DAT man:DAT his:NOM son:NOM, lit. '(to) the main his son'), where the dative (DAT) was originally some indirect object in predications like *sie entführten dem Mann seinen Sohn* (they:NOM kidnapped ART:DAT man:DAT his:ACC son:ACC, lit. 'they kidnapped (to) the man his son'; where ACC = accusative). These latter constructions (which are typically associated with some psychological involvement on the part of the P'or) are known as *dativus sympathicus*-constructions, or are referred to in the context of possessor raising or external possession. Since psychological involvement also correlates with the relative 'closeness' and inalienability of the possessive relation, it is customary to distinguish between inalienable and alienable possession. Alienable possession normally refers to material belongings as opposed to kinship and body-part relationships, and there are many languages which have standardized ways of distinguishing these domains. In addition to expressing a concept which is not just relevant for linguistics, possessive categories also have

specific functions in the discourse, which suggests that to a certain extent linguistic possession must be differentiated from non-linguistic concepts of possession.

1. Approaches to Possession

1.1 The Literature on Possession

The linguistic literature on possession concentrates on different aspects. Seiler's monograph (Seiler 1983) is still the most comprehensive attempt at dealing with the cross-linguistic evidence for the continuum of constructions in the domain of possession (see Sect. 1.2 below). Heine (1997) focuses mainly on predicative possession and on typical ways in which such constructions develop in the process of grammaticalization. Attributive possession is usually extensively described in traditional grammars under the headings of possessive pronouns and genitival constructions. McGregor and Chappell (1996) is a standard reference to the typology of inalienable possession, and Payne and Barshi (1999) focus on the typology of external possession. Other publications include discussions on the grammatical status of specific items from the domain of possession. For instance, it is sometimes unclear whether possessive pronouns behave like genitival arguments or like adjectives. The discussions in this area are rather technical and must be seen in the context of DP-analysis (for reference see Abney 1987, Löbel 1995). In what follows, this article will focus on some important issues from the typology of possessive constructions.

1.2 Details on Typological Research on Possession

The most difficult problem for the typological description of possession is the great variety of expression and the fact that there is no simple correspondence between a conceptual relationship of possession and traditional linguistic categories like possessive pronouns or possessive verbs (in fact, possessive verbs are cross-linguistically rather rare). For instance, a Latin construction like *mihi est liber* (me:DAT is book:NOM, lit. 'to me is (a) book') contains no 'classical' possessive category, but conceptually it figures as a possessive construction. Conversely, a construction like 'my train' in 'I've got to catch my train' does not really refer to the train which I own, though it does involve a 'classical' possessive pronoun. Finally, there are instances of so-called 'possessor deletion' as in the German *er hob die Hand* (lit. 'he raised the hand') vs. the English 'he raised his hand,' which unlike the German example contains an explicit possessive pronoun.

As a solution to these problems, Seiler (1983) proposes that the expression of possession constitutes an operational program ranging from minimal

explicitness of the relationship (indicativity) to maximal explicitness (predicativity). Indicativity literally means to 'point' at what one may take for granted, while predicativity establishes a relationship by overt means. The 'indicative' and less explicit techniques are mainly characteristic of the attributive pole (with constructions like 'my train'), while the most predicative type of construction is found in the area of possessive verbs (with constructions like 'I own a house'). For 'my train' the relationship is still very vague, while 'I own a house' is very specific about the relationship in question.

In this context, it is no coincidence that inalienable, inherent possessive relationships usually need less 'effort' to be encoded than alienable relationships. For example, in the Amerindian language Cahuilla the expression 'his eye' would just involve the direct juxtaposition of a personal pronoun and the lexical stem for 'eye,' while the expression 'his dog' needs the addition of a 'possessive classifier' meaning 'pet': compare *he-puc* (3.SG-eye, 'his eye'; where SG = singular) vs. *he-ʔas ʔawal* (3.SG-pet dog, lit. 'his pet dog'). In other words, the (inalienably conceived) body-part term 'eye' is inherently relational, such that the possessive relation between 'he' and 'eye' is more or less 'self-understood'; for 'dog' the situation is different, and the relationship between 'he' and 'dog' must be established by some relational item like 'pet.' By way of contrast, one would need far more effort in Cahuilla to use a word like 'eye' in a 'derationalized' sense. Thus, while 'the dog' is simply *ʔawal*, 'the eye' (in some abstract sense) would be *puc-il* (eye-DER; where DER = derationalizer). Seiler lists a number of techniques commonly employed for the expression of possessive relationships, which can all be placed on a continuum between maximal implicitness and maximal explicitness of the relation. These techniques include plain juxtaposition of P'or and P'ed ('N-N-constructions,' see above), connectives (CONN), possessive classifiers (possessive) cases, existential copula constructions, and possessive verbs. The Persian *iza:fa*-construction would be an example for connectives (cf. *ha:ne-je pedar* (house-CONN father, 'the father's house')), and for possessive classifiers see Cahuilla. Latin *domus patris* (house:NOM father:GEN) is an instance of a case construction. A case construction is a more 'explicit' technique than the connective technique in the sense that so-called 'cases' may allow far more oppositions than all-purpose connectives, etc.; thus, apart from using a possessive genitive, many languages also employ locatives in attributive possession (cf. Modern Icelandic *höfundur á mér* (lit. 'the head on me,' 'my head') which is fairly explicit way of specifying how the body-part relates to the P'or). Case constructions also include expressions like the German *der Mann mit dem Hut* ('the man with the hat'). Here the relationship of possession is expressed from a different perspective than *der Hut von dem Mann* (lit. 'the hat from the

man,' 'the man's hat'); in the former construction, the nucleus is the possessor, while in the latter the nucleus is the possessed. (For the change of perspective also see Sect. 1.3 below.)

With the help of existential copulas, the case constructions can often be turned into literally predicative expressions of possession (cf. the German *der Hut ist von dem Mann* (lit. 'the hat is from the man,' 'the hat belongs to the man') and Icelandic *ég er með bíl* (lit. 'I am with (a) car,' 'I have a car with me'). Finally, languages may also employ actual verbs of possession as in 'I have or own a book' and 'the book belongs to me,' etc. This technique allows the greatest number of oppositions (the number of lexical verbs is virtually limitless), and since this technique is the most predicative one in the sense of Seiler, it is hardly 'natural' in the context of inalienable and 'self-understood' possession. For example, clauses like 'I have a father' or 'I have a head' are considered deviant, unless modifications are added (cf. 'I have a nice father,' 'I have a swollen head'). Nevertheless, though in principle inalienable possession tends towards the 'indicative' pole, and alienable possession tends towards the 'predicative' pole, there are always possibilities of making the implicit explicit and the explicit rather implicit. For instance, Indo-European possessive pronouns may go back to locative constructions of much the same type as the ones which are now commonly used for attributive body-part possession in Icelandic (see above), and the Icelandic attributive constructions in question like *höfundur á mér* (lit. 'the head on me') originate in turn from predicative *dativus sympathicus*-constructions like 'he hit (on) me on the head.' Therefore, there appears to be some shift from the more explicit and predicative to the less explicit in the process of grammaticalization. At the same time, as a reaction to a decrease of explicitness, new explicit constructions may be coined. In this context, Seiler claims that indicativity and predicativity represent complementary principles which are in competition with each other in the operation of giving expression to conceptual possession.

Heine (1997), too, is interested in grammaticalization channels, but he concentrates on the lexical sources of (mostly non-attributive) possession and on the ultimate destiny of possessive items in other domains of grammar. As for non-attributive possession ('predicative possession' in a more restricted sense than in Seiler's framework), Heine (1997, p. 47) presents the following typology based on various conceptual 'schemata': 'X takes Y' ('action schema'), 'Y is located at X' ('location'), 'X is with Y' ('companion'), 'X's Y exists' ('genitive'), 'Y exists for/to X' ('goal'), 'Y exists from X' ('source'), 'as for X, Y exists' ('topic'), 'Y is X's (property)' ('equation'). As an example for the action schema Heine mentions Portuguese, while Turkish has a location schema. Somali has a companion schema, while the genitive schema is found again in Turkish. The goal schema is

manifested in Tamil and Hungarian, the source schema manifests itself in Ik (Nilo-Saharan), Cahuilla has a topic schema, and Russian has an equation schema. In many of these languages different schemata coexist. Again, there is no clear separation between possession and very many other kinds of conceptual domains.

For the different schematic types mentioned it is possible to identify very common paths of development and transitions to other categories. Especially postural verbs (e.g., 'stand,' etc.) often develop into locative copulas, and the resulting location schema ('X is located at Y') may develop into a companion schema ('X is with Y'); both the location schema as well as the companion schema then tend to be re-employed as expressions of possession (for companion cases ('be with') cf. Icelandic *ég er með bil* (see above), and for location cf. Finnish *Liisalla on mies* (lit. 'at Liisa is (a) husband,' 'Liisa has a husband')). The same construction types also often grammaticalize to expressions of aspect (Swahili has a 'be with'-progressive, and Icelandic has a 'be at'-progressive). Aspectual categories also commonly develop from possessively interpreted action schemata like 'to take X' (> 'to have X' > 'to have gone'), and aspectual categories may ultimately be interpreted as tense categories ('past tense').

The shortcomings of traditional descriptions of possessive constructions are most noticeable in the area of inalienable possession. The *dativus sympathicus*-constructions are extremely common, and the cases used in possessive constructions for the P'or or noun phrase include not only genitives, datives, locative constructions, and the plain juxtaposition mentioned above, but occasionally even accusatives (e.g., Faroese kinship relations). As a consequence, it is necessary to give special attention to alternatives to traditional grammatical encodings of possession. The book edited by McGregor and Chappell (1996) presents a rich cross-linguistic survey of inalienable possession; common strategies associated with inalienables apart from 'he hit me on the head'-constructions are 'incorporating' strategies like 'he is bigheaded' (vs. ?'he is bigcarred'). Quite typically, the P'or may not be mentioned at all on the possessed noun phrase (cf. the phenomenon of 'possessor deletion' (see above)). But conversely, inherent relationality may sometimes have to be obligatorily marked (lit. 'his hands-his'). As a variant of possessor raising giving prominence to psychologically involved possessors, also different honorifics may be used in the context of body-part relations (cf. Japanese, see Tsunoda 1996).

Payne and Barshi's definition (1999, p. 3) of 'external possession' covers more than the constructions used in possessor raising: here external possession denotes any construction in which the P'or figures as a core argument of the verb and in a constituent separate from that which contains the P'ed. This definition includes applicatives (e.g., Mixean, see Zavala 1999),

'double subject constructions' (Japanese, see Shibatani 1994) and expressions where the P'or is the subject of a verb with an incorporated P'ed (Mohawk, see Baker 1999). What is common to all these constructions is some difference of 'empathy,' 'discourse-prominence,' and 'fore-grounding' in the relationship between P'or and P'ed as compared to the 'standard' possessive constructions. In fact, all kinds of possessive constructions can be ordered in terms of the comparative discourse prominence for P'or and P'ed. With this in mind, it is necessary to be aware of some specifically linguistic functions of possessive categories.

1.3 The Linguistic Side of Possession

Different degrees of discourse prominence can be tested, among other things, with criteria like accessibility for relativization, etc. Languages differ considerably in the extent they 'normally' give prominence to possessors and possessed items, but there is usually variation between various options in the same language, too. Compare English 'her dog *who (= she)' vs. 'this dog of hers, who (= she),' where the ordinary possessive pronoun cannot be taken up in a relative clause, but the phrase 'of hers' can. Normally, there is some continuum of possessor prominence from possessive pronouns via personal pronouns in the genitive to actual arguments of the verb (in the dative or accusative, etc., as in 'possessor raising' constructions). And while the P'ed is totally inaccessible for relativization in 'the blue-eyed man *which (= the eyes) ...,' the P'ed can be relativized in 'the man with the blue eyes which (= the eyes) ...,' etc.

In this context, possessive constructions do not simply express some extra-linguistic concept, i.e., the constructions in question must also be judged with respect to their function in the discourse. This is particularly conspicuous in connection with genitive constructions. It is true that 'normally' the genitive phrase 'expresses' the possessor (cf. 'the man's car'), but sometimes the situation is reversed. Compare German *das Auto des Mannes ist alt* (lit. 'the car (P'ed: NOM) of the man (P'or: GEN) is old') vs. *der Besitzer des Autos ist alt* (lit. 'the owner (P'or: NOM) of the car (P'ed: GEN) is old'). The answer why it is the P'or who is in the genitive in the first example, and why is it the P'ed which is in the genitive in the second ultimately has to do with discourse pragmatics. The noun phrase in the genitive typically encodes a known referent which can be used for the identification of something which is less inherently identifiable. 'Normally,' it will be human P'ors who are 'better known' than inanimate referents or dependent referents like body-parts, etc., but in examples like German *der Besitzer des Autos mit dem Kennzeichen XY wird gebeten, sich mit der Polizei in Verbindung zu setzen* ('the owner of the car with the registration number XY is requested to contact the police') it is the inanimate

referent which happens to be better identifiable. In this case, the P'or will have to be expressed by a special relational noun (*Besitzer* 'owner'), but the genitival phrase is still basically used for identification in the discourse, even though it now encodes the P'ed. These considerations may also explain why many languages have paradigms like 'the man's car,' 'John's car,' 'his car,' 'my car,' while there is often not a corresponding construction like '*I with the car,' '*John with the car' (which in principle just looks at the relationship from another perspective just like 'the man with the car'): 'Normally,' referents like 'I' and 'John' are identifiable without further specification, while dependent items are not default referents in the discourse. Therefore it is quite 'natural' for possessed items to carry some additional marking for making them identifiable in the discourse (e.g., with reference to an animate, 'ego-like' P'or).

Also the distinction between so-called *eius*- and *suus*-possession ('of somebody else' vs. 'of his own') reflects differences of discourse prominence. In Modern Icelandic, the *suus*-possessive *sinn* only refers to prominent participants (usually a subject) within the clause. Conversely, *hans* (*eius*) is used mainly when the pronoun refers to a possessor mentioned outside of the clause. Interestingly, *hans* distinguishes masculine, feminine, and neuter with reference to the P'or, while *sinn* distinguishes masculine, feminine, and neuter only with reference to the P'ed. Hence, the 'distant' P'or will be far better retrievable by means of *hans* than by means of *sinn*, which prefers 'near' and very salient noun phrase referents. Since discourse-relevance is a direct correlate of high animacy and conceptual independence, it is clear why the linguistic treatment of possessive relations will tend to be associated with distinctions like [+/-animate] and [+/-alienable]. As animacy also correlates with control just like any relationship of possession, it is not surprising that there are conceptual shifts from possession to distinctions of agency (cf. 'I have beaten' (agentive) vs. 'I am beaten' (non-agentive)) and vice versa. Agent (AG) and patient (PAT) are also differentiated in nominalized possessor-of-the-act constructions (cf. 'Peter's (AG) beating (action) of the dog (PAT),' or Tongan *ko 'eku* (alienable) *taa'i 'o* (inalienable) *e kuli'i* (lit. 'it is my (active) beating of the (passive) dog,' I am currently beating the dog')). Apart from that, agent and patient relations have also frequently been observed to coincide with differences of imperfective vs. perfective aspect. From this point of view, the typical correspondences between possession, voice, and aspect are not surprising. Like the voice distinction, possession also implies some shift of perspective from an 'ordinary' discourse referent (who is animate and independent) to some referent which is usually inanimate and dependent. It is these shifts of perspective and the many alternative forms of encoding which make possession a highly interesting domain of study for linguistics and cognitive science.

Postal Systems

Postal systems are administratively coordinated communication networks that originated in antiquity, yet remain important today. During their 4,000-year history, they have changed significantly, making it hard to generalize about their scale, scope, and accessibility. Until fairly recently, for example, postal systems often conveyed people in addition to information and goods.

1. Overview

Most surveys of the world's postal systems are institutional genealogies. Postal systems beget one another in a grand procession of names, places, and dates. Such an approach has the merit of bringing together a wealth of anecdotal material not easily found elsewhere (Scheele 1970). Yet it exaggerates continuity, discourages systematic comparison, and obscures the role of the postal system as an agent of change.

This article takes a comparative institutional approach. The world's postal systems are divided into three groups: imperial, corporate, and national. The section on national postal systems is subdivided into three parts: origins, postal reform, and twentieth- and twenty-first-century developments. The article concludes with a brief discussion of postal systems and social science, with suggestions for future research.

2. Imperial Postal Systems

Imperial postal systems enabled political leaders to conduct diplomacy, plan military campaigns, and oversee routine administration. The most highly developed were those of the Persians and the Romans. The Persian postal system under Emperor Darius (521–486 BC) employed teams of mounted couriers to transmit clay tablets at 14-mile intervals along a 1,600-mile route that stretched from the Tigris River to the Aegean Sea. The Greek historian Herodotus praised its speed and regularity: 'Neither snow, nor rain, nor heat, nor gloom of night stays these couriers from the swift completion of their appointed rounds.'

The Roman postal system, the *cursus publicus*, was established by Emperor Augustus (29 BC–AD 14) and lasted 500 years. Relays of couriers with horse-drawn carts transmitted official dispatches along with government officials and their baggage. Routes extended throughout the empire and, during military campaigns, to generals in the field. Messages were written on papyrus, parchment, or wax-coated tablets, paper remaining unknown in Europe until after AD 1000. The relays explain the etymology of 'postal'; it was derived from *positus*, the past participle of *ponere*, 'to place.' Couriers traveled 50 miles per day—a speed rarely exceeded until the nineteenth century.

Access to the *cursus publicus* was restricted largely to government officials. For this reason, some scholars term it a government communication network, and reserve the term postal system for networks open to the general population. Merchants relied on private messengers, seafarers, or friends. Maritime links were particularly important for Christian apostles such as Paul, who used them to send epistles throughout the Mediterranean world.

3. Corporate Postal Systems

Long after the fall of Rome, imperial postal systems continued to flourish in Asia, South America, and the Middle East. In Europe, however, no comparable institution existed for centuries. When postal systems revived in the 1200s, their organizers were no longer imperial regimes, but corporate bodies, including the University of Paris, the monks of Cluny, and the German butchers' guild.

Corporate postal systems rarely maintained relays of mounted couriers and often lacked the trappings of power. Yet in several respects they marked a distinct advance. Many crossed political boundaries, establishing links *between* states as well as *within* them. Few were restricted, like the Roman *cursus publicus*, to government officials. Open access was facilitated by the recent introduction of paper, a light-weight writing medium that was easy to transport. The policy also helped defray costs, since travel was expensive and many corporate postal systems were self-supporting. Henceforth, the primary constraint for potential postal patrons was financial: postal rates were typically fairly high, limiting access to the well-connected and the well-to-do.

Among the most important corporate postal systems were those established by the Italian city-states. By the end of the thirteenth century, couriers linked Venice with Constantinople, and Florence, Genoa, and Siena with northern France. The most enduring was the *Corrieri Bergamaschie* that Amadeo Tasso established in Bergamo, near Milan, in 1290. This institution much impressed the Hapsburgs, who, in the 1400s, enlisted the Tasso and Delle Torre families to extend it throughout the Holy Roman Empire.

To oblige the Hapsburgs, the families Germanicized their names to Thurn and Taxis. Shortly thereafter, in 1489, Johann von Taxis became the Hapsburgs' first postmaster. Within the next few years, he and his brother Franz von Taxis established postal links between the Hapsburgs' far-flung domains and Rome, France, and Spain, and opened the service to the general population (Dallmeier 1977). Couriers carried a distinctive post horn, an instrument that remains to this day a symbol of the German Deutsche Post. Although the rise of the nation-state greatly restricted its scope, the Thurn and Taxis postal system survived until 1867, when it was bought out by the Prussian government (Behringer 1990).

4. National Postal Systems

4.1 Origins

Corporate postal systems stymied the rulers of the emergent nation-states in several ways. Most obviously, they created an unregulated communication channel that threatened political stability. In addition, they deprived rulers of a useful tool with which to monitor the flow of information and ideas. In response, nation-states throughout Europe, led by France and England, established postal systems under tight government control (Coase 1955).

The French and English postal systems originated, like the imperial postal systems of antiquity, as government communication networks. In France, the founder was Louis XI (1461–83), and in England,

Henry VIII (1509–47). In both countries, the early 1600s marked a decisive turning point. Within a few decades, both governments granted access to the general population, instituted a monopoly, established a rate structure and delivery schedule, and organized a surveillance mechanism to monitor their subjects' correspondence: the *cabinet noir* in France; the secrets office in England (Vaille 1946–55, Robinson 1948). Shortly thereafter, the English government mandated a major rate increase, transforming its postal system into a revenue source, which it would remain until the twentieth century (Dauntton 1985).

Beginning in the 1600s, national postal systems did much to hasten the emergence of the newspaper—at the time, a new form of political communication. This relationship was particularly close in England, British North America, The Netherlands, and Prussia. By permitting the regular transmission of information on current events, postal systems became, in effect, an early broadcast media. Having gained control of the means of communication, governments used it to foster a distinctive world view. In so doing, they helped forge the national identities that are such a fundamental feature of the modern world (Mueller 1986).

Nowhere was the relationship of the postal system and the newspaper closer than in the USA. In the 1790s, following the adoption of the federal Constitution, the American government invested its postal system with an educational rationale far more expansive than the fiscal rationale that had previously prevailed. The new mandate, codified in the Post Office Act of 1792, hastened the circulation of newspapers by conveying them at extremely low rates while enormously expanding the number of localities to which they could be sent (John 1995). A landmark in postal history, this policy may well have marked the first time a government deliberately subsidized the transmission of a particular kind of information.

By 1828, the American postal system, with almost 8,000 post offices, was larger and more geographically extended than any postal system in Europe. At this time, the USA boasted 74 post offices per 100,000 inhabitants, Britain 17, and France four (John 1995). Prior to the coming of the railroad and telegraph, the American government had established the preconditions for the disembodied public sphere that French traveler Alexis de Tocqueville (1835, 1840) would explore so perceptively in *Democracy in America*.

4.2 Postal Reform

Victorian commentators often hailed the postal system of their day as a fundamentally *new* institution that was little older than the railroad and telegraph. For the majority of the population, this was often true. Prior to the 1840s, postal rates remained so high that letter writing was, in practice, confined to the few.

Even in the USA, if a farmer or artisan received anything in the mail, it was more likely to be a newspaper than a letter.

In both Britain and the USA, the high cost of letter postage hastened the establishment of clandestine letter-delivery services in direct violation of the postal monopoly. Following the advent of the railroad in the 1830s, these operations expanded greatly, hastening the major rate reduction known as postal reform.

Postal reform began in Britain, where it was championed by educator Rowland Hill. Hill recognized that high letter rates encouraged illicit mail carriage, and posited that a major reduction would hasten a massive expansion in letter writing. To buttress his argument, he demonstrated in a famous pamphlet, *Post Office Reform: Its Importance and Practicality* (1837), that rates bore no relation to expenses. All but a tiny fraction of the cost of delivering a letter, Hill calculated, derived from its *routing* through the system rather than from its *conveyance* from sender to recipient.

Hill prevailed and, in 1840, the British government simplified the rate schedule and reduced the basic letter rate to one penny. Hill styled his reform uniform postage; it was commonly called penny postage. Hill's reform greatly increased mail volume, just as he had predicted. In addition, it hastened the advent of several familiar postal practices, including mandatory prepayment, mail boxes, and the postage stamp (Dauntton 1985).

Many governments followed Hill's lead. The USA lowered its letter rates in 1847 and 1851; France in 1848. Japan, eager to emulate the best practices in the West, established in 1870 a postal system modeled closely on Britain's (Westney 1987). Increased mail volume, in conjunction with the advent of the ocean-going steamship, hastened the proliferation of transnational postal treaties. These diplomatic initiatives were regularized in 1878 with the establishment of the Universal Postal Union (UPU), today a branch of the United Nations. Closely related to postal reform was the substitution of the railroad for the stagecoach as the preferred mode of conveyance. By the 1830s, stagecoach service had attained a high level of development, especially in Britain and France. Interestingly, Rowland Hill based his famous cost calculations on the stagecoach, rather than the railroad, which had yet to be widely adopted. Stagecoach speeds often averaged 10 miles per hour, a standard rarely matched since the demise of the *cursus publicus* of imperial Rome. The use of the railroad to convey mail posed various scheduling dilemmas and could increase postal costs; in the USA, for example, it quickly ran the postal system into debt. Yet it proved indispensable, greatly increasing carrying capacity and revolutionizing postal routing. In Britain, the USA, and most industrialized nations, it was long customary to sort the mail on-board moving trains, a practice known as railway mail.

Postal reform ushered in a golden age of letter writing. In many countries, the exchange of holiday greeting cards became a popular custom. Soldiers' letters emerged, especially in wartime, as a notable mode of literary expression. Although letter writing would, in the twentieth century, face competition from telephony, the habit persists, and, since the popularization of E-mail, may well be enjoying a revival.

In the decades preceding World War I, each of the world's leading postal systems—Britain, France, Germany, and the USA—undertook major new responsibilities. Each established a parcel post and instituted a rudimentary banking service known as postal savings. And each, with the exception of the USA, took over the telegraph and telephone, establishing a ministry of Posts, Telegraphs, and Telephones, known in France and elsewhere as the PTT (Bertho 1981, Perry 1992). This expansive era in postal history reached its apogee around 1900, when it was common for journalists to hail the postal system as the greatest business in the world (Fuller 1972).

4.3 Twentieth and Twenty-first Century Developments

In both the developed and the developing world, postal systems remain indispensable elements of the information infrastructure (Sinclair 1984). In the latter part of the twentieth century, however, much changed. Beginning around 1970, rapid changes in communications technology led many governments to re-evaluate the union of the postal system, the telegraph, the telephone. Deregulation followed. In Britain, the break-up came in 1981, and in France, in 1991.

The Internet poses a further challenge, yet, in a sense, it is nothing new. Since the mid-nineteenth century, postal systems have co-existed with earlier modes of electric communications. The USA is the originator not only of the Internet, but also of 40 percent of all the world's mail. In the early twentieth century, pundits routinely predicted that telegraphy would soon render mail delivery obsolete, yet telegraphy has been everywhere supplanted, while postal systems thrive.

Additional challenges stem from the emergence of new competitors, e.g., DHL in Europe, Federal Express and UPS in the USA. Express firms rely on improvements in air travel to compete head-on with the national postal systems in key high-value markets. In response, many governments have re-examined—and, in several cases, narrowed—the scope of the postal monopoly (Campbell 1994).

Postal systems have met these challenges in various ways. Many have reinvented themselves as public corporations, a transformation sometimes called privatization. If this trend continues, postal systems in the twenty-first century may share less with the national postal systems out of which they evolved than the corporate postal systems of medieval Europe. The

French postal system, known today as La Poste, has been a publicly traded corporation since the 1970s. The British postal system, the Royal Mail, has aggressively sought new markets. So, too, has the Deutsche Post, which issued its first securities in 2000, and the US Postal Service, which has not been a government department since 1970 and no longer receives a government subsidy.

5. Postal Systems and Social Science

Scholars agree that the printing press was an agent of change. Only recently, however, have postal systems been studied in a similar way. The last edition of the *International Encyclopedia of the Social Sciences* (1968) contained no entry on the postal system, and no references to it in the index.

The rise of the new institutionalism in history, sociology, and political science bodes well for postal studies. So too does the vogue for French literary theory, with its focus on the complexity of the communication process (Siegert 1993). Developments in information technology promise further insights, offering new perspectives on modes of communication that are seemingly being displaced. For postal scholars, Hegel's dictum holds true: the owl of Minerva flies at dusk.

Research opportunities abound. Comparative data remain scarce, especially for the period prior to 1840. Without it, it is hard to frame credible generalizations about what postal systems did and how they worked. Topics that invite exploration include the development and significance of scheduling; censorship and surveillance; postal privacy; communication networks and the rise of nationalism; challenges to the postal monopoly; changing rationales for postal systems; and the shifting meaning of the equal access ideal.

Postcolonial Geography

Historically speaking, a special relationship existed between geography and the making of empires. Pragmatic geographies of orienteering, surveying, mapping and description were the frontier technologies of the operations that brought distant territories under the control of metropolitan centers. As historian Edward Said famously noted in his book *Culture and Imperialism* (1993, p. 271), imperialism is ‘an act of geographical violence through which virtually every space in the world is explored, charted, and finally brought under control.’ At no time was the relationship between geography and colonialism more intimate than during the span of modern European expansion. Such worldly colonizations might be understood simply as metropolitan appropriations of the resources of other peoples and lands. Yet this material self-interest was motorized by a complex set of values that made these often audacious and violent appropriations make perfect moral sense to those whose interests were being served. Not least, deeply

embedded assumptions about racial superiority and apportionings of civility, gave legitimacy to these territorializations. The end of the nineteenth century marked the close of an era in which the discipline of geography was intoxicatingly enlivened.

The modern discipline of geography lives with this past. For a dwindling few it remains a source of nostalgic pride. For many it is source of considerable ambivalence. It is, in part, out of this ambivalence that some of the work that might claim the title ‘postcolonial geography’ emerges. The global authority assumed by imperial geographical knowledges was laid to rest finally by the self-reflexive shock wave that passed through the discipline in the mid-1980s. Geographers who had traditionally marauded across class, gender, race, and other divides began to interrogate the politics of representation associated with such reportage (see special issue of *Environment and Planning D: Society and Space* 1992). This was a symptom of a discipline that was hurriedly retreating from its own past.

To understand what postcolonial geographies are it is essential to understand what is meant by the term postcolonial. As the prefix suggests, postcolonialism refers to the state that comes after colonialism. Most simply, this is the political condition that arrives when a colony is granted independence from its colonial rulers. Many have questioned the ‘post’ of such postcolonialism. The movement from colony to independent nation–state is not a sharp break with the past. Postcolonial states remain complexly entangled in their colonial pasts, just as they are constantly negotiating various kinds of neocolonialism, be it in the form of geopolitical influence, cultural effect, or economic leverage. The persistence of various kinds of colonialism has led various scholars to note that the term postcolonialism is prematurely celebratory. Others are similarly skeptical, suggesting that the term does nothing more than describe a condition of a newly diasporic intelligentsia.

Those geographies to claim the term ‘postcolonial’ reflect a use common to the social sciences and humanities more generally. Here the term refers to an ongoing set of relationships and processes inaugurated by the experience of colonization. Postcolonialism is not then a state that arrives once colonialism ends, but a struggle that comes into being because of, and alongside, the fact of colonization. In this sense, colonial and postcolonial formations are cohabitants. For example, colonial authorities were always dealing with postcolonial effects produced by this cohabitation. This might have included certain subtle, but nonetheless unsettling hybridizations. More starkly, it might have included counter-colonial formations through which the colonized sought to reinstate their authority.

Not surprisingly, many different kinds of formations, periods, and circumstances have come to be described as postcolonial. Such elasticity in the term

postcolonial compromises both its descriptive and analytical worth. Yet postcolonialism is still a useful term to apply to a particular intellectual (and political) stance. Indeed, postcolonial studies are defined as much by their theoretical field of influence as they are their empirical concerns. Nowhere is this more evident than in the discipline of geography. Postcolonial geographies are varied in their subject matter, but may be drawn together as a loosely unified set of geographies intent on bringing into view a set of phenomena that work against colonial authority. This might include evident ruptures in the apparent coherence of colonial occupation, it might include the hybrid outcomes of cohabitation, the so-called 'minor' knowledges and alternative terrains of the colonized, and postcolonial formations that aim to wrest back control of territories.

Much of the current work within postcolonial geography, as with postcolonial studies more generally, is based on revisiting the site of colonialism in order that the silences that exist in the colonial record may be uncovered. This recovery project, it is assumed, will lead to a radical rethinking of the forms of knowledge and social identities authorized under colonialism. Historical geography has been much enlivened by this critical return to the imaginaries, logics, and practices of colonialism. In 1993 Livingstone (1993) published his elegant account of the geographical tradition, within which he paid particular attention to the relationship between European geography, race, and empire. In the same year Driver (1992) published an important article that 'unmasked' modern geography's relationship to European colonization. By demonstrating the way geographical knowledges framed other worlds, his paper drew the analytic terms set by Edward Said's landmark contribution, *Orientalism* (1978), into the heart of a rapidly postcolonizing discipline.

Critical appraisals of geographers and the knowledges they produced have continued as an important theme within the discipline. Harley's (1988) work on the relationship between cartographic knowledges and power, is exemplary in this regard. His re-appraisal of cartographic practices and colonialism contributed to an on-going scholarship (both within the discipline and outside) on cartographies and colonial power. The spatial emphasis in geography's critical engagement with the colonial archive is also evident in accounts of other, more populist, visual representational fields. Photography, for example, played an important role in bringing home the experiences, peoples and lands of those faraway new worlds (Ryan 1997).

Geographical practitioners, institutions, knowledge systems, and pedagogies of various kinds have succumbed to the scrutiny of this autocritique. Particular attention has been given to the systems of knowledge used to understand, order and benefit from the often exotic nature found in the new worlds. These knowl-

edge systems made meaningful peoples and lands that, from a eurocentric worldview, were so radically different they could at first only be understood as 'savages' or 'wastelands.' Two showcase collections of studies detailing diverse examples of geography's relationship to various imperialisms (old and new, European, and other) appeared in the mid-1990s (Godlewska and Smith 1994, Bell et al. 1995).

Delivering a gender sensitive perspective to the geographical critique of imperialism has shown that this is seemingly masculinist project, is one in which women (colonial and colonized) are complexly embedded, both as fellow adventurers and as objects of desire. The letters and journals of women who traveled to colonized lands have been an important source of information for rich scholarship on the women in the colonial project.

The global scale expansions of imperialism ground themselves in micro-geographies of occupation and domestication. As Jacobs (1996, p. 19) notes, the pure idea of imperialism 'tumbled into the fractured and erratic everyday practices of the personalities ... who were forced together in the making of colonies.' One of the key collective contributions of the now vast body of critical colonial geographies has been to point to the contingencies of colonialism as a located, place-specific practice. For some time a key concern of this work has been the way relations of differentiation and domination have been enacted in and through space, and how colonized subjects subvert or negotiate those spatial controls.

A significant subset of critical colonial and postcolonial geographies concerns the city. Although not a geographer, the work of Anthony King has been highly influential in shaping the direction of this inquiry within the discipline. His theory of colonial urban development outlined the economic, political, and cultural processes that gave rise to and defined the form of the cities of colonial territories. Colonial cities were important sites in the transfer of modern capitalist values to new worlds and functioned as important centers of power for administering indigenous people and resources. In these cities, town-planning ordinances about cleanliness and sanitation became the mechanism through which colonial assumptions about racial difference were translated into on-the-ground technologies of segregation and exclusion. Jacobs (1996) extends this urban postcolonial scholarship by documenting the ways in which imperial pasts and postcolonial struggles continue to shape contemporary cities. More recent scholarship has turned its attention to the way imperial geographies impacted upon the townscapes and spatial arrangements of the metropolitan cities that stood at the heart of empires. Driver and Gilbert (1999) offer an exemplary collection on the history of cross-mappings between empire and modern European cities.

The geographies accounted for thus far largely confine their attention to the archive or to historic

landscapes and territorializations. The intellectual project of making a critical return to the scene of colonialism is undertaken in the belief that it contributes to a decolonization of the discipline. Such a return can and does have its postcolonizing value, but there remains a certain ambiguity around just how postcolonial these modern adventures in critical colonial geography might be. Not least there is a tendency in these geographies for the colonized subject (the 'other') to be brought into view simply by way of the colonial discourses that framed them. Can attending to the colonial scene with a postcolonial lens dislodge the effects of that history? Or does it simply re-inscribe the colonial moment as the master referent of all that follows? Colonial constructs, practices, and landscape transformations have significant after effects, they flow into present times both sustaining vectors of domination and exploitation and providing the site against which alternate identities, places, and ways of being in the world are asserted. It is to the geographies that attend to the contemporary scene of postcolonialism that we now turn.

Racism and racialized difference rightly dominate the critical analysis of imperialism and the making of colonies, for it was on the basis of this register of difference that many of the most audacious imperial appropriations have been made. Despite this, there is an intellectual distance between the radical geographical tradition of studies of race and racism and geographies that describe themselves as 'postcolonial.' Some recent work has begun to converge around contemporary notions of whiteness, the postcolonial politics of antiracism and the emergence of new forms of postcolonial racism.

With geographical knowledges and technologies playing such a central role in the making of colonial territories, they have come to play an important part in the unmaking of these territories. There is, for example, a growing literature within geography on the use of cartographic technologies, place renaming, and alternative geographical knowledges, in various forms of postcolonial nationalism and indigenous rights movements, as well as newly commodified forms of conquest. Similarly, geographers have begun to show how modern environmentalisms are complexly entangled with colonialist assumptions about nature and race: bringing forth new kinds of (romantic) racisms and exclusions alongside of new possibilities for political alliance.

An exemplary body of self-consciously decolonizing geographical writing is the scholarship that has emerged around the racist spatial logic of settlement in Southern Africa. That lingering colonial construct of apartheid gave rise to stark geographies of differentiation and disadvantage based on racially defined 'group areas.' These racist spatialities called into being many passionately political geographies of reform. Similarly postcolonial geographies are emerging in the local scholarship of other former colonial territories and

settler states. Some of these geographies continue to remind us of the tenacity of colonial and neocolonial constructs and the way in which they are embedded in the physical and ideological landscapes of places and nations. This might include the ways in which the landscapes and identities of those once colonized are now being absorbed into new touristic circuits or commodity markets. Other postcolonial geographies genuinely reorient the concerns and subject matter of the discipline. They may install radically alternative evaluations of land and resources, that are directed away from dominant models of use and in so doing give legitimacy to previously marginalized ways of being in the world. They may chart hopeful examples of resistance to domination, be it in the form of minor subversions or stark oppositions. They may even be so optimistic as to speculate about new models of co-existence. What all of these emerging geographies of postcolonialism reveal is how specific historical and geographical contexts have delivered a peculiar political and moral imperative to the project of decolonizing the disciplinary gaze.

J. M. Jacobs

Postcolonial Law

Postcolonial theory is largely associated with South Asian scholarship, subaltern and literary studies, analyses of resistance, and a general rethinking of a dominant European historiography that places the 'West' at the center of the world. Postcolonial theory plays a particularly important function in its acknowledging and recovering the ongoing significance of colonized peoples in shaping the epistemologies, philosophies, practices, and shifting identities of what is taken for granted as dominant Western subjects and subjectivities. Most importantly in the context of law, postcolonial theory, and the various colonial sites through which it is inscribed and substantiated, punctuates the degree of violence and the technologies of power involved in understanding concepts such as modernity and capitalism as well as contemporary state and trans-state nationalisms.

That being said, postcolonial theory rarely considers the importance of law and imperial governance (however, see Baxi 2000, Spivak 1999). Likewise, legal scholarship has largely ignored the significance of a postcolonial perspective (see Darian-Smith and Fitzpatrick 1999). Certainly sociolegal scholarship has gone some way to bring to the fore some of the implications of gender, ethnicity, race, class, age, religion, and so on, in the formulating of the rule of law and the maintenance of its legitimizing practices. However, the particularly uncomfortable position offered by a postcolonial perspective, which places side by side the oppressed and the oppressor, and their enduring psychological and material interdependence, is generally treated as a radically different line of inquiry from that which seeks to analyse economic and political inequalities promulgated through a particular legal system. What, after all, do cultural and literary studies that focus on the colonial situation have to do with an empirical study of law in places such as the United States? In an attempt to dismantle this prevailing attitude of mutual exclusivity between

postcolonial and legal studies, discussed below are some of the insights postcolonial theory brings to bear on an understanding of contemporary legal processes in order to identify, analyse, and assess what is meant by the term 'postcolonial law.'

1. Defining a 'Postcolonial' Perspective

Throughout the late 1980s and 1990s, a considerable body of scholarship devoted to issues of postcoloniality emerged. And with this proliferation of research in Anglo/European universities, there was, and is still, much debate over the meaning and scope of postcolonial terminology (see Schwarz and Ray 2000, Loomba 1998, Williams and Chrisman 1994). Despite these ongoing deliberations, it is helpful to turn to the most significant implications of a postcolonial perspective which mark it as distinctly different from, yet complementary to, other contemporary theoretical investigations. This process will help to flesh out the contours of postcolonial studies and, at the same time, underscore its intellectual lineage.

Postcolonial studies emerged initially among Indian and British scholars in the wake of World War II and in an era of general demise of colonial regimes. Spurred on by radical Western thinkers such as Marx, Nietzsche, Althusser, Fanon, Jameson, Foucault, and Derrida, Edward Said's important publication *Orientalism* (1978), these scholars of historiography critiqued Eurocentric and Indocentric interpretations alike for their assumptions of superiority in European countries vis-à-vis the past and future of Indian people and a modernist concept of the Indian nation (Prakash 1990, 1992, O'Hanlon and Washbrook 1992, Chakrabarty 1992).

Building on Marxist, poststructuralist, and feminist theories, postcolonial scholars have played a major role in bringing to the fore the chronological and psychological relations between the former colonized and colonizers, whom, they argue, cannot be understood except in conjunction with each other (see Gandhi 1998). Postcolonial theorists do not claim that colonialism was experienced in the same way under different regimes, just as they recognize that today colonialism operates in very different ways from its earlier configurations. Nonetheless, while paying attention to the details of specific contexts, postcolonial scholars agree that, in order to understand all contemporary histories of peoples and places, irrespective of whether there historically existed in any given site an explicit colonial regime, it is crucially important to remain aware of the enduring presence of former colonial discourses that posit 'civilized,' 'progressive,' and 'just' Europeans against 'barbaric,' 'static,' and 'unethical' indigenous populations.

According to these scholars, colonial assumptions of Western superiority endure across time and across attempts to blur racial and ethical boundaries. While racism is not equivalent to colonial

regimes, categories of racial difference were used by colonial governments to varying degrees as strategies of power and control over indigenous peoples (Stoler 1989, Dirks 1986). Today, despite claims of increasing acceptance of multiculturalism and cultural diversity, racial categories and differences continue to exist, though often in less overt manifestations. And, according to many postcolonial theorists, these boundaries of difference are insurmountable given the psychological intersubjectivity between former colonizers and colonized which constantly necessitates a desire for re-representations of difference (see Fitzpatrick 1999). Drawing on a variety of theoretical perspectives—including an Hegelian master/slave dialectic, phenomenological essentialism, and psycho-analytical insights gleaned from Fanon and Lacan—postcolonial theorists such as Homi Bhabha, Gayatri Spivak and Benita Parry bring to the fore complex understandings of how oppressed peoples resist and seek empowerment (see Gates 1991).

In recognizing processes of mutual desire and negation between the 'master' and 'slave,' postcolonial scholars are forced to recognize the profound irony in attempting to present alternative historical narratives and identities other than those conventionally supplied by the West (Trivedi and Mukherjee 1996). The very moment of self-determination by peoples formerly colonized requires the adoption of European knowledge such as notions of progress and development, concepts of self and personhood, as well as forms of government, state-building, and, perhaps most importantly of all, law. Thus, according to a postcolonial perspective, all assertions of freedom and self-awareness require elements of mimicry and voyeurism. As Douglas Robinson has noted:

Postcolonial or subaltern scholars claim it is at once essential and impossible to forge a 'new' postcolonial identity: *essential*, because those colonial constructs were at once alien and negative, because they came from the outside and destroyed much of value in the indigenous cultures, and because an effective post-colonial politics requires the development of more positive indigenous visions: but also *impossible*, because colonial discourse continues to inform even these postcolonial attempts to break free of it, and tends to condition even the imagination of a 'new' (postcolonial) identity along 'old' (colonial) lines. (Robinson 1997, pp. 19–20)

A prominent postcolonial theorist, Dipesh Chakrabarty, has responded to the ironies of alterity by calling for the 'provincializing,' or decentering, of Europe and European epistemological knowledge. Chakrabarty (and others) argue that non-Western knowledge has been historically ignored and precluded from historiographical accounts of humanist understanding and intellectual endeavor (Chakrabarty 1992, 2000a). In an effort to critique 'the "Europe" that modern imperialism and (third world) nationalism have, by their collaborative venture and violence,

made universal,' Chakrabarty urges scholars 'to write into the history of modernity the ambivalences, contradictions, the use of force, and the tragedies and the ironies that attend it' (Chakrabarty 1992, pp. 20–21).

2. Postcolonial Law

Nowhere in the histories of modernity has the 'use of force, and the tragedies and the ironies that attend it' been so obvious as they are in the context of law. Law, in a variety of ways, was the formal mechanism and institutional frame through which colonial governments oppressed and controlled indigenous peoples. Of course, there are many varieties of imposition and reception of law, a few even categorized as voluntary. In some cases, such as in Africa (Mamdani 1996), this involved coopting native chiefs and traditional procedures of arbitration and dispute resolution. In other cases, such as Australia, the British declared the continent *terra nullius* or vacant, and on the basis that native populations were thought to be less than human they were deemed to have no law at all. As a result, traditional methods of peacekeeping were overlooked or deliberately obliterated. Law, emblematic of European rationalism, universal objectivity, individual property rights, and sovereign state authority, provided the justification and the discourse of capitalism, and its necessary corollary of social inequality, be it based on the grounds of gender, class, or ethnicity.

It is impossible to separate colonial from postcolonial law since each developed in collaboration and in conjunction against and through each other. The metropole has always been connected with its colonial peripheries, be these geographically distanced outposts beyond state boundaries, or socially and politically isolated enclaves (such as native reservations) within it. The process of decolonization and the emergence of new states throughout the twentieth century clearly demonstrates the extent to which independent nations have had to adopt modern forms of state building, and the institutions, bureaucracies, constitutions, and legal ideologies of their former oppressors in order to participate in national and international legal communities. The rule of law, the handmaiden of Western capitalist enterprise, exemplifies the postcolonial dilemma that requires new states and non-Western states to mimic and adopt, at least to a certain extent, the legal structure of so-called democratic society.

3. Postcolonial Law and Globalization

Prevailing discussions about law and globalization epitomize the ironies presented by postcolonial law. For instance, The World Bank, the United Nations, the European Union, GATT, NAFTA, and other international legal arrangements all require that, in

order for a country to participate in a global political economy, it must demonstrate commitment to, and adherence with, the foundational values of modern Western law. This does not mean that Western law, or more specifically Anglo/American law, remains impervious to the challenges and collaborations of interacting with different legal values and processes. In a postcolonial world, just as in the colonial situation, there are always ongoing modifications and appropriations between legal systems and the various cultural values that legal processes represent. One only has to think of human rights to appreciate the extent to which its apparently universal actual application has to be constantly modified according to prevailing social, political, and economic values existing within particular peoples and places. That being said, however, the dominance of Anglo/American law is overpowering and not easily destabilized.

An assumption of Western superiority is evidenced by a majority of United States and European socio-legal scholars who continue to treat the rule of law as a discrete entity or thing, much like the nation-state (which law has historically served), and religion (which law has in effect replaced), and not as a dynamic product of historically contested cultural (and colonial) interactions. Thus up to the end of the twentieth century, in arguments both for and against the enduring significance of the nation-state in the increasing context of globalization, the meaning of law is taken as a given, and it is only its spheres of centralized legal activity and influence that are being brought into question. As a result, legal analysts tend to look only at the privileged domains of legal interaction amongst lawyers, judges, business people, and entrepreneurs, and not from the perspective of ordinary people (e.g., Dezalay and Garth 1996). An important point is that what happens in the offices of international and state law firms, as well as bureaucratic and regulatory institutions, may have very little to do with the operation of law on the ground in the barrio, reservation, schoolyard, parking lot, hospital, jail, home-cleaning service, bank, and employment office. These realms of legal interaction, while not so overtly important in macroeconomic and political terms, are, nonetheless, where the majority of ordinary people interface with the law and understand its meanings. And it is in these realms of everyday legal interaction where challenges to static legal ideologies and definitions coagulate, solidify, and, in some cases (such as the riots against the World Trade Organization in Seattle in 2000), become articulated.

4. Challenges and Limits of Postcolonial Law

To really accept the challenges and resistances presented by postcolonial law, be it from within or from without the boundaries of the nation-state, requires that legal scholars accept that there is no universal legal code and legal objectivity. This in turn would

mean that the relative dominance of one set of legal values over another would be a constant topic of review and analysis. The naturalized centrality and superiority of an American/European legal perspective would be dislodged and, borrowing Chakrabarty's terminology discussed above, necessarily 'provincialized.' Given the relations between law, capitalism, and a global political economy, it is no surprise that Western legal scholarship has largely ignored, some would argue deliberately, the long-term implications of the presence of postcolonial law.

That being said, the ironies and limits of a postcolonial perspective applies to the context of law as it does elsewhere. Desires to elevate the singularity, independence, and significance of peoples formerly colonized, and their particular legal ideologies and practices, must also recognize the extent to which postcoloniality is a product—culturally, politically and economically—of the colonial enterprise. There is no obvious solution to how to move beyond the inherent limitations whereby postcolonial knowledge is posited as part of the enduring problem of Western oppression and domination of others. Still one thing seems sure: in order to reveal the intersections between legal processes and new forms of colonialism and imperialism that are emerging within the technological and economic innovations of the twenty-first century (such as the Internet), what is first required is a basic rethinking of the currently prevailing Eurocentric, modernist, state-bound understanding of what constitutes law.

E. Darian-Smith

Postcoloniality

Postcoloniality is the unprecedented, complex predicament faced by individuals, societies, and their governments after the end of European colonial rule. An increasing number of social scientists, especially in the 1980s and 1990s, have found conceptions of postcoloniality useful for characterizing many contemporary societies. Theories of postcoloniality have

emerged especially as more established alternatives—theories of modernization, of underdevelopment, of the Third World, and of revolution—have lost their power to explain the present and predict or guide the future. The premise of most postcoloniality theories is that 'The history of the West and the history of the non-West are by now irrevocably different and irrevocably shared' (Sangari 1995, p. 147).

Writings on postcoloniality range widely in discipline and scholarly methods, and might be typifiable first of all by an attitude, even a mood: disillusionment coupled with commitment, disillusionment with the conspicuous failure of decolonization to produce a world of peace, prosperity, and real liberation, coupled with commitment to diagnose that failure and seek improvements or alternatives. In a British colonial prison during World War II, Jawaharlal Nehru wrote that 'Out of this crucible of war, wherein so much is melting, we hope that something finer will emerge for the West as well as the East, something that will retain all the great achievements of humanity and add to them what they lacked' (Nehru 1982 [1946], p. 81). Thirty-seven years later, as he helped launch the 'Subaltern Studies' school of history, Ranajit Guha declared the 'historic failure of the nation to come to its own' in postcolonial India, its failure as either a bourgeois democracy on the European model or a socialist 'new democracy.' He declared the study of this failure 'the central problematic' for the historiography of India (Guha 1982, p. 7). Similarly, Frantz Fanon wrote in the late 1950s, in the midst of the Algerian anticolonial war, that 'Decolonization is the veritable creation of new men,' that 'the European game has finally ended; we must find something different,' and that 'It is a question of the Third World starting a new history of Man' (Fanon 1968, pp. 36, 312, 315). Thirty-five years later, in the Afterword added to his classic philological study *Orientalism*, Edward Said specifically abjured the idea of 'fixed identities battling across a permanent divide' of Europeans and others (Said 1994, p. 335), in favor of more nuanced multicultural critique of power. While some theorists voice a continuing optimism that, especially in Southern Africa, Eastern Europe, and Southeast Asia, the end of the twentieth century has inaugurated a new age of revolutions (e.g., Comaroff 1996), the dominant tendency in most studies of postcoloniality is critical dissection of utopian anticipations.

To date, discussion of postcoloniality has been more extensive in the Humanities than in the Social Sciences. Critical, often reflexive, theorizing about postcolonial identity and experience has been more extensive than social scientific research into political, economic, and cultural dynamics of postcoloniality. However, controversies in postcolonial theory have provoked fruitful research in anthropology, history, geography, sociology, political science, and other social sciences, characteristically entailing profound

political as well as analytic questions. Good available readers on postcolonial studies include Williams and Chrisman (1994) and Ashcroft et al. (1995). This article centers on efforts to address three powerful antinomies in postcolonial theory, concerning (a) the agency of dominated groups, whether they determine their own fate, (b) the power of the West, whether Western paradigms are inevitable, and (c) the goal of liberation, and when and how postcoloniality might ever end. The article concludes with the tensions between postcoloniality theory and postmodernism, and with efforts to relate postcoloniality and globalization, arguing against portrayals of globalization as the end of postcoloniality, in favor of depiction of the two as intrinsically related.

1. *Can the Subaltern Speak?*

In 1988, literary critic Gayatri Spivak posed the above question as a challenge to the 'Subaltern Studies' school of historians (Spivak 1988). The Subalternists, following Gramsci's theory of class politics in culture, have sought to uncover hidden realities of dominated people's experience and agency in South Asia. The 'Subaltern Studies' project, and Spivak's question, have led to debates and research globally on class, status, culture, and power especially in colonial and postcolonial societies.

The premises of the Subalternists have been, first, that prior histories of colonialism, decolonization, and the postcolonial nation-state have focused on elites, and second, that especially under colonial conditions, elite culture has not been hegemonic, i.e., has not established rituals and routines for social order unchallenged by 'subalterns' or lower class and status, dominated people. In order to explain why a unified postcolonial nation has failed to take shape, Subalternists seek to understand the social experience, collectivities and initiatives of 'subaltern' groups. The original South Asian 'Subaltern Studies' of peasant insurgencies and labor struggles have joined a much broader stream of scholarship on colonial and postcolonial politics, broader not only geographically but also topically, including especially in the 1990s many studies of sex and gender relations, institutions, and imaginaries. However, the issue of the failure of decolonization and the postcolonial nation-states remains central. Efforts have begun to identify positive, existing alternatives to 'the nation' as a form of social organization, not only in South Asia but also in East Asia (notably Duara 1995), the Americas and elsewhere, and also to understand the social legacies of specifically colonial and postcolonial state structures (e.g., in Africa (Mamdani 1996), in Indonesia (Pemberton 1994), and in India (Pandey 1990)).

In the context of research seeking to isolate colonial pathologies and celebrate successful resistances to them, Spivak's question attracted enormous attention because it challenged a second tier of scholarly

premises. Phrased with a literary critic's focus on voice, 'Can the Subaltern speak?' quickly metamorphosed into a question about coherent, autonomous agency, and initiative. Is it possible for 'subaltern' people to shape their own society and culture? Precisely as a radical among philologists, Spivak had insisted that representation in a literary or semiotic sense must be reconsidered in connection with representation in politics, representation in the sense of any capacity for a person to be the agent of, to stand for, the will of other people. Do subalterns have any real power to represent themselves, or is that precisely the lack that constitutes them as subaltern?

Social scientists have come to recognize empirical as well as theoretical issues here. In research on postcolonial societies, the question of subaltern political agency has intersected with studies of class and ethnic structure of anticolonial movements and postcolonial governments, and with studies of democracy in postcolonial conditions. While one tendency in contemporary scholarship is to discover unnoticed ways and means by which subaltern groups preserve themselves, maintain autonomous self-control, and even augment their life chances (e.g., J. C. Scott 1985), another trend is to seek aspects of political structure, global and local, that might account for the reproduction of extremities of domination and violence in postcolonial societies (e.g., Tambiah 1996), and a third trend is to seek to reintegrate the questions about colonial and postcolonial subalterns with studies of domination in metropolitan societies (e.g., Stoler and Cooper 1997). Are postcolonial governments especially likely to be bound to the interests of urban, elite, and ethnically marked subpopulations? Are 'subaltern groups' in such societies less likely to exercise routine rights as citizens, and more likely to sustain whole institutional apparatuses of avoidance and resistance, 'informal' economies, even labor migrations kept deliberately invisible to the postcolonial state? No consensus has emerged. However, it does grow increasingly clear at least that, systematically, the nation-state does not 'come into its own' in postcolonial societies, and 'subaltern' classes in them are neither powerless nor as powerful as citizens in the West.

2. *Provincializing Europe*

Is the postcolonial world destined (or doomed) to follow the West's lead? To fit Western molds? Is the history of the West the central axis of world history? If it isn't, then how can sense be made of colonial history? Research assessing the successes and failures of postcolonial societies that sought alternatively to emulate and to refuse Western models (China, Singapore, Japan, Malaysia, Indonesia, India, and many sites in Africa), especially concerning successes of non-Western capitalisms, and the failures of self-proclaimed socialist revolutions, suggest that efforts to understand the West either as 'exceptional,' successful

for particular cultural or material reasons, or as 'universal,' a distillation of necessities, both fail to grasp the more complex dynamics of the actual history of capitalism, colonialism, and the rise of the nation-state. Anticipations kindred to those of Fanon and Nehru, hoping more or less radically for a new order to supplant the civilization of Europe, were common among anticolonial intellectuals of the mid-twentieth century. These anticipations frequently entwined in a variety of ways with socialist and communist projects for social reconstruction and/or revolution, an end to a capitalist era. For this and other reasons, decolonization became deeply enmeshed in the narrow frame of the Cold War, and was dramatically reconceived within it. The question of the future relation of excolonies and excolonizers became, temporarily, reduced to matters of allegiance in a grand global dualism. Social scientists operated under the premise that all 'Third World' new nations were destined as they 'modernized' to join either the 'free' or 'Communist' worlds (see Pletsch 1981). However, by the end of the century much that was taken for granted in this Cold War common sense was in doubt, was under scrutiny, or was repudiated outright, not only concerning the viability of a revolution against capitalism but also concerning modernization and the nation-state.

In the late-twentieth century, great popularity accrued among scholars for Benedict Anderson's vaguely Marxist theory that the nation as an 'imagined community' was central to the century's global culture (Anderson 1983), but at the same time, disquiet about actual postcolonial nations and states led to new critical questions. Partha Chatterjee mounted the most influential challenge to the premise of the nation-state for excolonies. Chatterjee amplified and reconsidered the implications of parts of Anderson's argument, that 'the nation' was a form for politics linked intrinsically to Enlightenment social theories, a political format pioneered in the Americas and Europe, and then 'pirated' in already 'modular' format as colonies were refashioned and new nations built. Insofar as this is what happened, then, decolonization was not actually a break from Western hegemony. 'Europe and the Americas, the only true subjects of history, have thought out on our behalf not only the script of colonial enlightenment and exploitation, but also that of our anticolonial resistance and postcolonial misery' (Chatterjee 1993, p. 5). Chatterjee doubts that 'our imaginations must remain forever colonized' (Chatterjee 1993, p. 5). However, the question of how to decolonize political imagination, and whether or where it has already been decolonized, has been a provocative one for postcolonial studies. While another influential critic has argued that postcolonial critique of Western universalisms has opened a 'third space' outside both local, cultural particularisms, and modernist universalism (Bhabha 1994, pp. 36-9), others have defined postcolonialism instead as the

dream that this could be done, 'the need, in nations or groups which have been victims of imperialism, to achieve an identity uncontaminated by universalist or Eurocentric concepts and images' (During 1987, p. 3), or the quest for a new relationship with 'the intimate enemy' (Nandy 1983). In this sense, as Lenin once hoped that a United Front politics in colonies could use bourgeois nationalism as a stepping stone to a proletarian revolution, a postcolonial perspective is proffered by some as the key to a new political future. With or without such a dream, the matter remains of how to understand the impact of 'the West' and its (possibly parochial) universals on one-time colonies in both the past and the present. Touchstones for controversy have included 'world system' models of a globally coercive Western-centered economy, and models of globally hegemonic Western culture. World system economic models have largely been encompassed by approaches emphasizing the irreducibility of both global and local economic forces, and the necessity to understand both. While support increases for models of economic 'globalization' that see global economic forces and relations increasing in their influence over time, the causes of the rise of the West as the pre-eminent capitalist center, and the place of colonialism in that history, are still much debated. Similar controversies have followed models of globally hegemonic Western culture, notably Edward Said's landmark study of the kind of discourse he named 'Orientalism,' discourse that constitutes the East and West comparatively, the East as the inferior antithetical other. Said's study has been criticized, ironically, for itself overriding the possibility of non-Western political discourses, for itself undermining the possibility of a world history centered anywhere but the West. Studies have also begun of processes of cultural globalization and of the crucial process of the localizing intermixture of global and local cultural elements that clearly accompanies the development of global cultural connections, the process Hannerz has named 'creolization' (Hannerz 1992).

At their extremes, globalization models can be as simple in their symmetries as conceptions of postcoloniality can be stark in their asymmetries. Recharacterizations of global culture in terms of flows, links, and hybridities, and inquiry into 'modernity at large' (Appadurai 1996), have added an important complexity to studies of postcoloniality, undermining the starkness and simplicity of the colonizer-colonized dualism, and challenging the premise of continuing cultural superiority of the West. However, the situation of postcoloniality requires attention to asymmetries. Reconsidering the past, present, and future place of the West, postcolonial theorists have grown as skeptical of triumphalist visions of reversal, of a non-Western overcoming of Western culture, as they are critical of intrinsically colonial visions of Western superiority over the rest. In *Provincializing Europe*, Dipesh Chakrabarty suggests a way out of the anti-

nomies generated by efforts to reckon with Western domination (Chakrabarty 2000). The paradox in all postcolonialisms that seek a triumphant postcolonial succession to Europe at history's center, Chakrabarty shows, is that even in such a success, the historical structure would still be 'First in Europe, and then elsewhere.' Europe indeed pioneered the form of historicist explanation that gives time a single processual center, giving capital and its culture of Enlightenment a unified place, time, and pattern of development in Europe, while occluding all inassimilable complexities of its earlier and later history elsewhere. However, Chakrabarty argues for abandoning such historicism, in favor of a method which never confines universal history, and provincializes Europe not from a new center, but instead by understanding Western cultural history, also, as one of creolizations (to use Hannerz's term here). Following Chakrabarty (or the similar, 'anti-Hegelian,' argument of Duara (1995)), one can provincialize Europe, confront and unmake colonial asymmetries, without a triumphalism that will inevitably, fatally, unmask as mimicry of European colonialism's own naive historicist egocentrism. Reflection on how, in recent but past centuries, Europe encountered and came in particular, powerful, but not all-powerful, ways to embody and develop universals of capital, democracy, science, etc., might point toward alternative developments in the past and the present, and possibilities not yet recognized for the future, rather than renewing an imperative to overcome empires already dead. In any case, postcolonial theorists have grown weary of battle with colonial ghosts.

3. *When, and How, Can Postcoloniality End?*

It will now be useful, and easy, to clarify the distinction between postcolonialism and postcoloniality. If postcolonialism is the aspiration for a profound political perspective to emerge from the experience of decolonization, postcoloniality is the unprecedented political predicament that decolonization has delivered many societies. The antinomies that fuel the struggle to constitute a postcolonialist political vision are, in less ideological form, equally inescapable for those without postcolonialist aspirations. Postcolonialist quests for political mission via subaltern standpoints struggle over what to expect from and for subaltern political agency. However, vast, dominated, and politically active populations no doubt exist in subaltern positions in postcolonial societies. Any coherent postcolonialism would seem to require a history both centered on and decentering of Europe, but, no doubt, Europe did once dominate, in various and varying ways, the societies it colonized. The question of how, and whether, that domination can be (or has been) ended is crucial to the third antinomy for postcolonialism, the third aspect of predicament in postcoloniality.

Anticolonial theorist and activist Franz Fanon insisted on the goal of liberation, not mere decolonization, for European colonies. Decolonization was something done for, and to, one-time colonies, where the goal should be actual liberation. In fact, as Fanon perceived, in the aftermath of World War II, the European empires disintegrated with extraordinary rapidity, and (except for the French and Portuguese) with little violence: Fanon perceived why. In the atmosphere of the Cold War, Western powers and especially the newly pre-eminent United States greatly feared radical new states emerging from wars of liberation, and preferred to shape successor regimes and constitutions through a pre-emptive orderly process. As Fanon put it, the message flashing was 'for God's sake let's decolonize quick,' as the pieces of European empires were reconfigured into the nation-state form of 'self-determination' required by the new, US-fashioned United Nations (Fanon 1968, pp. 70, 79).

By many diagnoses, decolonization and not genuine liberation was what the new 'Third World' received. But the problem of what would constitute genuine liberation, and which groups merit it, has become increasingly complex. As Firth (2000) has demonstrated, rhetorics of decolonization and liberation have expanded and proliferated after the breakup of most of the European empires has already been accomplished, expanding to articulate aspirations both of groups within nation-states (Biafrans in Nigeria, Kurds in Iraq) and new kinds of groups (women, indigenous peoples, even environments). If the premise of the United Nations has been that the nation-state as a political form constitutes the ultimate form of self-determination for all peoples, that simple, symmetric premise has been called into question. While most reckonings of postcoloniality focus upon the need to overcome asymmetries past, another approach entirely is to reckon it the onset, rather than the aftermath, of something, the predicament constituted for capital-poor excolonies by their re-establishment within the formal symmetries, and limited liabilities, of the United Nations model (Kelly and Kaplan 2001). From this perspective, the goal of liberation itself has become a very specific trap, as formally independent and autonomous political standing comes systematically to entail perpetual clientage, expanding debts and ongoing substantive subservience to outside agencies and agendas. Like the 'free laborer' perceptively critiqued by Marx as free of all access to means of production, these liberated states are, by their very freedom and formal equality, radically limiting of the life chances of their citizens, especially their subalterns. In an interesting recent controversy, Tambiah (1996) rejects the arguments of Pandey (1990) explaining postcolonial communalist violence in South Asia as a legacy of colonial policies that emphasized and institutionalized communal political differences. Tambiah argues that endemic

political violence is a phenomenon of democracy especially in postcolonial conditions, conditions that engender a spiral of destructive, effervescent leveling crowds. The crowds seek not liberation but leveling, destruction of privileges perceived as unmerited, especially across ethnic lines.

Boundary issues have arisen concerning which societies are postcolonial, especially concerning East Asian societies never formally colonized, and the Americas where the legacy of earlier, Iberian domination and earlier independence movements must be calibrated with the history of European colonies in Africa, Asia, and elsewhere. Sociologist Haejoang Cho has argued forcefully that Korea and other East Asian societies were colonized by the West, with becoming colonized defined as coming to require foreign means, methods, and tools simply to live and to think (Cho 1992–94). For the Americas, Klor de Alva (1992) has argued that few or none of the societies outside the Caribbean are postcolonial in fact, that regardless of mestizaje ideologies, Latin American societies are descended not from colonized peoples but largely from the colonizers. As with most of Latin America, whether the United States is postcolonial depends upon the definition adopted. The question is most interesting when connected to different boundary issues concerning postcoloniality: its relations with postmodernism, and with globalization.

Is the post- in postcolonial the post- in postmodern? (So asked another literary critic, Appiah (1992).) Can either end? Dramatic, relativistic postmodernist proclamations that the Enlightenment universals are dead have been countered, Appiah argued, by the fact of misery in postcolonial societies, leading postcolonial political movements to ground their calls for new reforms in ethical universals. While postmodernism offered a first alternative vision to the stalled modernization logic of the Cold War, at present conceptions of both postcoloniality and globalization offer more dynamic alternative formulations. How, then, are postcoloniality and globalization connected? Some scholars envision globalization as the successor, the late capitalist liberator from postcoloniality, as the globe moves from Western modernity to modernity at large or to alternative modernities, negating all vestiges of asymmetric colonial relations. The counter argument (Kelly 1998) is that postcoloniality and globalization are two sides of the same coin, the coin of American power, phenomena not necessarily of a 'late' capitalism but certainly of the new form capitalism has taken under US leadership in the twentieth century. If this is the case, if decolonization and globalization are the fruit of US-led quests for political self-determination and economic open doors, then Europe has already been provincialized by an explicitly anti-imperial agenda, and the predicaments of postcoloniality are the consequences, precisely, of a postcolonialism already instituted. David Scott has perceptively observed, in the first book with 'After

Postcoloniality' in its title, that in the late twentieth century, in the wake of the global resurgence of liberal democracy and the failures of socialist states both Soviet and non-aligned, 'it is no longer so clear what "overcoming" Western power actually means' (D. Scott 1999, p. 14). Perhaps, then, the time has come for dividing 'the West' into its colonial European and twentieth-century American versions. In that case, postcoloniality could end only when American power is as thoroughly confronted as European power has been, and the limitations intrinsic to the formal symmetries of the political present are as fully overcome as have been the formal asymmetries of the colonial past.

Post-Keynesian Thought

1. Introduction

For Joan Robinson (1978; *CEP*, in reprinted Vol. 5, 1979, p. 210), ‘the expression *post-Keynesian*... [applied] to an economic theory or method of analysis

which takes account of the difference between the future and the past’: a helpful point from which to start but it must be remembered that the approaches to political economy reflecting Post-Keynesian thought are there for historical reasons and because of logical associations. Post-Keynesianism is a broad church. Overlaps at each end of a long spectrum of views are marginal, reflecting little more than hostility towards mainstream neoclassical economics and methodology, and conventional forms of Keynesian economics as opposed to the economics of Keynes. Some Post-Keynesians attempt to synthesize the principal strands. Others regard this as misguided. Post-Keynesianism should use a situation—and issue-specific method, a ‘horses for courses’ approach, itself an all-embracing structure at the methodological level.

In this essay historical origins are discussed first; it then deals with approaches to fundamentals issues political economists have tackled since the Physiocrats and Adam Smith theories of value, distribution, price-setting, accumulation, growth and the cycle, and the role of money and financial intermediaries, especially whether money is endogenous or exogenous. Post-Keynesian thought belongs to the tradition that the *raison d'être* of economics is its bearing on policy. Stress is put on the role of institutions in determining economic and political processes, the political philosophies of Post-Keynesians and the policies following from their theories.

All these issues, the methodologies implied in them, the particular ‘vision’ of the economy associated with each strand, are intertwined. This article concentrates on origins, pioneers, and issues. For a full cast list see, for example, Eichner and Kregel (1975), Hamouda and Harcourt 1988; reprinted in Sardoni 1992, Arestis 1992, Lavoie 1992.

2. Classical Roots

Keynes’s new theory reached back over neoclassical economics to join up with the pre-occupations and approaches of our classical forebears. Much that was integral to Keynes’s system, especially its Marshallian offshoots, was jettisoned, at least by Post-Keynesians sympathetic to the viewpoints of the classical economists and Marx. This rules out two prominent American Post-Keynesians, Sidney Weintraub and Paul Davidson, whose structures are amalgams of Marshall and Keynes and who are hostile to Marx, Michal Kalecki, and Piero Sraffa.

An important aspect of classical economics for Post-Keynesian thought is the organizing concept of the surplus—its creation, extraction, distribution, and use. It is the core of their system and its modern counterpart, dovetailing logically with a view of economic processes as dynamic, evolving, progressing organic systems, not the more static allocative process characterizing neoclassical economics until neoclassical growth theory emerged in the 1950s. Linked to the

concept is the notion of a class society, sometimes people, sometimes income, sometimes overlapping. Classes perform different functions. Each is treated as homogenous, with no need to start from the isolated individual economic agent of modern analysis.

Associated with the surplus concept is that of the long-period position, containing the centers of gravitation of the system (Smith's natural prices, Marx's prices of production, Marshall's long-period normal equilibrium prices (and quantities)). With them comes the view that *general* theory is analysis of interrelationships of dominant, persistent forces in society. Modern counterparts are Sraffa's work on value and distribution and Pierangelo Garegnani's (and others') long-period interpretation of Keynes.

3. The Marshallian-Keynesian Roots

Turning to the Marshall-Keynes connection, Marshall's system, as Keynes understood it and within which he perceived himself as operating up to *A Treatise on Money* (1930; *C.W.*, Vols. V, VI, 1971) is noted. Basic ingredients were emphasis on the long period, the real and money dichotomy, the logically prior need for a Say's Law long-period equilibrium position for the Quantity Theory of Money to explain the general price level. Keynes liberated himself from this to write the theory of a monetary production economy—*The General Theory* (1936; *C.W.*, Vol VII, 1973).

Effective demand occurs at the intersection of the aggregate demand and supply functions, usually implying involuntary unemployment. The money rate of interest (which clears the money, not the saving and investment market) rules the roost. Uncertainty is a permanent environment for important economic decisions, especially those concerning investment and holding financial assets for speculative and other purposes. The consumption function is stable, the investment function, volatile; they are connected by the Kahn-Meade multiplier. Finally (an aberration for most Post-Keynesians), the general price level is explained by short-period Marshallian analysis at the level of economy as a whole. These are the jumping-off points for American Post-Keynesians especially.

4. Keynes's Theory of Accumulation

Accumulation theories under our rubric start from, or incorporate, the ingredients of Keynes's theory. The details are usually stringently criticized. The recipes emerging mix the same ingredients in more acceptable ways. Within its own framework Keynes's theory was unacceptable. Keynes confused accumulation's stock and flow aspects by naming his principal concept the marginal efficiency of capital (*MEC*). Capital is a stock; he was mainly concerned with investment, a

flow, and so the marginal efficiency of investment (*MEI*).

Keynes's arguments why higher rates of accumulation are associated with lower *MEI* values, with short-period flow equilibrium achieved when $MEI = i$, (i = the rate of interest), were far-fetched or non-clinching. Keynes assumed rising marginal costs and (usually) marginal-cost pricing. At higher values of accumulation in a given situation, there are higher supply prices and lower *MEI* values. Individual free competitors have, in effect, rational expectations; it is as if they use the eventual equilibrium, not the market price of capital goods in their calculations. Otherwise, their combined actions could not bring about that overall rate of production of capital goods which establishes the appropriate supply price and *MEI* value equal to i .

Second, Keynes argues that because we do not know the future, we project the present into the future unless there are good reasons for not doing so. Higher investment levels are associated with higher sales, prices, profits, output, and employment. Keynes's investment analysis assumes that expected longer-period demand curves for the products concerned remain stable while future short-period supply curves associated with possible levels of investment move to the right, implying lower expected prices, quasi-rents and *MEI* values for investment projects now. If Keynes were true to himself, expected demand curves would move too. Lower values of prices, etc. would not necessarily follow. Keynes used a static analysis to analyze a dynamic process, a criticism first made by Kalecki reviewing in Polish *The General Theory* (1936, *C.W.*, Vol. 1, 1990, pp. 223–32), subsequently by Joan Robinson 1951–1980 and Tom Asimakopulos 1971.

They reacted by setting out the two-sided relationship between accumulation and profitability—actual investment is a major determinant of current profits; current profits, a major determinant of expected profits, which determine planned accumulation in situations of given financial conditions and long-term expectations. This is the basis of Kalecki's theory of distribution, accumulation, growth and the cycle, and Joan Robinson's famous banana diagram, Robinson (1962, p. 48).

Pasinetti (1997) remains true to Keynes, pointing out that the *MEI* soon became identified with the marginal product of capital, that investment was treated as a 'deepening' process responding to different i values. Pasinetti argues Keynes made no such claim—he argued that in a given situation, lower i values make more of the existing investment projects seem profitable *regardless of capital-intensity orderings*. Davidson (1972), too, accepted Keynes's analysis, using Keynes's alternative presentation to describe investment projects by their *NPVs* at ruling i (s). He used Keynes's spot, forward, and futures analysis to go from investment possibilities—prices exceed supply prices—to determine equilibrium flows per period.

5. *Post-Keynesian Theories of Value, Distributions, and Price Setting*

Post-Keynesian theories of value, distribution, and price-setting by, usually, an oligopolistic price-leader firm are now examined. Both sets of theories arise from dissatisfaction with supply and demand theories. The theories criticized and proposed as alternatives are macroeconomic. They arose from the empirical observation *cum* theoretical deduction of classical political economy that, with free competition, there is a tendency to a uniform rate of profit in all activities. Two questions arose: what is the origin?, and what determines the size of the system-wide rate of profits (Sraffa's usage) (Sraffa 1960) to which individual rates tend to be equal? The most explicit, refined answers were Marx's. He emphasized that the ultimate source of value is the difficulty of reproduction in a system of production of commodities by means of commodities (as opposed to utility and scarcity in the alternative tradition). Reconciliation is needed between the embodied labor values of commodities in the sphere of production and prices of production in the sphere of distribution and exchange. The latter contain the overall rate of profits and are the centers of gravitation of the system.

The other major alternatives to the neoclassical marginal productivity explanation of returns to capital and labor and shares of wages and profits are those Kaldor (1955–56) called Keynesian. He was not the first to set forth such a theory. Kalecki (1933, reprinted in 1971, pp. 78–9) had long before: 'capitalists may decide to...invest more in a given period than in the preceding one, but they cannot decide to earn more...therefore, their investment...decisions...determine profits,...not vice versa.' Kaldor located their origins in the widow's cruse story of *A Treatise on Money* (1930; *C.W.*, Vol. V, 1971, p. 125) Joan Robinson (1977; *C.E.P.*, Vol. V, 1979, pp. 184–96) provided a lucid account of Kalecki's theory. Consider the case of no consumption by rentiers, no saving by wage-earners and no government or overseas sectors. Profits (*II*) exactly equal investment (*I*), causation runs $I \rightarrow II$. Kaldor's version is the best known. Common features are different saving behavior at the margin as between wages and profits (and/or wage-earners and profit-receivers) and the Keynesian/Kaleckian proposition that investment leads and saving responds. Kaldor's theory is, paradoxically, long-period and relates to a fully employed economy. Kaldor argued, never coherently, that a growing economy must be fully employed in the long-period sense. Planned saving and investment (and their share of full employment income) are equalized when the income distribution is such that the matching amount of saving is forthcoming.

The process bringing equality depends upon Kaldor's (claimed) empirical observations that while short-term money prices and money-wages are sticky,

so that changes in income equalize saving with investment, longer-term prices are more flexible than wages. These differential changes continue until equality is secured, implying that modern wage-earners have real wage levels so far above the classical-Marxian subsistence levels that they passively accept what remains after profit-receivers have first bite of the cherry: the opposite of the older scenarios in which wages had to be met and the surplus available for profits (and thus accumulation) is what is left.

The other theories under this heading are short-period and not constrained to be at full employment. Saving is equalized with investment by changes in activity and income distribution as profit margins change relative to wage costs, a rest state usually exhibiting involuntary unemployment. (In the most developed models there are roles for the government and overseas sectors.)

The most rigorous presentation of modern classical theory is Sraffa's *Production of Commodities by Means of Commodities* (1960). Sraffa's model is formally similar to Leontief's input-output model; the *conceptual* interpretation is different. With production with a surplus and explicit wage rate (*w*) and rate of profits (*r*), Sraffa shows we must know from outside the value of one of the distributive variables. (The classical economists and Marx chose *w*, Sraffa chose *r*.) The prices of production and the value of the other distributive variable are simultaneously determined. The prices of production are centers of gravitation in the particular circumstances of the time, around which market prices fluctuate—or perhaps on which they converge. (Modern work suggests they do not necessarily do *either*.)

Sraffa starts with a circulating, single-use commodity model, then takes us through non-renewable and/or addable to resources (land and rent) and joint production (to analyze durable capital goods, not wool and mutton). He ends with the choice of techniques in the investment decision, showing the possibility of reswitching, destroying the conceptual foundation of a well-behaved demand curve for 'capital' in the alternative tradition.

6. *The Size of the Mark-up*

Alfred Eichner's version (1976) is the most widely known variant of the theory of mark-up size (apart from Kalecki's 'degree of monopoly' theory). Eichner related its size to the investment plans and financial requirements of oligopolistic firms. As his investment function is flawed, we present here as representative Adrian Wood's (1975) long-period steady-state model of an oligopolistic firm, steady-state because expectations of the values of relevant variables are realized. It is a partial analysis—with a given level of aggregate demand, the firm strives for its optimum share of

demand for the industry's products at the expense of other firms in the industry.

The firm wants its sales revenue to grow as fast as possible, subject to two constraints formalized as an opportunity and a finance frontier. The former reflects that there is eventually a trade-off between profit margin size on turnover and sales revenue growth. Increasing growth requires the margin to be squeezed by a price cut, a rise in sales costs, or both. Assuming one best-practice technique, and given external financial conditions, each growth rate of sales requires a particular margin to finance the capacity to make it possible. The two frontiers' intersection defines the margin associated with highest growth rate. Introducing choice of techniques defines a family of interacting frontiers. Because opportunity frontiers move out at a decreasing rate—greater investment per unit of sales lowers costs at a decreasing rate—while finance frontiers fan out proportionately—the margins, growth rates locus forms a concave curve containing a maximum margin, growth rate combination.

Wood's analysis is in Golden Age logical time—expectations realised, no incompatibilities present. Harcourt and Kenyon (1976, reprinted in Sardoni 1992, pp. 48–66) set the problem in historical time—disappointed expectations determine what happens next—using Salter's vintage analysis. The logical, historical time distinction is due to Joan Robinson (1962, pp. 23–9). Setting the price which finances the accumulation program simultaneously determines the accumulation needed to satisfy expected future sales and still profitable existing capacity (in the sense of covering variable costs) able to contribute to future sales. Frederic Lee (1998) tells the Post-Keynesian price theory story from the earliest times to the present.

7. *Post-Keynesian Accumulation: Moses and the Profits*

Post-Keynesian theories of accumulation were stimulated by Harrod's immediate pre- and post-second world war contributions towards a dynamic economics 1939; 1948. Harrod in effect rediscovered the systemic instabilities of capitalism Marx brought out in his reproduction schemas analysis. Marx asked: what conditions must be satisfied, period by period, in order that aggregate demand and supply, and their compositions, match? This threw up the impossibility of these being achieved by capitalists doing their own things with regard to production, employment, and accumulation.

Harrod obtained the same result by bringing out the long-period destabilizing effects of a momentary gap between planned saving and investment when short period stabilizing effects are abstracted from by assuming the immediate achievement of investment planned for each short period. The growth rate of income allowing planned saving to equal investment

might be such that if business people had known it, they would not have planned those investment levels. The saving and investment functions are so related that excess demand (supply) situations are to the right (left) of the equilibrium position; the system gives the wrong signals as to what to do next. Unless the system is growing at the warranted rate (g_w) (the growth rate allowing expectations and plans to be realized), it moves away from it—all regardless of whether g_w coincided with the natural rate of growth (g_n), the growth rate implied by the economy's supply-side characteristics.

Solow and Swan interpreted Harrod as assuming a fixed capital-output ratio, and wondered whether this was responsible for his disturbing results. As pioneering Keynesians, they assumed an all-wise government removed effective demand puzzles. They asked whether in a long-period sense, Marshall's 'dynamical principle of substitution seen ever at work' allowed a competitive price mechanism to give appropriate price signals, causing the production methods chosen by accumulators to lead g_w towards g_n . The answer is 'yes' in the simplest one, all-purpose commodity models. These results attracted the Cambridge, UK growth theorists' attention. Already suspicious of smooth continuous substitution possibilities, they wished to bring in the 'book of blue prints' approach (long 'at home' at MIT and elsewhere within a different context). The Cambridge UK theorists were loathe to leave out aggregate and effective demand. Their writings mostly remained within the confines of steady-state growth models, learning to walk before running, except for Kaldor who used his distribution mechanism to equalize g_w with g_n .

Kalecki, Josef Steindl, and Richard Goodwin followed a different path, one eventually congenial to Kaldor and Joan Robinson. Kalecki initially developed trendless cycles; in his last paper (1968, reprinted in Kalecki 1971, pp. 165–83) on these themes, trend and cycle were indissolubly mixed: 'the long-run trend [is] but a slowly changing component of a chain of short-period situations ... [not an] independent entity' [Kalecki 1968, reprinted in 1971, p. 165].

This view was developed independently by Goodwin, reaching maturity in 'A Growth Cycle,' Goodwin (1967). He used the Volterra prey-predator model; the analogy of 'the symbiosis of two populations—partly complementary, partly hostile—is helpful in ... understanding ... the dynamical contradictions of capitalism, especially when stated in a ... Marxian form' (Goodwin 1967, reprinted in 1982, p. 167). He analyzed the wages, profits fight, and feedbacks, spawning an expanding literature.

Goodwin integrated effective demand and production interdependence in Goodwin and Punzo (1987). This impressive eclectic book reflects influences from Marx, Schumpeter, Keynes, von Neumann, Joan Robinson, Sraffa, and Kalecki, the developments of catastrophe theory, the concept of 'bifurcation,' and the

Volterra prey-predator biological analogy. Goodwin concentrated on the nature of evolutionary structures experiencing from time to time large jumps and breaks, his key to the cyclical development of economies characterized by production interdependencies.

Joan Robinson (1962) synthesized these ideas in her banana diagram. From Kalecki she derived a relationship between actual accumulation and achieved profitability; from Keynes she derived the 'animal spirits' function relating desired accumulation to expected profitability, itself a function of achieved profitability, in a situation of given financial conditions and long-term expectations. With plausible conjectures about the shapes and positions of the two curves, iteration takes the economy to a stable intersection point where the expected and desired are achieved, her version of Harrod's g_w . It is not a solution of Harrod's (or Domar's) problem; there is no reason why g_w coincides with g_n . Nor are there any mechanisms to take it to g_n . Even if the economy attains g_w , nothing ensures that it will not be driven away in the future—neither relationship can be expected to remain stable.

Discussing *The General Theory* twenty five years on, Joan Robinson signaled the change of method lying behind her analysis in 1956 and 1962.

'The short period is here and now, with concrete stocks of the means of production in existence. Incompatibilities in the situation...determine what happens next. Long-period equilibrium is not at some date in the future: it is an imaginary state of affairs in which there are no incompatibilities in the existing situation.' Joan Robinson (1962, reprinted in *C.E.P.*, Vol. 3, 1965, p. 101).

These developments constitute an attack on the procedure of setting up theoretical issues as searches for existence and uniqueness of equilibria, themselves determined by factors independent of those responsible for stability, local, and global. Similarly, the applied procedure of separating trend from cycle with independent factors responsible for each is also discarded.

8. Post-Keynesian Method

There are two views on method within historically defined Post-Keynesian thought. Increasingly, commentators put neo-Ricardians in a class of their own; The author does not agree. Sraffa's critique of neo-classical economics and positive contributions are integral parts of the historical and logical developments, especially when his underlying Marxism is recognized. The neo-Ricardian stance (on method) is identified as common to all strands of political economy until the 1920s when neoclassical economists, including Hayek, sensed the incoherence of the

concept of the marginal product of capital and its relationship to the long-period method. They reacted by changing the questions and method to the temporary equilibrium analysis of, for example, J.R. Hicks's *Value and Capital*. Neo-Ricardians argue that general theory can only be written about the characteristics of long-period positions reflecting the ultimate outcomes of relationships associated with persistent forces. The economist's role is to identify these, making rigorously explicit their interrelationships. This, they argue, was common to Smith, Marx, and also Marshall who fitted the 'new' supply and demand theories into the old method, making long-period equilibrium prices and quantities the heart of the *Principles*. Therefore, Keynes's theory must be long-period to be a true revolution Garegnani, Eatwell, Milgate, Rogers, and Krishna Bharadwaj refer to passages in *The General Theory* supporting this. Short-period theory has no role in its own right, as opposed to situation-specific analysis at different levels of abstraction.

For Kalecki, Kaldor, and Joan Robinson and their followers, and Paul Davidson and his (the theories differ considerably), the long-period method is a non-starter for descriptive analysis. (For doctrinal debates even Joan Robinson granted it a role. If conjectures or concepts are shown to be incoherent under ideal conditions, this is a legitimate critique of approaches, conceptions, intuitions, and theories.) For descriptive analysis, we must start from a given short period with inherited historical circumstances and accompanying expectations. Long-term expectations and factors are relevant for some current decisions, e.g. investment, pricing; short-term expectations and factors are relevant for others, e.g. production, employment. The story unfolds from one short period to another. (We have simplified: some current activity results from past decisions; some current decisions are relevant for future activity. This led Keynes to abandon period analysis, despairing of finding a determinate time unit into which all relevant interrelationships could be fitted.) There is an element of convergence in the discipline recently because this philosophy underlies work on path-dependence even when the *theory* is neoclassical.

These new developments link back to old approaches to method. Keynes, following Marshall, argued that which variables were regarded as endogenous (determined) and which were exogenous (determining) were arbitrary on any absolute criteria. The crucial decider was the issue in hand.

'The object of our analysis is, not to provide a machine, or method of blind manipulation, [furnishing] an infallible answer, but to provide...an organized and orderly method of thinking out particular problems; and, after we have reached a provisional conclusion by isolating the complicating factors one by one, we...go back on ourselves and allow...for the probable interactions of the factors amongst

themselves...the nature of economic thinking,' Keynes (1936; as in *C.W.*, Vol VI, 1973, p. 297).

Marshall hoped we would get definite, if partial, results and, if we went right round the economy, would be able to bring all results together in a full, overall picture. He forgot that the procedure was inconsistent with his deeper vision that economic processes were akin to systemic interrelated biological processes. (Jan Kregel argues that the *problem* is intractable.)

Sheila Dow (1991) stresses the unifying methodological aspect of Post-Keynesian thought, justifying diverse methods. She recalls to mind Keynes on method and theorizing: there is a continuum of languages which runs from poetry and intuition through lawyer-akin arguments to mathematics and formal logic. Each has a role depending upon the issues, or aspects of issues, discussed. Keynes's emphasis was championed by George Shackle, his favourite example was Keynes's use of 'sentiment.' It could not be defined mathematically, but it gave insights, conjured up atmosphere, invoked the environment of situations analyzed. Kregel (1976) identified in *The General Theory* three models of economic reality of differing degrees of complexity, the most complex being that of shifting equilibrium. The methods were common to Keynes and Post-Keynesians when modeling decision-making in uncertain environments.

Post-Keynesians following Goodwin, Kalecki, and Joan Robinson eschew the Marshallian (or even Keynesian) method; others combine a similar 'vision' of society with explicit use of the Marshallian/Keynesian method or, even earlier, the classical economists' implicit method. Outstanding examples include Pasinetti whose many years work on a multi-sectoral growth model came to fruition in 1981 (with a simple exposition in 1993). Pasinetti integrates Keynes's macroeconomic aggregates with the production interdependence of the classicals, Marx and Sraffa. He sets out the consistency conditions required to maintain full employment growth in a multi-sector model in which the demands for commodities over time follow their respective Engels curves, technical progress occurs and, in later stages of the analysis, the economy is open, trading with and borrowing from or lending to, the rest of the world. The best-known exposition of his insights is Pasinetti (1962); he obtained the 'remarkable result,' $r = g/s_c$. It has proved extremely robust as complications have been added—international trade, government, financial intermediaries, endogenously determined saving ratios.

Another major contribution is Marglin's contribution to the conflict inflation literature (1984). (Rowthorn (1977) derived the same results.) Marglin has a Keynesian-Marxian 'vision' but is Marshallian in method. His aim is to establish long-period 'equilibrium' relationships—short-period stations approach long-period crosses which stay 'put' until and

after they are reached. His principal result is that sustained rates of inflation allow disappointed aspirations of wage-earners and capitalists to be shared in uneasy but sustainable truces.

Post-Keynesian thought starts from real world observations, for example, Kaldor's famous 'stylized facts': broad empirical generalizations holding, in a rough and ready way, for long runs of historical time, requiring situation-specific theories to explain them. Kaldor pioneered the theory of cumulative causation, a deep idea learnt from Allyn Young (and Gunnar Myrdal) Young alerted Kaldor to the pervasive existence of dynamic increasing returns in economic life. Kaldor exploited these illuminations, and inter-regional relationships, to analyze specific periods of economic history.

A wolf pack analogy illustrates the contrast between mainstream axiomatic, equilibrium theory and Post-Keynesian cumulative causation theory. The former thinks of a wolf pack running along. If some wolves stray, powerful forces return them to the pack. The latter identifies powerful forces making those leaving the pack get further ahead or fall further behind, at least for long periods of time—hence the rejection of the equilibrium concept in descriptive analysis.

9. Endogenous Money

Keynes, before and after *The General Theory*, was an endogenous money person, arguing that the demand for money, especially for credit, helped determine the interest rate and the supply of money. Was his stance in *The General Theory*, where he is interpreted as having an exogenous money supply with the interest rate, the price allowing it to be voluntarily held, an aberration? The answer (given most recently by Sheila Dow (1997) is that the money supply is *given*, not *exogenous*. By 1937 he reverted to type when discussing the finance motive for holding money (read, demanding credit)—he had banks creating credit in response to demands for finance for investment projects, a base from which start Post-Keynesian debates on money and credit demand and supply.

Within these discussions, there are claims that the money supply is entirely demand (not supply) determined, summarized in the phrase. Horizontalists versus Verticalists, see Moore (1988). Moore's position is extreme. Most reject the verticalist interpretation, a stance attributed to much mainstream theory, but allow important roles for credit rationing and rising interest rates in determining outcomes in the financial assets market. It is almost universally argued that meeting demand for funds for investment and now, with credit for all, consumption too, creates deposits. This contrasts with the mainstream view that deposits of present and past saving initiate potential lending by financial intermediaries. The former view was fervently expressed by Keynes: 'The investment

market can become congested through shortage of cash, never...through shortage of saving.' (C.W., Vol. XIV, 1973, p. 222). Kalecki independently arrived at the same view. Post-Keynesians start from here, responding to new institutional developments and refining, extending the analysis. They reflect the major change James Meade attributed to Keynes: Keynes changed us from looking at the world as a saving dog wagging an investment tail to one in which an investment dog wagged a saving tail.

Within this set of discussions, some stress the stock aspects of money and financial assets, others, the flow aspect of credit as finance for important expenditures. Associated with this distinction are Post-Keynesians concentrating on one period only in their analysis of money—accommodationists. They contrast with structuralists, stressing period by period analysis in the manner of the mature Kalecki and John Hicks. The upshot is to preserve Keynes's liquidity preference theory when explaining demand for money and financial assets, levels and patterns of interest rates and banks extending credit guided by their liquidity preference, so that not all demand is necessarily accommodated, see Cottrell (1994).

10. Policy

The connection between Post-Keynesian analysis and the real world includes a healthy preoccupation with policy. The mean Post-Keynesian's policy proposals match the mean Bastard Keynesian's—a slightly left of center package deal of monetary, fiscal and incomes policies, combined with a longer-term commitment to freer trade while preserving protective positions until 'the time is ripe' and preference for fixed exchange rates (with institutional means allowing orderly realignments now and then). Revamping Bretton Woods's structures, to remove built-in contractionary biases, guides suggestions on the international stage. Deregulation of financial markets and 'freeing up' of exchange rates unleashed an era of instability following the tranquil experience of 'the Golden Age of Capitalism.' This has led to attempts, e.g. the Tobin tax on foreign exchange transactions, to curb the excesses of speculative movements in the foreign exchange markets, stock exchanges, and property markets.

Where Post-Keynesians feel they have the upper hand is in their argument that cumulative causation processes characterize the workings of markets and economic systems. If such processes operate it is harder to argue for beneficial systemic effects from speculation—that it reduces fluctuations and gets the market (system) to underlying long-period equilibrium positions more quickly than otherwise would be the case. If they are not there, speculation makes matters worse. We are led to middle way programs between ruthless

laissez faire (but not that competitive) capitalism and authoritarian, inefficient, centrally planned economies. Heinrich Bortis (1997) profoundly analyzed the philosophical, political and economic aspects of these developments. He synthesized three major stands of Post-Keynesianism: the neo-Ricardian approach to capture the longer term aspects of economies' developments, the Kaleckian-Robinsonian, their cyclical aspects, and the American Post-Keynesians, short-period behavior in product and money markets under uncertainty. To this he allied a democratic socialist platform, with philosophical foundations and a comprehensive outline of policy, nationally and internationally. Another stalwart is John Cornwall. Over the years he developed his original theoretical critique of Harrod for supposing that g_w and g_n were independent of each other and supplemented his analysis of the implications for growth of systemic supply and demand interdependence, with a steady stream of down-to-earth, humane recommendations for institutional reforms, see Harcourt and Monadjemi (1999).

Bortis and Cornwall were influenced by Kaldor. Kaldor's last book (1996), contains his mature views on how the world works: policy proposals are in the last chapter. He has long emphasized the importance of industrial increasing returns and different pricing behavior as between the (export) products of primary producing countries and countries producing industrial goods. He combined policies for relative stability in exchange rates worldwide with international buffer stock schemes for primary commodities. The latter serve the dual purpose of reducing fluctuations in prices and incomes which damage the economies producing these commodities (and those buying them) while simultaneously providing worldwide liquidity for trade and capital movements, a provision free of disadvantages arising when one major country's currency performs this role, as happens now.

Postmodern Urbanism

1. Postmodernism in Urban Studies

In the field of urban studies, three principal references are discernable in postmodern thought:

- (a) a series of distinctive cultural and stylistic practices that are in and of themselves intrinsically interesting;
- (b) the totality of such practices, viewed as a cultural ensemble characteristic of the contemporary epoch of capitalist society; and
- (c) a philosophical and methodological discourse antagonistic to the precepts of Enlightenment thought, most particularly the hegemony of any single intellectual persuasion.

Implicit in all these approaches is the vision of a 'radical break,' i.e., a discontinuity between past and future trends (whether cultural, political-economic, or philosophical).

The pivotal point of departure in a postmodern urbanism is that just as the tenets of modernist thought have been undermined and a multiplicity of new ways of knowing put in their place, so, analogously, in postmodern cities the logics of previous urbanisms have evaporated; and in the absence of a single new imperative, multiple forms of (ir)rationality clamor to fill the vacuum. The localization, sometimes literally the concretization, of these multiple logics is creating the emerging time-space fabric of what may be called a postmodern society. The contradictions between a modernist and a postmodern urbanism are encoun-

tered most directly in the differences between the 'Chicago School' and the 'Los Angeles School' of urban structure.

1.1 *The Chicago School*

The most enduring of the Chicago School models was the zonal or concentric ring theory (Burgess 1925). Based on assumptions that included a uniform land surface, universal access to a single-centered city, free competition for space, and the notion that development would take place outward from a central core, Burgess concluded that the city would tend to form a series of concentric zones. At the core of Burgess's schema was the Central Business District (CBD), which was surrounded by a transitional zone, where older private houses were being converted to offices and light industry, or subdivided to form smaller dwelling units. The transitional zone was succeeded by a zone of workingmen's homes, which included some of the oldest residential buildings in the city, and stable social groups. Beyond this, newer and larger dwellings were to be found, occupied by the middle classes. Finally, the commuters' zone extended beyond the continuous built-up area of the city (where a considerable portion of the zone's population was employed).

Other urbanists noted the tendency for cities to grow in star-shaped rather than concentric form, along highways that radiate from a center with contrasting land uses in the interstices. This gave rise to a sector theory of urban structure, advanced in the late 1930s by Homer Hoyt (1939), who observed that once variations arose in land uses near the city center, they tended to persist as the city grew. Distinctive sectors thus expanded out from the CBD, often organized along major highways. The complexities of real-world urbanism were further taken up in the multiple nuclei theory of C. D. Harris and E. L. Ullman (1945). They proposed that cities have a cellular structure in which land uses develop around multiple growth-nuclei within the metropolis—a consequence of accessibility-induced variations in the land-rent surface and agglomeration (dis)economies.

Much of the urban research agenda of the twentieth century was predicated on the percepts of the concentric zone, sector, and multiple nuclei theories of urban structure. However, the specific and persistent popularity of the Chicago concentric ring model is probably related to its beguiling simplicity and the enormous volume of publications produced by adherents of the Chicago School.

1.2 *The Los Angeles School*

During the 1980s, a group of loosely associated scholars began to examine the notion that what was happening in the Los Angeles (LA) region was

somehow symptomatic of a broader socio-geographic transformation taking place within the US. Their project was based on certain shared theoretical assumptions, as well as the view that LA was emblematic of some more general urban dynamic. One concern common to all adherents of the LA School was a focus on restructuring, which included deindustrialization, the birth of the information economy, the decline of nation-states, and the rise of the Pacific Rim. Such proliferating logics often involved multiple theoretical frameworks that overlap and coexist in their explanations of the burgeoning global/local order—a heterodoxy consistent with the project of postmodernism.

1.3 *From Chicago to LA*

Based on the differences between Chicago and LA, the distinction between a modernist and postmodern urbanism may be summarized as follows: whereas traditional concepts of urban form imagine a city based on a single central core that organized its hinterland (Chicago-style), in postmodern urbanism it is the hinterlands that organize what is left of the center (as in Los Angeles).

2. *Postmodern Urbanism: Urban Form and Urban Process*

Contemporary urban development in southern California provides a wealth of evidence that is symptomatic of a burgeoning postmodern urbanism.

2.1 *Edge Cities*

Joel Garreau (1991, p. 3) noted the central significance of Los Angeles in understanding contemporary metropolitan growth in the US. He asserts that: 'Every single American city that is growing, is growing in the fashion of Los Angeles,' and claims there are 26 edge cities within a five-county area in southern California. The classic location for contemporary edge cities is at the intersection of a suburban beltway and a hub-and-spoke lateral road. The central conditions that have propelled such development are the dominance of the automobile and the associated need for parking, the communications revolution, and the entry of women in large numbers into the labor market. One essential characteristic of the edge city is that politics is not yet established there. Into the political vacuum moves a 'shadow government'—a privatized proto-government that is essentially a plutocratic alternative to normal politics. Shadow governments can tax, legislate for, and police their communities; but they are rarely accountable, are responsive primarily to wealth (as opposed to numbers of voters), and are subject to few constitutional constraints (Garreau 1991, p. 187).

2.2 *Privatopia*

'Privatopia,' perhaps the quintessential edge-city residential form, is a private housing development based in common-interest developments (CIDs) and administered by homeowners' associations (McKenzie 1994, p. 11). Sustained by an expanding catalogue of covenants, conditions, and restrictions (or CC&Rs), privatopia has been fueled by ideology of 'hostile privatism' that has provoked a culture of non-participation. McKenzie notes how this 'secession of the successful' has altered concepts of citizenship, in which 'one's duties consist of satisfying one's obligations to private property' (1994, p. 196).

2.3 *Cultures of Heteropolis*

Provoked to comprehend the causes and implications of the 1992 civil disturbances in Los Angeles, Charles Jencks (1993, p. 32) zeroes in on the city's diversity as the key to LA's emergent urbanism. The consequent built environment is characterized by transience, energy, and unplanned vulgarity. Jencks views this improvisational quality as a hopeful sign, since it accepts the different voices that create a city, suppresses none of them, and makes from their interaction some kind of greater dialogue (1993, p. 75). This is especially important in a city where 'minoritization' is 'the typical postmodern phenomenon where most of the population forms the "other"' (Jencks 1993, p. 84).

2.4 *City as Theme Park*

California in general and Los Angeles in particular, have often been promoted as places where the American (suburban) dream is most easily realized. Many writers have used the 'theme park' metaphor to describe the emergence of its associated cityscapes. For instance, Michael Sorkin (1992) describes theme parks as places of simulation without end, characterized by a-spatiality, plus technological and physical surveillance and control. What is missing in this new cybernetic suburbia is not a particular building or place, but the spaces between; that is, the connections that make sense of forms (p. xii). What is missing, Sorkin maintains, is connectivity and community.

2.5 *Fortified City*

The downside of the southern Californian dream has been the subject of countless dystopian visions. In one powerful account, Mike Davis noted how southern Californians' obsession with security has transformed the region into a fortress. This shift is manifested in the

physical form of the city, which is divided into fortified cells of affluence and places of terror where police battle the criminalized poor. These urban phenomena, according to Davis, have placed Los Angeles 'on the hard edge of postmodernity' (Davis 1992a, p. 155).

2.6 *Interdictory Spaces*

Elaborating upon the notion of fortress urbanism, Steven Flusty observed how various types of fortification have extended a canopy of suppression and surveillance across the entire city. His taxonomy of interdictory spaces (1994, p. 16–17) stresses how spaces are designed to exclude by a combination of their function and cognitive sensibilities. Some spaces are passively aggressive. Other configurations are more assertively confrontational. Flusty notes how combinations of interdictory spaces are being introduced 'into every facet of the urban environment, generating distinctly unfriendly mutant typologies' (1994, pp. 21–33). Some are indicative of the pervasive infiltration of fear into the home; others betray a fear of the public realm.

2.7 *Historical Geographies of Restructuring*

In his history of Los Angeles between 1965 and 1992, Ed Soja (1996) attempts to link the emergent patterns of urban form with underlying social processes. He identified six kinds of restructuring, which together define the region's contemporary urban process. In addition to 'Exopolis,' the city without (a massive simulation of what a city should be), Soja lists: 'Flexcities,' associated with the transition to post-Fordism, especially deindustrialization and the rise of the information economy; and 'Cosmopolis,' referring to the globalization of Los Angeles, both in terms of its emergent world-city status and its internal multicultural diversification. Three specific geographies are consequent upon these dynamics:

- (a) 'Splintered Labyrinth,' which describes the extreme forms of social, economic, and political polarization characteristic of the postmodern city;
- (b) 'Carceral' city, referring to the 'incendiary urban geography' brought about by the amalgam of violence and police surveillance; and
- (c) 'Simcities,' the term Soja uses to describe the new ways of seeing the city—an epistemological restructuring that foregrounds the postmodern perspective.

2.8 *Fordist and Post-Fordist Regimes of Accumulation and Regulation*

Many observers agree that one of the most important underlying processes in the contemporary political

economy is represented by the shift from a Fordist to a post-Fordist industrial organization. Allen Scott's basic argument is that there have been two major phases of urbanization in the US. The first related to an era of Fordist mass production, during which the paradigmatic cities of industrial capitalism (Detroit, Chicago, Pittsburgh, etc.) coalesced around industries that were themselves based upon ideas of mass production. The second phase is associated with the decline of the Fordist era and the rise of a post-Fordist 'flexible production.' This is a form of industrial activity based on small-size, small-batch units of (typically subcontracted) production that are nevertheless integrated into clusters of economic activity (Scott 1993). Post-Fordist regimes of accumulation are associated with analogous regimes of regulation, or social control. Perhaps the most prominent manifestation of changes in the regime of regulation has been the retreat from the welfare state, which has led many people to the brink of poverty just at the time when the social welfare 'safety net' is being withdrawn.

2.9 Globalization

The global/local dialectic is another important (if somewhat imprecise) *leitmotif* of contemporary urban process. In his reference to the global context of LA's localisms, Mike Davis (1992b) claims that if LA is in any sense paradigmatic, it is because the city condenses the intended and unintended spatial consequences of post-Fordism. He insists that there is no simple master logic of restructuring, focusing instead on two key localized macro-processes: the over-accumulation in southern California of bank and real estate capital, principally from the East Asian trade surplus; and the reflux of low-wage manufacturing and labor-intensive service industries, following upon immigration from Mexico and Central America. Through such connections, what happens today in Asia and Central America will tomorrow have an effect in Los Angeles.

2.10 Politics of Nature

The natural environment of southern California has been under constant assault since the first colonial settlements. Human habitation on a metropolitan scale has only been possible through a widespread manipulation of nature, especially the control of water resources. On one hand, southern Californians tend to hold a grudging respect for nature, living as they do adjacent to one of the earth's major geological hazards, and in a desert environment that is prone to flood, landslide, and fire. On the other hand, its inhabitants have been energetically, ceaselessly, and sometimes carelessly unrolling the carpet of urbanization over the natural landscape for more than a

century. This uninhibited occupation has engendered its own range of environmental problems, most notoriously air pollution; but it also brings forth habitat loss and dangerous encounters between humans and other animals. In this sense, a postmodern urbanism is axiomatically an environmental issue (Wolch and Emel 1998).

In sum, these diverse dynamics suggest an urban process:

(a) that is driven by a global restructuring and permeated and balkanized by a series of interdictory networks;

(b) whose populations are socially and culturally heterogeneous, but politically and economically polarized;

(c) whose residents are educated and persuaded to the consumption of dreamscapes even as the poorest are consigned to 'carceral' cities;

(d) whose built environment, reflective of these processes, consists of edge cities, 'privatopias,' and the like; and

(e) whose natural environment is being erased to the point of unlivability.

3. The Postmodern Urban Condition

In their model of postmodern urbanism, Dear and Flusty (1998) synthesize the diverse spatial manifestations of the postmodern urban process into a vision of 'keno capitalism.' According to their characterization, urbanization is occurring on a quasi-random field of opportunities. Capital touches down as if by chance on a parcel of land, ignoring the opportunities on intervening lots, thus sparking the development process. The relationship between development of one parcel and nondevelopment of another is a disjointed, seemingly unrelated affair. While not truly a random process, it is evident that the traditional, center-driven agglomeration economies that guided urban development in the past no longer apply. Conventional city form, Chicago-style, is sacrificed in favor of a noncontiguous collage of parceled, consumption-oriented landscapes devoid of conventional centers, yet wired into electronic propinquity and nominally unified by the mythologies of the (dis)information superhighway. The consequent urban aggregate is characterized by acute fragmentation and specialization—a partitioned gaming board subject to perverse laws and peculiarly discrete, disjointed urban outcomes.

The validity and full potential of the concept of postmodern urbanism can be judged only by a thorough comparative urban analysis that goes beyond Los Angeles (Dear 2000). Four contemporary emphases seem especially promising:

(a) world cities, or the emergence of a very few 'megacities' involved in key command and comfort functions in the globalizing political economy;

(b) dual cities, or the burgeoning polarizations between rich and poor, powerful and powerless, computer literate and illiterate, etc.;

(c) hybrid cities, or the fragmentation of existing social alliances and the rise of unprecedented hybrid categories and places; and

(d) 'cybercities,' or the radical undermining of conventional geographies by the telecommunications revolution.

M. J. Dear

Postmodernism in Geography

The impact of postmodernism on the field of geography has been particularly intense and far-reaching, perhaps more so than in any other social science. Although still controversial, with few geographers specifically identifying themselves as postmodernists, postmodern and related *poststructuralist* critiques of traditional modes of interpreting and explaining geographical phenomena have influenced scholarly research and teaching in nearly all branches of the discipline. Especially influential has been postmodernism's role in shaping the development of what has come to be called *Critical Human Geography* and in the rethinking of such core concepts as space, place, region, and environment (see also *Postmodern Urbanism*). At the same time, this postmodernization of geography has contributed significantly to expanding geography's impact on other disciplines, both in the social sciences and the humanities. Geographical writings on postmodernism and postmodernity have been an integral part of the recent resurgence of interest in concepts of space and place across a wider spectrum of academic disciplines than ever before in the twentieth century.

1. The Postmodern Turn in Geography

Postmodernism entered geography as an offshoot and extension of critical responses to the positivist 'spatial science' paradigm that began to dominate the discipline in the 1960s. These critical responses took two major forms. A radical or *Marxist Geography* consolidated in the 1970s as a critique of prevailing modes of explanation in spatial science and as a means of making geography more socially and politically relevant. Rather than focusing primarily on statistically measurable surface appearances and searching for empirical regularities based on the frictions of distance and spatial covariation, how one geographical pattern or distribution correlates with another, Marxist geographers analyzed and explained what they called *specific geographies* as socially constructed outcomes of underlying processes such as class formation and capitalist accumulation. This carried with it a strong emphasis on structural explanation of geographical phenomena (see *Structuralism*) and gave rise to a specifically geographical (urban, regional, international, ecological) political economy perspective that would influence the discipline significantly in subsequent years.

The second stream of critical response, developing initially as *Humanistic Geography*, also concentrated on alternative modes of explanation, but emphasized the role of human agency and subjectivity much more than the effects of powerful structuring forces emanating either from society or the environment (Ley and Samuels 1978). Drawing on phenomenology, exis-

tentialism, and hermeneutics as well as traditional forms of cultural geography and landscape analysis, these geographical humanists were less concerned with space and political economy than with *place, nature-society relations*, and the interpretation of *cultural landscapes*. Continuing long-established links with anthropology, this reinvigorated form of *Cultural Geography* would also influence the development of postpositivist critical human geography over the next several decades as an important countercurrent to the Marxist critique.

By the early 1980s, the spatial science paradigm had passed its peak of influence and many new approaches were entering geography, each competing to define the leading edge of postpositivist research. At the same time, significant critiques were developing both within and between Marxist and humanistic geography (and within spatial science as well), adding further to the proliferation of new perspectives. Perhaps the most challenging critiques came from feminist geographers, who saw an exploitative and demeaning *masculinism* inherent in every branch of what would be labeled modern geography. This patriarchal order was not only expressed in the workplace (e.g., in university privileges, hiring, salaries) but also in the very practice of geography, whether theoretical or empirical, positivist, Marxist, or Humanist. The feminist critique echoed on a broader platform many other concerns over what was perceived as an excessive narrowing of perspectives affecting and constraining the development of (modern) critical human geography. It was in this atmosphere of increasing epistemological fragmentation and escalating internal critique of modern geographical practices that postmodernism first entered the disciplinary discourse.

The deepest divisions within postpositivist geography revolved around traditional philosophical dichotomies or binary oppositions: Subject–Object, Idealism–Materialism, Agency–Structure. Their particular expression, however, took the form of an opposition between approaches that emphasized spatial political economy vs. those that stressed place-based culture. In the late 1970s, there had been some efforts to bring these opposing positions together, most notably in the writings of Derek Gregory. Influenced by the social theorist Anthony Giddens, also then at Cambridge University, Gregory (1978) argued for a critical synthesis of ‘structural’ and ‘reflexive’ approaches to geographical explanation that would go beyond their traditional antagonism to create a new, socially and politically ‘committed’ critical human geography. Gregory was one of the first geographers to recognize the potential relevance of postmodern and closely associated poststructuralist debates to achieving this goal, and for the next two decades would be a leading voice in adding a postmodern, poststructuralist, and, later, postcolonial perspective to geographical research, theory, and teaching (Gregory and Walford 1989, Gregory 1994).

In addition to the influence of Gregory’s work and the growing impact on geography of Giddens’s structuration theory, there were other developments in the early 1980s that attempted to overcome the divisions and fragmentation of postpositivist geography by at least in part introducing some aspects of the postmodern and poststructuralist critiques (Olsson 1980). In retrospect, however, the key turning point in the postmodernization of geography came from outside the discipline, with the publication (in 1984) of Fredric Jameson’s *Postmodernism, or the Cultural Logic of Late Capitalism*. Jameson, a widely recognized Marxist literary critic and cultural studies scholar, had recently become interested in continental European theories of space, place, and architecture, and especially in the work of the French philosopher and urbanist Henri Lefebvre. Then teaching in the History of Consciousness program at the University of California-Santa Cruz, Jameson had organized a lecture tour by Lefebvre in the previous year and hosted his stay as visiting professor at Santa Cruz in 1984.

While he saw architecture as the ‘privileged’ language of postmodernism, Jameson was aware of the new developments in critical human geography and gathered a group of geographers, urbanists, and architects, mainly from California, at a conference to celebrate Lefebvre’s creative spatial theories. When the article appeared, presenting a postmodern and explicitly spatial critique that effectively bridged Marxist political economy and critical cultural studies, innovatively interpreting emerging forms of contemporary urban geography, and calling for a new ‘political esthetic’ based on what Jameson termed a ‘cognitive mapping’ of ‘postmodern hyperspace,’ its effect on geography was particularly powerful.

The impact was especially intense among geographers working in California and, in particular, in Los Angeles, from whose geography Jameson drew some of his most imaginative examples and where there already existed one of the largest clusters of critical human geographers in the US. In the ensuing years, the geography and the geographers of Los Angeles would play a leading role in defining postmodernism and extending its impact on the discipline.

2. Postmodernism Seen from Los Angeles

By the mid-1980s, after decades of relative neglect by urban studies scholars, Los Angeles had become the research focus for a group of geographers and urban planners interested in making theoretical and practical sense of the new urbanization processes that were transforming the contemporary city, not just locally but elsewhere as well. The earliest work on this *urban restructuring* emphasized the radical political economy perspective that was so central in Marxist geography, but there was an openness to alternative perspectives

and practices that arose in large part from the close connections that had developed between geography and urban planning at local universities such as UCLA and USC. These connections linked theorizing the political economy of urban restructuring to the practical demands of public policy, urban politics, and local community activism.

Developing from these early studies was a conceptual framework that saw in the restructuring of Los Angeles the emergence of a new era of urban and regional development affecting cities all over the world in the aftermath of the tumultuous urban crises of the 1960s. This new kind of urbanism and urban geography was interpreted as the product of deep changes in the local, regional, and national economy associated with the rise of *post-Fordism*, increasingly *flexible* methods of industrial production, and the powerful local effects of *globalization* and new information technologies (Scott 1988; see also *Economic Geography*; *Industrial Geography*; *Technology Districts*; *Economic Restructuring: Geographic Aspects*; *Information Society, Geography of*). Built in to this primarily economic conceptualization of urban restructuring was also a critical postmodern interpretation that saw in the dramatic changes taking place in the century's last three decades the rise of a distinctively postmodern as well as post-Fordist urbanism.

In 1986, a special issue devoted to recent research on Los Angeles appeared in the journal *Environment and Planning D: Society and Space*, with an editorial introduction by Scott and Soja describing Los Angeles as the most representative, if not paradigmatic, city of the late twentieth century. The journal, with its founding editor Michael Dear and close editorial ties to British geographers such as Derek Gregory and Nigel Thrift, had quickly become the major journal for current debates relating geography to social theory and cultural studies since its origins four years earlier. In this special issue, two articles appeared, one by Dear and the other by Soja, that were the first explicit statements arguing for a postmodern perspective in geography and planning. Drawing on the changing geography of Los Angeles and the innovative urban scholarship of Jameson and Lefebvre, the authors described postmodernism in three related ways: as a *method* of textual and visual representation, as a contemporary *condition* of everyday life, and as a comprehensive epistemological *critique*. In each of these approaches to postmodernism in geography, emphasis was placed on the distinctiveness of the present era, on what is new and different in the contemporary world, an emphasis that in the broadest sense defines a postmodern perspective.

Defined as a method of textual and visual representation, postmodernism aimed at the intentional *deconstruction* of what were seen as outmoded modernist practices of writing geography, with the intent of opening up creative new alternatives. Rather than

accepting the impress of powerful continuities with the past, for example, there would be playful and disruptively sequenced historical references, accentuating the synchronic and the simultaneous rather than a sequential diachronic narrative. The orderliness of visual form and textual narrative was similarly deconstructed through collage, pastiche, interjected verse, and other unruly modes of literary and visual representation. Explanation and interpretation thus became increasingly involved in *discourse analysis*, with geographies seen as complexly constructed 'texts' to be discursively 'read' as simultaneously real and imagined, a spatial version of the language games and deconstructive practices of such leading postmodernist philosophers as Lyotard, Derrida, and Foucault.

Postmodernism defined as an empirical condition of contemporary life was much easier to accept in geography than what appeared to many to be merely a fashionable and unduly confusing style of writing. That at least part of the world had entered what could be described as a postmodern era and that there were *postmodern geographies* and a *postmodern urbanism* worthy of being studied as such posed relatively little challenge to most geographers. The growing role of economic and industrial geographers in making practical and theoretical sense of the restructuring processes affecting the contemporary world reinforced this widening impact, and helped to create a close association between the geographical condition of postmodernity and the impact of post-Fordist economies of flexible production, globalization processes, and the information society. Just how extensive this empirical postmodernization was, whether it was positive or negative or both, and, especially, how it should affect the practice of geography beyond the description of places like Los Angeles remained much more controversial.

The greatest resistance arose, not unexpectedly, over postmodernism as a deep epistemological critique, especially after subsequent writings by Dear (1988) and Soja (1989) pushed this critique into the very core of geography as a discipline. They argued that all forms of explanation in (modern) geography were fundamentally flawed, for, among other reasons, they rested on epistemological assumptions that excluded too many important issues and voices, especially related to gender, race, class, and what postmodern critics call the marginalized 'Other'; were based on all-encompassing or totalizing metanarratives that too confidently proclaimed the possibility of obtaining complete and accurate knowledge about human geographies; and were excessively bound up in oppositional binaries that left little room for alternative forms of knowledge production. Without abandoning modernism and modern geography entirely, Dear and Soja contended that the restructuring of empirical geographies that had been taking place in the last third of the twentieth century had so changed the contemporary world that established methods of analysis

and explanation in geography, postpositivist or otherwise, could no longer be so confidently relied upon. New and different approaches, an assertively postmodernist geography rather than simply a descriptive geography of the postmodern condition, needed to be opened up and explored.

3. *Postmodernism in Geography: 1989–Present*

Two books published in 1989 were particularly influential in shaping the directions that would be taken by postmodernism in geography in the 1990s: Soja's *Postmodern Geographies: The Reassertion of Space in Critical Social Theory* and Harvey's *The Condition of Postmodernity: An Enquiry into the Origins of Cultural Change*. Both authors were rooted in Marxist geography and political economy, and shared a deep commitment to the creation of a historical materialism that was simultaneously profoundly geographical and spatial. Where they differed most was in the degree to which this construction of a historical and geographical materialism required a critical deconstruction and reconstitution of the ontology and epistemology of Marxist analysis itself.

Harvey adaptively recognized the challenge to radical geographical analysis posed by the postmodern condition but remained confident in the persistent power of historical (and geographical) materialism as a critical methodology for understanding and changing the contemporary world. There were many aspects of the condition of postmodernity that were new and different from the past, but they could best be understood through a more geographical Marxism that viewed postmodernity as just the most recent phase of capitalist development rather than as a disruptive or epochal break with the past.

Soja was more avowedly a postmodernist, insisting that a much deeper restructuring of Marxism was necessary to engage effectively with contemporary geographical realities. He called for a radical rethinking of two fundamental or ontological premises embedded in Marxism, one relating the social and the spatial dimensions of capitalist societies and the other linking time and space, history and geography. Following Lefebvre, Soja argued that there was a more balanced and mutually causal relation between society and space, a sociospatial dialectic that had been submerged in Marxism's overemphasis on social relations of production and aspatial class analysis. Similarly, he saw a persistent privileging of history over geography, the temporal over the spatial, in a particular form of *historicism* that severely constrained the development of a balanced and mutually interactive historical and geographical materialism. He called instead for a more balanced and three-sided ontology and epistemology that dynamically related the spatial, social, and historical dimensions of human

existence (spatiality, sociality, and historicity), with no one of the three inherently privileged over the others (Soja 1996).

The contrasting positions taken by Harvey and Soja on the implications of postmodernism were virtually ignored in the immediate reaction in geography to the two books. Instead, their publication by two prominent male geographers authoritatively writing about postmodernity provoked a concerted response from feminists to what was perceived as another round of masculinist appropriation of the discipline's leading edge of research and theory. Both were accused of 'flexible sexism' (Massey 1991), of living in 'Boy's Town' hopelessly 'lost in space,' of imposing their authoritative power too forcefully, no matter how different their positions on postmodernism. Many of the harshest feminist critics shared an interest in Marxist geography and in the postmodern critiques of modernism, but were suspicious of the particular directions suggested by Harvey and Soja for the future of critical human geography.

The end result of this confrontation and critique was both a deflection and a *refraction* of the impact of postmodernism. A new generation of geographers, especially in Great Britain, set the confrontation aside to work in many different ways at applying postmodernist and poststructuralist perspectives to geographical analysis and interpretation, avoiding both the narrowed historical materialism of Harvey's approach to the postmodern condition and the overly enthusiastic celebrations of postmodernism associated with the work of Soja and Dear.

To an unusual degree, some version of the postmodern epistemological critique (often subsumed under the safer sounding label of poststructuralism) was absorbed into an increasingly eclectic critical human geography in the 1990s, but more as a justification for theoretical and methodological pluralism than as an encompassing or integrative philosophy. Continuing debates about explanation in geography were significantly expanded in scope and increasingly focused on such issues as the construction of *difference* and *identity*; the relations between *space*, *knowledge*, and *power*; the pervasive problems of *representation*; and the increasing confusion of the real and the imagined in *cyberspace* and *hyper-reality*. Growing attention was given to different scales of geographical analysis, ranging from studies of the human body, the most intimate geography, to the new landscapes being produced by the globalization of capital, labor, culture, and information flows. Nearly every subfield became opened up to a multiplicity of interpretive perspectives, including cartography (see Harley in Barnes and Gregory 1997) and geographical information systems (Pickles 1994), with little concern for establishing an overarching theorization or disciplinary paradigm.

Feminist geographers such as Doreen Massey (1994), Gillian Rose (1993), and Linda McDowell

(1993) were particularly influential in shaping the continuing and open-ended postmodernization of geography, cautiously promoting a gender-based postmodern critical epistemology as part of the widening pluralism of interpretive methodologies. Similarly, Kathy Gibson and Julie Graham (writing as Gibson-Graham 1996) called for new directions in Marxist geography based on their reinterpretations of contemporary feminist, postmodernist, and poststructuralist theory. The new cultural geography, building on the early work of Cosgrove and Daniels (1988), Duncan (1990), and Barnes and Duncan (1992), moved increasingly closer to critical cultural studies and deconstructive discourse analysis, with perceptive readings of cultural landscapes as texts and 'signifying practices.' Cultural and political economy perspectives were partially reconnected through a growing interest in the *postcolonial critiques* of scholars such as Edward Said, Gayatri Spivak, Arjun Appadurai, and Homi Bhabha (Gregory 1994, Soja 1996), while geographical studies of the body, sexuality, the unconscious, and the formation of human subjectivity, drawing on the psychoanalytical theories of Lacan as well as the ideas of Foucault and Lefebvre, created other kinds of bridges between subjective place-based culture and spatial political economy (Pile and Thrift 1995, Pile 1996).

There has also developed a vigorous antipostmodernism in the 1990s, even among those whose work most geographers would associate with a postmodern perspective. Many Marxist geographers, for example, continuing to follow David Harvey's lead (see Harvey 1996), have narrowed postmodernism almost entirely to being a politically diverting and divisive aspect of the contemporary *condition* of global capitalism. Efforts to continue to press a postmodern epistemological critique are therefore seen as politically retrogressive and antagonistic to the radical project of historical and geographical materialism. At the other end of the political spectrum, more conservative geographers frequently reduce postmodernism to superficial and often foolish playfulness, blunting any challenge to their established convictions. But very few geographers today are without an opinion on postmodernism or unaware of its impact on the discipline.

As the new century begins, it can be argued that postmodernism and the interpretive approaches associated with it (poststructuralism, postcolonial critiques, post-Marxism, postmodern feminism, methods of deconstruction and discourse analysis) have been absorbed into geography as an integral part of the contemporary discipline (see such recent overviews of modern and postmodern geography as Barnes and Gregory 1997, Benko and Strohmayer 1997, Peet 1998, Massey et al. 1999; see also Jones et al. 1994 and Watson and Gibson 1995). Postmodernism has been blunted and deflected in its boldest claims, continues to be actively resisted by many, but remains part of

the consciousness and imagination of most human geographers.

The achieved and continuing impact of postmodernism can be summarized in several ways. First, it has helped to bring geography into closer contact with social theory and philosophy, and nearly every branch of the social sciences and humanities, from film studies and literary criticism to anthropology and economics. This has contributed in turn to what might be called a 'de-disciplining' of geography: an opening up of its traditional borders with other fields; a wider diffusion of its core concepts and ways of studying space, place, region, and environment; and the emergence of an extraordinary pluralism within geography with respect to theory, epistemology, and methods of empirical analysis. Intense frictions and disagreements remain, to be sure, but there may be no other time in its existence as a distinct discipline when geography has been so paradigm-free and yet so critically engaged with the major issues and events of our times. While these developments are not entirely due to the impact of postmodernism, it has certainly played a stimulating role.

E. W. Soja

Postmodernism in Sociology

Prominent fields of postmodernist research have been work and organizations, political action, science and technology, commodification, consumption, gender, media, and popular culture. Classical sociological topics like symbolic consumption have been further explored and enriched. Sociological postmodernism has also pioneered domains like computers and the Internet. It is to be expected that in the future postmodernist research will evolve in the direction of concrete field studies, with an emphasis on the cultural forms induced by computers and the Internet.

In sociology, postmodernism designates (a) a cluster of theoretical and meta-theoretical approaches; (b) an analysis of postmodernity, understood as encompassing the social and cultural features of late capitalism; (c) an extension of sociological inquiry to new domains; and (d) new forms of sociological expression. Sociological postmodernism is thus a form of sociological analysis, a kind of sociological sensibility, and a sociologists' social and intellectual condition at the same time. Its varieties share a series of theoretical

and methodological premises, but differ in their conclusions and research programs. Core common elements are: (a) avoiding recourse to a set of universally valid assumptions as theoretical and methodological foundations, together with (b) the key role ascribed to notions like subject, identity, text, and symbol in the analysis of society.

1. Origins of Postmodernism

The term 'postmodernism' has been used in Latin-American literary criticism since the 1930s, and in Anglo-American debates since the 1940s, in order to designate new forms of expression in their relationship with the aesthetic of modernism. In history, the term was used by the British historian Arnold Toynbee in *A Study of History* in 1947 and designated the latest phase of Western civilization. In sociology, it was introduced by Amitai Etzioni's book *The Active Society* in 1968. Starting with the early 1970s, the term appeared more and more frequently in sociological texts in France, North America, and the UK. At that time, it was already common stock in literary theory and criticism. An essay written by the French philosopher Jean-François Lyotard, *The Postmodern Condition: A Report on Knowledge* (1979) played a seminal role in making this term widely known and used in the social sciences. Therefore, postmodernism was partially a conceptual import; its diffusion in the 1970s was part of a wider innovative movement in the discipline, marked, among others, by the rise of social constructivism and feminism. At the same time, it continued and reformulated a series of topics already present in sociology.

The intellectual roots of sociological postmodernism can be identified in the works of some key nineteenth and early twentieth century philosophers, sociologists, and linguists. Karl Marx's critique of capitalism, Georg Simmel's analysis of modernization processes, Friedrich Nietzsche's critique of epistemology, and Ferdinand de Saussure's theory of language play here a prominent role. The French structuralist movement (Claude Lévi-Strauss's anthropology, Roland Barthes's semiotic theory, Jacques Lacan's psychoanalysis), and the poststructuralist one (Michel Foucault, Jacques Derrida), Ludwig Wittgenstein's later works, and Clifford Geertz's anthropology have also played a considerable role. Among other influences there are the Frankfurt School (Walter Benjamin, Theodor Adorno, Max Horkheimer, and Herbert Marcuse), symbolic interactionism, ethnomethodology, and phenomenological sociology.

2. The Tenets of Postmodernism

There are two main tenets, mirroring the distinction between postmodernism and post-modernity: while the latter designates the social and cultural features of

late capitalism, distinguishing them from earlier phases (modernity), the former designates a theoretical and methodological program, as distinct from earlier (modernist) ones.

2.1 The Analysis of Postmodernity

The analysis of postmodernity developed at the beginning of the 1970s, continuing a preoccupation already found in the works of Georg Simmel, Thorstein Veblen, and the Frankfurt School. Postmodernity is a late phase in the evolution of the capitalist system, seen either as a continuation and intensification of modernity, or as a substantially new stage. It is characterized by the transition from manufacture to a decentralized services economy; science and complex technological systems play a key role here. Decentralization, together with the pervasiveness of expert and technological systems in all domains of everyday life lead to a fragmentation and diversification of social identities. The electronic media (television, computers, video) are prominent in the constitution and presentation of social reality; visual and linguistic symbols become pervasive, while popular cultural forms diversify and expand. Society is therefore fragmented and heterogeneous; social order is always local and contextual, and works as an assemblage of symbolic codes. Production and consumption, social stratification, as well as personal and collective identities become dependent on such codes. They are understood as a support, a medium for, and an outcome of social action. This notion becomes a general explanatory paradigm: every domain of societal organization can be seen as a symbolic system and analyzed accordingly.

Consequently, sociology (an outcome of modernity itself) should take fragmentation, decentralization, relativization, and the mediated character of social reality into account; it should adapt its own tenets, claims, as well as its own modes of analysis and representation to these changes. Starting from these premises, Zygmunt Bauman (1992) has argued that notions like sociality, habitat, self-constitution, and body are better suited for the analysis of contemporary social processes than the traditional concepts of society and order.

2.2 The Critique of Modernist Sociology

During the 1980s, a second theme made its way from philosophy and literary theory into sociological debates. It was a critique of the status of sociological theory as a modernist product, and it drafted a new methodological program. This debate raised a series of questions about the validity claims of scientific theories, the nature of scientific truth, and the status of the knowing subject, arguing that: (a) all knowledge is contextual and local; (b) the validity claims of any

scientific theory are not to be found in some abstract, universal criteria, but are rather the results of either negotiated consensus or power struggles; and (c) as a consequence, the knowing subject does not dispose of universal criteria to ascertain the validity and truth of his or her knowledge. The subject should not be seen as autonomous with respect to an objective, given world, but rather as the product of social circumstances. Since knowledge has a contextual and local character, it follows that scientific theories are re-interpreted according to local conditions: they are open-ended and cannot be controlled by their authors. Scientific theories are not determined by external validity and truth criteria; they work as systems of symbols enabling certain courses of social action and promoting a certain worldview. On these grounds, there should be a structural similarity between texts and social order: both are locally determined, network-like, open-ended systems of symbols requiring certain kinds of action from the actors embedded in them.

Notions like text and performance should occupy a prominent place in the analysis of social phenomena. Sociology should focus on investigating and describing how symbol systems work in particular social contexts, instead of producing all-encompassing theories. This claim, together with the one that the knowing subject is the product of social circumstances, have sometimes been described in a more radical form as 'the end of sociological theory' and the 'death of the author,' respectively. A corollary of these arguments is that sociological theories should acknowledge the fragmentation and diversity inherent in the local character of knowledge; they should explore their consequences for the world we live in, and should experiment with new modes of representation—like poetry, or dialogical forms. To some extent, these epistemological claims overlap with those of the first strand of postmodernist sociology. However, we encounter an important difference: while the first strand derives the fragmentation, relativization, and diversification of knowledge from social changes, the second one takes them as stemming out of a number of epistemological, universally valid first principles.

At the end of the 1980s and in the early 1990s, such meta-theoretical topics were intensely debated in sociology and, for a short time, even eclipsed the first strand of postmodernism. However, the acceleration of globalization processes brought social analysis to the forefront again.

3. The Methodology of Postmodernist Sociology

One important methodological aspect is the anti-positivist and antiverificationist stance: there is no totalizing explanatory model and no universally valid verification procedure. Postmodernist sociology stresses the role of qualitative methods in the analysis of contemporary social phenomena, as a consequence

of the prominence of visual and linguistic symbols. While some authors (Richardson 1997) emphasize interpretation and subjectivity, others (Lemert 1997) argue that methodology must preserve objectivity and logical consistency. There has been an increased sociological interest for discourse analysis, understood as a cluster of techniques for grasping the emergence, functioning, and context-boundedness of symbolic codes. Ethnographic methods, earlier reserved for the study of 'exotic' societies or of marginal social phenomena, also play an important role. This has increased the interest for texts and writing processes as sources of conceptual enrichment in sociology. Poetry, drama, or dialog are promoted as legitimate complements to the established, academic expository modes. Hybrid forms of sociological expression have appeared too—for example, in works combining academically written texts, poetry, and artwork (Haraway 1997).

4. *Fields of Postmodernist Research*

Postmodernist analyses have been prominent in domains like work and organizations, political action, science and technology, commodification and consumption, gender, media, and popular culture. George Ritzer (1993), for example, has examined the new forms of work which emerge in the knowledge-based, global economy: they are characterized by fragmentation, local specialization, flexibility, and mobility, on the one hand, and by global dispersion and typification, on the other. Under these circumstances, the temporal and spatial conditions of work change substantially: while the lifespan of products shortens, they need to be replaced faster, and worktime expands. Tensions arise between requirements for flexibility and mobility, on the one hand, and typification, on the other. New directions in commodification and consumption complete this picture. Commodification is understood as the unrelentless expansion of market exchange, which reshapes social relationships according to its own logic; the pendant of this process is the increased social significance of the act of consumption. Jean Baudrillard (1972), for example, has argued that symbolic consumption becomes one of the main social mechanisms through which individual and collective identities, as well as social relationships are defined and reproduced.

In political sociology, the analysis has focused on political discourses and symbolisms, on the spectacular form taken by political events, and on the role of television as a medium for political action. Another direction has been to examine the strains put on democracy by the media-induced forms of political action, and by the globalized economy. Authors like Chantal Mouffe (1992) have asked whether the new economic and political conditions do not require devising new forms of democratic participation and of political action.

With knowledge lying at the core of the postmodern society, science has been a domain of sustained investigation. The focus has been on the changes brought about by the new information and biomedical technologies in social life, as well as on the role and effects of complex technological systems. Bruno Latour (1991) and Donna Haraway (1997), among others, have argued that such systems are so pervasive and deep-reaching, and that social life is dependent on them to such an extent that new forms of social symbiosis have emerged; these are described with the help of notions like the cyborg society, hybrids, or networks of human and nonhuman actors. These authors have called for a revision of the conceptual apparatus of sociology on the grounds of the relationships between human actors and technical systems.

A further domain of investigation, situated at the crossroads between feminist and postmodernist sociology, has been that of gender and sexuality. Postmodern diversification brings forth a fragmentation and multiplicity of gender and sexual identities. The distinctions between genders become blurred; some forms of sexual identity formerly considered marginal gain a new significance, and new sexual identities emerge (e.g., transsexuality). Owing to the local and contextual character of knowledge, the gender specificity of knowledge and experience has to be taken into account. Several authors (e.g., Smith 1990) have explored the ways and the implications of gender-specific knowledge in the workplace, the field of politics, popular culture, and the public sphere.

One of the key domains in which the impact of postmodernist sociology has been felt is that of the electronic media and communication. Since the social changes brought about by computers and television have been considerable, questions arise about new, media-induced forms of social life and organization. According to Jean Baudrillard, among others, large portions of the social world are now media generated, and whole series of political and social events have a media-supported existence: they exist as simulacra, as symbolic codes which can be reproduced endlessly, without making recourse to an original. Other domains of investigation have been computers in the workplace, or the media-induced forms of social life, like those arising in and around the Internet (Turkle 1995). Finally, postmodernist sociology has also considerably influenced the subfields of cultural and urban studies, reinvigorating a research tradition which goes back at least to the Chicago School of sociology.

5. *The State of Postmodernist Research*

Postmodernist sociology has been around for approximately three decades; while controversial and contested for some of its more radical theoretical stances, many postmodernist ideas have made inroads into mainstream sociology. At the same time, it has

continued and enriched a series of themes already present in classical sociology—like the sociology of consumption, or the study of popular cultures. It has also pioneered some new domains of research—the study of Internet cultures, of the media, or (together with ethnomethodology) that of the impact of computers. Together with feminist sociology, it has had a considerable influence on the sociology of gender and sexuality. Its empirical, domain-oriented impact has been more significant than that of its pure theoretical tenets.

6. New Research Directions

The cultural forms induced by the electronic media (e.g., the culture of software programmers, of Internet users) have not been studied in depth until now. The changes in consumption patterns and market relationships brought about by the Internet, the rapid rise of popular electronic exchanges, the Internet's role in the globalization processes are topics which await deeper exploration too. It is to be expected that postmodernist sociology will evolve more and more in the direction of empirical, concrete field studies, focusing on these phenomena.

Postmodernism: Methodology

If methodology is defined as referring to the foundations of knowledge, as how we perceive and understand reality, as well as how we study it, then there is not only a single implicit postmodern methodology. There are several. But all challenge the methodological assumptions associated with rigorous, modern social science inquiry, be it qualitative or quantitative (Dickens and Fontana 1994). Indeed, there are serious philosophical differences between postmodernism and the enlightenment norms of traditional science. Some postmodernists are uninterested in generalization, definitive explanation, replication, validity, reliability, etc. Neither prediction nor theory building are a major concern. They look to deconstruction as method. Deconstruction tears a text apart, revealing its contradictions and assumptions. Other postmodernists criticize modern methodology and seek to revise it, to build upon it. They look for alternatives to what they call the old, past, closed conventional social science methods inherited from the natural sciences. But they do so without entirely rejecting reason, consistency and coherence of argument. Although they abandon foundations, they retain what they call preferences.

Many postmodernists see the need for new standards for evaluating knowledge. Their criteria are likely to be subjective in nature, including, for example, flexibility, sensitivity, and interactivity. They look for beauty, strength, or force in a text. Some value elegance of expression and style, and seductiveness of content while others say that such criteria are community specific and so cannot be enumerated. Still other postmodernists willingly employ more direct valuations, such as negation of oppression, exploitation, and domination, or the affirmation of liberation, freedom, insubordination, and resistance as key standards (Rosenau 1992).

1. A Postmodern Methodological Focus

Postmodern methodology focuses on the margins and postmodern social scientists highlight the unique and the unusual. They concentrate on the enigmatic

and appreciate the unrepeatable. They seek to multiply paradox, to invent ever more elaborate repertoires of questions as much as to determine answers. They look to 'differance' (Derrida 1972) rather than sameness, regularity, and synthesis. 'Differance' is a structuring principle that tells us that definition rests not on some inherent characteristics of a thing but rather in terms of its negative and positive references to other texts. It also suggests that in the end, definition is never final, always postponed, deferred forever (Derrida 1981).

Postmodern methodology seems driven by substantive concerns quite different from those modern social scientists focus upon. Postmodernists direct their attention to everyday life and they gravitate toward mininarratives or stories. Postmodern social science is a 'systematic commentary on the knowledge of daily life' (Bauman 1990). This means examining what is assumed to be quite ordinary and attributing a new importance to it. Postmodern social science makes room for the unexpected, the mystical, and the metaphysical. Concepts such as fate and spirituality are, once again, legitimate (Griffin 1988).

1.1 *Linking Substance and Method*

If there is a close association of substance and method, then conventional social science methods are not helpful given the postmodern focus on the margins, the unexpected, the paradoxical, and the unrepeatable. Empirical methods require repeatability so that careful measurement can be carried out and statistical norms met. But the subject matter of interest to postmodernists does not recur necessarily and its very interest may be in the fact that it is transient, constantly in flux, and difficult to capture. Because of their substantive foci, these postmodernists require methods that are open and flexible, rather than highly structured, codified, and technically detailed. They must be adaptable to a great variety of situations because of the range of potential application. There is no easy methodological recipe for doing this type of research.

1.2 *Going Beyond Qualitative Methods*

Postmodernists would reject any argument that their methodology is simply qualitative social science in a different guise. The gamut of modern qualitative approaches developed over the years (from observation to participant observation) retains a preoccupation with generalization and replication as much as an appreciation of complexity. Those employing conventional qualitative methods in social science have invested enormous energy in separating out what is procedurally acceptable from the unqualified. All this is abandoned in the postmodern methodology

that embodies an attitude of humility and respect. It does not try to convince others that its own methodological perspective is right, superior, truthful, objective, the best assessment, or the source of the only correct answer. It does not settle on solutions or give privileged voice to any particular, singular point of view. It does not attribute authority to authorship. It queries and interrogates constantly. It follows its own advice: no new metanarrative. A metanarrative is a global worldview, a 'mastercode' that assumes the validity of its own truth claims.

2. *An Upbeat Postmodern Methodology*

What methodological alternatives does postmodernism have to offer vis-à-vis modern social science methodology? It emphasizes personal wisdom, lived experience, and knowledge as rich sources of material that inform writing and research. We are counseled to look to music, art, poetry, and literature instead of census data and public opinion polls. A postmodern social scientist would have more confidence in feelings, faith, empathy, emotion, insight, sensitivity, intuition, imagination, subjective judgment, and introspection as method. Postmodern social scientists are obviously and openly more comfortable with these than with an exclusive confidence in reason and logic. But by praxis, if not discourse, some postmodernists communicate that their alternative methodologies are of most value if disciplined by reason and logic. This amounts to coming to terms with the best of the Enlightenment heritage but without being intimidated by it. It suggests a refusal to accept the authority of modern science but also a desire to salvage from it whatever is of interest, such as the possibility of an interactive and reciprocal relationship between, say, reliable knowledge and meaningful participation in the public sphere, the creation of social life and political action, the enhancement of personal development, self-expression, self-determination and collective praxis (Jennings and Graham 1996). Doing social science might also have to be fun, enjoyable, entertaining rather than somber, listless, and mundane (Bakhtin 1973, Todorov 1984). It would not seek to demonstrate the obvious so much as to highlight the overlooked and the unrecognized.

2.1 *Methodology as Art and Literature*

Postmodern social science is often viewed as vision and art more than trained observation. It disperses any clear distinction between self and other; fact and values; author, text, and reader. It is inspired by the cultural and contextual preoccupations of anthropology where the distinction between literature and

science was never clearly established. Anthropology had to be content with differing 'evocative devices of metaphor and imagery' because it was so difficult to arbitrate between different narratives from the past (Richardson 1988). Postmodern social science methodology centers on 'listening to,' and 'talking with' the other (Tyler 1986). The reader 'writes' the postmodern text and in so doing postmodern social science gives voice to those previously silent. It empowers through the methods of interpretation and criticism.

Postmodern methodology employs a literary capacity and it re-invigorates the mininarrative as a story that is worthy of notice even if it is not necessarily true in the modern sense of science. Storytelling is both a method and a means to emancipatory power (Newman and Holzman 1999). The need to reconcile various stories, narratives or research findings may or may not be urgent. The postmodernism tolerance for diversity and its indulgence of discrepancy reflect the fact that there is no rush to create, to construct, to accumulate, and to impose new knowledge in the modern sense.

2.2 Methodology as Interpretation

Postmodern methodology is interpretive but postmodern interpretation bears but slight resemblance to the more conventional social science forms of interpretation. Modern social science understands interpretation to be the careful consideration of data with the goal of locating patterns. Meaning is not arbitrary and some interpretations are assumed to be better than others. But neither does postmodernism resemble hermeneutic interpretation that is more subjective and less ambitious than modern social science's interpretation. Hermeneutic interpretation, unlike postmodern interpretation, seeks to probe the 'silences,' to uncover a deeper meaning, masked and hidden perhaps, but waiting to be discovered (Dreyfus and Rabinow 1983, Madison 1988). There is a current within postmodernism that says there simply is no 'meaning' to uncover. In many ways hermeneutic interpretation accepts truth, universality, and a shared discourse (a community of understanding).

Postmodern interpretation is *introspective*, *intersubjective*, and *anti-objectivist*, a form of individualized understanding. Postmodern theories of interpretation no longer 'ground,' they rather 'mediate' (Kugler 1988). They range from 'interpretative reason' (Bauman 1990) to prayer and chanting as 'interpretative communication.'

2.3 Methodology for a Complex Intertextual World

Postmodernists see the world as so complex that any direct causal statements relating to reality would

necessarily be simplistic. They argue that it is impossible to establish temporal priority in a simple fashion. They similarly are suspicious of modern versions of time that clearly delineate the past from the present, and include a strict version of linear time or geography. Their preference is for a present-oriented social science that erases linear time and ignores strictly bounded forms of geography. Their analysis emphasizes postmodern intertextuality, including, for example, chaos theory with its view of nonlinear social dynamics, and a definitely more complex version of reality (Young 1992).

If the social universe for these postmodernists is intertextual, this has an impact on their methodology. Relationships, interconnections, and interactions are areas of substantial interest. Conventional research tools are hardly appropriate. Quantitative methods isolate and simplify what is being studied, holding as many extraneous variables as possible constant so as to tease out causal, predictive associations. These postmodernists seek methodologies that integrate what is being studied with all that is related to it even if this complicates the research task, because in the end explanation in any absolute sense may be impossible.

2.4 Relativism and Questioning Postmodernists

Postmodernism is plagued, because of its European philosophical precursors, with the charge of relativism (Gellner 1992) but many postmodernists defy this heritage and reject relativism. This is especially true for the postmodernists who come from a philosophically committed heritage: Marxism, feminism, environmentalism, peace movements, ecology groups, and religious studies (Griffin 1988, 1990, Kumar 1995, Leonard 1997). This leads them to argue that while deconstruction is an interesting first step to a postmodern methodology, it is limited because its goal is to undo all constructions. Deconstruction's intent is not to improve, revise, or offer a better version of the text, so they reject it. Postmodernism, in this view, must ultimately move to reconstruction and by extension, methodology remains essential.

3. Methodology Defined Narrowly

If methodology is defined narrowly as the rules and regulations of inquiry, then postmodernists must question the whole undertaking, arguing that there is no such thing as a post-modern methodology. 'Rules,' as such, are modern, not postmodern in character because they imply hierarchy, a series of good-bad evaluative criteria, an assessment on the basis of a set of agreed upon standards. Postmodernists reject rule-bound approaches as 'metanarratives.' Critics of

postmodernism, however, respond that the absence of rules is itself a rule, the rule that 'anything goes' (Feyerabend 1975, Heller 1987) and that there is, thus, a postmodern methodology.

4. Rejecting Methodology Altogether

Postmodernists, inspired by Heidegger and Nietzsche, are antiscience and anti-Enlightenment, and this leads to an absolute relativism and to methodological nihilism. This postmodern orientation emphasizes the hopelessness and meaninglessness of life; theirs is the pessimistic, dark side of postmodernism (Rosenau 1992).

Some such postmodernists practice epistemological impossibilism. They do not intend to provide 'clear reasoned defense.' They tell us their texts offer 'no consistent argument' and that 'not all points made are "necessary."' They boast that by design 'some essential matters are forgotten' (Corlett 1989). To insist that these postmodernists develop a self-conscious methodology is to 'do violence' to their views, to impose one's own perspective, and thus diminish them by forcing them to acknowledge your views (Ashley and Walker 1990a, 1990b, Lyotard 1988). In the end, from this postmodernist methodological perspective, we can never really know anything, not even our own feelings and emotions. These postmodernists speak of the death of the author (as agent) and of the absence of the subject (as a real person) with a specific identity. This means that they escape agency, accountability, and responsibility. They deny causality, question efforts to represent reality (through social science theory), and they contend that all interpretations are equally interesting (Miller 1981).

All textual meaning, all interpretation, is undecidable within this postmodern perspective, because there is no final sense of a text and everything is a text in this postmodern world. No interpretation can be regarded as superior to any other (Latour 1988). There is a multiplicity of readings and these postmodernists refuse to privilege one statement over another. 'Every understanding is a misunderstanding' (Culler 1982, Norris 1988). Within this intellectual framework there is no need to bother about methodology at all.

5. Conclusion

Postmodern methodologies will be judged in the long term by their product. In the arts and literature, postmodern methods can be fascinating, challenging, and interesting. They stimulate creativity and innovation as exemplified by the writings of Umberto Eco, Italo Calvino, Milorad Pavic, and Salman Rushdie. They dissolve the boundary between fiction and social critique as the works of Jean Baudrillard and Michel

Foucault so well illustrate. The fruitfulness of postmodern methodologies in the applied social sciences is yet to be demonstrated. Many feel them to be seriously flawed and epistemologically dubious. Post-modern methods contributed little toward the solution of the greatest social problems of the twentieth century. But then, that is not what they set out to do; it was never the intent.

P. V. Rosenau

Postmodernism: Philosophical Aspects

'Postmodernism' is a term that defies simple definition. Although earlier uses are recorded, the term has been widely used since the 1960s to refer to a range of antimodernist attitudes and strategies in art criticism, architecture, and literary criticism. References to postmodernism in philosophy and social theory did not become common before they appeared in the work of Lyotard and Rorty during the early 1980s. Philosophical postmodernism quickly became associated with the idea of a 'crisis' in representation, abandonment of the belief in a universal subject of reason and value, and the rejection of unitary schemas of progress inherited from the Enlightenment. In place of these foundational motifs of modern thought, postmodernism emphasized difference, diversity and irreducible conflict in human affairs rather than unity and the possibility of harmony.

There are several reasons why postmodernism should be 'a particularly unstable concept' (Bertens 1995, p. 12). First, the concept of postmodernism stands in a variety of complex relations to other concepts such as modernism, poststructuralism, deconstructionism, modernity and postmodernity. Since

the meaning of these concepts is equally uncertain, so our understanding of 'postmodernism' will be affected by the particular meaning attached to these related concepts. Second, to the extent that postmodernism is considered a cultural movement alongside others such as romanticism, positivism, or structuralism, then it too will encompass a variety of distinct aesthetic and intellectual strategies. Bertens' *The Idea of Postmodernism: a History* begins with illustrations of the sometimes contradictory ways in which the term has been employed. For example, by 1970 modern painting had long abandoned the idea that representation or narrative were essential to its art. In explicit reaction against modernism understood as the self-reflexive exploration of the formal possibilities of painting, postmodern painting involved a reprise of representation and narrative. In a similar fashion, postmodern architecture rejected the formalism of the postwar International style and embraced historical and vernacular styles. By contrast, at least in some of its manifestations, literary postmodernism involved a move in the opposite direction away from narrative and representation towards a form of radical self-reflexivity. Bertens concludes that, depending on the artistic discipline, 'postmodernism is either a radicalization of the self-reflexive moment within modernism, a turning away from narrative and representation, or an explicit return to narrative and representation. And sometimes it is both' (Bertens, 1995, p. 5). In view of the many different phenomena to which it has been applied, it is common for discussions of postmodernism, to begin, as this one has, with the claim that the term has no clear meaning (Eco 1985, p. 65, Rorty 1999, p. 262).

1. Modernity/Modernism

Just as modernism is often regarded as a response to the process of modernization which transformed the material conditions of European society during the nineteenth century, so postmodernism is often presented as a consequence of the restructuring of capitalism at the end of the twentieth century. The historical period of modernity which extends from the middle of the eighteenth through to the middle of the twentieth century saw the development of industrial capitalist infrastructure and means of production such as railways, automobiles, air transport, electricity, and telegraphic and telephonic communication. It also saw the growth and modernization of cities, the spread of public schools, hospitals, and prisons, and the development of bureaucratic and rational procedures for the government of social life. 'Modernism' is commonly used to refer to an artistic sensibility which embraced innovation and change. In its early stages, modernism involved a positive sense of living at the dawn of a new era. To be modern implied an heroic commitment to action and to revolutionizing oneself

as well as the means of artistic production, hence the dynamic of successive avant-gardes in the particular arts. During the latter part of the nineteenth and the early years of the twentieth century, modernism meant experimentation with the style and form of the various arts.

Theorists of postmodernity assert a parallel connection between the changes associated with the restructuring and globalization of late capitalism and the emergence of a postmodern culture. Two of the leading theorists, Fredric Jameson and David Harvey, argue that changes in technology, urban space, and forms of consumption have created the conditions of a new mode of experience of self and others (Jameson 1991, Harvey 1989). In particular, they argue that the 'compression' of social space and time which results from new electronic and communications technologies is reflected in a new cultural sensibility. Moreover, just as the modernist commitment to the destruction of traditional ways of life and thought was often linked to a tragic sense of loss, so some theorists of postmodernity argue that a similar kind of homelessness is generated by the late twentieth century mutations in our experience of space and time. Jameson is among those who take a negative view of the cultural experience of postmodernity on the grounds that it does not sustain a sufficiently robust sense of self and history. He argues that the rapid evolution of postmodern urban space has overtaken 'the capacities of the individual human body to locate itself, to organize its immediate surroundings perceptually, and cognitively to map its position in a mappable external world' (Jameson 1991, p. 83). On his account, postmodernity is experienced as incapacity in the face of complex and discontinuous social spaces and as disorientation in the absence of a rich sense of the past or future. The result is a widely documented fragmentary and schizophrenic experience of subjectivity, along with a tendency towards affectless repetition or 'blank parody' of past forms of artistic and cultural production.

For others, modernist and postmodernist alike, the appropriate affective response to change is much less one of nostalgia for older ways of being at home and more a question of orientation towards the future. Nietzsche, who is in many respects the source of much postmodern philosophy, took the condition of 'homelessness' as a metaphor for the condition of those, like himself, who looked forward to 'the strengthening and enhancement of the human type': 'We children of the future, how *could* we be at home in this today?' (Nietzsche 1974, p. 338). In their efforts to make positive sense of the experience of being estranged from the social world in which they must live, postmodernists often have recourse to the concept of irony. Richard Rorty calls ironists those who are conscious of the contingency and mutability of the 'final vocabularies' employed to make sense of their lives, yet nonetheless committed to the values which

those vocabularies embody (Rorty 1989, p. 73). Umberto Eco argues that the postmodern attitude is encapsulated in the irony which acts and speaks in full awareness of the degree to which all our ways of acting and speaking involve repetition of the past: 'the postmodern reply to the modern consists of recognizing that the past, since it cannot really be destroyed, because its destruction leads to silence, must be revisited, but with irony, not innocently' (Eco 1985, p. 67).

While postmodernism is supposed to involve rejection of the presuppositions of modern art, philosophy, and social theory, commentators and users of the term hesitate over whether postmodernism is primarily a temporal or a typological concept. The prefix and the manner in which the term has been employed in the arts suggest a temporal reference, even though estimates of the beginning of the postmodern era range from the 1860s to the 1980s. But some theorists of postmodernism in the arts and culture treat it as simply the radicalization of tendencies already present in the modern. In philosophy, Rorty argues that, to the extent that postmodernism stands for anything distinctive, it refers to a pluralism shared by a range of modern thinkers such as Nietzsche and William James (Rorty 1999). In similar fashion, Jean-Francois Lyotard argues that postmodernism in painting stands for an aesthetic of the sublime which embraces the ever-renewed attempt to 'present the unrepresentable' (Lyotard 1983). For these reasons, Eco suggests that postmodernism should not be chronologically defined but rather treated as 'an ideal category—or better still, a *Kunstsollen*, a way of operating. We could say that every period has its own postmodernism, just as every period would have its own mannerism' (Eco 1985, p. 66).

2. Unity and Plurality

A feature of many cultural responses to the transient, fleeting and ephemeral character of modern life is their attachment to ideas of unity, whether in the object to be represented or the artefact to be produced. Thus, for example, modernists believed that a machine or a city could be a unified, smoothly functional object, and a novel or work of art could be a complete, self-contained meaningful entity. Where there is experimentation with diverse modes of representation, this is undertaken in the attempt to convey a single complex and multifaceted reality. And even where there is a dizzying succession of conceptions of the nature of a particular art such as painting, there is nevertheless a conviction at each stage that at last the truth has been found.

Even though 'modernism' does not have the same currency as a classificatory term in philosophy and social theory as it does in the arts, there are epistemological parallels to this modernist attitude towards

unity. Modernist thought would be that which tolerated perspectivism only on the assumption that there is a single, intelligible reality to be presented. Even when there is an acceptance of surface incoherence, as in Marx's account of the contradictions of capitalism or Freud's account of conscious behavior, this is balanced by the discovery of an underlying structure which produces such contradictory effects. In this sense, Harvey argues that modernism 'took on multiple perspectivism and relativism as its epistemology for revealing what it still took to be the true nature of a unified, though complex, underlying reality' (Harvey 1989, p. 30). By contrast, postmodernism is associated with the acceptance of plurality in both ways of being and ways of knowing. In opposition to the ideal of unified objects of knowledge, whether texts or artefacts, postmodernism refers instead to networks, open systems, or the dissemination of meaning. In opposition to the modernist ideal of unified science, postmodernism upholds the idea of irreducible difference and even incommensurability among the varieties of knowledge.

3. Poststructuralism and Postmodernism

Postmodernism coincides with the work of a number of French thinkers who came into prominence at the end of the 1960s, notably Baudrillard, Deleuze, Derrida, Foucault, and Lyotard. By different intellectual paths, these thinkers rejected the idea that theories and concepts simply represent a pre-existing reality. For some, such as Derrida or Baudrillard, this conclusion was reached via a radicalization of Saussurian theses about the arbitrariness of signs and the manner in which their sense is derived from differential relations to other signs. For others, such as Foucault, similar conclusions were reached via Kantian views of the role played by language and thought in the construction of its own objects. A consequence of Foucault's historicization of the Kantian idea that objects of knowledge are determined in part by the underlying rules governing discourse is that 'truth' acquires a history and can no longer be measured solely against an independent reality.

While it is true that the work of Foucault and others does imply a form of historical relativism with regard to truth, it is overstating the case to suggest that the resultant 'crisis in representation' amounts to 'a deeply felt loss of faith in our ability to represent the real, in the widest sense' (Bertens 1995, p. 11). It is not our ability to represent reality but rather what Deleuze calls the representational 'image of thought' that is impugned by poststructuralist epistemology (Deleuze 1994, pp. 129–67). Foremost among the influential philosophical assumptions which make up the representational image of thought is the idea that thought naturally seeks truth. For Rorty, too, what lies at the heart of postmodernism in philosophy is the abandonment of the correspondence theory of truth and

the 'theologicometaphysical belief that Reality and Truth are One—that there is One True Account of How Things Really Are' (Rorty 1999, p. 262). A less negative characterization might say that postmodernism does not so much reject the idea that thought represents reality as embrace more complex views of what representation entails. In this manner, Foucault's genealogies of punishment and sexuality drew attention to the ways in which what passes for truth in the social sciences is bound up with the exercise of power over individuals and populations. More generally, postmodernism has drawn attention to new aspects of social reality, such as the systems of thought and language which condition public discourse. It has also given rise to new kinds of analysis of cultural and social phenomena: genealogical, deconstructive, narratological, and so on. In these ways, postmodernism has given rise to new research methods and new objects of analysis in anthropology, sociology, and other social sciences (Clifford and Marcus 1986, Dickens and Fontana 1994). In addition, postmodernism has been widely taken up in jurisprudence and the philosophy of law, where it has been described as the most influential trend at the end of the twentieth century (Litowitz 1997, p. 1).

4. Universalism and Freedom

One of the most influential formulations of postmodernism in philosophy was that provided in Lyotard's *The Postmodern Condition* (Lyotard 1984), first published in 1979. Here, Lyotard uses 'modern' to refer to any form of knowledge which seeks legitimation by appeal to some 'grand narrative, such as the dialectics of the spirit, the hermeneutics of meaning, the emancipation of the rational or working subject, or the creation of wealth.' He then defines the postmodern attitude as one of 'incredulity towards metanarratives' (Lyotard 1984, pp. 23–4). Lyotard is not concerned in this essay with postmodernity understood as an historical epoch, since his inquiry is limited to 'the condition of knowledge in the most highly developed societies' (Lyotard 1984, pp. 13). Rather, his aim is to show that the supposed transcendent status of scientific knowledge is an illusion sustained by a certain narrative language game. He argues that the privileged status of scientific knowledge is destined to disappear once it is accepted that this status depends upon a narrative which privileges science over other kinds of language game. This narrative of legitimation has either followed the French Enlightenment link between the pursuit of knowledge and human emancipation, or the German Idealist construal of history as the process of the realization of reason through the sciences. Lyotard asserts not only that these 'metanarratives' have lost their appeal but that the very idea of transcendent legitimation has given way to forms of legitimation which are local and immanent in particular social

practices and forms of life. The postmodern condition therefore is the state in which we must accept this plurality of micronarratives and address the conflicts that arise other than through the imposition of a single master narrative.

In *Modernity—An Incomplete Project*, Habermas (1983) provided an influential response to Lyotard and other poststructuralist thinkers. He characterized the philosophical project of modernity as the desire for unification of the three spheres of cultural value distinguished by Kant—the theoretical, the practical, and the aesthetic—and for the application of the results of these distinct kinds of judgment to the improvement of everyday life. According to this view, the project of modernity consisted in the effort of Enlightenment thinkers ‘to develop objective science, universal morality and law, and autonomous art, according to their inner logic. At the same time, this project intended to release the cognitive potentials of each of these domains to set them free from their esoteric forms. The Enlightenment philosophers wanted to utilize this accumulation of specialized culture for the enrichment of everyday life—that is to say for the rational organization of everyday social life’ (Habermas 1983, p. 9). The major obstacle preventing the realization of this project, according to Habermas, lay in the manner in which these spheres have become separated from one another, both institutionally and in their internal logics and forms of argumentation, and in the manner in which they have become increasingly separated from a lifeworld dominated by the instrumental rationality of the theoretical sphere.

Habermas’s solution to this problem appealed to the procedural rationality implicit in language use, or what he calls ‘communicative reason,’ as a means to restoring the possibility of intersubjective consensus. Both his diagnosis and his solution to the problem of modernity are founded upon the Enlightenment belief that universal standards of judgment are necessary for the development of both reason and moral progress. By contrast, postmodern thinkers reject the idea of progress in human affairs in favor of the idea that there are many ways in which the present differs from the past. In common with Lyotard, they reject the idea of universal standards of judgment, value or ‘legitimation.’ Although Habermas characterizes French thinkers such as Foucault, Derrida, and Lyotard as ‘young conservatives’ (Habermas 1983, p. 14), most of them do not wish to abandon the ideals of freedom and emancipation but only the approach which links these to universality, unity, and consensus and does so in the name of the Enlightenment.

In response to Habermas’s criticisms, Foucault presented his practice of genealogy as serving the cause of freedom, while suggesting that it represented a critical ethos or attitude towards the present which had always belonged to the Enlightenment. Genealogical criticism does not seek to identify the universal

structures of human knowledge and moral action, but rather takes the form of an historical investigation into the means by which we have been constructed as certain kinds of subject. Against the presumption that human reason is an unchanging and undivided faculty, Foucault views reason as divided among the distinct rationalities embodied in particular systems of thought and practice such as ‘medicine,’ ‘discipline,’ or ‘sexuality.’ The aim of this type of historical investigation, Foucault suggests, is to determine ‘in what is given to us as universal, necessary, obligatory, what place is occupied by whatever is singular, contingent, and the product of arbitrary constraints’ (Foucault 1984, p. 45). Thus, in contrast to the idea that progress in human freedom depends upon the extension of the sphere in which universal rationality governs social life, Foucault presents progress in human freedom in negative terms as the escape from particular forms of domination. For many poststructuralist theorists, freedom is not linked to the achievement of universal standards of value or to the hope that dissensus will eventually give way to consensus. Rather, it is dissensus and the experience of irreducible difference which are the conditions of freedom and creativity or change in human affairs.

5. *Difference and Multiplicity*

In his later work, Lyotard introduced the concept of the differend in order to characterize the postmodern condition with respect to political and moral judgment as the situation in which conflict between two parties cannot be resolved for lack of a rule of judgment common to both (Lyotard 1988, p. 9). Foucault also described his critical attitude towards the present as one which endorsed differentiation from the past rather than movement towards some future identity (Foucault 1984). However, the recent origins of this concern with difference must be sought in the philosophical work of Deleuze and Derrida published during the 1960s. Both sought to elaborate a non-dialectical concept of difference, which would see it neither as the simple contrary of identity, nor as ‘dialectically’ identical with identity (Descombes 1980, p. 136). Hegel was a focus of their criticism because he represented the culmination of a metaphysical tradition which treated identity as primary and difference as the derivative or secondary term. In *Difference and Repetition*, Deleuze (1994) explicitly rejects the link which Hegel forged between difference and contradiction, arguing that contradiction is not the condition or ground of difference but on the contrary: ‘It is not difference which presupposes opposition but opposition which presupposes difference, and far from resolving difference by tracing it back to a foundation, opposition betrays and distorts it’ (Deleuze 1994, p. 51). Limitation or opposition is a distortion of difference, according to Deleuze, because difference in

itself implies 'a swarm of differences, a pluralism of free, wild or untamed differences' (Deleuze 1994, p. 50). Similarly, in *Of Grammatology*, Derrida (1976) drew upon Heidegger's concept of the ontological difference between being and beings and Saussure's concept of the differentiation which gives rise to units of signification in a sign system to draw attention to the movement of deferral and differentiation (*différance*) which underlies all production of meaning (Derrida 1976, pp. 56–65).

Both Deleuze and Derrida were concerned with the problem of how to conceive of the identity of objects such as meanings, texts or signs which are subject to continuous variation, or how to envisage a form of unity which is not identical with itself. To this end, Derrida relied upon a series of concepts such as *différance*, the trace and iterability, while Deleuze relied upon a concept of open or variable multiplicity derived from Bergson. The concept of multiplicity, he and Guattari suggest, 'was created precisely in order to escape the abstract opposition between the multiple and the one, to escape dialectics, to succeed in conceiving the multiple in the pure state, to cease treating it as a numerical fragment of a lost Unity or Totality or as the organic element of a Unity or Totality yet to come, and instead distinguish between different types of multiplicity' (Deleuze and Guattari 1987, p. 32). In his collaborative work with Guattari (Deleuze and Guattari 1987), the concept of abstract multiplicities provided the formal structure for the elaboration of a series of philosophical concepts of such things as desire, language use, and forms of social organization. Deleuze and Guattari defend their idiosyncratic practice of philosophy as the invention of new concepts in order to bring about new ways of speaking and acting.

A distinction is often drawn between 'postmodern' theorists, such as Deleuze–Guattari, Derrida, and Foucault, and theorists of postmodernity such as Jameson and Harvey. The theorists of postmodernity tend to adopt a broadly Marxist approach to society and culture, and to the cultural phenomena they see as representative of the social totality, in order to pass judgment. Their 'modernist' social theory presupposes that a total picture is possible and that cultural phenomena can be understood as effects of a certain economic 'logic.' They proceed on the assumption that critical distance is possible and that an appropriate interpretative framework will provide such distance. By contrast, the 'postmodern' theorists tend to abandon economic or other forms of historical determinism, along with the idea that a totalizing theory of society and history is possible or desirable, in favor of the idea of multiple, overlapping, and divergent histories written from the distinctive perspective of particular social groups, peoples, or interpretative frameworks (power, desire, the body, etc.). This distinction is not absolute, since there are those such as Baudrillard, Foucault, and Lyotard who might be

included in both camps although at different stages of their careers. However, it is characteristic of post-modern theorists that their work involves a self-conscious attempt to theorize in a different manner, while also searching for critical strategies which do not rely upon a normative standpoint outside or apart from the object of criticism.

6. *Simulacra and Simulation*

Philosophies which seek to make difference an object of affirmation must do more than reverse the traditional hierarchy between identity and difference. The mere inversion of hierarchy does not change the fundamental relation between the elements involved, nor does it change the nature of those elements. For this reason, Derrida's practice of deconstructive philosophy always envisaged a further stage after the initial hierarchy has been overturned which would involve 'the irruptive emergence of a new "concept," a concept that can no longer be, and never could be, included in the previous regime' (Derrida 1981, p. 42). In the course of his essays he produced or drew attention to a series of such paradoxical concepts, including the trace, writing-in-general, metaphoricity, and Plato's *pharmakon*, all of which served to disrupt conceptual oppositions and hierarchies in philosophy. Similarly in *Plato and The Simulacrum* (Deleuze 1990, pp. 253–66), Deleuze argued that the concept of simulacra served to undermine or 'overturn' the primacy of identity as this was embodied in Plato's conception of a model or form of which reality is only an imperfect copy.

However, it was the sociologist Jean Baudrillard who took up the concept of simulacra and applied it to aspects of everyday life. In his earlier work, Baudrillard had argued that industrial society at the end of twentieth century had entered a new phase in which consumption rather than production served to structure social relations. He argued that the Marxian view of commodities as useful items produced in order to realize exchange value must be replaced by a semiotically informed view of commodities as signs, produced in order to realize their 'sign value' as differential elements of a social code of signification. In a series of essays published during the early 1980s, Baudrillard built upon this analysis and other accounts of the power of mass media to argue that society had entered a new era in which simulation had replaced representation as the dominant principle of signification. The essays translated in *Simulations* (Baudrillard 1983) combined a Nietzschean inspired critique of metaphysics with a descriptive account of the present stage of social life as a regime of simulacra in which the distinction between reality and the forms of its representation has broken down.

According to Baudrillard, there are many areas of social life, such as the media, where signs or other

representations do not faithfully represent a prior reality but function in its stead. For practical purposes we live in a hyper-real social world of representations without referents, images without originals. The proliferation of media transmitted information and the speed with which it circulates creates a perpetual cultural present in which contemporary society has begun to lose its capacity to retain its own past.

7. Criticism Without Foundations

While critics object to the nihilistic, impressionistic and highly selective nature of Baudrillard's descriptions, his analyses of technological, media, and political events as simulations served to draw attention to this pathological feature of the experience of social reality at the end of the twentieth century. His essays have been criticized for their failure to provide any stable foundation for criticism. However, Baudrillard openly acknowledges their ironic and hyperbolic style, describing them as 'theory-fictions' intended to provoke and to challenge contemporary common sense rather than convince by evidence or argumentation. Such a provocative function is often invoked in defense of postmodern theory. At best, it is argued, postmodern approaches serve to problematize established concepts and to draw attention to ways in which traditional universalist and humanist assumptions function to exclude or marginalize differences.

Postmodern theory is also criticized for its limited and negative approach to normative issues. Critics assert that the anti-universalism of Foucault, Lyotard, and others is incapable of providing grounds for moral or political judgment much less comprehensive programs for social reform. Defenders argue that their aim is both more limited and more modest, namely to work on the limits of what it is possible to think or to say and thereby to contribute to the emergence of new norms which may also become bases for judgment. To those who argue that the task of problematizing existing ways of thinking or challenging existing norms is ultimately of limited importance, postmodernists reply that not to do so is to limit the possibilities for thinking and acting differently. For this reason, they argue, the ethos or *Kunstwollen* of postmodernism should be seen as a necessary element of every genuinely critical approach.

Postsocialist Societies

'Postsocialist societies' is the general term for the former socialist countries which are in the course of full or partial restructuring of social life. The problem

of their definition (in many cases as 'postcommunist societies'), which ignores substantial differences in their past, is examined, along with certain common and significant problems that have acquired a specific form in the 'process of transition.'

1. Definition

The term 'postsocialist societies' itself raises a serious problem: societies which were considered (call themselves or identified as) socialist, and which have renounced the 'socialist course of development' since the 1989/90 changes in government, have practically no content of their own. These societies are classified in one and the same group, defined in one and the same way from the perspective of their past—their existence as 'socialist societies'—which they have renounced. On the other hand, this definition from the perspective of their past suggests that they are presumed to be societies in the course of self-identification—seen as transition from totalitarianism to democracy, from centrally planned to market economy—which have embarked on the arduous course towards building civil society.

This raises a serious question of the possible criteria by which a concrete national society would shed its 'postsocialist' label, that is, would have ultimately defined itself and be defined from the perspective of the present rather than of the past. At what stage does the present existence of the respective society provide sufficient grounds for regarding it as a society with sustained development based on values asserted in it (and shared by its citizens)?

Changes in the form of government are a necessary but not a sufficient prerequisite for radical restructuring of social life, for significant and sustainable changes in the concepts of the world, of human relations, and individual actions. That is precisely why the term is 'postsocialist societies' rather than 'postsocialist states'—the form of state government may or may not be socialist, whereas the declared renunciation of the 'socialist course of development' in itself does not free a society of the values, ideas, and expectations accumulated over the years, nor of the established relations and groups, and the very attitudes to and mechanisms of their establishment. At the same time, the course of self-identification of the 'postsocialist societies' is indefinite—their point of departure is known, but one cannot know for sure what they will ultimately become.

Of course, this is a generalization only, since the majority of 'postsocialist societies,' those in Europe, are expected to embrace precisely democratic values, a market economy, and civil society as the pillars of self-identification—most of them have not merely declared this but are making real progress in this respect. They are apparently aware that they will no longer be

labeled as 'postsocialist societies' once they complete the process (already under way with the majority) of accession to the European Union (EU). In other words, for those national societies the criteria of recognition of a completed process of self-identification are the same as the criteria of fully-fledged EU membership, which in itself means that they have already chosen a course of development, that their development is predetermined—all they have to do is attain the ultimate objective. This does not apply to the non-European 'postsocialist societies' such as China, or to many of the ex-Soviet republics (some of which are European in purely geographical terms); nor does it apply to the special case of 'rump' Yugoslavia.

2. Differences from the Past

The term 'postsocialist' creates a false impression of uniformity of the societies in question (even though this definition is indefinite itself) and, respectively, of uniformity in the process of departure from their previous development as socialist. This idea is largely based on the previous term 'socialist societies' which, along with everything else, has the ideological function of hiding or belittling the internal distinctions of the respective 'socialist societies,' as well as of rendering as entirely insignificant, from the perspective of their existence as 'socialist,' the differences in their previous development and the concrete process of their 'transformation' to socialism. They are 'socialist societies,' and all details of the history of their transformation to socialism and of the national specificity of their existence are insignificant. Yet it is precisely those formerly 'insignificant' differences (declared and considered insignificant, but to a large extent also virtually insignificant from the perspective of 'the general line' of development, of the rallying of the respective societies into the 'socialist camp'), which also largely determine the form of renunciation of the 'socialist course of development,' that have become significant accelerators or impediments—generally speaking, significant determiners of the national specificity of the existence of the concrete societies as 'postsocialist,' as well as of the pace and consistency of the transition period, of the ways of reaching national consensus on the parameters of the change, and of the actual concept and definition of 'national consensus.'

Forgetting the history of the formation of a particular nation-state and the way in which it 'embarked on the road to socialist development,' and/or failing to take into consideration the influence of national specificity on the existence of the respective society as socialist, usually results in overemphasizing the impact of international institutions (economic and financial, as well as political) whose actions are guided by economic and geopolitical interests, as well as of the

role of the personality of the respective political leaders (in the concrete 'postsocialist society'). Thus the changes and their pace in 'postsocialist societies' (especially in Europe) prove directly and crucially dependent on 'foreign' interests or the individual abilities of politicians. Consequently, individual/group responsible action proves impossible or, rather, pointless. Even if it were possible, its ineffectiveness is readily justified by counteracting 'external forces' or inactive 'internal factors.'

Social scientists, among others, are accountable for the formation of explanatory models centered on the two above-mentioned variables. In an effort to explain the transition period and its problems, they deviate from their scientific position under pressure from their partisan allegiance; concentrate on the present, 'forgetting' history; resort to biased selection of historical facts to legitimate their interpretation of events; build a macroexplanatory model of transition in general, ignoring national differences; or cite separate facts or data from opinion polls without the historical-theoretical framework requisite for their interpretation.

The production and public presence of such 'explanatory models' of the problems of the transition period, actually generate further tensions in the post-socialist society. First, they are explanatory and deliberately created for the purpose of introducing ultimate clarity among ordinary citizens about current developments; second, they are even more convincing on the strength of their authors' scientific prestige; third, they are qualitatively heterogeneous—rather than just different—interpretations, and at the same time each one of them claims to be the only truthful interpretation. This lopsided way of 'understanding' developments, history, the origin of problems in social life, of events and political actions, proves to be yet another factor (along with political allegiance and social position) that antagonizes individuals and groups.

3. *Present Similarities or Key Problems of Transition*

Two ranges of problems may be identified: problems associated with identity and problems associated with social interaction. Although they are not confined to postsocialist societies only, these problems have acquired special significance and a specific form. They may also be generalized as 'political,' 'economic,' or 'social' from a macrosociological perspective on social reality, on the processes occurring within the latter, and their specific intertwining. The macrosociological perspective proposed here is based on the understanding that the restructuring of a society which has renounced the socialist principles and norms (or, generally speaking, any society in the course of self-identification as something that is qualitatively dif-

ferent) proceeds from the presumption of the major significance of the changes in the ways of thinking and action and is seriously impeded by the continuing effect of previous models of thinking of the world and the others, patterns of behavior, and mutual relations of individuals and groups.

3.1 *Problems of Identity*

These problems concern apparently quite heterogeneous phenomena which, however, are experienced by the individual or group in a similar way as problems of self-identification: from 'nationalism,' which has become indicative of postsocialist societies, to 'unemployment' and 'poverty,' which are rarely treated as problems of identity (defined foremost as social and economic problems).

The preoccupation with national/ethnic identity, which has apparently divided (albeit in quite different ways) the postsocialist societies, stems from two specific features of the ideology upheld in socialist society: national/ethnic specificities within the boundaries of a separate state and between the states from the 'socialist camp' are insignificant—the significant self-identification is 'socialist citizens' (which does not mean that ethnocultural differences have been forgotten within the separate states, or that they never were an undisclosed reason for actual social inequality); the significant difference is directly associated with significant self-identification—the localization of everything 'strange,' 'there,' beyond the 'iron curtain.'

The disintegration of 'the camp' and the fall of 'the wall' dividing the two worlds, inevitably rejecting the validity of significant self-identification and difference, generates the need of 'national' self-identification. Whereas the question 'Who are we?' focuses the attention inwards, on the 'national community' and back in history, on the national community's existence and formation before its 'depersonalization,' the attempt at defining 'us' (who are united within a state) has exposed differences and has led to intolerance and discrimination against different ethnic and/or religious minorities. This process, common to all post-socialist societies, has acquired qualitative specificity (largely determined according to the constitution of the respective 'socialist societies'): from violent disintegration of multinational states (the Soviet Union and Yugoslavia), to the peaceful division of Czechoslovakia, to the more or less conflict-ridden confrontations between 'national majority' and 'ethnic/national minorities' in Bulgaria, Romania, Hungary, and elsewhere. Yet the common problem of emphasizing internal differences (by origin, language, religion) has remained beyond the qualitative specificity: internal differences which are thought to be significantly distinctive of people to the point of their

existence within more or less closed groups, and perception of respective individuals as significantly predetermined by their 'belonging' to those groups. Regardless of the self-perception of the respective individuals, 'the others' ascribe identity to them and treat them (engage in or avoid relations with them) from the perspective of this identity.

The problematic process of identification with European (Western) values unfolds against the background of these 'internal' problems of self-identification and ascription of identity. This process is problematic mainly because of the complex and contradictory combinations of three commonplace ideas: 'We are European,' 'We have had a tragic destiny (not without the involvement of the West), now the West should help us become like them,' 'Once we are admitted to the European Union, we shall become Europeans.' Although the images and expectations underlying the apparently unambiguous images of 'Europe,' 'the West,' 'we are European,' 'we shall become Europeans' are quite different, their focus is arguably on 'become like them,' whereas the principal dimension of the process of 'becoming' is the expected well-being.

This is not accidental. And it is directly associated with another aspect of the identity crisis in post-socialist society—unemployment and poverty. These two related but different problems are doubtless indicative of the scope of the economic crisis, but their personal aspect concerns the deepest layers of individual identity, largely because the status of being unemployed is unfamiliar, virtually absent in the experience of the 'socialist individual,' whereas poverty is a process which individuals who have found themselves in a postsocialist society do not associate with democracy and a market economy.

3.2 Problems of Social Interaction

The change (or, rather, the orientation towards change) in the principles of organization of social life triggers tensions at all levels of social interaction. At the level of the individual, these tensions take the form of a large-scale crisis in human relations. At the level of institutionalized interactions, they are manifested in 'corruption' of significant proportions.

The 'crisis in human relations' could be reworded too—as a moral and a political crisis, as well as a problem of interethnic relations. For the everyday person, however (insofar as we can talk about an everyday person in a world where 'what is taken for granted'—if anything at all—is always questioned), this problem appears as tensions in relations, as a failure to understand the 'other' (or vice versa), avoidance of certain others, isolation of and from strangers, and so forth. That problem covers the whole

range from the closest social environment—family, relatives, friends—to neighbors and colleagues, to functional relationships with anonymous others.

The problem generally defined as a 'crisis in human relations' actually results from the intertwining and superimposing of diverse manifestations and echoes of political, economic and cultural values and other changes on the macrosocial level. The realized opportunity of being different in our political preferences and allegiance, in our economic status, of choosing between different cultural models, of adhering to different values, has inevitably destroyed established models of family, friendly, neighborly, business, and interethnic relations. Yet 'new' models may appear only as a result of a long and complex process of construction, mutual adjustment, and assertion—they are not something that can be borrowed (imported, grafted), or something that becomes valid simply because it is (or appears to be) 'better.'

Similar to nationalism, corruption has become emblematic of postsocialist societies. And just like nationalism, corruption is not an unfamiliar phenomenon in Western societies. Moreover, corruption is an affliction of democratic society insofar as the latter has sufficiently large opportunities for responsible decision making, instead of the strictly prescribed rules for any action which are typical of any totalitarian society and relieve its members of responsibility. Yet the opportunity for responsible decision making is also an opportunity for irresponsible action. In the post-socialist society, the complex and contradictory intertwining of still effective old schemes of control and decision-making, and the deficiency of new norms (both on the institutional level of laws, regulations, ordinances, etc., as well as on the level of individual and group consciousness—role models, values, notions, etc.) turn corruption into an epidemic. The affliction acquires huge proportions due to, *inter alia*, the internally contradictory perception of corruption: on the one hand, it is seen as an inevitable relation in a situation of transition, of reformulating and re-regulating of institutions, social positions, rules, and so forth, which are invisibly present in the social sphere and are manifested in status, security, possessions, and money of those who have effected the replacement; on the other, corruption is embodied in the bribe-taker, insofar as bribe-takers are those who have rare resources, by rule of power, which many other persons would like to use. However, the bribe-giver is simply one of many: bribe-givers do not control the 'rules' of replacement, the way of negotiations, the size of the bribe to the bribe-taker, they are simply 'this person' who has happened to be in this position and, in this sense, anyone may end up in this position. Thus the bribe-taker is regarded as an irresponsible power-holder and the bribe-giver as 'any one of us' forced by the circumstances, and therefore not responsible for their involvement in relations of corruption.

Post-traumatic Stress Disorder

1. Introduction

Psychological responses to the experience of traumatic events have long been recognized, although the meaning attached to and the terms used to describe such

reactions have varied over the years, and continue to do so, influenced by the prevailing beliefs and interests of the time and depending on the culture studied. 'Post-traumatic stress disorder' (PTSD) is the term now given, at least in Western psychiatry, to a constellation of symptoms which may follow exposure to a traumatic event, and which cause clinically significant distress or impairment in social, occupational, or other important areas of functioning. The word 'trauma' is derived from ancient Greek surgical terminology, meaning an injury stemming from penetration of the body defense (intactness) such as skin. Exposure to major trauma does not cause psychiatric disorder in all those who experience it, possibly due, at least in part, to differences in vulnerability and resilience. The concept of PTSD has been extended from adults to include children, although it is still uncertain to what extent the developmental status of the child influences the symptoms (Scheeringa et al. 1995). The child's perception of its family's reaction to a disaster may also be relevant.

Unfortunately, the recent burgeoning of interest in PTSD has perhaps given some the idea that PTSD is the only response after trauma. This is not the case (see Udwin 1993 for a discussion regarding children). It should be emphasized at the outset that PTSD is only one of a number of possible psychological sequelae of traumatic experiences, and the concept is not without its critics.

2. History

Early descriptions of the reactions of individuals and societies during the pre-Christian period, including the Sumerian, Hebrew, and Ancient Greek eras, are described by Boehnlein and Kinzie (1992). More recent examples which have been described include the response of Samuel Pepys, as described in his diary after the Great Fire of London in 1666. Pepys wrote of his 'dreams of the fire and falling down of houses,' and even six months later described how he was unable to sleep 'without great terrors of fire' (Daly 1983). Charles Dickens, the English novelist, was involved in a railway accident in June 1865, and also helped in rescuing others. He subsequently became anxious about travelling, and wrote, 'I am not quite right within, but believe it to be an effect of the railway shaking' (Trimble 1984). Two years after the accident, he was still experiencing 'sudden vague rushes of terror' (Ackroyd 1999).

The development of the railways stimulated interest in the psychological responses to traumatic events. Doctors at that time noted that there were many victims of railway accidents who appeared to suffer no physical injury and yet who complained of a variety of symptoms. Indeed, the term 'compensation neurosis' was introduced in 1879 following the increase in

invalidism reported after railway accidents. Some argued that post-traumatic symptoms were the result of physical damage to the nervous system following relatively mild trauma. John Eric Erichsen, a professor of surgery at University College Hospital, London, used the term 'railway spine' to describe such injuries. A contrary view was taken by others. Herbert Page, a London surgeon, proposed in 1885 that accident victims were suffering from 'nervous shock,' attributable to a functional (psychological) disturbance rather than physical injury. Jean-Martin Charcot, a Parisian neurologist, supported the psychological model, arguing that the syndrome of 'railway spine' was a form of hysteria. He believed that, in the immediate aftermath of an accident, the victims were in a suggestible state and that their own idea of physical injuries influenced the development of symptoms. Charcot, in turn, influenced Sigmund Freud, who later suggested that the physical symptoms of hysteria were due to the repressed memories of traumatic events. The development (in many countries) of workmen's compensation acts, which provided for financial compensation to those injured during the course of work, also led to increased interest in the psychological effects of traumatic experiences (Trimble 1984).

A major influence on the development of the concept of PTSD has been war. The belief that the psychological responses to traumatic experiences were the result of physical injury or dysfunction of the central nervous system was strongly held and represented in the concept of 'shell-shock' which prevailed during the First World War in Europe. During the First World War, the British Army reported that seven to ten percent of the officers and three to four percent of the other ranks suffered 'mental breakdowns' (Gersons and Carlier 1992). Some soldiers were treated as cowards and deserters, and punished. The number of death sentences passed was 3,500, of which approximately 282 were executed prior to 1917. However, many more were considered ill and in need of treatment (Deahl 1997). Some, such as the Scottish doctor, William Rivers, saw the problem as a psychological one, and tried psychological techniques, such as abreaction and catharsis, as well as simply letting the person talk about their traumas. Rivers held that repression explained how an individual suppressed painful and terrifying experiences, and that these later became converted into physical and mental symptoms. World War II also produced large numbers of psychiatric casualties, despite more stringent recruit selection. Mental disorder accounted for 31 percent of medical discharges from the British Army.

After wars, increased rates of mental illness have been reported in service veterans who have seen combat. For example, between 1964 and 1975, 3.14 million US servicemen and women served in the war in Vietnam. Approximately 58,000 died and 300,000 were wounded. Of combatants, 20 percent witnessed

atrocities or abusive violence. It has since been estimated that, of all US Vietnam veterans, approximately 15 percent (450,000) currently suffer from PTSD, whilst an additional 11.1 percent of male and 7.8 percent of female veterans suffer at least some symptoms of traumatic stress related to the experience in Vietnam (see Deahl 1997 for a review).

Psychological sequelae in both adults and children, including PTSD, have now been reported after a wide variety of traumatic events, such as a fire in a nightclub in Boston (Lindemann 1944), and, more recently, after a variety of both human-made and natural disasters, kidnapping, torture, and road traffic accidents, as well as in rape victims, after abuse, in refugees, after domestic violence, and even after childbirth. Epidemiological studies suggest that PTSD or subthreshold PTSD may be present in a significant proportion of a population, although it may not be recognized as such. Comorbidity may be present.

3. Classification

Attempts have been made to categorize responses to traumatic experiences. Publication of the first edition of the *Diagnostic and Statistical Manual of Mental Disorders (DSM-I)* (American Psychiatric Association 1952) coincided with the Korean war, and included the categories of 'gross stress reactions' and 'anxiety neurosis/transient situational disturbance' with reference to 'response to overwhelming environmental stress.' The second edition (*DSM-II*) (American Psychiatric Association 1968), which developed during a period of relative global peace, eliminated the diagnostic category of gross stress reaction.

In 1980, diagnostic criteria for PTSD were described in the third edition of the *Diagnostic and Statistical Manual of Mental Disorders (DSM-III)* (American Psychiatric Association 1980). These criteria were based on information obtained from Vietnam veterans, and probably also reflected the experience of Holocaust concentration-camp survivors from World War II. The diagnostic criteria were modified in the revised edition (*DSM-III-R*) published in 1987. There was increasing emphasis on avoidance phenomena. It was acknowledged that children may be affected, that 'survivor guilt' was not a primary feature, and that symbolic reminders of the trauma may be important.

Meanwhile, in Europe, the ninth revision of the *International Classification of Diseases (ICD-9)* (World Health Organization [WHO] 1978) incorporated the subcategories of 'acute reaction to stress' and 'adjustment reaction' following exposure to acute stress. Acute reaction to stress described transient responses to exceptional physical or mental stress, lasting only a few hours to a few days. Adjustment reactions were longer lasting, but usually lasted only a few months.

The diagnostic criteria are presently defined in the *Diagnostic and Statistical Manual of Mental Disorders*

(*DSM-IV*), published by the American Psychiatric Association in 1994, and *The ICD-10 Classification of Mental and Behavioural Disorders*, published by the World Health Organization in 1992. There is also the publication *The ICD-10 Diagnostic Criteria for Research* (World Health Organization 1993). According to *ICD-10*, PTSD is a delayed and/or protracted response to a stressful event or situation (either short- or long-lasting) of an exceptionally threatening or catastrophic nature (including serious accident). Typical symptoms include episodes of repeated reliving of the trauma in intrusive memories or dreams, a sense of numbness and emotional blunting, with feelings of detachment from other people, inability to enjoy activities, and avoidance of activities and situations reminiscent of the trauma. Other symptoms, such as hyperarousal of the autonomic nervous system, hypervigilance, an enhanced startle reaction, difficulty sleeping, anxiety, and depression may also be present. The *ICD-10 Diagnostic Criteria for Research* are similar, but specify that there must be persistent remembering or 'reliving' of the stressor in intrusive 'flashbacks,' vivid memories, or recurring dreams, or in experiencing distress when exposed to circumstances resembling or associated with the stressor. In addition, for the diagnosis of PTSD to be made using these criteria, there should be an actual or preferred avoidance of circumstances which resemble or are associated with the stressor, which was not present before exposure to the stressor, and either an inability to recall, either partially or completely, some important aspects of the period of exposure to the stressor, or persistent symptoms of increased psychological sensitivity and arousal (not present before exposure to the stressor), as shown by any two of the following—difficulty sleeping, difficulty concentrating, irritability or outbursts of anger, hypervigilance, or an exaggerated startle reaction. These symptoms should have started within six months of the stressor.

According to *DSM-IV*, PTSD occurs after a traumatic event in which the person experienced, witnessed, or was confronted with an event or events that involved actual or threatened death or serious injury, or a threat to the physical integrity of self or others. The person's response should have involved intense fear, helplessness, or horror. For the diagnosis of PTSD, the individual should be persistently re-experiencing the traumatic event, such as experiencing recurrent and intrusive distressing recollections of the event (which, in children, may be manifest in repetitive play in which themes or aspects of the trauma are expressed), having recurrent distressing dreams of the event (in children, the content of the dreams may be less recognizable), acting or feeling as if the traumatic event were recurring, experiencing intense psychological distress at exposure to internal or external cues that symbolize or resemble an aspect of the traumatic event, or experiencing physiological reactivity on exposure to internal or external cues that symbolize or

resemble an aspect of the traumatic event. There should be evidence of persistent avoidance of stimuli associated with the trauma and numbing of general responsiveness (not present before the trauma), as indicated by three (or more) of the following: efforts to avoid thoughts, feelings, or conversations associated with the trauma, efforts to avoid activities, places, or people that arouse recollections of the trauma, an inability to recall an important aspect of the trauma, markedly diminished interest or participation in significant activities, a feeling of detachment or estrangement from others, a restricted range of emotions, a sense of a foreshortened future. There should also be at least two persistent symptoms of increased arousal (not present before the trauma), such as difficulty falling or staying asleep, irritability or outbursts of anger, difficulty concentrating, hypervigilance, an exaggerated startle response. These symptoms should have lasted more than one month and be causing clinically significant distress or impairment in social, occupational, or other important areas of functioning. 'Delayed-onset' PTSD may be seen where a person initially appears to have dealt with a traumatic experience but, perhaps years later, symptoms of PTSD develop, possibly after a reminder of the original trauma or after a relatively trivial incident.

While diagnostic classification systems are useful, they are not a checklist, and clinical judgment is considered essential in their use. Criteria are not 'written in stone' but evolve in the light of clinical experience and information from research. For example, there is ongoing discussion about the validity of the 'stressor criterion,' since PTSD may occur after seemingly minor accidents. It seems likely that, in the future, there will be attempts to eliminate as many differences as possible between the ICD and DSM systems of classification (see *Nosology in Psychiatry*).

4. Theoretical Models

The concept of PTSD has been accompanied by a variety of theoretical models (neuropsychiatric, psychoanalytical, cognitive-behavioral) to explain its origins and maintenance in the traumatized individual. For example, a number of psychobiological findings in PTSD, such as altered autonomic function and alterations in the hypothalamic-pituitary-adrenal axis, and studies of endogenous opioids (such as enkephalins) may be relevant (see *Endocrinology and Psychiatry*). Psychoanalytic models include those which regard the re-experiencing phenomena as primary, leading to defensive functioning, and those which regard the reaction to the stressor as a failure of adaptation. Common to all dynamic models is a concern with the meaning a person gives to a traumatic event and/or its aftermath. Behavioral models of PTSD have used the principles of conditioning theory to explain the development and maintenance of PTSD,

while cognitive models of PTSD have included the concepts of learned helplessness, the attributional style of individuals, cognitive appraisal, and, more recently cognitive-processing theory. However, no single model offers a comprehensive view of PTSD. It has also been suggested that an understanding of memory may assist in the understanding of the phenomenology of responses seen after traumatic events. It is to be hoped that a clearer understanding of the origins of PTSD will help in the development of effective therapeutic techniques.

5. Assessment

There are a number of questionnaires or scales which may be used to help assess the psychological responses of traumatic events. Davidson et al. (1997) describe a 17-item self-rating scale for PTSD, which measures each *DSM-IV* symptom on five-point frequency and severity scales. Costello et al. (1998) have described a new measure of life events and PTSD for children and adolescents aged nine to seventeen years, for use in both epidemiological and clinical studies. One of the most widely used questionnaires in either research into, or clinical work on, the psychological sequelae of traumatic events, is the Horowitz Impact of Event Scale (Horowitz et al. 1979). This is a 15-item self-rating scale with two subscales: intrusion and avoidance. It is normally used to assess the response after a single traumatic event, rather than after exposure to a chronic stressful situation. It gives a subjective estimate of the frequency of intrusive recall of the traumatic event and of attempts to avoid such recall, and thus a measure of psychological disturbance when compared to normative data. It does not include questions about physiological reactivity and cannot, therefore, be used to make any diagnosis. It was not originally designed for use with children but has been shown to be useful in those aged eight years and over. A score of 20 or above is often considered to be a cause for concern for civilians in peacetime, although others have used a score of 30 or above to indicate significant post-traumatic stress.

6. Treatment

A variety of approaches are presently used, both in adults and in children. In adults, behavioral and cognitive approaches have been increasingly used over the past 15 years or so, usually involving exposure (either real-life or imagined), cognitive therapy, or anxiety management training. Clinically, exposure and cognitive restructuring are often included in an anxiety management program. Psychotherapy may be individual, group, or with a family. A further technique, 'eye movement desensitization and reprocessing' (EMDR), may be a useful therapeutic technique, but its value and the mechanism of any effects that it has

require further elucidation. There is little evidence that drug treatments have a central role in the treatment of PTSD.

The emphasis when treating children has been on cognitive behavioral approaches that aim to help survivors of a traumatic event make sense of what has happened and to master their feelings of anxiety and helplessness. Sometimes support may be appropriately offered in groups. Since children live with adults, whose reactions to events are part of the context of that event for the child, most treatment plans for children should involve both families and schools. This may be especially relevant when the adults have themselves experienced the traumatic event. Distress in the adults may mean that they are less able to recognize distress in the children for whom they have responsibility, or that they are relatively unavailable to respond to the children's needs (see *Child and Adolescent Psychiatry, Principles of*).

Further research is needed to evaluate the effectiveness of the differing therapies and also to determine the effectiveness of screening populations at high risk of PTSD (for example, after a major disaster) to find out whether any interventions may prevent the development of PTSD or other psychiatric morbidity in those identified as being especially at risk. However, there is no clear evidence that offering counseling routinely to all survivors of traumatic events is helpful—indeed, there is some suggestion that it may be harmful (Wessely et al. 2000).

7. Areas of Controversy

PTSD is an evolving concept. There has been continuing debate on whether individual, as opposed to stressor characteristics, are decisive in the development of PTSD. It may be inappropriate to use a single medical concept to describe the responses seen after different traumatic experiences. Distress after the experience of traumatic events has been variously interpreted in the past. The current emphasis on the 'medicalization of distress' in Western cultures may, perhaps, reflect the prevailing expectations of that society and culture. It is still unclear whether it is appropriate to use a concept which has developed in Western psychiatry to other cultures, and how appropriate it is to extend the concept to describe the responses seen after a wide range of traumatic events. The present classifications assume a dichotomous rule—disorder is either present or absent, with no opportunity to consider severity.

An important consequence of the diagnostic category of PTSD is that it has facilitated, and perhaps encouraged, claims for compensation after traumatic events. Clinicians undertaking forensic assessments are advised that diagnostic criteria are clinical guidelines, and that there may be an imperfect fit between questions of ultimate concern to the law and information contained in a clinical diagnosis.

8. Conclusions

The concept of PTSD is an evolving one, of uncertain value, and it seems likely that there will be further developments and refinements in our understanding of individual responses to traumatic events, and how best to describe and classify them. The importance of developmental influences, the significance of symptoms in differing cultures, and the risk and protective mechanisms involved require further attention.

Potlatch in Anthropology

'Potlatch' refers to a ceremonial exchange complex of aboriginal peoples of the Northwest Coast of North America. Originating in precontact practices, the potlatch evolved in the nineteenth century into a quasicommercial system of acquiring prestige through large gifts—and occasionally destruction—of native and trade goods. Among the Kwakiutl of Vancouver Island and neighboring groups, the potlatch came to include a supplemental economy of loans and interest, allowing for prestations so large that they beggared the host. This extreme form, appearing between roughly 1870 and 1930, earned it a central place in the ethnographic imagination.

1. History and Origins

1.1 Precontact Trade and Ceremonial Exchange

'Potlatch' derives from the Chinook jargon word *patshatl*, to give. Chinook jargon was a trade language centered in the Columbia River basin, but extending north to the central Northwest Coast. It predates European contact, and served as a *lingua franca* among groups engaged in aboriginal trade. Archeological evidence suggests the existence of intergroup ceremonial exchange alongside precontact trading relations. However, it is clear that such exchange was both quantitatively and qualitatively different from the historic potlatch. It involved modest amounts of animal pelts and a few types of prestige goods, and was known under different labels in different areas. It reaffirmed but likely did not alter rank relations within and between groups. Thus, it is fair to say that the potlatch, as a translocal institution, was a product of the fur-trade era.

1.2 The Fur Trade: Influx of Wealth

The early fur trade of the 1770s and 1780s involved Russians, Spanish, British, and Americans. Trade focused on the sea otter and was conducted primarily from ships. This had a limited effect on aboriginal groups. However, by the late 1780s the sheer number of trading vessels, and the shift to land-based trading, had begun to bring changes. The transfer of the Spanish colony on Juan de Fuca Strait to the British in 1793 marked the beginning of a process that would see Hudson's Bay Company forts established all along the coast, and eventually a substantial colony at Victoria. To the north, the Russians established a fort at Sitka, in Tlingit territory, and to the south, Americans established posts on the Columbia in the 1810s. The shift to land-based trade brought with it an influx of wealth and trade goods, as well as epidemic disease, and a broad range of new cultural influences.

Despite the negative effects of contact, the early nineteenth century was characterized by an efflorescence of art and expressive culture on the Northwest Coast. Nowhere is this seen more clearly than in the plastic arts. The introduction of metal woodworking tools and, somewhat later, commercial paint, allowed for an explosion of art in the form of masks, architectural elements, storage vessels, and free-standing monumental sculpture. Such objects were commissioned with new commercial wealth; these objects, in turn, were vehicles by which this wealth was displayed and validated. Wealth had always been closely associated with rank. The problem arose in that rank was ideologically a closed system: a limited number of ranked positions, associated with titles, privileges, and symbolic property ('crests') were believed to exist, and these positions were filled in accordance with regular principles of descent and succession. However, during the fur trade period *nouveaux riches* rose to prominence. New crests were created for them by artists who were experimenting with both themes and techniques. Simultaneously, such persons also staked claim to unused traditional crests or those in dispute. The potlatch was the forum in which such claims were made public, and were either validated or rejected by the larger community.

1.3 The Dominion Period: Response to Traumatic Change

After the 1860s, which saw both Canadian Dominion and the US purchase of Alaska, aboriginal groups were increasingly encapsulated within Euroamerican political, social, and economic institutions. Simultaneously, the full effects of disease mortality were being felt, producing upheavals in aboriginal society. The potlatch, an effective means of dealing with demographic and social change, was mobilized to address issues such as the amalgamation of groups, the lack of personnel to fill important rank positions,

changing relations with Euroamericans, and changes in the relative status of local groups. In the process, potlatches became larger and more expansive. A wide range of aboriginal practices, such as shamanic winter dances, became incorporated within the potlatch. Simultaneously, the potlatch replaced intergroup violence, which was suppressed, as a means for gaining prestige at neighbors' expense.

During this period, the potlatch was suppressed by Canadian authorities, who passed a 'Potlatch Law' in 1885. Although unenforceable for most of its existence, it did result in famous prosecutions and convictions of Kwakiutl potlatchers in 1923. In addition to criminal punishment, the state seized 'potlatch goods,' including ritual objects. These provided the basis of ethnological collections at museums in Ottawa and Toronto. In the 1970s and 1980s, these items were returned to Kwakiutl communities at Cape Mudge and Alert Bay, which have built museums to house them.

2. Geographical Range and Variation

2.1 The Northern Potlatch

The northern region, consisting of matrilineal societies, used the potlatch primarily in the context of funerals and succession. For the Tlingit and Haida, potlatches were between moieties, and stressed co-operation and solidarity between hosts and guests. A minor theme of competition was introduced, with two separate guest groups attempting to outdo each other in the degree of 'comfort' provided to the host. Tsimshian potlatches were similar, but, lacking moieties, were somewhat more agonistic. They were associated with marriages, as well as other life-crisis rituals; marriage was seen in oppositional terms. In addition, potlatches were used to make territorial claims.

2.2 The Southern Potlatch

South of the Tsimshian, social organization was cognatic, with a matrilineal orientation in the north becoming more patrilineal in the south. Among the Nootka, potlatches were essentially private entertainments sponsored by a chief for his people, and thus stressed social harmony. Elsewhere, however, potlatches were primarily agonistic. Marriage potlatches, including those held to repay bridewealth, were couched in military terms. As group membership and rank were less fixed in cognatic societies, they were more the object of political manipulation, and thus of representation in the potlatch.

2.3 The Kwakiutl Potlatch

The extreme example of agonistic prestation was provided by the Kwakiutl, who live in northeastern

Vancouver Island and the adjacent islands and mainland. During the 60 years after Dominion, the potlatch intensified to the point that Benedict (1934), in her flawed analysis of Boas' material (Boas 1966), described the Kwakiutl as 'megalomaniacal' and 'paranoid.' Fierce competition among brothers, cousins, and affines for succession to titles, the existence of numerous latent titles, the rise of a *nouveaux riche* class called 'Eagles,' and a system of intergroup ranking, all contributed to the intensity of the potlatch, which participants viewed as warfare by other means. Potlatches opened with guests arriving in war regalia, and a mock battle on the beach, reminiscent of the murderous raids that were endemic to this area.

Kwakiutl potlatches were predicated on rivalries between chiefs and, by extension, their groups. In addition to the usual means of amassing wealth, would-be hosts engaged in a system of loans with 100 percent interest, which allowed lenders to build fortunes quickly, and borrowers to obtain last-minute infusions. The currency was Hudson's Bay Company blankets, supplemented and eventually replaced by cash. Copper shields were the ultimate valuable; bid up in previous transactions, 'coppers' reached cash values of several thousand dollars. In addition, trade goods played an increasing role. By the start of the twentieth century, manufactured items such as shotguns, washing machines, and pool tables were given away, along with quantities of flour, rice, cloth, and utensils. In some of the most extreme potlatches, goods including coppers were destroyed.

3. Functional Accounts

3.1 The Potlatch as Total Social Phenomenon

The French sociologist Marcel Mauss (1990) noted that the potlatch is an integral element of the rank system of Northwest Coast societies. It is a mechanism by which claims to rank status are validated or challenged, and changes in social order are communicated to the larger community. The potlatch rests on opposition between host and guest. The host—a chief or high-ranking person and, by extension, his social group—was concerned with conducting certain types of business: naming heirs, contracting marriages, conducting funerals, proclaiming new titles and privileges. This business was witnessed, in a juridical sense, by the guests, who were paid for their service. Potlatch gifts went beyond mere payment for services, however, since they were also taken as *prima facie* evidence for the validity of the claim.

Wealth was a necessary concomitant of high rank. High-rank positions implied a certain degree of extraordinary power, similar to the *mana* of Polynesian chiefs, which necessarily resulted in wealth. Inability to provide an abundant potlatch would seriously undermine the legitimacy of the claimant's assertions. By the same token, an extravagant potlatch could

'fasten on' a title, merging the holder's social identity with the permanent qualities of the title. Such acts were seen as a sort of reincarnation, by which the living title holder became incorporated in the title, which encompassed the holder's predecessors and mythical founder. For chiefly positions, the ascendance of a new holder was often marked by events symbolic of the (re)creation of the social world, including human sacrifice, the razing of old chiefly houses and poles, and their replacement by new ones.

In chiefly succession potlatches, a broad range of political, legal, and economic issues were implicated. In all groups, chiefly titles involved territorial claims of some sort. These titles were based on mythical narratives, set locally, and taking place at the beginning of human history, thus staking aboriginal claim to land. In some groups, such as the Nootka, such territorial claims were very specific and resembled Western notions of ownership. In all Northwest Coast cultures, chiefs were minimally seen as stewards of the land and its inhabitants, and were responsible for regulating relations between human and nonhuman populations (which were believed to include more than the flora and fauna recognized by biological science). This was accomplished by ritual means, including prayers, attraction magic, and first fruit rituals. The latter were used to regulate the seasons on fish and game. Although the informing ideology was moral, not ecological, such regulation had the effect of conserving resources.

The potlatch thus involved relations between the social group and the nonhuman outside world, the prehuman myth world, and the group's ancestors. In this way, the group was situated within a larger universe, and was thus defined and delimited. Potlatches likewise served to delineate the internal organization of society, and the functional relations obtaining between its components. In a general sense, one potlatches to one's affines, who constitute the friendly other. In northern matrilineal groups, this opposition was absolutely clear. Especially in the moiety system of the Tlingit and Haida, one's affines were a separate corporate group; the cooperation of the two sides presented an image of social totality cosmological in scope.

3.2 The Potlatch and Marriage Exchange

Potlatches were associated with marriage in most areas; even where they were not, the potlatch was transacted between affines. Politically, potlatches were vital in renewing alliances among groups. Among the northern groups, whose aristocrats practiced preferential cross-cousin marriage, long-term stable exchange relations involving two or more local groups were established. Such groups provided political, military, and economic support, as well as external validation of chiefly claims. Among cognatic groups, no such long-term structural relations existed, but

were rather produced and reproduced in a series of exchanges tied to specific marriages (payment and repayment of bridewealth, naming of children, funeral of a spouse). The connection between marriage and potlatching was so strong that in groups such as the Kwakiutl, Bella Coola, and Heiltsuk, aristocrats would engage in serial monogamy and even fictive marriage in order to obtain prestige from potlatching. Potlatching varied along several dimensions (size, number, occasion, agonism, and others) depending on the precise configuration of kinship, descent, and marriage rules.

3.3 *The Potlatch and Ecological Variation*

Since the 1960s, materialist scholars have viewed the potlatch as a virtual homeostatic mechanism, distributing personnel and food efficiently through space and time. The earlier conception of the Northwest Coast as free from food pressures is justly rejected. The potlatch is seen as having four distinct, but inter-related functions: (a) spurring overproduction, (b) encouraging storage of food, (c) allowing for the exchange of food for prestige goods, and (d) regulating group membership and territorial boundaries, matching resources with personnel. This approach assumes local variation in resources, a condition that does not exist everywhere, but is more pronounced in the north. Item (d) was effected much more often by warfare than by potlatching. However, these remain at least potential functions of the potlatch.

3.4 *Rank, Class, and Political Power*

Northwest Coast society was stratified by both rank and class. Potlatching was the domain of chiefs and nobles; however, both commoners and slaves played important roles in amassing resources. By definition, only persons with titles were in a position to potlatch. Potlatching thus reinforced vertical, as well as horizontal, social divisions. Simultaneously, potlatching was the mechanism by which social mobility was integrated into the social system.

The potlatch both manifested and represented political power. By drawing together a large number of guests, especially if they were from far away or their chiefs were especially high ranking, a host was demonstrating his prestige and political network. The material goods and food distributed were an index of his land holdings and their productivity, which ultimately depended upon the chief's legitimacy. Potlatches were fora for authoritative political discourse, defined technically as monologic, multichannel, redundant communication. A significant aspect of this communication was an illocutionary speech act. This was supplemented with nonverbal media, including plastic arts and dance. The political success of a potlatch was usually measured in terms of the degree to which these utterances remained unchallenged.

They may be challenged either directly, in rivalry gestures, or more subtly through various sorts of corrosive discourse, including humor. However, in some groups, such as the Kwakiutl, such elements were institutionalized within the structure of the potlatch. This had the effect of heightening tensions within the potlatch, and giving it a more game-like structure, in which a wide range of outcomes was possible.

4. *Problems of Reference*

4.1 *Reification*

Given the degree of variation over space and time, it is unclear that the potlatch, *as such*, exists. Rather, our understanding of it is conditioned by reifications imposed by government agents and missionaries, anthropologists, and aboriginal people themselves. The Potlatch Law of 1885 first tried to specify 'the Indian festival known as the "Potlatch"'. Problems of reference significantly delayed successful prosecution of the law. During this intervening time, the symbolic labor of many people served to bring descriptions and practice closer together.

4.2 *Invention of Tradition*

Aboriginal people themselves reified the potlatch by defining their ceremonial praxis as potlatch, a foreign word and concept mediated through Euroamerican society. By the time Franz Boas recorded ethnographic data among the Kwakiutl in the 1890s (Boas 1966), the concept of potlatch was present. This consciousness of 'the potlatch,' on the part of both Boas and the Kwakiutl, was shaped largely by the existence of the Potlatch Law. Clearly, aboriginal practice and self-awareness of practice were conditioned by exogenous expectations and categories. It is not surprising that during a period of rapid change such an invention of tradition would occur. It allowed aboriginals to retain symbolic control of their destiny, by redefining novel structures and practices as traditional. Because of this useful quality, potlatching remains a common practice today.

4.3 *The Potlatch as Anthropological Totem*

The potlatch remains one of the most durable anthropological concepts, despite the reanalyses and deconstructions to which it has been subjected. Beginning with Boas, anthropologists defined potlatch as both self and other, transparent and exotic. This contradictory and mediational quality has made potlatch an especially useful metaphorical vehicle. Potlatch has been viewed as, *inter alia*, metaphorical banking, warfare, and mental illness. At the same time, various aspects of Western societies, including

politics and consumer capitalism, have been compared to potlatch. Its hybrid nature, and its origins in the desire on the part of Euroamericans to describe aboriginals, and aboriginals to represent change and continuity, make it an attractive concept, but one that resists critical usage.

Poverty and Child Development

Income poverty is when a family's income fails to meet a federally established threshold; this threshold differs across countries. In general, living at or below a

poverty threshold signifies that a family lacks basic financial resources, and thus children may lack access to necessary resources including food, shelter, and health care. Historically, the measurement of poverty as well as research linking poverty to child development has been an Anglo-Saxon endeavor (Smeeding et al. 2000). However, international organizations, such as the United Nations Children's Fund (UNICEF), have fostered global concern. A growing body of research suggests that poverty has consequences for children's well-being. Internationally, the prevalence of poverty among families with children has profound implications for researchers, policy makers, and practitioners concerned with children's development.

This article, divided into three sections, reviews the literature on the role of income poverty in the lives of children and families. The first section considers different measures of poverty as well as international trends in child poverty. Second, a review of recent studies examining the association between poverty and children's physical, cognitive, and emotional development is provided. The last section reviews the potential pathways through which poverty may influence children's health and well-being. The conclusion briefly highlights broad policy implications.

1. Measuring Poverty and International Trends

1.1 Income and Poverty

In most countries, income poverty typically is defined by official poverty thresholds. Those families whose income falls above the poverty line are considered 'not poor,' whereas, families whose incomes are at or below the threshold are considered 'poor.' Two general types of thresholds exist, absolute and relative. *Absolute poverty thresholds* are based on an absolute level of resources; as such, a family's poverty status is not influenced by other families' incomes. For instance, the USA has an absolute poverty threshold based on anticipated food expenditures (thrifty food basket), taking into account household size, and multiplied by three; the thresholds are adjusted annually for changes in cost of living. In contrast, Canada and most Western European nations employ relative poverty thresholds. A *relative poverty threshold* is calculated by comparing a family's resources to that of the average family. These thresholds are, generally, defined by half of the median or mean income of all households in the respective country. Thus, other families' incomes can change a family's poverty status, even if their income is relatively stable over time.

1.2 International Trends in Child Poverty

Using the poverty measures described, international comparisons of child poverty rates are considered. Comparisons of the proportion of children living in

Figure 1ⁱ

Percentage of children living in poverty in industrialized nations using relative and absolute measuresⁱⁱ

ⁱAdapted from: Bradbury and Jantti 1999

ⁱⁱRelative poverty rate is 50 percent of overall national median income for survey year. Absolute rate is \$15,299, based on 1995 US official poverty line for a two-parent family with two children

poverty in industrialized countries vary depending upon the type of poverty measure utilized (see Fig. 1, Bradbury and Jantti 1999). Using a relative measure, where families living at or below 50 percent of the national median income are considered to be poor, the USA ranks 24th out of 25 in terms of low child poverty

rates, despite general economic prosperity. With the exception of the USA and UK, countries with higher levels of national income tend to have lower relative child poverty rates than countries in economic transition (Bradbury and Jantti 1999, Smeeding 1997). However, if an absolute measure of poverty is applied

using the 1995 US criteria, this pattern shifts. Although the child poverty rate in the USA declines only slightly, the country's ranking jumps to 12th place, while Russia and Hungary, countries in economic transition, have child poverty rates of 90 percent or higher. In contrast, child poverty rates remain low in the Nordic countries and Germany and are not appreciably altered by changing poverty measures (Bradbury and Jantti 1999).

The overall level of economic development of a country is not the only factor influencing child poverty trends, as over time, countries with similar levels of development fared differently. Diverse demographic differences between countries, such as the prevalence of single-parent versus two-parent families, account for some of the discrepancies, as well as different roles assumed by governments for fighting child poverty. International poverty rates also are affected by the inclusion or exclusion of social transfers including unemployment benefits, illness or disability assistance, income assistance, and housing benefits (Eurostat 1999). Within the European Union (EU) countries, the USA, and Canada, poverty rates drop from approximately 20 percent to 25 percent when transfers are included as part of a family's annual income (Eurostat 1999, Smeeding 1997). Countries generally considered 'welfare leaders,' namely the Nordic countries, have, on average, lower poverty rates than other countries with fewer social programs.

2. Poverty and Child Health and Well-being

This section provides an overview of the effects of poverty on child health and well-being. The findings are discussed for five developmental age groups: prenatal to two years, early childhood (3 to 6 years), late childhood (7 to 10 years), early adolescence (11 to 15 years), and late adolescence (16 to 19 years). Each age group incorporates at least one significant transition in a child's life, such as school entrance or exit or biological maturation. The developmental challenges confronted during each period are relatively universal and may entail new modes of adaptation to biological, psychological, or social changes. The domains of well-being addressed include: physical health; school readiness and achievement; and behavior, social, and emotional problems. Each age period is associated with somewhat different indicators.

The review presented draws heavily from several recent endeavors to investigate the influence of poverty on child development. The first initiative is a cross-national comparison of key child indicators reported by UNICEF (2000), which provides a macrolevel view of how countries' overall levels of economic development affect child well-being. The second effort is a comprehensive evaluation of research on poverty and children's physical, emotional, and cognitive devel-

opment. This analysis by Brooks-Gunn and Duncan (1997) provides a 'risk assessment' of the effects of poverty on child health and well-being at a single point in time by examining outcomes for poor and nonpoor children drawn from large, national cross-sectional studies, primarily in the USA. Additional figures are reported from Canadian national data (Ross et al. 1989, Ross and Roberts 1999). In contrast, the final undertaking, an interdisciplinary initiative to conduct parallel evaluations across multiple data sets with income data measured over the life course, centers on understanding the role of the dynamics of poverty (depth, timing, and persistence) on a range of outcomes, after accounting for child and family background characteristics. These results on the long-term effects of poverty on children and youth were described in a volume, *Consequences of Growing Up Poor* (Duncan and Brooks-Gunn 1997); statistical criteria were used to determine the magnitude of income effects reported.

2.1 Physical Health

A country's level of economic development is associated with key indicators of child health; in developing countries (primarily those in sub-Saharan Africa and South Asia), over half of all deaths among children five years of age or younger are associated with malnutrition (UNICEF 2000). In many of these countries, AIDS/HIV is also contributing to rising infant mortality rates.

Research in the USA and Canada indicates that before children are born, poverty takes a toll on their health; children from poor families are approximately twice as likely to be low birth weight (less than 2,500 grams) than children who escape poverty (Brooks-Gunn and Duncan 1997, Ross and Roberts 1999, Ross et al. 1989). Other threats to poor children's health include lead poisoning and experiences with hunger as well as increased risk of mortality, hospitalization, and stunting (small for height). Poor children display more health problems and disabilities than do children from affluent families (Newacheck et al. 1993). When the longer term effects of poverty are considered, living in poverty during the childhood years has been found to be associated with stunting later in life (Duncan and Brooks-Gunn 1997).

2.2 School Readiness and Achievement

Access to basic education is associated with a country's level of economic development, such that in many developing countries, at least one-third of children are not enrolled in primary school, resulting in lower literacy rates compared with industrialized countries (UNICEF 2000). Among children of all ages, living in

poverty is also associated with deficits in cognition and achievement (Brooks-Gunn and Duncan 1997, Ross and Roberts 1999, Ross et al. 1989). Findings from US studies indicate that poor children 3 to 17 years of age are about one and a half times more likely than nonpoor children to display learning disabilities. Among school-age children, poverty increases the risk that children repeat a grade, perform poorly in school, are expelled or suspended from school, and obtain low scores on tests of school readiness and achievement. By late adolescence, poor youth are more likely than their nonpoor peers to drop out of school and to be unemployed. Taken together, these studies point to the disadvantage poverty bestows upon children's academic development; however, they do not shed light on the long-term effects of poverty on achievement.

A series of studies by Brooks-Gunn, Duncan, and colleagues have sought to understand the longer term effects of poverty on young children's cognitive and school outcomes. Findings have been highly consistent; after accounting for family and child background characteristics, income has large effects on young children's cognition, verbal ability, and achievement with a large effect defined as about five to six points on standardized tests. The depth of poverty is also important; children who were very poor (deep poverty defined as incomes 50 percent or less than the poverty threshold) scored particularly low on measures of cognitive and school achievement. The number of years a child lives in poverty matters as well for children's school readiness, particularly living persistently (all years) in poverty.

Longitudinal studies of young adolescents in the USA and Canada, generally, report small to modest income effects on indicators of school performance including grade placement and grade point average (Duncan and Brooks-Gunn 1997). Among studies of late adolescence, income was also found to have small to moderate associations with measures of completed schooling (Haveman and Wolfe 1994). The timing of poverty is important for late adolescent achievement; experiences with poverty during early childhood, as opposed to other developmental periods, are most salient for educational attainment (Duncan and Brooks-Gunn 1997).

2.3 Behavior, Social, and Emotional Problems

Similar to health and achievement, the threats to poor children's social and emotional health are great. A country's level of economic development places children at risk for exposure to hazardous and exploitative labor as well as conflict, war, and violence (UNICEF 2000). Even in the USA, poor children are twice as likely to be the victim of a violent crime and live in unsafe neighborhoods than nonpoor children (Brooks-Gunn and Duncan 1997). Among older children in Canada, poor children exhibit higher levels

of emotional problems than nonpoor children, and are approximately twice as likely to have psychiatric and conduct disorders than their nonpoor peers (Ross et al. 1989). Finally, among adolescents in the USA, the rate of teenage unmarried parenthood is three times higher among poor female adolescents than nonpoor youth. These risk figures suggest that poor children and youth are faring at less than an optimal level.

In longitudinal studies, family income has small to moderate associations with the prevalence of young and school-age children's behavior problems as reported by parents and teachers (Brooks-Gunn and Duncan 1997). The depth, timing, and persistence of experiences with poverty during early childhood also are linked to children's socioemotional well-being. Finally, small to moderate income effects on adolescent anxiety and hyperactivity have been reported (Duncan and Brooks-Gunn 1997).

3. The Pathways between Poverty and Child Development

In the previous section, the direct effects of poverty on children's and youth's health and well-being were reviewed. Together, the research presents a consistent picture of the harmful effects of poverty, particularly during early childhood. To increase our knowledge about the influence of poverty on children's development, it is necessary to identify the pathways between poverty and child development. This exercise is particularly constructive for drawing policy implications. Several possible processes have been hypothesized to transmit the effects of income to child development; each is reviewed in turn.

3.1 Home Environment

The quality of the home environment is a salient mechanism through which income may alter child development. The home environment entails: emotional warmth displayed by parents while interacting with their children; provision of stimulating and learning experiences in the home; and physical surroundings, such as safety of play areas and cleanliness. Poor children are likely to be raised in less emotionally, cognitively, and physically enriching environments than children from more affluent families. Several studies of young children have found that quality of the home learning environment accounts for a substantial share of the effect of poverty on children's achievement and behavioral outcomes.

3.2 Child Care and Schools

Child care and schools are important contexts for children that may transmit the effects of low income to developmental outcomes. During young childhood,

high quality child care and early intervention programs have demonstrated short-term and long-term benefits for poor children's academic, social, and behavioral outcomes (Yoshikawa 1994). Moreover, these programs have the potential to enhance parenting outcomes as well, such as mental health and parenting skills. Among older children and youth, income effects on achievement outcomes may operate in large part through school characteristics, such as quality, climate, and demographics (Jencks and Mayer 1990).

3.3 Parenting Behavior

Economic hardship resulting from income loss, unemployment, job instability, and economic insecurity rather than low income *per se* is another potential mediator of income effects on child well-being. According to this 'family stress model,' economic hardship is associated with parental stress and depression which leads to more inconsistent, unsupportive, harsh, and punitive parenting practices. These reduced quality parent-child interactions, in turn, are associated with emotional and school problems in children (Conger et al. 1994, McLoyd et al. 1994).

3.4 Parental Mental Health

Maternal emotional well-being may be a path through which poverty affects child development; it may operate directly on child well-being or through parenting, as discussed under the family stress models. Substantial evidence exists that poverty has negative consequences on adult mental health (Kessler 1997). Additional studies reveal links between maternal emotional well-being and children's behavior (Velez et al. 1989). One study of young children found that income might have an indirect effect on children's behavior and cognition by means of maternal depressive symptoms and coping skills (Duncan et al. 1994).

3.5 Neighborhoods

An additional mechanism through which family income may impart its effects to child outcomes is neighborhood of residence. Inadequate income constrains the choice of where a family chooses to live, and as such, low income families may reside in very poor neighborhoods characterized by crime, unemployment, lack of resources, few role models, and absence of adult supervision of children and youth. A growing body of research indicates that neighborhood conditions affect children's development above and beyond family income, rather than indirectly (Leventhal and Brooks-Gunn 2000). Affluent (compared with

middle income) or high SES neighbors appear to have beneficial effects for children's school readiness and achievement outcomes, while low income (compared with middle income) or low SES neighborhoods have negative consequences for children's and youths' emotional and social well-being. Neighborhood residence, notably income/SES, is also associated with quality of home environment, parenting practices, quality of child care and schools, and peer group attributes.

3.6 Health Care

Accessibility to health care is another pathway through which poverty may operate on child health and well-being. Although children from economically disadvantaged families are in poorer health, they are less likely to receive health care services or receive services of lower quality than children from more affluent families (Newacheck et al. 1993). Several studies suggest that access to quality care may mitigate health-related problems.

3.7 Exposure to Violence

The final process by which poverty may exert an influence on child well-being is exposure to violence inside as well as outside of the home. Children's exposure to violence as either a witness or a victim may account in part for the link between income and children's health. Both family and neighborhood income are associated with exposure to violence (Martinez and Richters 1993, Sampson et al. 1997). Exposure to violence, in turn, is associated with psychiatric symptoms.

4. Conclusion and Future Directions

In conclusion, large international discrepancies are seen in child poverty rates. Poverty rates, however, depend upon the type of measure used, demographic differences across countries, and government policies. The research indicates that poverty has negative short-term and long-term influences on a host of child outcomes. In addition, the timing, depth, and duration of experiences with poverty are also important; deep and persistent poverty during early childhood are especially detrimental to child well-being. Increasingly, researchers are beginning to explore the potential pathways through which poverty transmits its deleterious effects to children's development. There is growing evidence that the home environment and parental behavior are primary mechanisms of influence. Such knowledge is crucial for policies seeking to counter the negative consequences of poverty for poor children and their families. These policies can target

family resources directly or the mechanisms through which poverty operates on child development. In addition, policies can impact children directly through, for example, assistance with child care, or indirectly through a policy's impact on the family unit and neighborhood, for instance labor policies. Policies that coordinate the needs of both children and their parents are likely to be more efficacious than those that focus solely on one or the other. An important task for researchers will be to evaluate the effects of poverty-related policies on children's development.

Poverty and Gender in Affluent Nations

Women are more likely to be poor than men in nearly all Western nations, with the greatest disparity found in the USA. The underlying causes for women's poverty vary across nations but generally fall into one of three main categories—demographic composition, economic conditions, and government policy. In this article, poverty is defined, and the advantages and disadvantages of different poverty measures are noted. Then, the recent scholarship on gender and poverty is briefly reviewed, and women's poverty rates in various Western, industrialized countries are compared. Finally, the three primary causes of women's poverty are discussed.

1. Definitions of Poverty

The concept of 'poverty' is relatively new, having only entered the public lexicon in the latter half of the twentieth century. Poverty can be defined in either absolute or relative terms. It is typically measured with respect to families—not individuals—and is adjusted for the number of persons in a family (because larger families are assumed to need more income but also to benefit from economies of scale). *Absolute* measures of poverty (typically used in Anglo countries such as the

USA and the UK) define poverty in relation to the amount of money necessary to meet basic needs such as food, clothing, and shelter. *Relative* poverty measures (typically used in European countries and by academic researchers) define poverty in relation to the economic status of other members of the society. One half of the median family income is often chosen as the poverty threshold. Absolute and relative measures of poverty reflect divergent ideas about the meaning of poverty—whether it represents the inability to afford basic necessities, or comparative economic disadvantage—and both have advantages and disadvantages. The advantage of an absolute poverty measure is that it clearly indicates whether or not a family's income is sufficient to sustain a minimal level of subsistence.

However, if an absolute threshold is adjusted only for inflation, during periods of economic growth that same threshold will increasingly reflect a greater level of relative destitution. Relative measures avoid this problem because they are linked to the average standard of living: when median income goes up, the poverty threshold goes up. Yet, because of this practice, 'poverty' in one country may imply a vastly different economic status than 'poverty' in another country. Relative measures are particularly affected by the income distribution: in countries with a more unequal distribution, poverty rates will be high; in countries with a more equal distribution, they will be low—regardless of the actual standard of living that 'poverty' represents.

2. Women's Poverty in Comparative Perspective

The salience of gender for understanding poverty was first noted by Diana Pearce (1978) who coined the term 'the feminization of poverty.' Pearce observed that women and children living in female-headed

families were over-represented among the poor, and that the proportion of adults in poverty who were women had been increasing. Since that time, various scholars have used data to examine trends in men's and women's poverty rates—and the ratio between them—in order to explore how economic status may be affected by gender (see, for example, McLanahan et al. 1989, Casper et al. 1994). Feminist scholars have raised important issues about the gendered nature of welfare state policies (Folbre 1984, Gordon 1990, 1994, Orloff 1993, O'Connor et al. 1999) and the inequitable distribution of the costs of children (Folbre 1994a, 1994b).

Because poverty is measured at the family level, for married couples, poverty is by definition the same for women as for men: if a married-couple family is classified as poor, the husband, wife, and any children are all considered to be poor. Only for single individuals (defined by most researchers as neither married nor cohabiting) can the rates of poverty differ by gender. Thus, differences in the proportion of the population that is single, and differences in the poverty rates of single men and single women, underlie the overall gender differences in poverty both within and across nations.

Table 1 presents poverty rates in eight Western, industrialized nations. A relative measure of poverty is used, and an individual is counted as poor if he or she lives in a household with disposable money income that is less than half the median for households in the nation, adjusted for size. The table presents poverty rates for all women and men, for single women and men, and for two groups of single women that are particularly disadvantaged—single mothers and elderly women living alone.

Overall, the table highlights three fundamental observations about gender and poverty in highly industrialized nations. First, within each of the demo-

Table 1
Poverty rates for select demographic groups in eight industrialized nations^a

Country (year) ^b	All women	All men	Single women	Single men	Single mothers ^c	Elderly women living alone
Australia (1994)	10.7	8.2	24.7	14.8	38.6	62.1

^a Poverty is defined as less than 50 percent of a country's median income. All columns except the last are for nonelderly adults ages 25 to 54; the final column refers to elderly women ages 65 and older. 'Single' indicates that an individual is neither married nor part of a cohabiting male/female couple.

^b Years of data for the first five columns are shown in parentheses. For the figures on elderly single women, years of data are as follows: Australia 1989, Canada 1991, Germany 1989, Netherlands 1991, Sweden 1992, U.K. 1991 and US 1994.

^c Single mothers are women living with a child under the age of 18 and without an adult male.

graphic groups shown, poverty levels vary across the nations observed. For example, Sweden has very low poverty rates for most categories, while the USA has notably higher poverty rates. Second, in all but one country shown, women are more likely to be poor than men; the exception is Sweden, where men are slightly more likely to be poor than women. In the USA, the gap between women's and men's poverty rates is the highest—about four percentage points. As would be expected—since the single population drives the gender differences in poverty—the gender gap in poverty rates is larger for single individuals than for the adult population overall. Again, Sweden runs counter to the trend, with a lower poverty rate for single women than for single men. For all other countries, the difference in poverty rates between single men and women ranges from about three percentage points in France to more than 15 percentage points in the USA.

The third observation is that among single women, single mothers and elderly women living alone are two groups that face particular economic disadvantage. For single mothers, poverty rates are 25 percent or higher for all countries shown except Sweden; in Australia, Canada, and Germany, about 40 percent of single mothers are poor; and in the USA, nearly half of all single mothers live in poverty. For elderly women living alone, poverty rates range from 3 percent in The Netherlands to 62 percent in Australia, with rates of more than 40 percent observed in both the USA and the UK.

3. Why are Women Poor?

There is no single explanation for why women are poor—and why they have higher poverty rates than men—particularly as one looks across countries that have vastly different histories, cultures, and social and economic contexts. Three primary factors have emerged, and each will be discussed in turn.

3.1 Demographic Composition

Since differences in poverty rates by gender are fundamentally determined by the size and characteristics of the population that is single (neither married nor cohabiting), the demographic distribution in various countries has an important effect on women's poverty rates. Several major demographic trends have led to an increasing proportion of adult women (many of whom have children) living separately from men. First, differential mortality rates by gender imply that women live longer than men, and women are, thus, more likely to live alone in their later years. Since single elderly women have higher poverty rates than either men living alone or women living

Table 2
Single mothers in eight industrialized nations

Country (year)	Single mothers as a percent of all women ages 25 to 54
Australia (1989)	7.8
Canada (1994)	8.5
France (1989)	5.8
Germany (1994)	7.0
Netherlands (1991)	6.0
Sweden (1992)	9.9
United Kingdom (1995)	9.8
United States (1994)	12.7

Source: Data are from Smeeding et al. (1999) using the Luxembourg Income Study (LIS).

with a spouse (Smeeding 1997), in countries with a greater proportion of elderly women living alone, poverty rates for women will be higher. Yet, mortality rates among Western, industrialized nations are not highly variant; therefore, poverty among elderly women living alone has only a modest impact on overall gender differences in poverty compared to the second major demographic factor, the rise in single-parent families.

Increases in divorce and nonmarital childbearing have led to notable growth in the number of single-mother families. Although the extent of single parenthood varies across countries, the trend has been remarkably similar—single parenthood has increased in nearly all Western, industrialized nations since the 1960s (McLanahan and Casper 1995). Table 2 shows single mothers as a percentage of all women ages 25 to 54 for eight industrialized nations. Of the countries shown, the proportion of single mothers ranges from 5.8 percent in France to 12.7 percent in the USA (Smeeding et al. 1999).

If the economic costs of rearing children were evenly distributed between mothers and fathers, then even if the parents were not married, the sex-poverty ratio would not be affected. However, in reality, single parenthood has a much greater affect on women's poverty rates than men's (McLanahan and Kelly 1999). Women are more likely to have custody of a child following divorce or nonmarital childbirth, and many fathers who live away from their children do not provide adequate financial support for them. Having co-resident children decreases a household's economic status by definition, because children require economic resources but do not contribute any additional income. Unless the government provides generous financial support when the noncustodial father fails to pay (as is the case in Sweden), in countries with a high proportion of single mothers, poverty rates for women will be high. For this reason, the prevalence of single motherhood represents the major demographic factor underlying the gender disparity in poverty rates.

Table 3

Economic characteristics of women and single mothers ages 25 to 54 in eight industrialized nations

Country (year)	Labor force participation rates		Mean earnings ^a	
	All women	Single mothers	All women	Single mothers
Australia (94)	63.0	49.3	\$15,522	\$11,904
Canada (94)	73.1	63.2	\$17,391	\$16,922
France (89)	57.2	70.3	\$13,671	\$14,083
Germany (94)	68.0	67.4	\$15,033	\$14,745
Netherlands (91)	50.0	38.1	\$13,650	\$10,946
Sweden (92)	88.0	83.8	\$13,075	\$12,362
United Kingdom (95)	60.5	37.7	\$15,196	\$13,597
United States (94)	74.2	71.8	\$21,186	\$18,547

^a For those who have non-zero earnings. Figures are in 1994 US dollars, adjusted for purchasing power parity of each country.

3.2 Economic Conditions

The rise in female labor force participation, especially among married women with children, represents one of the most dramatic socioeconomic changes in the West in the latter half of the twentieth century. Table 3 shows that labor force participation rates for all women (in eight countries) range from 50 percent in The Netherlands to 88 percent in Sweden; employment rates for single mothers vary between 38 percent in The Netherlands to 84 percent in Sweden. While women are increasingly entering the labor force, their employment rates remain lower than those of men. Further, women have average earnings that are significantly lower than those of men. As shown in Table 3, women's average earnings (among those who have any earnings) range from approximately \$13,000 in Sweden to about \$21,000 in the USA; earnings for single mothers vary between about \$11,000 in The Netherlands to \$18,500 in the USA.

Because, relative to men, women have less income from earnings to support themselves and their children, women are more likely to be poor. (This, however, is not a factor affecting elderly women's poverty as the elderly are no longer of working age.) Yet, earnings *per se* are not the only reason why women have higher poverty rates. Rather, the fact that women disproportionately bear the responsibility of rearing children has important indirect effects on their economic status. In particular, caring for children limits the amount of time that women are able to work (as well as the energy they may have available to invest in their work), and it also increases the costs of working because women must pay for out-of-home child care (not counted in the poverty measure). In addition, women who reduce their work hours or leave the labor force in order to care for children lose vital work experience which affects both their earnings and their seniority in the workplace.

3.3 Government Policy

All individuals and families receive income from two primary sources—the market and the state—in addition to any private transfers they may receive. Government policy has a significant effect on women's economic well-being because it can either obviate or intensify the inequalities that result from the operation of the market economy. Among single individuals living without children, government policy has little impact on women's poverty because men and women are largely treated the same. Although there may be some differences between elderly men and women in how pensions are allocated in various countries, differences in government policies primarily affect the economic status of single mothers and their children.

Welfare states vary dramatically in the extent to which they 'socialize' the costs of children. Feminist scholars have noted that many members of society benefit from children being brought up well (Folbre 1994a, 1994b), and yet market mechanisms fail to equitably apportion costs for this 'public good' (Christopher et al. 2001). In countries where more of the costs of childrearing are borne by governments instead of parents, women's poverty rates tend to be lower. In general, single mothers tend to benefit if a greater proportion of welfare assistance is universal rather than means-tested, because they are not faced with high marginal tax rates on their earnings that result from decreased welfare benefits. The overall level of income assistance provided to single mothers varies notably across industrialized nations; mean transfers for single mothers as a percentage of median equivalent income range from 22 percent in the USA to 71 percent in The Netherlands (unpublished tabulations of Luxembourg Income Study data by Timothy Smeeding and Lee Rainwater).

Numerous scholars have developed typologies that classify welfare states along particular dimensions.

Table 4

Poverty rates for children in single-mother families^a before and after government programs^b

Country (year)	Pretransfer poverty rate	Post-transfer, post-tax poverty rate	Percent decline
Australia (1989)	73.2	56.2	23.2
Belgium (1992)	50.7	10.0	80.3
Canada (1991)	68.2	50.2	26.4
Denmark (1992)	45.0	7.3	83.8
Finland (1991)	36.3	7.5	79.3
France (1984)	56.4	22.6	59.9

a Single-mother families are families where one female adult resides in the household; cohabiting-parent families are not included here. Poverty is defined as 50 percent of a country's median adjusted income.

b Government programs include income and payroll taxes and all types of government cash and near-cash transfers. Child care and other non-cash benefits are not included; this is particularly important for countries such as France which provide generous child care subsidies that are not reflected in these calculations.

Probably the best known is by Esping-Anderson (1990) which classifies welfare states into three categories according to decommodification (the ability of individuals to subsist apart from labor and capital markets) and stratification (differences between classes).

(a) *Social democratic states*, typified by the Scandinavian countries, promote gender equality and provide the most generous support to single-parent families. These nations emphasize full employment, and work and welfare are intricately intertwined, with some part-time public jobs provided for mothers. Many benefits and allowances are universal, supplemented by specific programs targeted to needy families. Women's employment is encouraged by the provision of high-quality childcare services and extensive parental leave. Also, the government guarantees that support is provided to children who do not live with both parents. Because of these policies, mothers are able to combine work and parental responsibilities and to 'package' income from both market and government sources.

(b) *Conservative-corporatist nations* also have generous transfer systems, but they are more traditional with respect to family values and expectations (largely due to the significant influence of the Church). Benefits are generally targeted toward families (rather than individuals), and inequalities across families and households may be sustained. An important component of welfare policy is social insurance, which is linked to labor force participation and may differ by

occupation. Austria, France, Germany, and Italy are representative conservative-corporatist states.

(c) In the *liberal welfare states* (notably the Anglo countries), assistance is primarily means-tested with modest universal transfers, primarily paid to the elderly or disabled. Emphasis is on the market and individuals' labor force activity as the primary means for resource allocation. Benefit levels are typically meager when compared to average wage levels, and recipients are often stigmatized by nonrecipients. Supports for working mothers, including public childcare, are limited, with little or no paid parental leave. Parents who live away from their children are expected to pay child support, although the government does not provide any assistance for children of noncustodial parents who fail to pay. Because welfare benefits are income-tested, women have a difficult time combining work and welfare in order to escape the 'poverty trap.'

These variations in welfare state policy lead to dramatic differences in the economic status of women and children. Table 4 presents poverty rates for children living in single-mother families both before and after government taxes and transfers are included in income (while childcare and other non-cash benefits are not included). The table shows that, with several exceptions, the percentage decline in the poverty rates roughly clusters according to the three categories of nations in Esping-Anderson's typology. Government tax and transfer policies reduce the poverty rates in each of the four social democratic nations shown in the table (Denmark, Finland, Norway, and Sweden)

by 68 percent or more. In the corporatist nations, poverty reductions fall in the middle of the spectrum with a 60 percent decline in France and a 56 percent decline in Italy. Germany is an important exception, with its government policies reducing poverty for children in single-mother families by fully 90 percent. The lowest reductions in poverty rates are noted in the liberal states, such as 26 percent for Canada, 23 percent for Australia, and 15 percent for the USA. The UK represents another exception because its policies reduce poverty by 76 percent—a much greater decline than in the other liberal states.

Some feminist scholars have criticized Esping-Anderson's framework because it emphasizes workers' dependence on employers while ignoring women's dependence on men. Orloff (1993) argues, for example, that welfare regimes should be judged by the extent to which they allow women to establish independent households. In contrast, other feminist scholars have raised questions about women's dependence on the welfare state (Gordon 1990, 1994) and gender biases in the welfare state (Nelson 1990).

4. Conclusion

Ultimately, reducing women's poverty in industrialized countries requires the convergence of all three factors—demography, the market economy, and government policy—to better support women and their children. This is because women's economic status depends on whatever resources they can conjointly obtain from the family, the market, and the state (Christopher et al. 2001). First, women's poverty is closely tied to whether the responsibility for children is shared equally between mothers and fathers. Private transfers, regulated by the government, may be just as important as public transfers in compensating for the demographic changes that have resulted in women bearing a disproportionate share of the cost of children. Second, women benefit from market economies that pay men and women equally. Despite the recent gains in wages relative to men, women (especially mothers) earn less than men in all Western countries. Countries that promote gender equity in wages and that maintain high minimum wages reduce the poverty rate of all women, especially single mothers. Third, government policy can be assessed both in terms of the level of support provided to single mothers and the extent to which public support encourages or discourages labor force participation. In particular, childcare subsidies and parental leave policies enable women to balance their responsibilities as parents and workers, which ultimately reduces poverty and increases economic independence.

Poverty and Gender in Developing Nations

Poverty as used in contemporary literature is an economic measure of income or consumption. A person or household is considered below the 'poverty line' if such income or consumption falls below a minimum standard needed to provide basic human needs. Economic development in developing countries is considered successful when the gross national product (GNP) increases and raises the per capita income. Rapid population increase dilutes the impact of GNP and led to international family planning programs as one approach to poverty reduction. This direct connection between economic development and population decrease is often questioned. The insensitive implementation of family planning programs has been widely criticized by women who initiated the emphasis on women's education and health to reduce both poverty and family size at the 1994 United Nations International Conference on Population and Development in Cairo (see *Reproductive Rights in Developing Nations*).

The poverty line is linked to a minimum standard within each country which varies by country, region, or culture. Attempts to compare income poverty across societies has led the World Bank to utilize the Purchasing Power Parity (PPP) that accounts for currency fluctuation and local consumption habits and is commonly referred to as the market-basket approach.

Although economic measures dominate the literature on poverty and on development, critics have objected to such sterile methods of accounting. Additional indicators of wellbeing have been combined into more textured indices of progress or poverty. The social aspects of poverty do not lend themselves to such aggregation. To understand the multidimen-

sional nature of poverty, scholars are today investigating a broad range of social and cultural practices as well as governmental policies. Only with this comprehension of the causes of poverty can more effective programs for poverty alleviation be designed. This effort has taken on increased urgency in light of current economic trends which have exacerbated income disparity within countries and pushed more people into poverty (Lundberg and Milanovic 2000).

Differential patterns of poverty are experienced by women and men due largely to their social roles and responsibilities. The increase in the number of women-headed households throughout the world, caused by rapid economic transition, migration, and urbanization, has led to the dissolution of many traditional support systems. As a result, women must both nurture and provide a livelihood for their children in an economy that privileges full-time work away from home. This double burden limits both a woman's choice of jobs and her mobility, thus reducing her income causing the feminization of poverty.

Even within needy families, women may be poorer than their husbands because they have little control over how income or food are allocated. Food aid programs now deliver food directly to poor women who show more equity in feeding their children Pinstrup-Andersen et al. 1999. Similarly, development agencies have focused more of their income projects on women (see *Economic Development and Women*). While some critics argue that loading additional work responsibilities on women has created a crisis of time, others demonstrate that income increases women's household bargaining power (see *Family Bargaining*). Conservatives object to programs that provide women with jobs because they believe that upsetting the gender division of labor encourages further disintegration of families. In contrast, feminists argue that the focus on welfare programs to alleviate the worst aspects of poverty will do nothing to reduce the subordination of women. Recent approaches to alleviating poverty emphasize asset creation and housing rights to empower women.

The first section explores the broadening of definitions, measures, and social indicators of poverty. The second section presents arguments for a gendered approach to poverty alleviation and discusses studies that elaborate on, or question, earlier assumptions. The last section describes significant programs designed to assist women out of poverty and reviews salient criticisms of them.

1. Definitions and Causes of Poverty

Defining poverty in economic terms alone raises issues of the accuracy of statistics in developing countries and encounters the range of moral objections to valuing life only in material terms. Development

agencies are aware of the unreliability of data from developing countries yet cognizant of the demands by policy makers for easily replicated measures. To compare poverty globally, the World Bank uses estimates of local income expressed as US\$1 and US\$2 per day to identify levels of poverty, estimating that in 1998, 1.2 billion people worldwide had consumption levels below \$1 a day and 24 percent of the population of the developing world and 2.8 billion lived on less than \$2 a day (World Bank 2000).

1.1 Indicators Beyond Income

As the GNP became the common method of measuring progress, critiques appeared. Alternative measures, such as the Physical Quality of Life Index (PQLI) promoted by the Overseas Development Council in Washington DC in the 1970s, used indicators for life expectancy, infant mortality, and literacy for an index that often reversed ideas of improved life through increased income. For example, Saudi Arabia rated high for income and low for PQLI while Sri Lanka had a low GNP and a high PQLI. These indicators actually measure women's status, though that was not the original intent, since poor health for women results in high maternal mortality that often also means high infant mortality while women's literacy reflects educational opportunities and cultural openness.

Following this trend, the Human Development Index (HDI) refines these indicators into three indices based on life expectancy, education, and gross domestic product (GDP). Utilizing these and other indices, the Human Development Report makes explicit the need for gender analysis in the Gender Development Index (GDI) and the Gender Empowerment Measure (GEM). Saudi Arabia is placed in the medium human development list but ranks low in GDI and has no entry for GEM. Three developing countries, Sri Lanka, Thailand, and Jamaica, have a GDI rank that is more than 10 points higher than the HDI rank (UNDP 1998).

In 1997 the Human Development Report introduced the Human Poverty Index (HPI) to emphasize that poverty is much more than a lack of material wellbeing, but also a denial of opportunities to live a healthy and creative life and enjoy both self-esteem and the respect of others. While the HDI measures national progress, the HPI measure the deprivations of those who are left out of progress (UNDP 1998 p. 25). Significant is the finding that the US has highest human poverty among the 17 developed countries listed although it has the highest per capita income measured in PPP.

1.2 Social Aspects of Poverty

As world poverty increases, development agencies are searching for more accurate social indicators for edu-

cation, health, access to services and infrastructure. Other nonincome dimensions of poverty are being studied to tease out and evaluate illusive patterns of vulnerability, social exclusion, and gender inequities. Analyses of poverty in terms of access to social capital, entitlements to food, income, land, and houses are being conducted. These indicators do not lend themselves to aggregation into a single index. Rather this broadening of research reflects the complexities of addressing social aspects of persistent poverty (Chambers 1995). Reports on urban poverty in cities around the world and programs that improve the lives of the poor have been published in three issues of *Environment & Development*. In preparation for the World Development Report 2000/1 on Poverty and Development, the World Bank commissioned a wide range of working papers (World Bank 2000). Gendered poverty is the concern of studies produced by the United Nations Research Institute for Social Development (UNRISD 1999). The Inter-American Development Bank on causes of intergenerational transmission of poverty has resulted in an initiative on early childhood programs.

1.3 Structural Influences on Poverty

Economic and political forces external to culture and community also contribute to the current trend of increased poverty and income disparity around the world. The rapidity of the present economic transitions toward global trade and largely unfettered markets is exacerbating income disparity and contributing to the increase in poverty. Economic prescriptions to improve creditworthiness of countries, such as the Structural Adjustment Policies (SAP) of the International Monetary Fund and the World Bank, are widely blamed for the reduction of health and education budgets in those countries. Subsequently, these financial institutions have instituted changes in conditionality to require governments to balance cuts in the social safety net with other measures to reduce expenditures by trimming bloated bureaucracies or eliminating inefficient industrial projects.

Governments privilege different groups through macroeconomic choices regulating trade, investments, and food policy, among others (UNRISD 1999). Urban poverty is much influenced by the actions of city and municipal governments. Inefficient and corrupt bureaucracies contribute to income inequality and limit the effectiveness of poverty alleviation programs. In 1999, research teams in 23 countries held *Consultations with the Poor* (Narayan et al. 1999). A large majority of the poor said they were worse off, had fewer opportunities, and were more insecure than in the past. Most had little good to say about government personnel or services and turned to their own networks and institutions for support. The presence of non-governmental organizations (NGOs) was uneven; their programs received mixed reviews, often seen as

irrelevant because, despite the goals of participation espoused by NGOs, the poor do not feel that their voices are heard.

2. Poverty as Gendered

The gender division of labor traditionally allocated domestic production to women, activities that included providing subsistence as well as care to their families. The shift from labor exchange to a monetized economy tended to leave women with tasks and responsibilities that are not paid and therefore are excluded from national accounts. Opportunities for men to earn money are more plentiful but may require migration for short or long periods of time, weakening family cohesion and kin networks while changes in traditional status hierarchies as well as income paths increases insecurity. Once men earn money they often feel entitled to spend it on drinking, gambling, or women rather than on their families. These events, drinking, insecurity, and lack of kin supervision, have led to a worldwide epidemic of domestic violence and AIDS (see *Domestic Violence: Sociological Perspectives*).

2.1 Women-headed Households

The same transitions encourage the increase of households headed by women (see *Economic Development and Women*; *Economic Globalization and Gender*). Definitions of and data on women-headed households are contested, as are most statistics in developing countries. Estimates of 30 percent have been found valid since 1975, but studies have refined categories to note the numbers of widows, or of women with children returning to parental homes and becoming invisible. Women-headed households are perceived as the poorest, though regional and class variations are noted. The International Food Policy Research Institute (IFPRI) reported that women-headed households in more than half of the countries examined in Asia and sub-Saharan Africa are poorer than households containing adult men. Recent household studies link urban poverty not only to gender but to life cycle, age, and housing options. Food security is of prime concern in poor households; women are more likely than men to direct more resources to food and children (United Nations 1995, p. 129). These findings have important implications for poverty alleviation programs.

2.2 Time Pressures of Women's Double Day

In order to purchase needed commodities or pay school fees, women are pushed to earn income as well

as carry out domestic production. The dual responsibilities of women tend to limit their income opportunities and have generally resulted in women earning less than men in most of the world. Statistics on women's work, along with a discussion of problems of the definition of work and the imprecision of much data, are frequently published by the UN's Statistical Division (United Nations 1995). Time-use studies underscore the fact that women work longer hours than men in a large number of countries (see *Time-use and Gender*). This has led feminist scholars to promote appropriate technology to reduce women's work burdens (Tinker 1987). Others deplore the labor-intensive poverty programs since heavy physical work, called for in such poverty alleviation projects as road building, reduce the already limited nutritional reserves of poor women (UNRISD 1999). Government cost reduction programs that cut social spending generally add to women's time pressures as they increase hours of care-giving to children and relatives and often sacrifice income activities in the process (Moser 1996).

3. Poverty Alleviation Programming

Poverty reduction has been a major goal of economic development since the thrust toward basic human needs and redistribution with growth identified in the Second Development Decade, 1970–80 documents. The focus on basic needs encouraged development programs to address the concerns of people not just countries and promoted the women in development movement. Pressures from the growing global women's movement forced the debates over structural adjustment and free trade to consider their impact on women (see *Economic Development and Women*). At the end of the twentieth century, a New Policy Agenda emerged which considered market-led growth as the primary engine for reducing poverty. In developing countries, agriculture and labor-intensive activities were expected to provide employment. The role of the state was limited to service delivery, assisted by NGOs and other civil society organizations. The fact that the unfettered global market economy has led to more poverty has forced rethinking of poverty and its alleviation as noted above.

3.1 Programs to Alleviate Poverty

In the 1970s poverty alleviation programming was focused on rural areas. Appropriate technology was introduced to reduce women's energy and time required for subsistence activities such as collecting water and fuel, and processing food. Improved cookstoves and water-seal toilets also reduced the needs for water and fuel. Time saved became available for

literacy programs or income activities which at first were ill-adapted to poor women's skills (see *Economic Development and Women*).

3.2 Microcredit and Microfinance

Most current poverty alleviation programs focus on savings, credit for microenterprise, and the organizing home-based workers through NGOs. In combination these programs assist the poor women and men to accumulate assets and expand ties within the community which in turn encourages investments in human capital and creates social capital. The impact is more dramatic for women than men in those traditional societies where women and men are segregated socially, where women's mobility is severely limited, and where women's work is largely unremunerated. Not surprisingly, two of the most successful microcredit programs are in Bangladesh, the Grameen Bank, and India, SEWA (Self-Employed Women's Association). Savings are a prerequisite for credit which is utilized to start or improve tiny entrepreneurial activity from raising a goat to selling street foods to marketing fish. All programs require frequent attendance at group meetings which function both to break down caste, ethnic, and kin barriers and provide mechanisms for wide-scale organizing. SEWA has spearheaded the rapid expansion of Homenet, a worldwide organization for home-based workers which advocates for the extension of pensions, health benefits, and childcare to these workers. Meetings of these organizations promote the sharing of information on health, contraception, nutrition, and dealing with domestic violence as well as on business techniques. Women learn the benefits of investing in the health and education of their children, especially daughters. The Grameen Bank is proud of the number of children of members now attending secondary schools and colleges.

Profits from microenterprise and the savings programs have allowed women to purchase more durable assets such as a house or agricultural land. Many urban NGOs support programs by which the poor obtain housing through sweat-equity and credit. Women as the primary family caretakers need the security of shelter. Most laws or customary practices in developing countries still privilege male ownership of house and land (see *Land Rights and Gender*). Registration for these assets remains an obstacle though laws and traditions are changing, often under pressure from NGOs (Tinker and Summerfield 1999). The surplus of widows from war and AIDS has recently convinced both Uganda and Rwanda to allow women to inherit land. Globally, the rise of women-headed households and absentee partners, now exacerbated in postconflict regions, and their critical need for shelter has prompted the Gender Unit of the United

Nations Centre for Human Settlements to mount a campaign for security of house tenure for women (UNCHS 1999).

Programs to provide income and housing to women empower them and enhance their household bargaining position (see *Family Bargaining*). The social capital gained through membership in organizations enhances women's community presence and provides them with a voice in elections. Such power addresses gender inequalities and provides ways for women to rise out of poverty.

Poverty, Culture of

The culture of poverty concept was developed in the USA during the 1960s primarily through the best-selling ethnographic realist publications of the cultural anthropologist Oscar Lewis, who tape-recorded eloquent life histories of the urban poor. He reprinted numerous versions of his definition of the term 'culture of poverty' in short journal articles and also in the introductions to his books on family life among Mexicans, Puerto Ricans, and Cubans living in shanty towns and ghettos (Lewis 1961, 1966a, 1966b, 1967). Lewis's culture of poverty struck an academic identity politics nerve, and at the turn of the millennium the concept remained enmired in a bitter polemic over how to analyze and engage politically the persistence of poverty in the midst of postindustrial plenty.

1. Ideological Backdrop to the Culture of Poverty

In the USA, irrespective of the theoretical orientation of researchers, most discussions on poverty polarize around value judgments concerning individual self-worth or around racial/ethnic stereotypes. US attitudes towards poverty are rooted in the country's colonial Calvinist/Puritanical heritage and are exacerbated by the historical importance of racialized hierarchies that have legitimized genocide, slavery, colonization, and immigration control. This helps explain why the culture of poverty concept continues to generate so much emotional heat while shedding so little conceptual light. The uses and misuses of the concept offer a fascinating case study in the sociology of knowledge illustrating the political interfaces between theory, empiricism, art, and ethnocentric moralizing in the social sciences.

Poverty research throughout history has been more successful at reflecting the biases of an investigator's society than at analyzing the experience of poverty. The state of poverty research in any given country emerges almost as a litmus for gauging contemporary social attitudes toward inequality and marginalization. For example, while Lewis's books are read by a US public as an individualistic interpretation of the persistence of poverty that blames victims, in France his work is interpreted as a critique of society's failure to remedy the injuries of class-based inequality under free market capitalism.

2. Defining the Culture of Poverty

The socialist sociologist Michael Harrington was the first prominent academic to use the phrase 'culture of poverty' in a major publication. His book, *The Other America*, documented rural poverty in Appalachia and represented a moral call to action that anticipated the War on Poverty initiated by President Johnson in 1964 (Harrington 1962). As a first-generation son of impoverished Jewish immigrants who was influenced by Marxism in his youth, Lewis shared Harrington's social democratic commitment to combating poverty (Rigdon 1988, Harvey and Reed 1996). Ironically, however, Lewis's popularization of the culture of poverty concept is said to have tolled an intellectual death knell to the optimistic idealism of the mid-1960s that advocated eradicating poverty through direct state intervention (Katz 1989). This is because Lewis's definition of the culture of poverty stressed that a significant minority of the poor (approximately 20 percent) were trapped in self-perpetuating cycles of dysfunctional behaviors and attitudes: 'By the time slum children are age six or seven they have usually absorbed the basic values and attitudes of their subculture and are not psychologically geared to take full advantage of changing conditions or increased opportunities' (Lewis 1965a, p. xlv).

This kind of psychological reductionist and individualistic interpretation of the persistence of poverty resonated with US popular blame-the-victim discourse. Ironically, in the same articles or book introductions in which he defined the culture of poverty, Lewis also included radical political statements contradictory to the implication that poverty is caused by self-perpetuating deficient value systems. For example, in his *Scientific American* version of 'The Culture of Poverty' he quotes Frantz Fanon, praises Castro's Cuba, and criticizes 'free-enterprise, pre-welfare-state stage capitalism' for spawning the culture of poverty (Lewis 1966b). At the same time he states that 'it is much more difficult to undo the culture of poverty than to cure poverty itself,' and advocates 'psychiatric treatment' for poverty in the USA (Lewis 1966b, p. 25).

In other words, the culture of poverty concept was confused theoretically at its inception. Unfortunately, Lewis never managed to clarify what he intended to mean. His published correspondence reveals that he was profoundly disturbed by the blame-the-victim interpretation of the causes of poverty that he triggered in the USA: 'There is nothing in the concept that puts the onus of poverty on the character of the poor' (Lewis 1967, p. 499).

The notion of a culture of poverty, consequently, should not be treated as a full-blown theory. As presented by Lewis, it was merely a bundle of some 70 traits which he did not link to a particular processual or dynamic logic. In fact, he never even listed all 70 of the traits that he claimed existed. The theoretical sloppiness of the culture of poverty concept may well be a product of the McCarthyist anticommunism in US academia that impinged on Lewis during his formative years in the 1950s. Four decades after their inception, his lists of culture of poverty character traits appear embarrassingly arbitrary, ethnocentric, and psychologically reductionist (Lewis 1966a, p. xlviii):

... a high incidence of maternal deprivation, of orality, of weak ego structure, confusion of sexual identification, a lack of impulse control, a strong present-time orientation with relatively little ability to defer gratification and to plan for the future, a sense of resignation and fatalism ... male superiority, and a high tolerance for psychological pathology of all sorts.

3. *The Policy Implications of the Culture of Poverty*

In the late 1960s and 1970s Lewis's culture of poverty concept produced an outpouring of political and academic reactions, primarily in the USA but also in Mexico and Puerto Rico (Leacock 1971, *Alteridades* 1994). Despite conceiving of his work as a call for the expansion of public-sector intervention on behalf of the poor, his concept took the popular intellectual spotlight off the need for structural economic reform, and glossed over the social power dynamics revolving around class, ethnic, gender, and colonial inequalities. Policy makers, if they paid any attention to the culture of poverty concept, interpreted it as advocating the need to rehabilitate the deficient cultural value systems of poor children through the agency of psychiatric social workers. For example, in the applied policy realm Lewis consulted in the development of the Head Start Program in the USA (Rigdon 1988), which has been criticized retrospectively as an attempt to 'take inner-city preschoolers who live in lead-painted, rat-infested tenements without steady heat or hot water, and metamorphose them into bright-eyed, upper-middle-class overachievers' (Bourgeois 1995, p. 325). Significantly, in the year 2001, Head Start was still

identified by both liberals and conservatives as one of the only successful antipoverty programs of the 1960s.

4. *The Theoretical Implications of the Culture of Poverty*

Unfortunately, most of the hostile academic responses to Lewis's culture of poverty concept have limited themselves to contradicting Lewis's empirical assertions, rather than to critiquing theoretically his psychological reductionism, his sloppy use of the culture concept, and his failure to link in a dynamic manner macrostructural political and economic forces—including gender power relations—to ideology, culture, and individual values (Valentine 1968, Stack 1974; for a political economy exception, see Katz 1989; for a feminist literary criticism exception, see Franco 1989). The bulk of the negative reaction hinges on a political concern for replacing the negative imagery of Lewis's painful but expressive ethnographic portraits of the everyday suffering of urbanized families, with positive images of the worthy poor, struggling for upward mobility against all odds. A late 1990s rehabilitating of the culture of poverty concept from a Marxist perspective dismissed the virulence of the US progressive reaction against the culture of poverty concept as a sectarian 'ultra Bolshevism' that swept the New Left when the general public was drifting ideologically to the Right following the War on Poverty. This precipitated a 'fruitless game of radical one-upmanship' among frustrated intellectuals, who were completely marginal to public political discourse, and who chose instead to devote their energies to proving their dedication to protecting the image of the poor (Harvey and Reed 1996). More importantly, the urgent righteousness of the anti-culture of poverty social science literature is comparable to the polemics against Moynihan's 1967 patriarchal attribution of the 'tangle of pathology' in the black family as being the central cause for the persistence of poverty among urban African-Americans (Rainwater and Yancey 1967).

The angry denial by academics of the existence of the types of violence and self-destructive behaviors described ethnographically by Lewis among the vulnerable families that he tape-recorded and described reveals how far removed intellectuals can be from the inner-city street. Although Lewis's writing deserves criticism for presenting his subjects in a decontextualized pornography of violence, sexuality, and emotional brutality, none of the behaviors or personalities described by Lewis should shock anyone who is familiar with everyday life in the US inner city or Latin-American shanty towns. On the contrary, Lewis's ethnographic realist descriptions, unfortunately, still ring true four decades after they were written. His disturbing material, however, demands

theoretical explanation and political contextualization, and that is where both Lewis and his critics and admirers have largely failed. By confining the debate to a worthy vs. unworthy poor dichotomy, the internecine squabbles between leftist, liberal, and conservative academics mimetically reproduce the right-wing hegemony in popular US culture that equates poverty with sinfulness.

Arguably, the polemics of righteousness that the culture of poverty prompted scared a generation of social scientists away from ethnographic analyses of inner-city poverty in the USA and, to a lesser extent, around the world (Wilson 1987, pp. 13–16). Indeed, accusations of supporting a ‘culture of poverty interpretation’ are still frequently invoked in polemical identity politics attacks between academics over any representation of poverty that is not flattering to poverty’s victims (cf. Lassalle and O’Dougherty 1997). Hence the virulence of the ‘underclass debate’ in sociology spawned by William Julius Wilson’s book *The Truly Disadvantaged* during the late 1980s through the 1990s (Katz 1989, Wacquant 1997).

From a theoretical perspective, the legacy of the culture of poverty debate has impoverished research in the social sciences on the phenomenon of social suffering, everyday violence, and the intimate experience of structural oppression in industrialized nations. Most importantly, by remaining mired in debates driven by identity politics, researchers have minimized the painful experience of day-to-day survival among the persistently poor. Epidemiological data on the associations between social class interpersonal violence, domestic violence, health outcomes, education outcomes, substance abuse, etc. are simply ignored by most poverty researchers in the USA.

The vacuum of critical intellectual engagement with the phenomenological experience of poverty has allowed right-wing academics subscribing to facile neoliberal blame-the-victim interpretations to capture popular imagination and policy debates—especially in the USA. Social or cultural reproduction theory, which emerged out of studies of poor youth at the intersection of the disciplines of education, sociology, and anthropology during the 1980s and early 1990s, offered a critical theoretical alternative. By focusing on the power dynamics of the interface between culture and social inequality, social/cultural reproduction theorists address the empirical reality of the existence of patterns of interpersonal self-destruction without obscuring structural political forces. Although vulnerable to critique for being overly functionalist, these theories allow for the reinscription of agency among the poor, as well as an autonomous role for culture in political economy (Bourdieu and Passeron 1977, Willis 1981).

Few serious social science researchers, if any, at the dawn of the twenty-first century would dare utilize the term ‘culture of poverty’ in their analysis, despite the fact that their empirical and theoretical work addresses

cultural expressions of social suffering due to the entrenchment of urban poverty in industrialized and postindustrialized societies. The problematic analytical and political utility of the culture of poverty concept demonstrates how dangerously essentializing the phrase ‘culture of ...’ can become with respect to any concept. Indeed, anthropologists cannot agree upon a useful definition for culture; nor do they understand how it operates without turning it into a black box of totalizing essences (Gupta and Ferguson 1997).

The culture of poverty furore reminds us that academics fight so hard over so little especially when marginalized political perspectives are at stake. At the turn of the millennium, much of the world’s population survives precariously in shanty towns, housing projects, tenements, and homeless encampments where mind-numbing, bone-crushing experiences of poverty engulf the socially vulnerable. Meanwhile, concerned academics continue to fiddle in their ivory towers, arguing over how to talk correctly about the structural violence of poverty.

P. Bourgois

Poverty in History

1. The Concept of Poverty

There is no universal concept of poverty which can be applied to all cultures, societies, or times. Nowadays, poverty is usually defined in relation to the medium-income level of a society, and the poverty line is drawn where a family has less than 50 percent of this medium income available. Such seemingly 'exact' definitions are not possible before general income statistics were generated by statistical offices in the twentieth century (with forerunners in some of the most developed countries in the nineteenth century, and even earlier in some cities).

Some researchers have sought to define an absolute level of poverty by drawing the borderline at the minimum input of calories which a person needs to survive. But even this definition cannot be used as a universal measure since this minimum differs with age, sex, climate, the individual body, health, and the kind of work a person does. Moreover, poverty certainly begins before a person dies of hunger. Therefore, 'poverty can be defined objectively and applied consistently only in terms of the concept of relative deprivation' (Townsend 1979, p. 31). But what is relative deprivation?

2. The Size of Poverty

If we were to take present standards of living in advanced societies as a yardstick, most people, probably more than 90 percent, in all cultures and ages, would have to be defined as paupers. Only rulers, their

immediate entourage, and some large landholders and merchants were free of poverty. Most people working in handicrafts or on the land whom we would term today as the middle classes lived at least at the borderline of poverty. When the harvest failed, epidemics arrived, or war devastated a region—and this occurred frequently even in Europe up to the seventeenth and eighteenth centuries—they could be driven into misery. In other regions of the world, where periods of drought or torrential rains recur regularly, it is even today difficult for the majority of people to work themselves out of poverty.

For Western Europe we have sporadic estimates of the size of poverty for single cities and smaller regions since the later middle ages, and by Gregory King for a whole country, England, in 1688. They vary considerably, partly because the criteria used often remained vague and depended on the prejudice and the purpose of the author or institution taking the numbers. In some relatively well-to-do cities like Toledo, Lyons, Verona, Augsburg, Amsterdam, and Norwich in the sixteenth and seventeenth centuries, the poor numbered between 5 and 10 percent of the population in 'normal' times, rising to between 20 and 30 percent in times of wars, epidemics, or harvest failures. Similar figures have been found for some rural hinterlands of such cities, e.g., around Nuremberg or Zurich. (Jütte 1994, p. 53).

According to Gregory King, however, paupers constituted the majority of the population of England at the end of the seventeenth century. While half a million families (comprising about 2.7 million persons) increased the wealth of the country, about 850,000 families (comprising more than 2.8 million persons) decreased it by depending on others for their livelihood (Mathias 1983, p. 24). Other contemporaries give, however, different figures.

In eighteenth century France estimates of the size of poverty vary according to the definition between one-third and half of the population. When, during the French Revolution, the definition of poverty was sharpened by excluding beggars, vagabonds, and others, 'unwilling to work' the Comité de Mendicité stated that 39 percent of the working men were not able to support a family of five persons (Hufton 1974, p. 22).

One can distinguish at least three different measures used by officials in Western Europe in early modern times to count their paupers. The first was to count the recipients of welfare in one way or the other. This depended, of course, on the welfare policy applied at a particular location. Known figures vary from 2 percent for the city of Berlin in 1665 (but 7.2 percent in 1799) to 14.8 percent in Trier in 1623. But it is also known that in nearly all cities, the majority of people who applied for welfare were refuted. (In Amsterdam in 1799 37,500 received help, while 81,080 were refuted.) The second measure were censuses of the poor. These were rare, and the few available figures vary between

9.5 percent in Valladolid, Spain, in 1561 and 20–25 percent in Huddersfield, England, in 1622. The third method is to count the ‘fiscal poor’: the people (mostly heads of households) exempted from taxes because of poverty. Here we find a much higher level. The lowest available figure is 4.7 percent for Cologne in 1582 while the highest was 77 percent for Verona in 1635. Most other cities record shares of the tax-exempt households between 35 and 50 percent (Jütte 1994, pp. 46–56).

Taking into account that most of these figures stem from cities in the wealthier parts of Europe, it is easy to imagine the degree of poverty in other regions, particular the notoriously poorer mountainous regions, or the countryside in Eastern Europe, not to speak of the less developed continents.

3. *Who Are the Paupers?*

Certain groups of paupers can be found in all cultures and centuries, for instance, the bodily or mentally handicapped who are not able to work, and father- or motherless children (except those who live in extended families). Very often mothers with fatherless children are being reported amongst the poor. Finally, elderly people, particularly widows, frequently fell into poverty, at least before old age pensions were introduced in the late nineteenth and twentieth centuries. Even then they rarely received pensions high enough to support them. These people can be called ‘structural poor.’ They probably formed the 5–10 percent of paupers registered even in well-to-do cities and regions. In addition are those who have become temporarily unable to work because of sickness or injury, particularly during wars or natural disasters. One could term them ‘cyclical poor.’ Their numbers could swell easily to more than half of the population if events like epidemics, crop failure, or war devastated a region. At such times usually all those who lived on the margin of subsistence—until very recently the majority of the population—fell into deprivation.

All these groups have been seen since the Middle Ages by both worldly and religious authorities as ‘deserving poor,’ to help whom was a task for church, local or central governments, and private charity. They are to be distinguished from the ‘undeserving poor’: able-bodied idlers, beggars, vagrants, vagabonds, and prostitutes, who had to be educated or penalized, being expelled or—since the sixteenth century in Europe—put into workhouses or prisons (often one and the same).

For modern observers the biggest group are, however, the ‘working poor’: small peasants or handicraftsmen day laborers in cities as well as in the countryside, and the unemployed. Nor should slaves be forgotten. Though not all slaves in ancient Europe or seventeenth to nineteenth century America were

poor—some had learned crafts or worked as privileged servants, even as artists or managers—the great majority certainly were, and slavery existed also in other cultures and in some European countries as late as the seventeenth and eighteenth centuries.

4. *The Causes of Poverty*

For analytical purposes one can distinguish between different causes of poverty but one has to be aware that in reality they often were intertwined. Jütte (1994) distinguishes between accidental, cyclical, and structural causes. Accidental causes are, for instance, sickness, which counted according to the English Poor Law Commission in 1909 for ‘at least one-half of the total cost of pauperism’ (p. 21). In early modern Europe plague, influenza, typhus, typhoid fever, or smallpox did not only kill large segments of the population but also impoverished many of those who had survived. Warfare is another ‘accidental’ cause. Bad harvests, as well as periods of accelerated population growth and structural changes in the economy, Jütte counts as ‘cyclical,’ while he sees ‘structural’ reasons mainly in demographic patterns: persistent large families with many children and a non-secured old age. One would have to add seasonal causes to this typology. In northern countries each winter produced unemployment and poverty.

Another analytic scheme could be to distinguish between natural, demographic, sociopolitical, and economic causes of poverty. In all pre-industrial societies man was subject to natural conditions and disasters: drought or flooding, fire, unbearable heat in summer, or ice-cold storms in the winter time could stop his activities, and the natural fertility of his land limited his productivity. Richer or poorer soil, the availability of transport routes on rivers, lakes, and oceans, the availability of raw materials, like wood, copper, or iron ores determined the results of his labor. Demographic factors played an important role—as long as productivity could not be raised markedly, population growth could lead to increased poverty. Sociopolitical factors influenced the degree of and the distribution of wealth and poverty in all cultures, societies, and ages. Centralized or decentralized power, the strictness or looseness of social and political hierarchies, the degree and distribution of freedom, serfdom, or slavery amongst the population influenced also the living standards. Where geographic mobility was restricted, as in the case of slaves and serfs, people could rarely evade poverty by moving to better places. Where upward social mobility was restricted even hard work could help little to improve the lot of the lower strata of society. Here India with her caste system is probably the worst case, but Chinese and Eastern European peasants also fared worse than Western European ones, or Europeans in their new

settlements overseas. Economic conditions are closely connected to the political and social order. Where market conditions could develop a growing minority at least had the chance to escape poverty. But economic development did not occur harmoniously and evenly. The rise of one sector or region could cause impoverishment in another. When Dutch and English woolen products flourished in northwestern Europe in the sixteenth and seventeenth centuries, Italian cities suffered from the new competition. When Indian cotton products appeared on the European markets, the European woolen and linen producers had a difficult time, and when the British and Western European textile industries mechanized their production in the late eighteenth and nineteenth centuries Indian calico producers lost out.

Since the Industrial Revolution numerous such displacements took place and led to regional and branch- or industry-wide pauperization. Most, but not all, were temporary and could be stopped by adjustments to new technologies or other activities. Social and geographical mobility helped to absorb such shocks. There was, however, no overall impoverishment connected with industrialization. On the contrary, rather, the growth of productivity connected with mechanization and rationalization improved even the lot of the poorer segments of the population in the long run. The social problems at the beginning were caused rather by the population growth, which accelerated noticeably from the later eighteenth century. Without industrialization and the growth in productivity in agriculture too, Malthus' law that population grows faster than productivity would not have become obsolete.

There has been a long discussion amongst economic historians of Britain about whether the standard of living of the working classes during the Industrial Revolution improved or deteriorated. There is agreement that it improved from the 1830s when productivity grew recognizably and regularly and the growth of industry created more better-paid jobs. The pessimistic school maintained, however, that between about 1780 and 1830 the living standard of the workers deteriorated. This discussion suffers from a lack of adequate statistics, particularly of consumer prices and regional differences. As always when structural changes occur, there were winners and losers. The winners were skilled laborers and those who could move to better-paid jobs in growing regions; the losers were the immobile, unskilled people in areas not enjoying growth in industry, trade, and services (Fischer and Bajor 1967, and an ongoing discussion in the *Economic History Review*).

The discussion was first aired amongst British social reformers and Members of Parliament in the 1820s and 1830s, culminating in F. Engels' famous book on the situation of the working classes in England (1845) in which he painted an unrealistic picture of the idyllic life of the workers in the putting-out industry and

contrasted it with that of the industrial workforce. It was also influenced by the last grave subsistence crisis which occurred in parts of Western Europe during the second half of the 1840s. Ireland in particular, but also regions on the continent like Silesia, was hit by bad harvests including a nearly total loss of potatoes, the poor man's main food. Millions died or emigrated. The not-yet-mechanized linen industry could not compete with mechanized cotton industry. Pauperism seemed on the rise again, but this was a cyclical rather than a structural phenomenon. Since the middle of the nineteenth century living standards of workers improved in most countries of Western Europe and North America without, however, erasing poverty. In many countries serious empirical work on the size and causes of poverty began only now, culminating (amongst others) in the seventeen volumes Charles Booth published between 1889 and 1897 about *Life and Labour of the People of London*.

5. Welfare Policies

There is agreement amongst students of poverty that (modern) welfare policy began only in the nineteenth century, with the onset of social security schemes. But to care for the poor was seen as a moral obligation in all major religions and it was institutionalized at very early stages of history. Compassion was, however, only one reason for this: the other was fear, for paupers were regarded as dangerous. This twin motivation runs right through the centuries. The second motive, fear, seems to have dominated public policy in the Roman Empire, but early Christians insisted that *caritas* was essential. The Early Fathers of the Church, like St. Augustine, preached that poverty was a virtue and some founders of Christian orders, as in the case of St. Francis of Assisi, obliged their brethren to adhere to it. The Church and its monasteries were thus the main bodies responding to the fate of the poor during most of the Middle Ages, though not the only ones. Self-help played a role not only amongst families and neighborhoods but also in the craftsmen's guilds, which cared for their sick people and sometimes for the widows and elderly masters. Brotherhoods existed not only for journeymen but sometimes also for unskilled laborers, and in the later Middle Ages in some cities such as Frankfurt, Strasbourg, or Zurich even for 'the blind and the lame' (Fischer 1982, p. 29). In other countries, such as Spain, confraternities which enrolled men and, in some cases, women from different occupations, offered mutual aid alongside spiritual welfare to their members. Christian belief convinced wealthier citizens to secure their salvation by giving alms, establishing foundations for the poor or leaving parts of their fortunes to institutions such as hospitals.

Hospital pauperum already constituted small centers of welfare in the early Middle Ages. Often they cared for twelve persons, symbolizing the twelve apostles. In

the twelfth and thirteenth centuries many such hospitals were founded, not only by bishops and monasteries but also by kings, princes, merchants, guilds, and cities. About 600 of such hospitals existed in England in the middle of the fourteenth century. Some of them specialized, for example, in the care of children or of old people, or of those with certain maladies like leprosy. Often they supplied only minimal help, not even food was necessarily provided, and their inhabitants received permission to beg. Medical care was an exception since very few physicians were available. Most of the hospitals in the smaller towns remained all-round institutions for helpless people, but a few housed several hundred people.

In the later Middle Ages cities took over some such hospitals or founded new ones. They installed poor relief administrators, who began investigations of individual cases of poverty and made surveys for their towns or districts. Poor relief was to be made more efficient and rational; pure almsgiving was no longer enough. The 'deserving poor' were to be separated from the 'undeserving' ones. Orderly procedures were being introduced in administering poor relief. This was particularly marked in northern and central Europe while in France, Spain, and Italy worldly authorities remained more reluctant to take poor relief out of the hands of the Church.

This rationalization and bureaucratization began well before the Reformation, and afterwards Catholic and Protestant regimes did not necessarily follow different policies—both, for instance, tried to educate the poor, particularly the children, though with meager results. But there were differences as to the centralization or decentralization of such policies. Mainly Protestant cities centralized their institutions into a 'common chest' to exercise better control. In the German Empire the Imperial Diet of 1497 declared that each community should take measures to care for its own poor, and this principle was enacted in the Imperial Police Ordinance of 1530 which remained in force until the end of the Empire in 1806. Switzerland, The Netherlands, Britain, and the Scandinavian countries followed similar paths, while in the Mediterranean countries the many decentralized institutions remained more or less undisturbed.

While Britain is seen as the pioneer of a general poor tax in 1572, the municipality of Paris had introduced such a tax already in 1551 after the French King had given it the authority 'to supervise and conduct all things required for the treatment and the relief of the poor' (Jütte 1994, p. 119). But Britain pioneered early modern poor regulations in several respects. Already in the middle of the fourteenth century Parliament ordered that the working poor should be distinguished from beggars, and in 1388 tried to restrict the mobility of beggars. From the 1530s to around 1600 numerous statutes were enacted, of which those of 1572 and 1596 became known as the 'Old Poor Laws,' which remained in force until 1834. The Judges of the Peace

had to select four men of substance to act as overseers of the poor. These men had to raise the poor tax, distribute help, and take care of the education of orphans. They were supposed to punish beggars and vagabonds, and could establish houses for correction. As in other countries, the result of their endeavors was very uneven. The poor taxes always fell short of the needs. It has been estimated that only 7 percent of the expenditure for the poor originated from taxes—by far the greater part came from private donations and charitable trusts which were established by wealthy citizens. One rich Londoner alone set up institutions for the poor in 216 communities (Fischer 1982, p. 43f.). Such trusts also ran hospitals and schools.

In the minds of the early modern poor administrators and the wider public, education to work became more important than poor relief. Therefore, workhouses were established in the major cities and some smaller towns. The hope was that they would both accustom the poor to work and produce some profit. Usually they failed in both respects. Particularly in The Netherlands, the Scandinavian countries, and in Germany they became rather a combination of workhouse and house of correction, the famous example being the Amsterdam *tuchthuis* founded in 1595. In smaller towns such houses often tried to perform four functions: educating orphans, getting adults to work, penalizing beggars and criminals, and taking care of handicapped or sick people.

The English Poor Law of 1834 was supposed to remedy the ages-old deficiencies in welfare policies. After a Parliamentary Commission had found that the 'Old Poor Law,' by prescribing assistance to every needy person, had actually provided a disincentive to work, the new law stipulated that only such paupers who were willing to live (and work) in poorhouses should get relief. It turned out that there were not enough such institutions to house everybody who did not find work on his own or did not earn enough to survive, particularly with a larger family. The new law did not remove the ancient causes of poverty, neither could it take care of the temporary unemployment of industrial workers, but it revived the discussion about social problems in the country. A whole set of measures had to be taken to improve the lot of the poorer classes: while more employment was to be created by industry, transport business, and services. Parliament regulated child and female labor, and began to enforce safety measures at the workplace, while local communities improved the housing and sanitary conditions. In 1876 about 19 percent of the population were insured by voluntary Friendly Societies, relatively more than in Germany's obligatory health insurance in 1885, but the most needy could not afford the contributions. Private charity remained, therefore, important in Britain. In 1897 Britain introduced obligatory accident insurance, in 1908 old age pensions, and in 1911 a combined health- and unemployment insurance.

Other European countries were faster in creating obligatory accident-, health-, and old age insurance. But unemployment, one of the most important reasons for poverty, was being regarded as non-insurable even at the end of the nineteenth century. In Germany, unemployment insurance came into force only in 1927. Most of these insurances were quite inadequate at the beginning. They covered industrial workers only in some branches, not day-, farm-, and home-workers, thus excluding the poorest part of the labor force. Bismarck's Old Age Insurance provided means only at the age of seventy when most people had died already, and widows received only 20 percent of the earning of their husbands in accident insurance. But the principles of a modern welfare state were established, and the basic institutions for it were created before or shortly after World War I.

Poverty Law

'Poverty law' refers to two distinct but related topics. One has to do with the welfare state, or more particularly, that part of the welfare state that seeks to address the needs of the poor. In the United States, as is true of all advanced industrial economies, many programs fit this definition. In this article, the definition will be restricted to income support for single mothers and their children—the program formerly called 'AFDC' (Aid to Families with Dependent Children) now replaced by 'TANF' (Temporary As-

sistance to Needy Families). Although not the largest program, by far, it is the most controversial. This is the program that is referred to as 'welfare,' which has become the code word for the stereotype inner-city, African-American woman, often a substance-abuser, having children to stay on welfare, and breeding a criminal class. 'Welfare' is the word used to describe the 'underclass' in America.

The second and related meaning of 'poverty law' refers to the legal rights revolution that blossomed in the 1960s that focused on welfare and other poverty issues. Although Americans have always resorted to the judicial system to try to further political goals, the modern era can probably be dated from the court victories of the National Association for the Advancement of Colored People (NAACP) and its offshoot, the Legal Defense Fund (LDF, also known as the 'Inc. Fund'). The LDF victory in *Brown vs. Board of Education* (1954), where the US Supreme Court declared school desegregation unconstitutional, ushered in an incredibly active period of law reform litigation brought by a wide variety of legal service, public interest, and private lawyers. In addition to civil rights (for women, other racial and ethnic minorities), consumers, and environmental protection, rights were won for the mentally ill, the disabled, children with learning disabilities, health care patients, criminal defendants, prisoners, gays and lesbians, and so forth. The particular concern of this article is with lawyers who worked on behalf of the poor.

The two parts of 'poverty law'—'welfare' and poverty lawyers—will be discussed together, because their developments were intertwined.

1. Aid to Single Mothers Prior to the 1950s and 1960s

Programs to provide income support for poor single mothers were enacted by the states between 1910–20. They were part of the Progressive Era Child Saving Movement. Social reformers, alarmed at the number of immigrant children growing up in the urban slums, expanded the definition of child neglect and removed children from what they considered to be baleful living conditions and sent them to either farms in the mid-West or reformatories. Juvenile courts were established at the turn of the century with jurisdiction over 'delinquent, dependent, and neglected' children. The latter two were considered 'pre-delinquent.' Then, the Child Savers decided that if the home was just poor, but otherwise 'fit and proper,' perhaps the mother could be supported with a grant as an alternative to removing the children. The programs were called 'Aid to Dependent Children,' (ADC) although popularly known as 'Mothers' Pensions.' In most jurisdictions, they were administered by the juvenile or county courts, assisted by local charities, to make sure that the homes and the mothers were 'fit and proper.'

This early history set the pattern for the next 40 years. The programs were locally administered, small, and basically restricted to white widows. Other single mothers—divorced, separated, never married, and of color—were not considered 'fit and proper.' The consequences of exclusion were severe. Those who were excluded were lumped together with the rest of the 'undeserving poor'—childless adults, the long-term unemployed, others who were excluded from other assistance programs. The 'undeserving poor,' including most single mothers, were thus required to support themselves as best they could in the paid labor market. The establishment of the American welfare state, in 1935, changed the pattern for single mothers only slightly. ADC became a grant-in-aid. The Federal Government assumed about half of the costs and set a few eligibility and procedural conditions, but substantive and administrative control remained with the states and the counties.

AFDC (Aid to Families with Dependent Children, 1962) changed radically starting the late 1950s and early 1960s. The previous system of exclusion collapsed and the rolls and costs exploded. In 1950, two million people were on the rolls; in 1960, three million; then 13 million by the end of the 1980s. Costs rose from about \$500 million in 1950 to about \$23 billion. Most dramatically, however, was the change in the demographic characteristics of the rolls. In streamed the previously excluded—divorced, single, never married, with increasing proportions of nonwhites. There were various reasons for the changes—the massive migration of African Americans out of the rural south to the northern cities; the entry of women into the paid labor force; the severe unemployment in the inner cities, with the accompanying increase in poverty; rising social unrest, disorder, crime, and riots (during the early 1960s, there were riots in 24 cities); the pressure exerted on local governments by the Federal Government's War on Poverty; the welfare rights movement, and the legal rights movement; the courting of innercity voters by the Democratic Party; and the rise of single mother families. This was the era of the Great Society. A variety of federally sponsored local initiatives and activist groups attacked local institutions and practices, including welfare. The federal courts, War on Poverty lawyers, and welfare rights organizations, such as the National Welfare Rights Organization (NWRO), forced open the state AFDC gates. Welfare became a 'right'; social movement groups actively recruited potential eligibles, reaching more than 90 percent in the early 1970s. Welfare was now in 'crisis.'

2. The War on Poverty; Poverty Lawyers

The first legal aid society was established in 1876 in New York City to ease the transition of German immigrants. Thereafter, with the prodding of the

American Bar Association, organizations spread serving the various needs of the poor. By the early 1960s, there were 249 offices. However, the individual offices were small and underfunded. The caseload was mostly landlord-tenant, consumer, and family matters, but few divorces, adoption, bankruptcy, and juvenile proceedings. Legal aid offices did not want to get involved in morally controversial issues. The work was individual service cases. There was no attempt at law reform, test case litigation. The first public defender system was established in 1910. The public defender system grew much more slowly than legal aid. In contrast to legal aid which was based on private charity, the public defender depended on public funding.

The big change in legal services for poor came with Kennedy Administration (1961–1963). Legal rights for the unrepresented was an integral part of the New Frontier and then President Johnson's War on Poverty. The overarching strategy was 'community action,' whereby the poor would help themselves (with lots of government support). If the poor were to be empowered, they would need legal help. There was a struggle, however, over the model and control of legal services. Local bar associations pressed for an expansion of their established individual service offices. The alternative model came from the more aggressive, test-case, law-reform activities, primarily, but not exclusively the NAACP and particularly, the LDF. It would be hard to overestimate the influence of the LDF class action, law-reform strategy during this period. Aided by an activist federal judiciary, at the stroke of the judicial pen, so it seemed, legal rights and legitimacy were given to disadvantaged groups. This prospect of significant social change via the legal system had an enormous appeal to activist, young, elite lawyers. The US Supreme Court, led by Chief Justice Earl Warren, and the NAACP litigation seemed the perfect example of what law and lawyers could do. This was a period of enormous social activism, particularly with civil rights. Although there were the usual compromises with the bar associations as to the organization and funding of legal services, the aggressive, law-reform approach became the most important influence in the development of the War on Poverty's Office of Economic Opportunity (OEO) Legal Services program (1965), as well as in foundation support for consumer, environmental, and public interest law. As we shall see, it also became the focus of the conservative attack on Legal Services.

The specific model for Legal Services was the Ford Foundation's Grey Areas program, where community-based legal services was visualized as an integral component of the tools necessary for the militant self-assertion of the poor and the disenfranchised. Legal services were offered for a range of activities—education, employment, welfare, health and mental health, individual service, and community development. The dominant approach was using test

case litigation to establish new rights and the rule of law in dealing with government administrative agencies. The most important legal needs of the poor were thought to be those that concerned their relations with public service programs such as welfare and housing.

While many ideas and organizations contributed to the development of Legal Services, three stand out. One was the influential article by Charles Reich (1964), then a professor at Yale Law School, who argued that relationships with government should receive the same status and protection as traditional property rights. He coined the term, the 'new property.' The other was the articles published by Jean and Edgar Cahn (1964, 1970) which presented the case for neighborhood, activist legal services offices. The third was the support for Legal Services by the American Bar Association which became crucial not only in the contests with local bar associations, but also against the rising conservatism specifically directed at Legal Services.

By 1966, OEO was giving US \$20 million to 130 local legal services organizations throughout America. The local offices, in turn, were supported by a half dozen backup centers which provided research support for the litigation activities. From the mid-1960s to mid-1970s, Legal Service lawyers and their allies won a significant number of cases in a variety of areas. The US Supreme Court held that welfare could not be denied simply because the mother cohabited with an unrelated male (the 'man-in-the-house' rule); that states could not withhold welfare or provide lower benefits to the poor who migrated from other states. The most significant welfare case was *Goldberg vs. Kelly* (1970) which held that welfare was a statutory entitlement and that before welfare could be terminated, the client had a due process right to a trial-type hearing at the administrative level with the right of judicial review. During this period store-front offices would advise welfare clients of their rights, both statutory and administrative. Aided by lawyers, clients were emboldened to confront the line staff, and, in certain parts of the country, organize mass demonstrations and sit-ins at local offices. Significant victories were won in both federal and state courts—for example, persons were entitled to a due process hearing to contest the repossession of property or eviction from public housing; the mentally disabled had the right to be represented by an attorney in commitment hearings and if confined to an institution, a 'right to treatment.' In addition, significant legislation was also passed—e.g. the Voting Rights Act, the Americans with Disabilities Act, the Education for All Handicapped Children Act, which, among other things, sought to guarantee parent participation in school special education decisions.

Goldberg vs. Kelly was the high-water mark. Legal Services lawyers tried to establish that the right to a basic income was a fundamental right that deserved the same protection as other fundamental rights, such

as speech, religion, and the right to be free from racial discrimination. But the Supreme Court almost immediately took back what it gave in *Goldberg*. The Court held that welfare regulation was similar to other economic and social matters and could be regulated according to a less exacting standard of reasonableness. Subsequent cases applied the 'reasonable regulation' standard in upholding maximum grants regardless of family size, percentage reductions of AFDC grants as compared to grants for the aged, blind, and disabled, lower amounts of school funding in poorer districts, and unannounced caseworker visits as not violating the Constitutional prohibition of unreasonable searches and seizure.

By this time, the reaction to the activism of the 1960s began to take hold. Not surprisingly, Legal Services' successes against government agencies aroused the hostility of state and local political leaders. Legal Services earned the undying enmity of Ronald Reagan, as governor of California (1967–69) when one of the offices successfully blocked his attempts to cut back on welfare and health care for the poor. From time to time, governors attempted to prevent Legal Services offices from bringing suits against government agencies or on behalf of particular clients (e.g., migrant workers).

3. *Change in Welfare*

Reflecting the liberal moment, the first response of the Kennedy Administration to the 'welfare crisis' was social services to strengthen families and help them towards self-support. The 'social service amendments,' however, never provided much money or services. Rolls continued to grow, and the social service approach was abandoned in 1967. Thereafter, the conservative approach took over. The perception was that AFDC, especially at the local level, was out of control. The program was overly complex, administratively impossible, and hence, subject to rampant 'waste, fraud, and abuse.' The first reaction of the conservatives was a major overhaul of administration. Many of the complex rules were abolished (most notably, those providing for special grants to meet special needs).

Caseworkers were downgraded to eligibility technicians (often with little more than a high school education) whose main task was to monitor rules and reduce errors. The Federal Government imposed strict error-rate standards on the states, and the states, in turn, imposed strict standards on local county administration. The various state and local programs became increasingly rationalized and computerized, all designed to check eligibility and financial payments. Grants to families were either reduced or, more commonly, not allowed to keep pace with inflation. Average grants declined by 45 percent between 1970 and 1996.

The second response was to return to first principles. Those previously excluded from AFDC were required to work in the paid labor market; they were part of the 'undeserving' poor. The conservatives argued that they did not lose their negative moral ascription merely because misguided liberals allowed them into the AFDC program. Beginning in 1967, the first federally-imposed work test for able-bodied AFDC recipients was enacted (WIN, the Work-Incentive Program). Liberals vigorously fought WIN, arguing that if nonwelfare mothers were not required to work, then it was unfair and punitive to require welfare mothers to work. The conservatives said that these historically undeserving women were morally different from mothers who were either man-dependent or self-sufficient. Over the next 20 years, there was a standoff. The work programs, both state and federal, never succeeded in the sense of either reducing rolls and costs through employment, or setting the poor to work, or imposing sanctions for failure to comply. It was administratively easier and less costly to simply defer the vast majority of work-eligible welfare recipients.

Both sides remained unhappy. The conservatives continued to attack the 'entitlement state' on the grounds that there are responsibilities as well as rights in the social contract. Then, in the late 1980s, the liberals changed. They now agreed that AFDC mothers should be expected to work. They gave two reasons. Since the majority of nonwelfare mothers were in the paid labor force, it is only reasonable to expect welfare mothers to work. Second, families are better off, both materially and socially, when the adults are gainfully employed. The Family Support Act of 1988 attempted to strengthen the work requirements. In the meantime, states began to experiment with welfare-to-work programs under waiver from the Federal Government.

The welfare 'crisis' continued to boil. President (then candidate) Clinton promised to 'end welfare as we know it.' The 1994 mid-term elections produced a strongly conservative Republican Congress, which enacted the Personal Responsibility and Work Opportunity Act of 1996. AFDC was abolished, replaced with Temporary Assistance to Needy Families (TANF). State authority over welfare, already considerable, was increased by converting the federal entitlement into block grants. The work requirements were strengthened significantly, now enforced by two sets of time limits: recipients can no longer receive aid for more than two consecutive years (states have the option of shorter limits); and there is a cumulative 5-year lifetime limit. States are required to move an increasing percentage of recipients into work or work-related activities; states are required to reduce grants for recipients who refuse to engage in work or work activities. In addition, there are many 'family values' conditions—for example, requiring mothers under 18 to live with their parents or in adult-supervised

settings; requiring cooperation in the establishment of paternity; states can refuse to pay for children conceived while the mother was on welfare; or deny cash assistance for life to persons convicted of a felony (which, in most states, could be possession of a small amount of marijuana). The Act also modifies several other programs which can impact on the wellbeing of the poor—health care, food stamps, disability, and so forth.

The consensus behind the work provisions (as well as the family values) is that welfare encourages dependency with all its attendant ills for both the adults and the children. Tough work requirements, enforced by time limits, will not only reduce welfare costs, but, more importantly, replace the entitlement status and permissiveness of the current system with values of responsibility and self-sufficiency. TANF explicitly rejects education and training in favor of the ‘work first’ strategy. The argument for this strategy is: (a) there are plenty of jobs for those who want to work; (b) by taking any job, even an entry-level job, and sticking with that job, a person will move up the employment ladder; (c) the problem with welfare recipients is that they do not have the motivation or the incentives to leave welfare and enter the paid labor market; and (d) state programs have shown that recipients can be moved from welfare to work.

Many states began implementing their programs between 1993 and 1995. In the meantime, starting in 1994, AFDC, nationwide, began a sharp decline—from 5 million families to 2.8 million, in 1998. State and Federal politicians, of course, are claiming ‘success’ for the welfare reforms. Aside from the fact that the declines in the rolls started well before the initiation of the welfare-to-work programs, the evidence from the state programs is that comparatively few recipients entered the labor market as a result of the programs and they earned very little more than the controls. For example, in the most ‘successful’ program—the standard-bearer for the ‘work first’ strategy—Riverside, California—at the end of the demonstration, two-thirds of the experimentals were not working and over half never worked during the entire 3-year period.

The reasons for the lack of success of the state programs are that the assumptions behind the ‘work first’ strategy are totally misconceived as to who welfare recipients are, why they are on welfare, and the characteristics of the low-wage labor market. Despite the impressive job growth, there has been a stagnation, if not decline, in the wages and benefits for the less skilled, less educated worker. Jobs are increasingly contingent or short-term. Most Americans may be better off, but the bottom fifth of the population is worse off; the average annual income of this group is US \$8800 (1999), down from US \$10,000 in 1997. Despite the stereotype, most welfare recipients are adults with small families (1.9 children on average), and are on welfare for relatively short periods—

between 2 and 4 years. They have extensive labor market connections and many combine welfare with work. But work is uncertain. Jobs disappear, child care breaks down, there are family and transportation problems. They return to welfare because they are usually ineligible for unemployment benefits (leaving a job for family reasons is a ‘voluntary quit’).

The welfare reforms do little, if anything, to meet these problems. Despite the job growth, there is a shortage of jobs for the low-skilled in many inner cities. Welfare recipients are in tough competition. Most lack a high school degree; they have young children; and they often have transportation problems. They have to rely on informal child care, which is often uncertain and still costs between a fifth and a third of monthly income. They do not have health insurance. And many have additional barriers—lack of skills, and networks, poor health, depression, abuse and violence. Although ex-recipients much prefer work to welfare, they are rarely better off financially and still remain in poverty. As the rolls decline, more of the hard-to-employ are left. In the meantime, sanctions are increasing and the two-year time limits on welfare are due. While there is very little data on those who have been turned away from welfare but are not in regular employment, in general, poverty and hardship is increasing for families, with potentially very serious impacts on the children. In 2000, nationwide more than a third of the homeless are families, an increase of more than ten percent since 1985. In the past, AFDC provided at least some financial stability.

4. *A Crippled Legal Services*

When President Reagan took office in 1981, he proposed no funding for Legal Services for seven successive budgets. The program survived, but funds were sharply cut, forcing significant reductions in staff. Consequently, groups of cases (e.g., bankruptcies, disability-benefits) had to be dropped by many offices. The Nixon Administration (1969–74) had also tried to abolish the program and distribute the funds to the states. When that plan failed, the compromise was to create an independent corporation, the Legal Services Corporation (LSC) (1974) and, for the first time, restrictions were imposed on the kinds of cases that Legal Services could handle—school desegregation, the draft (the Vietnam War), abortion, post-conviction civil challenges. The back-up centers were eliminated. On the other hand, the Corporation’s budget was increased dramatically, from US \$71 million in 1975 to US \$321.3 million in 1981. In that year, the LSC made annual grants to 323 programs which employed 6218 lawyers in 1425 offices providing legal assistance in over 1.2 million matters. That was the last increase. The 1994 Republican Congress made deep funding cuts (from US \$400 million to US \$278) as part of a three-year plan to abolish Legal Services altogether,

and added the most severe restrictions to date. Congress prohibited all class actions; eliminated the collection of attorneys' fees; prohibited participation in administrative rulemaking, lobbying, litigation on behalf of prisoners, representing drug-related public housing evictions, representing certain categories of immigrants, and challenging state, welfare-reform laws under any circumstances—even if such laws violate the US Constitution or federal laws.

The restrictions went into effect in August 1996, and Legal Services had to withdraw from more than 600 class-action lawsuits across the country. In 1997, Legal Service programs employed about 3500 attorneys. They were assisted by about 59,000 private attorneys, mostly on a pro bono basis. The program closed 1.2 million cases and provided services for 1.9 million clients. In 1998, the budget for Legal Services was actually US \$21 million less than in 1980. The American Bar Association has estimated that only about 20 percent of the legal needs of the poor are being met. Thus, at a time when there is growing inequality and poverty, when more than 40 million Americans lack health care, and when the poor are facing one of the harshest welfare reforms in recent history, they are also being denied effective legal assistance.

In 2001 the US Supreme Court (*Legal Services Corporation vs. Velazquez* (2001)), held that the restriction on legal services lawyers from challenging welfare reform statutes or regulations in the course of representing individual clients seeking welfare benefits was unconstitutional; perhaps a new chapter on representing the poor will open.

5. The Welfare State in Western Europe

In the US, the current welfare reform can be looked at as a continuation of American welfare policy. From the earliest days of the colonies, the central mission was to separate out the 'deserving' poor from the 'undeserving.' The latter were defined primarily in terms of the labor market—are they able-bodied, could they work? If so, then no welfare. The mission of welfare policy was to exclude, rather than include. Excluded were the deviants—the moral deviants—and this was carried out at the local level. In the USA there is no concept of 'social citizenship.'

Europe could not have been more different. In the decades following World War II, until the oil shocks of the 1970s, despite the differences between countries, the basic approach was universalism, inclusion. There were significant protections and supports for workers, and generous benefits for those who were not in the labor market. The basis for the European welfare state was full-employment prosperity, that is, the system was successful as long as most people were not drawing significant benefits, but rather, were working and contributing to the welfare state. It was this prosperity

that allowed the nationalist, peak, corporatism bargaining—concertation—between labor and government. Labor would agree to wage restraints in return for jobs and benefits.

By 2000, much had changed. The demographics of the welfare state have changed to an aging population, greatly increasing pension and health care costs. In addition, for most of the Continent, the economies have been sluggish with persistent long-term employment. Increasing proportions of the long-term unemployed are the vulnerable—youth, immigrants, lone mothers. The current dilemma is that with the high rates of persistent, long-term employment, demands are being made on the welfare state. But under the European Union monetary restrictions, neither tax increases nor budget deficits can be used to finance the increased demands.

Thus far, efforts to develop social protections at the European level have not been successful. There is now pretty much of a consensus that negative integration—the removal of trade barriers, the free flow of labor—is far different than positive integration which requires fundamental changes in government structures, decision making processes, claims to legitimacy—and, most important, solidarities across borders. In fact, the present differences among European welfare states are so significant, that most commentators believe that national institutions are too embedded to converge on a common approach.

When the conservatives were in office, the argument was made that the reason for the sluggish economies is that the generous welfare state has made labor too costly, thus preventing job growth. In the global economy, the foundations of the welfare state—a society of steady, well-paying jobs—are being replaced by major changes in both economic structures (low paying, part time work) and demographics (declining proportion of workers as compared to retirees), the disabled, an increasing proportion of women in the paid labor force, the rise in lone parent families, and immigrants. The foundations of the present welfare state—the intact family, male breadwinner—are no longer valid. The 'passive' solutions of unemployment—early retirement and long-term unemployment and disability—are no longer feasible. Pointing to the US and UK experience, conservative politicians and EU officials argue that labor has to become more 'flexible' and labor market protections have to become more 'active'—that is, encourage people to re-enter the labor market by shortening the period of unemployment benefits, requiring training, education, and employment, raising the retirement age, and tightening disability.

The voters rejected these arguments and the Social Democrats have replaced most conservative governments. While promising to protect the welfare state, they are acutely aware of the constraints on budget deficits or raising taxes. Some countries—Sweden, Denmark, and the Netherlands—have been able to

emerge from the recession in the early 1990s, maintain or re-establish concertation between major employers and labor, and protect their systems of social protection. In other countries, the Social Democrats are struggling. There have been some changes—the proportion of unemployed who qualify for benefits has been declining, there is more use of means-tested benefits, the reduction of benefits in some jobs, the abandonment of centralized wage bargaining in some countries. Most countries are trying to replace ‘passive’ benefits with an ‘active’ labor market policy. But so far, these changes have been incremental, and the basic welfare states are still intact. It has proven easier to change markets than social welfare states.

While there is still strong social support for basic welfare state programs, the effective, political resistance, it is argued, basically applies to the existing workforce, not the excluded workers and the vulnerable groups. In the meantime, even though transfers may not have been significantly reduced, we see the quiet undermining of the welfare state—the break-up of national collective bargaining, the growing disparity in wages, the spread of low-wage work, and hostility towards immigrants. The deterioration of the labor market will undermine the social welfare provisions. As pointed out, it was the combination of earnings and benefits that accounted for the comparative equality in Europe. In the final analysis, the foundation of families rests on the economic viability of the adults. Two things are happening in the labor market. As noted, large numbers of the vulnerable population are increasingly facing more-or-less permanent exclusion from the labor market. Others will be increasingly forced back into the labor market, but good, permanent jobs will not be there. An effective active labor policy requires both a large public investment and an integrated infrastructure of labor market institutions, a commitment to some basic income equality, together with a strong safety net. As a growing number of people become dependent, the political pressure increases to restrict income support for the able-bodied. Although there is an increase in need-based and conditional benefits, and there seems to be still strong support for retirees and for children, the crucial question is how solid is the support for the able-bodied? At the present time, welfare policy in Western Europe is at an impasse.

Poverty: Measurement and Analysis

The issue of low income and poverty has concerned social scientists for centuries. In 1776 Adam Smith linked economic poverty directly with the lack of ‘not only the commodities which are indispensably necessary for the support of life, but whatever the custom of the country renders it indecent for creditable people, even of the lowest order, to be without’ (Smith 1776, Book V, Chap. II, Pt. II, Article 4th). Interest in this problem was a natural accompaniment of efforts to understand why nations experience economic growth. If the economy of a nation grows, it is only natural to wonder how the fruits of this growth will be distributed among people and why some people are excluded from

the benefits of economic prosperity. A primary issue is to define poverty precisely, and then to document its extent consistent with this definition, that is, to count the poor. Having identified the poor population, questions regarding the nature, causes, and cures of poverty follow naturally. The process of measuring poverty and analyzing its causes and consequences has advanced social science research methods and techniques.

1. The Measurement of Poverty

The most prominent early effort to measure poverty was undertaken by B. S. Rowntree in 1902, in his attempt to assess the extent of poverty in York, England (Rowntree 1902). Since that time, there have been numerous attempts to measure poverty in a variety of countries or more narrowly defined areas.

Although reducing poverty is a nearly universal goal among both nations and scholars, there is no commonly accepted way of identifying who is poor. Some argue for a multidimensional poverty concept, such as being 'housing poor' or 'health poor' or lacking in social contacts, thought of as social deprivation. Economists tend to prefer a concept of hardship that reflects economic position or economic well-being, somehow measured; that concept has come to dominate the measurement of poverty.

The measurement of economic poverty seeks to identify those families whose economic position, defined in terms of *command over resources*, falls below some minimally acceptable level. In addition to requiring a definition of economic well-being, the measure must specify a *minimum level of well-being* (or 'needs') in terms that are commensurate with 'resources.' Sen (1983) considered the needs standard (or poverty line) to have 'some absolute justification of its own,' a level below which 'one cannot participate adequately in communal activities, or be free of public shame from failure to satisfy conventions' (p. 167). An ideal poverty measure would allow for differentiation according to household size and composition and would enable people to compare the level of access with resources over time.

Having determined the measure of household resources, the needs standard—or poverty line—appropriate for various households allows one to compare the level of household resources with its needs, and thereby to indicate if the family is poor or not poor. When this process is followed for all households in a nation (or some other jurisdiction), one obtains the *poverty rate*, or the percentage of the people (or households) in the jurisdiction who are living in poverty.

Within this economic perspective, a number of economic well-being indicators have some claim to identifying the economic position of households. For

example, the official US poverty measure relies on the *annual cash income* of a family, and compares this with some minimum income standard or 'poverty line.' Alternative—and equally legitimate—measures suggest that the level of *annual consumption* better reflects a family's level of living, or that some measure of a family's *capability to be self-reliant* or a family's *own assessment of economic well-being* are superior concepts for measuring the level and composition of poverty. No matter which perspective is adopted, a large number of judgments and choices are necessary for developing a concrete poverty measure. For example, if income is taken to be the best indicator of economic status, is annual, multiyear, or lifetime income the appropriate measure? Should we examine pretax, pretransfer income or income after accounting for taxes and/or transfers? Should in-kind income be counted or not? Each decision implies both a different poverty rate and poverty population and a different set of antipoverty policies. Finally, irrespective of the decisions made, the resulting poverty measure can be either absolute or relative. The indicator is absolute if the definition of needs is fixed, so that the poverty line does not vary with the standard of living. A relative poverty measure reflects changes in the overall standard of living of the society.

1.1 Absolute Income Poverty Measures

The most prominent absolute income poverty measure is that of the USA, which is the only industrialized country to have an official poverty measure. See Ruggles (1990) and Citro and Michael (1995) for further discussion of the US definition and other definitions. Since the late 1960s, the nation has reported on the level of national poverty and the composition of the poor population. This indicator seeks to identify those families that lack sufficient annual cash income to meet what is judged to be their annual needs. The needs indicator is a fixed income threshold, constructed originally as a multiple of the food needs of households of different sizes and compositions. This threshold changes only as the price level changes, but not as average incomes in society change.

This and other income poverty indicators have a particular philosophical basis. The implied social objective is that, together, the community's efforts and those of the individual should ensure that some minimal level of living is attained. Although people may experience hardship in many dimensions—education, housing, food, social contacts, security, environmental amenities—only a sufficiently low level of money income matters in determining who is poor. Such a measure also presumes that money income is a good proxy for welfare (or utility), and that a particular year's income is an acceptable indicator of longer-run income.

Aside from taking exception to the social objective that underlies the official measure, most other criticisms of it focus on the adequacy of the annual cash income measure of 'command over resources.' While the current cash income numerator of the poverty ratio may reflect the extent to which the family has cash income available to meet its immediate needs, it indicates little about the level of consumption spending potentially available to the family. For many families, annual income fluctuates substantially over time owing to unemployment, decisions to change jobs, or changes in health. Even as an indicator of a family's ability to meet its immediate needs, the current income measure is flawed—it reflects neither the recipient value of in-kind transfers (e.g., food or medical care subsidies) which support the economic well-being of low-income families, nor the taxes for which the family is liable. Similarly, while current cash income—and hence the official poverty measure—reflects financial flows in the form of interest and dividends from the assets held by individuals, the assets themselves are not counted, nor is the value of leisure (or voluntary nonwork) time reflected in the measure. The arbitrary nature of the denominator of the poverty ratio—the minimum-income-needs indicator—has also been criticized. Given the weak conceptual basis and the crude empirical evidence on which the dollar cut-offs rest, including the equivalence scales designed to account for the income needs of different family sizes and structures, the official US poverty lines are viewed generally as arbitrary.

These weaknesses have stimulated efforts in the US to improve the official poverty measure. In 1995, a panel appointed by the National Research Council issued its report suggesting revisions in the official measure. The poverty thresholds were modified so as to reflect a broader commodity bundle of needs (relative to the food need basis of the current thresholds) and a new set of equivalence scales. Moreover, the measure of resources was revised to include the value of in-kind transfers received by a household and to exclude estimates of the labor and income taxes for which the household is liable. (see Citro and Michael 1995). While alternative versions of this new measure are being published, the new measure has not yet been adopted formally.

1.2 Relative Income Poverty Measures

Use of a relative income poverty measure takes into consideration changes in the overall economy (in terms of wages and prices); it stresses the relationship of the resources of a living unit to those available to other living units in the society.

One prominent relative poverty definition, used extensively by the European Community, considers those with incomes less than one-half of the median income to be in poverty, hence reflecting the view that

poverty is only meaningful when compared with overall income or spending levels. Often, a one-half of median income standard is used in the analysis of poverty in the European Community, but more recently, a 60 percent of the median standard has been adopted (see Bradshaw 2001).

In addition to the arbitrariness of the 50—or 60—percent threshold, this measure has other weaknesses. Critics point out the weakness of a relative measure in assessing the efficacy of antipoverty efforts. Moreover, the relative income standard ensures that the poverty threshold will rise most rapidly in periods of economic growth, during which time those at the bottom of the distribution also experience real growth in both earnings and consumption. Hence, even though poor families may perceive themselves as better off during a prosperous period, the poverty rate may not fall, thus overstating the poverty problem. As Ruggles (1990) has stated: 'poverty cannot decline under a relative poverty measure without some change in the shape of the income distribution as a whole.'

1.3 Consumption-based Poverty Measures

A primary criticism of income poverty measures is that the annual income concept on which they rest is a poor indicator of the permanent income (or lifetime resources) of the family unit. Using such a measure, a wealthy family with a well-educated head and substantial assets, but a year of low income, would be classified as 'poor.'

One proposal designed to avoid this problem involves use of measured family consumption to determine poverty status, based on the argument that family consumption is a superior proxy for the family's permanent income, or family command over resources. Slesnick (1993) argues that income measures of poverty are 'severely biased' (p. 2) in that *temporarily* low-income families are regarded as *permanently* needy. The consumption-based poverty indicator proposed by Slesnick uses household real consumption expenditure per equivalent adult (taken to be the quotient of real household consumption and a household-specific cost-of-living index and an equivalence scale) as the indicator of resources.

Slesnick's consumption poverty measure has been criticized on several grounds. One particularly salient criticism concerns the arbitrary and potentially misleading equivalence scales developed by Jorgenson and Slesnick (1987) that are employed. (see Triest 1998). While other consumption-based indicators (see Cutler and Katz 1991) have shown a growing poverty rate over the last two decades, the Slesnick measure suggests that poverty in the USA has been decreasing secularly over that period.

In general, the largest impediment to utilizing a consumption-based index is the difficulty of obtaining complete and accurate family expenditure data, at

least relative to measuring a family's income. Furthermore, consumption may not fully reflect a family's true well-being; it is possible that simple frugality may be mistaken for poverty.

1.4 Subjective Measures of Poverty

An alternative view of poverty is the 'Leyden School' approach, which relies on the subjective responses of individuals to questions that seek their impressions of their own economic position or well-being, relative to some norm. (see Hagenaars 1986, van Praag et al. 1982). As with income and consumption poverty measures, subjective poverty indicators are based on an 'access to resources' concept, but because subjective thresholds change over time, these measures are relative poverty indicators.

Subjective poverty measures are based on survey responses to questions regarding the minimum level of income or consumption that respondents consider to be 'just sufficient' to allow them to live a minimally adequate lifestyle. If families respond that their own level of living exceeds that minimum, it is possible by observing their actual income to infer both a poverty line and a poverty rate. Because subjective measures are based on individual opinions of what constitutes 'minimally adequate' or 'enough to get by,' they require that individual perceptions of these notions reflect the same level of real welfare for all respondents.

A number of subjective measures have been developed and tested, mainly in Europe. Despite rather minor differences in terminology and question phrasing among these measures, they have yielded highly diverse results. The effectiveness of subjective measures is also limited by the nature of the data collection method. Most estimates are based on small sample sizes, yielding large standard errors.

1.5 Inability to be Self-reliant as a Poverty Measure

One additional poverty indicator should be mentioned—one that views those who are without the capability to be self-reliant as the ones with the lowest economic position. This view rests on two considerations, one conceptual and the other practical. The *conceptual reason* is the more basic. This position has its foundations in the writings of Sen (1992, 1997), who argued 'that the basic failure that poverty implies is one of having minimally adequate capabilities,' (1992, p. 111) and hence that 'poverty is better seen in terms of capability failure than in terms of the failure to meet the "basic needs" of specified commodities' (1992, p. 109).

There is also a *policy-related reason* for developing a capability measure of poverty. In recent years there has been renewed civic debate regarding appropriate norms and standards for individual responsibility and

behavior, and hence the appropriate role of the state. A prominent viewpoint in this debate has emphasized the merits of individual independence (relative to reliance on government programs), the negative effects of government programs on individual behavior, and the desirability of a smaller economic and social policy role for government. If society is to base policy on the central social goal of 'economic independence,' then it would seem important to identify the size, composition, and growth of the population of citizens who do not have the capability to be independent in a market economy.

An example of such a capability-based poverty measure is based on the concept of a family's net earnings capacity (the amount that the adults in a family could earn if they worked full time, full year, adjusted for the constraints on working at capacity due to health problems or disability and the expenses required if all of a family's working-age adults did work at capacity). If earnings capacity is less than a poverty threshold, the family is defined as 'unable to be self-reliant,' and in poverty (see Haveman and Bershadker 2001). A related measure of family capability is Becker's (1965) concept of 'full income,' which includes both income realized through market work and the value of leisure time.

Measuring 'self-reliant poverty' requires several implicit conventions, norms, and assumptions. For example, such a measure is reliable only if the 'norm' of full-time, full-year work is an accepted, socially determined norm representing the full use of human capital. Of necessity, attribution of poverty status to any particular family requires prediction from statistical estimates rather than values measured in survey data (such as income), and hence may be viewed as less objective than, say, income-based measures.

2. The Analysis of Poverty

Since the mid-1960s and the US declaration of a War on Poverty, social science researchers have addressed a number of issues concerning the nature, causes, and cures of poverty. In the process, substantive additions to economic knowledge and to research methods have been developed.

2.1 Understanding the Determinants of Poverty: Demographics, Discrimination, Human Capital, Immigration, and Macroeconomic Performance

A major objective among social science researchers has been to understand the processes which combine to result in some people failing to attain minimal standards of economic well-being. Although the number of such processes and institutions is very large, and the interactions among them complex, research has been concentrated in several areas.

The underlying *demographic structure* of the population—age, gender, family arrangements, fertility choices—plays a major role in determining whether families or individuals are poor. For example, the share of the population that is elderly, and hence unable to be self-reliant through work and earnings, influences the prevalence of poverty in a society. Research has tracked the poverty status of the older population and evaluated the ability of older people to escape poverty given their own resources and social support. Similarly, changes in the prevalence of single-parent families caused by rising divorce and non-marital childbearing rates are also fundamental determinants of poverty. Families with children but only a single adult tend to be restricted in their ability to be self-reliant from own earnings. Social scientists have studied the trends and determinants of these choices in an effort to better understand the causes of poverty.

If the attitudes of the majority of the population toward minority groups are such as to lead to lower payments for equivalent work or to inferior schooling, housing, or mobility opportunities, poverty rates among minority groups would tend to be high. Given the prevalence of racial minorities among the poor population, the possible causal role of *labor market, education, and housing discrimination* has been an important topic of study, especially by economists. While the existence and extent of racial income gaps had been studied prior to the 1960s, later research delved deeper than previous work in measuring and explaining the sources of these income gaps. See Cain (1986) for a review of this line of analysis. Given that competition would be likely to erode the effects of discriminatory behavior by employers (Becker 1957), research turned to explanations involving ‘statistical discrimination’ and ‘market signaling’ as the basis for continued discrimination as a cause of poverty.

The role of *education and training*—human capital—in enabling people to attain self-sufficiency also became a focus of poverty research and analysis. The question of the effect of increases in schooling on individual earnings occupied the efforts of numerous researchers, and education came to be analyzed as a process that created human capital. Estimates of the rates of return on schooling seemed to justify diverting resources from private sector investments in physical capital to public investments in education. Rosen (1987) surveys the literature in this area. While economists focused on the earnings returns from schooling, other social scientists sought to document the effect of schooling on student attainment (such as test scores), social mobility, and economic status. This research documented the complexity of the processes by which some children succeed while others fail, and led to a search for improved data and statistical methods capable of disentangling the effects of education on attainments. This ‘human capital’ approach to schooling carried over to numerous studies of the

effectiveness of governmental programs designed to provide skills and training to adult workers. See Heckman and Lochner (2000) for a review and interpretation of the evidence on the economic effects of education and training.

Concern with the problem of poverty in the USA coincided with a rapid increase in *immigration*, often of individuals with low levels of schooling or language competence. The potential impact of immigration in eroding wage rates for unskilled workers in urban labor markets containing large numbers of immigrants became an important policy and research issue.

The effect of the overall performance of the economy on the poverty rate was also the subject of substantial research and analysis, beginning in the 1960s. During the 1970s, economic growth and low unemployment seemed to be powerful instruments in reducing unemployment. However, during the 1980s and early 1990s, economic growth seemed to have lost its antipoverty effectiveness. Evidence suggests that during the 1990s, the level of poverty was again responding to macroeconomic performance. See Haveman and Schwabish (2000) for a review of this research and for recent evidence.

2.2 Understanding Social Mobility, Status Attainment, and Income Dynamics

Research on the causes of poverty have tended to focus on static issues—factors that appear to be causally related to low economic position. Simultaneously, a complementary line of research addressed questions of the dynamic processes by which people either succeed or fail to attain economic position—processes that indicate the openness or fairness of society. While research on these social mobility processes had been undertaken prior to the 1960s, those studies were limited by the absence of both a conceptual framework and data on individuals over time—longitudinal data—necessary to trace these dynamic patterns. The early 1960s witnessed a number of important research contributions designed to increase understanding of the process of social mobility. One of the most central of these presented a causal model of the socioeconomic life cycle, distinguishing the interactions among three primary life phases: family, schooling, and work (see Duncan and Hodge 1963). The socioeconomic status of the job was taken to be the ultimate indicator of success, with family back-ground and schooling (as an intervening variable) viewed as the determinants of that status. This framework stimulated several empirical studies of these relationships, yielding insights into changing intergenerational correlations involving occupations and income, changes in the degree of social mobility, changes in the role of education in fostering mobility, and changes in mobility patterns between whites and nonwhites. A variant of this approach sought to

identify the factors that contribute to social or economic status, distinguishing those that relate to exogenous family and background factors from those amenable to policy influence. Two prominent examples of this approach are Jencks et al. (1972, 1979). Family characteristics and choices and intellectual inheritance were seen as playing important roles, but school quality and the racial mix of neighbors and peers were found to be less important. Haveman (1987) reviews and critiques this research.

While these analyses were revealing, they demonstrated the difficulty of making progress in this area without detailed data on individuals and families that tracked their attributes and performance over time. The Panel Study of Income Dynamics, the National Longitudinal Surveys, and the Survey of Income and Program Participation are among the most prominent and high quality of these data collection efforts. Extensive use of them has enabled major advances in understanding the nature and causes of poverty, including the lengths (or persistence) of poverty and welfare stays among the poor, trends in income trajectories among families with various characteristics, the identification of the long-term or permanently poor population, and estimates of the relative roles of family background, schooling choices, neighborhood characteristics, and labor market discrimination in determining the probability of being poor. A complementary field of study has used these data to explore the determinants of these family characteristics (e.g., poverty-level incomes, single-parent status, low parental education, welfare reciprocity), schooling quality, neighborhood characteristics, and own schooling and fertility choices on a variety of children's attainments (see Haveman and Wolfe 1995, Duncan and Brooks-Gunn 1997).

2.3 Antipoverty Effects of Policy Interventions

Poverty researchers have also sought to describe the various policy measures in place to assist poor families and to identify changes in or alternatives to these policies that might be effective in reducing poverty. Probably because the main antipoverty efforts were in the area of income support measures, analysts concentrated their assessments on such policies. A voluminous literature describing the nature of income support policies and critiquing their incentive (efficiency) and equity characteristics has influenced policy changes over the period since the 1960s. These analyses revealed low 'take-up' rates among people eligible for support, horizontally uneven support patterns among equally poor people, the uncertain rationale for and implications of providing support via in-kind benefits vs. tax subsidies vs. cash transfers, the relative effectiveness of alternative programs in reducing poverty rates or the intensity of poverty, and the presence of incentives for undesirable behaviors (e.g., reductions in work, increases in family breakups, and

nonmarital childbearing) implicit in the structure or administration of the programs.

These descriptive and policy analysis studies played an important role in guiding numerous antipoverty policy reform efforts that have occurred over the past several decades, including proposals for 'negative income tax' plans, work-related subsidies, the substitution of in-kind for cash benefits, and 'welfare-to-work' initiatives. They also provided a catalog of important questions for which answers would be relevant in designing effective policy: how large are work effort reductions in response to income transfers? Has public income support reduced family stability, increased unemployment, reduced savings, or increased nonmarital childbearing? (see Haveman 1987).

2.4 Labor Supply, Family, and Fertility Effects of Income Support Policy

Concerns with the work incentive effects of income support policy have dominated debates over this antipoverty strategy. Numerous analysts responded to this concern with empirical studies documenting the extent of these behavioral responses to public income support programs. These studies, employing a variety of survey data and empirical methods, found that public benefits tend to reduce employment probabilities, lower work hours per year if working, and possibly reduce wage rates among both recipients and potential recipients of benefits.

Most of the early studies employed cross-sectional survey data in order to measure the responses of individuals to the increased income from transfer benefits and the reduced effective wage rate associated with working. Later studies relied on the results from carefully designed 'social experimental' studies of these potential responses (see below). The essential characteristic of these studies is the random assignment of families to alternative forms of transfer program designs (in terms of the generosity of income guarantees and the extent of 'benefit reduction' rates), and the observation of the behavior and performance of these families over subsequent years. Both forms of studies confirmed that, as expected, work effort falls as nonlabor income rises and as the effective wage rate falls. While the estimates varied widely, nearly all of them raised serious questions about the efficiency and effectiveness of this income support approach to helping poor people.

While these studies focused on the work effort responses of people to the availability of income support, other analyses (including randomized approaches) tested the family structure, childbearing, health care utilization, housing quality, and welfare utilization choices of low-income families in response to both welfare-type policies and reform efforts in the educational, housing, health insurance, and public employment areas. Danziger et al. (1981) and Moffitt (1992) have surveyed this research.

3. Poverty Research and Social Science Methods

In addition to adding to the body of knowledge regarding the nature, causes, and cures of poverty, the growth of poverty-related research since the 1960s has also contributed to the development of new research methods of general applicability in the social sciences (Haveman 1987). Four contributions deserve mention.

The first contribution consists of a new field of evaluation analysis and research. As analysts, in response to the demands of policy makers, focused on the poverty problem, an emerging analytical area, evaluation research, was also being spawned. Interest in this applied research approach extended far beyond the poverty issue, but research on social and antipoverty policy issues provided this then-nascent subdiscipline with some of its basic methods and case studies. Without the emphasis of policy makers on the need to evaluate the effectiveness of the numerous new antipoverty initiatives, it is unlikely that this field of analysis, with its journals and professional organizations, would have developed as rapidly as it has, and in the same directions.

Second, as noted above, randomized social experimental research was first applied to proposed policy interventions in the poverty area—the negative income tax proposals, school and housing vouchers, employment and training measures, and so on. Without the emphasis on the effect of antipoverty policy interventions on family economic status during the 1960s and 1970s, it is unlikely that this important social science research method would have attained the status it now holds among social science researchers.

One of the problems that analysts face in assessing the effects of policy and other changes on the behavior of people is the need to rely on samples of observations that may be composed of individuals who are selectively included in the sample, and hence unrepresentative of the larger population for which inferences are desired. This concern dominated the study of labor markets well before demands to assess the impacts of antipoverty measures, especially in the employment and training area, where factors that determined the presence of a person in a research sample were also determinants of the effect that was being studied (see Ashenfelter 1978). Several approaches to this problem were developed by econometricians (see especially Heckman 1979), and these statistical tools became a standard part of applied statistical analyses.

Finally, in part because of the development of large representative samples of national populations, analysts began developing computer models designed to simulate the effects on the income, well-being, and behavior of each observation in a data set of actual or proposed policy measures. The application of such microdata simulation models found its most welcomed audience among analysts concerned with the effects of changes in taxation and income transfer policy on low-

income families. Without the impetus provided by the need to assess the impacts on poor people of proposed policies, this advance to predictive model building would not have occurred. This research methodology is assessed in Citro and Hanushek (1991).

R. H. Haveman

Poverty Policy

Poverty policy or the politics of poverty is a constituent element of social policy. It covers public action that aims to deal with poverty when and if poverty is seen as a public issue. While various forms of poverty or pauperism have always invited some action of close communities, the term poverty policy is reserved for interventions in which the modern state has played a role.

1. The Political and Intellectual Context

Poverty policy is informed by public policy in general or social welfare policy in particular. These policies are by their very nature ideologically loaded. The political labels to be applied may be debated. For the present purpose the conventional political categories of conservatism, liberalism, and social democracy appear

useful. The ideology based on the supremacy of the market will be termed neoliberalism. Conservatism and neoliberalism may be situated more to the right, liberalism and social democracy more to the left of the political spectrum. By means of these categories an involved pattern will be presented in an oversimplified way to offer an intellectual context for poverty policy.

The political right perceives poverty as an individual rather than a social problem, attributing its causes to the variations in individuals' merits and achievements. One conservative position adds as a main cause of individual failure genetic inheritance that explains for instance the poverty of the intellectually 'inferior' races in America (Herrnstein and Murray 1994). The variation between individuals being natural, poverty itself is seen as a natural and inevitable phenomenon. Its alleviation for altruistic reasons may be approved of, but attempts at its eradication are rejected as futile. Conservatives may prefer voluntary charity as a means of poverty alleviation. Neoliberals may accept state intervention in the form of a well-targeted safety net for the truly needy. The political right usually regards poverty policy as the only acceptable type of social welfare policy.

In a left perspective, poverty is considered as the outcome of social inequalities generated by the economic, political, and social power structure, by the unequal distribution of all the forms of capital. Poverty policy is seen as a must to alleviate immediately the lot of the poor by means of public redistribution. The prevention of the continuous reproduction of poverty is also a major concern, though. This objective requires broader public policies. Public intervention should promote a fairer access to all socially relevant material and symbolic resources, which in turn requires curbing the domination of the market over society. The success of such policies depends on, among other things, the empowerment of people and strong economic and social rights. In this broader policy framework, poverty policy becomes residual.

2. History

Poverty policy followed closely the economic and social changes connected with unfolding capitalism in Europe from about the fifteenth century. Four periods may be distinguished, although their contours are inevitably vague.

2.1 The Beginnings of a Public Policy Concerning the Poor

Central intervention focusing on the poor was prompted by several factors. The closely knit primary communities—the family, the neighborhood, the parish, the feudal manor, later the guild—endorsed for a long time the care of the weakest members unable to survive without this protection, who would have

otherwise endangered the cohesion or the stable reproduction of the group. The ability of self-help of the small communities was slowly eroded by wars, epidemics, the laicization of society, the loosening of feudal bonds, new forms of mobility, and an increasing number of marginalized vagrants. Most of these processes were connected to urbanization and industrialization. Following these developments, the number of the unsupported poor multiplied while the traditional forms of spontaneous or organized charity were waning. The direct encounter with the misery and the physical suffering of the poor affected uncomfortably their betters, whose sensibility had increased with the Enlightenment (Mollat 1978). More importantly, the poor have become dangerous. They may have caused direct personal danger through unrest, banditism, or subsistence crime. The more indirect danger was that they represented or exuded physical and moral 'evils' (Swaan 1988). The two aspects of increasing poverty—physical suffering and threats to public safety—invited Janus-faced interventions. The politics of poverty combined from the start the functions of policing (control and punishment) and of helping (poverty alleviation) (Geremek 1987). Legal regulations at the local or central level combining these two functions appeared with increasing frequency from the fifteenth and sixteenth centuries onwards (Castel 1995) in most Western countries and even in Eastern Europe. Until the early seventeenth century, the policing element was probably stronger (under the reign of Henry VIII between 1509 and 1547, 72,000 vagrants were executed in England). The supportive function became more explicit in the first major Poor Law of Europe adopted in England in 1601. This was the Elizabeth 43 Act for the Relief of the Poor. In its Section 2 it declared: 'It is agreed and ordered by the present Assembly that each town shall provide carefully for the relief of the poor, to maintain the impotent, and to employ the able...' The French ordinance of Moulin of the same year applies almost identical wording. At this time even if regulation was central, its implementation was the duty of the local authorities in collaboration with the churches and voluntary organizations. Despite the more explicitly prescribed obligation to give assistance, the policing function never disappeared.

Poverty policy was beleaguered from the earliest times by several dilemmas. One of them was the separation of the genuinely helpless from the able-bodied poor. Those belonging to the first group—the sick, the invalid, the frail elderly, sometimes orphans or widows—were usually considered as deserving help. The members of the second category were mostly seen as undeserving of support. It was assumed that they could maintain themselves were they not work-shy or lazy. It was acknowledged only very late—towards the end of the nineteenth century or even later—that the majority of the able-bodied poor would have been willing to work had they had access to a job. Another

lasting problem was the separation of the local poor from strangers. The locality was willing to endorse the responsibility for its own poor but was keen to exclude strangers; hence the various acts concerning the duties of provision and the rights to expulsion of the settlements, and also the practice of visible stigmatization of those getting assistance or of those allowed to beg in the locality. These regulations were ubiquitous from Pennsylvania in North America to the town of Győr in Hungary. A third problem centered on the level of assistance. This level was haphazard at least until the wide acceptance of the 'less eligibility' principle defined by the (English) New Poor Law of 1834. The principle implied that 'the pauper's condition should be rendered less eligible, or more unpleasant than that of the poorest paid independent laborer.' The workhouse was then conceived of so as to assure maximum feasible less-eligibility. The principle has also been applied to define the level and the modalities of access to other types of assistance. A further dilemma that lost its edge by now was the choice between so-called indoor and outdoor relief. Indoor relief meant the poorhouse or the workhouse not only in England but all over Europe and America (termed, for instance, *Hôtels de Dieux* and *hospitaux pour renfermement des mendiants* in France) from the sixteenth century onwards. The regulation of poor relief in Elberfeld, Germany, became the model for organized outdoor relief only in the nineteenth century.

2.2 *The Handling of Industrial Poverty*

With the unfolding of capitalism, the character of poverty changed. The number of the urban poor multiplied, and urban destitution acquired tragic dimensions. Early nineteenth century legislation dealing with urban hygiene, or the Factory Acts protecting young children and mothers, were concerned less with utter poverty than with the survival of the whole community. Public assistance continued to play its role often with a strong punitive edge, but it also acquired new dimensions. The workers were affected by new insecurities as compared with the 'pre-industrial' poor. The risks of grave accidents, of unprovided old age, or of job losses all increased, and were slowly recognized as new causes of poverty. Moreover, the workers started to organize and mobilize themselves. The expansion of political rights forced the states to be more responsive to the pressures of vocal political thinkers and of popular movements. From the last third of the nineteenth century progressive taxation, various branches of social insurance, and in a few countries fully or nearly universal flat-rate benefits were added to the instruments of public redistribution. The monopolistic role of poverty policy within social welfare policy was thus ended. From the early twentieth century some countries—Sweden in the first

place—formulated more ambitious projects about the improvement of the working and living conditions of the whole community, and about the abolition of poverty as well as of a separate and autonomous poverty policy.

2.3 *The Welfare State and Poverty Policy*

During and after World War II, the extension of public responsibility for all-encompassing social security became an accepted, albeit never uncontested, principle in most developed capitalist states. The seminal document founding the idea of the Welfare State was the Beveridge Report, a proposal prepared for the British government published in 1942 under the unassuming title 'Social Insurance and Allied Services.' It proposed to fight by means of universal benefits and services the five 'giant evils,' Want, Disease, Ignorance, Squalor, and Idleness—that is, to end poverty and its root causes. The experiences of World War II, a widespread appeal of left ideals, and the enforced competition with the 'communist' world in Central and Eastern Europe triggered all over Western Europe the development of social protection, increasingly underpinned by labor law and social law.

The welfare state project was never and nowhere fully successful. Yet in its three ascending decades it considerably reduced social inequalities, deep and even shallow poverty, and improved the working, living, and housing conditions and the existential security of the majority. Poverty policy did not disappear, but in most countries its role—and the role of social assistance—have become marginal (Hatzfeld 1971, Esping-Andersen 1990). The situation was different in the USA where universal schemes were never accepted and their function was fulfilled by the targeted schemes devised within the framework of poverty policy. However, from the 1960s on, the War on Poverty and the project of a Great Society improved the welfare programs. For about 15 years they became more generous and better adjusted to needs. The results are contested by many on the right. Yet statistical evidence shows that the poverty rate fell by about half, some inequalities were reduced, and housing, health, and nutrition indicators rose also among those on the assistance rolls.

In Central-Eastern Europe, pre-war poverty policy had many elements in common with the most conservative, more punitive than generous systems of Western Europe. After World War II, the modern systemic differentiations were supplanted by a monolithic system in which a single party's politics dictated the rules of all subsystems such as the economy, law, or social policy. Welfare policy was absorbed by the economy, which was in its turn dominated by politics. Poverty policy did not exist for two more reasons. On the one hand, price policy, full employment policy, broad and almost all-encompassing health, pension, etc., schemes were constructed so as to produce a not

too unequal income distribution, and to prevent relatively successfully the emergence of deep poverty. On the other hand, the dominant ideology denied the existence of the poverty that still existed, and therefore did not make any provision to handle it. It had no need and no space for a specific poverty policy, leaving many social ills unattended (Ferge 1986).

2.4 *The Withdrawal of the Welfare State and the Revival of Poverty Policy*

Following the oil shock and the advent to power of the Reagan and Thatcher administrations, the tide turned. A neoliberal agenda has unfolded requesting less state intervention in the operation of the free market and the retrenchment of the social state. The collapse of totalitarian state socialism bolstered this process.

The new trends affect the traditional institutions of social policy. Universal solutions with access tied to citizenship rights are losing ground. In the case of social insurance, there are efforts to privatize it, to weaken its solidary (nonactuarial) components, and to lower its standards. The efforts to deregulate the labor market have weakened labor rights and increased the number of working poor. The consequences are increasing poverty and unmet needs. The countries in 'transition' are inordinately hit by these changes. The solution offered everywhere is the increased role of poverty policy, particularly of means-tested benefits. The political support of programs targeted only to the poor may be so weak, however, as to threaten subsistence rights seriously.

The new ideology has affected social policy everywhere, albeit not to the same extent. The European welfare states having integrative programs with strong historical roots and wide public support were less affected than other parts of the world. In the USA even the welfare programs seem to have suffered severe cuts (Piven and Cloward 1982, Katz 1993). In many Latin American and 'postsocialist' countries, proposals figuring on the neoliberal agenda are replacing the former, more comprehensive solutions. In other parts of the world where welfare policies hardly existed before, they seem to appear mainly as variants of poverty policy. In East Asia this is explained by the Confucian ideology of self-reliance and familism (Goodman et al. 1998). In desperately poor third-world countries poverty policy seems to be the only alternative to improve the situation, albeit the mobilization and empowerment of the poor seem to acquire greater weight than in earlier poverty programs (World Bank 2000, United Nations 1998).

3. *Current Theory and Research*

Theory and research on poverty and on poverty policy are strongly interwoven. An attempt is made here to focus on the policy aspects. One school of thought

deals with the theoretical and political possibilities of poverty reduction on a world scale. It explores the possibilities and instruments of global redistribution. Supranational agencies, particularly the United Nations, the International Labor Office, and more recently the World Bank as well as some civil organizations, are stimulating this research. Many elements of these endeavors are summarized in the Report of the UN World Summit on Social Development held in 1995. A second trend deals with the role of poverty policy within public policy. It explores the respective roles of the state, of civil society, and of the market (economic growth) in decreasing poverty and social exclusion. The main question is whether the 'trickling down' of economic growth is a sufficient condition to lift the poor or whether additional public and civil efforts are needed. If the latter is the case (as research seems to show), the question is whether focusing on the poor is sufficient, or a broader approach is warranted. A third large field explores the instruments of poverty policy and of their evaluation. These are partly methodological issues mentioned in Sect. 4. Some of them have acquired momentous theoretical importance. The age-old problem of poor relief, the kernel of the 'social question,' was always how to separate those worthy of help and compassion from the undeserving poor. The growing number of able-bodied poor because of lasting unemployment and the increase in single parenthood and low-paid jobs put the issue again forcefully on the agenda. One direction of research—more to the left—looks for 'third way' solutions including investment in human capital and the creation of acceptable jobs. The conservative research agenda is involved in proving the harms of welfare programs that stifle incentives, destroy stable families and lead to a dependency culture.

4. Distributional Issues

If help is to be given, it has to be known at least who to give it to, what to give and how, and how to assess the results of the policy.

4.1 Who Are to Be Helped?

The poor and the needy may be defined in different ways in poverty research and in poverty politics. In research the definition may be based on objective or subjective, or on absolute or relative poverty criteria; it will depend on whether the research relates to one country or is comparative, whether it describes one point in time or covers processes—let alone the idiosyncratic outlook of the researcher. Poverty policy usually applies definitions which relate to one country and one time-point, albeit they may change with time. The main instrument of targeting help is the minimum income or assistance level, which becomes *de facto* a poverty line. Those under the line may get help. The poverty line (unlike in research) has to be unam-

biguous. It is usually defined by central or local governments on the basis of pragmatic considerations. It may be lower than a scientifically based adequate minimum income standard (Eardley et al. 1996).

The poverty line may relate to the individual, the family, or the household. In the last two cases different weights may be assigned to family or household members, that is, different equivalence scales may be applied (OECD 1997). In addition, poverty policy may target help also to those who are above the poverty line but whose resources are insufficient to cover some special needs. Examples are assistance offered to cover unusually high housing costs or health costs, or in the case of a crisis situation.

4.2 Who to Give to, in What Form, and How Much?

Help may not be offered to all those under the poverty line. The selection of the beneficiaries is in part a political issue discussed above. Methodologically it has to be decided whether to apply only an income test, or a means (resource) test comprising an income test and an asset test, or whether to add also various behavior tests (a work test, a cohabitation test, and such like). The form of the provision also matters. There are arguments for and against assistance in cash to be used freely, or tied in some way, given in kind or in intermediary forms such as vouchers or food stamps. When a poverty line is established, the policy may be to offer enough assistance to cover the whole poverty gap (the difference between the set line and the actual income) or to alleviate only the situation of the poor without eliminating the poverty gap. The adequacy of the provisions is a further major issue. The European Union has strongly and repeatedly recommended a 'right to sufficient resources' or a minimum income for all as a measure to reduce poverty and to promote social integration (Schulte 1997). In other parts of the world governments may accept poverty lines well below the adequacy level either because of insufficient resources or because of ideological reasons (Veit-Wilson 1998). The provisions may then still assure subsistence, or only mere survival, or not even that (Gans 1995). The 'less eligibility' principle appears still to survive.

4.3 The Assessment of the Policies

The methods of evaluation of poverty policy were developed partly in connection with the war on poverty in the USA, and partly by independent researchers in Britain and elsewhere in Europe. Evaluation deals with such issues as the efficiency and effectivity of the various programs (to what extent did they reach the target groups and did they solve the problems); the measurement of the impact of policies on horizontal and vertical equity; the costs of relief; the public acceptance of different programs; the reasons of varying take-up rates; the merits and

demerits of social assistance based on right or on discretion; the dangers of emergence of poverty traps, unemployment traps, or savings traps—all hampering efficient help. The assessment of the negative incentives mentioned above as one of the most important theoretical issues requires involved research methods, too (Haveman 1987).

5. The Future

The future of poverty and of the orientation of poverty policy depends to a large extent on political forces. Supranational agencies, the United Nations in the first place, are committed to poverty reduction on a global scale, with emphasis on the poorest countries. The attainment of this objective would require a stronger international state with economic mandates and a stronger international civil society to curb the strengthening market—conditions different to fulfil.

The future of individual countries will depend on the global trends, but also on their own policies. One may expect the continuation of the trends described in Sect. 2.4 with some variations and innovations (McFate et al. 1995). In the European Union and in some left-liberal circles there is a search for new instruments to combat poverty and exclusion such as the citizen's basic income (Parijs 1992), or a new integration of economic and social policy (Atkinson 1995). This orientation implies a reduction of the role of means testing in favor of more encompassing public policies. These proposals usually meet with the resistance of economically and politically strong groups.

All in all, at the start of the new millenium there are genuine threats of widening within- and between-country inequalities, of growing poverty and of the increasingly harsh treatment of the poor whose right to subsistence is questioned. The problem is not so much the scarcity of resources as their distribution. Vigorous public and poverty policies would be needed to achieve more equity in order to prevent major tensions.

Z. Ferge

Poverty, Sociology of

Sociologists have long written about the topic of poverty, as have economists and other social scientists. Indeed, this article is complemented by several others with similar themes. Readers may therefore want to also consult other entries as well (e.g., *Poverty:*

Measurement and Analysis; Poverty and Gender in Affluent Nations). Here we begin with a basic description of the nature and causes of poverty as seen by sociologists, and second with the techniques used to measure poverty by sociologists and other social scientists in both national and cross-national contexts. Our study also focuses on cross-national comparisons with rich countries.

1. Sociology and Poverty

Because the fundamental concept of poverty concerns itself with having too little resources or capabilities to participate fully in a society, the study of poverty has found a wide following in sociology. Sociologists have been more interested in the explanation of poverty than in its measurement, though almost all sociologists believe that poverty statistics are meaningful social indicators of basic needs (Townsend 1993, Piachaud 1987, Ringen 1985). Sociological interests in poverty center around the ideas of the 'culture' of poverty and the effects of 'place' on poverty. The urban—central city—ghetto aspects of this issue are well treated in the work of Wilson (1987), Massey and Denton (1993), and Massey (1996); Harrington's classic work, *The Other America*, covers rural deprivation as well (1962). Roles of culture, power, social structure, and other factors largely out of control of the individual are the main forces that sociologists use to explain poverty. The basic working hypothesis is that individuals are strongly influenced by the physical and cultural context in which they live. 'Neighborhood' exerts a strong influence on behavior and concentrated poverty in central city ghettos therefore has a strong effect on future life chances and long-run deprivation. Indeed, in the United States, this has spawned interest in the so-called underclass, which goes beyond poverty alone to include all persons with dysfunctional behaviors living in 'bad' neighborhoods (Mincy et al. 1990). The European term for a similarly disaffected population is 'social exclusion' which is also beyond poverty measurement *per se* (Room 1999, Hills 1999, Glennerster et al. 1999).

Gender and household structure also frequently play a role in sociological theories of poverty (e.g., Miller 1996, Ringen 1985). As women's roles in society often leave them with care-giving responsibilities, with low-paying careers and jobs, and therefore in poor economic circumstances, poverty is often high among single female parents and elderly widows. Thus, we find a preponderance of women in poverty in most rich nations (Casper et al. 1994, McLanahan et al. 1989, Christopher et al. 2001).

In general, sociologists are critical of the economist's perspective of free choice models whereby individuals control their own destiny and are therefore the cause of their own poverty (Piachaud 1987). Some sociolo-

gists even feel that poverty has a functional role to play in capitalist society (e.g., Gans 1972). Ultimately, however, sociologists, like all other social scientists, need to first establish the breadth and depth of this social phenomenon called 'poverty' before they can meaningfully analyze it and explore its ultimate causes and remedies. Thus, we turn to measures and comparisons of poverty employed by sociologists and other social scientists within and across nations.

2. Poverty in Rich Nations: Concepts and Measures

We begin by noting that poverty measurement began as an Anglo-American social indicator. In fact, official measures of poverty (or measures of low income) exist in very few nations. Only the United States (US Bureau of the Census 1999) and the United Kingdom (Department of Social Security 1993) have official poverty series. Statistics Canada publishes the number of households with incomes below a low income cutoff on an irregular basis, as does the Australian government. In Northern Europe and Scandinavia, the debate centers instead on the level of income at which minimum benefits for social programs should be set. In other words, their concept of insufficient 'low income' is directly fed into programmatic responses to social needs (Björklund and Freeman 1997).

While poverty measurement is an exercise that is particularly popular in the English-speaking countries, most rich nations share the Anglo-Saxon concern over distributional outcomes and the well-being of the low-income population. There is no international consensus on guidelines for measuring poverty, but international bodies such as the European Statistical Office (Eurostat 1998), the United Nations Development Programme (UNDP 1999), the United Nations Children's Fund (UNICEF 2000), and the Organization for Economic Cooperation and Development (OECD 2000), have published several cross-national studies of the incidence of poverty in rich countries in recent years. The large majority of these studies are based on the Luxembourg Income Study (LIS) database which can be accessed remotely via Internet at www.lis.ceps.lu. Some examples of these studies include Förster (1993), Smeeding et al. (1990), Kenworthy (1998), Jäntti and Danziger (2000), and Smeeding et al. (2000), many of which are directly available online from the LIS web page.

The measure of poverty in rich nations involves the comparison of some index of household well-being with household needs. When command over economic resources falls short of needs, a household (or person or family) is classified as poor. Well-being refers to the material resources available to a household. The concern with these resources among most social scientists, including sociologists, is not with material

consumption, *per se*, but rather with the capabilities such resources give to household members so that they can participate fully in society (Sen 1983, 1992). These capabilities are inputs to social activities, and participation in social activities gives rise to a particular level of well-being (Coleman and Rainwater 1978, Rainwater 1990). Methods for measuring a person's or household's capabilities differ according to the context in which one assesses them, either over time or across nations or among subpopulations within a nation.

Most sociologists recognize that all advanced societies are highly stratified (e.g., Townsend 1979). Hence, some individuals have more resources than others. The opportunities for social participation are affected by the resources that a household disposes, particularly in nations like the United States where there is heavy reliance on the market to provide such essential services as health care, post-secondary education, and child care. Money income is therefore a crucial resource. Of course, there are other important kinds of resources, such as social capital, noncash benefits, primary education, and access to basic health care, all of which add to human capabilities (Coleman 1988). These resources may be available more or less equally to all people in some societies, regardless of their money incomes.

Sociologists believe that there are many forces in rich societies that reduce well-being by limiting capabilities for full participation in society, including inadequacies in neighborhoods where people live. Sociologists are therefore interested in racial discrimination, neighborhood violence, low quality public schools, lack of good jobs, and job instability, all of which increase economic insecurity, reduce human capabilities, and increase poverty (e.g., Massey 1996).

2.1 *Absolute vs. Relative Poverty*

An absolute poverty standard is defined in terms of a level of purchasing power that is sufficient to buy a fixed bundle of basic necessities. A relative standard, on the other hand, is defined relative to the typical income or consumption level in the wider society. The purchasing power of a relative poverty standard will change over time as society-wide income or consumption levels change; an absolute poverty standard will change only with the prices of commodities. Most sociologists inherently favor the relative definition of poverty.

And, in fact, all measures of poverty or economic need are relative, because context is important to the definition of needs. The World Bank uses poverty measures of \$1 to \$2 per person per day—or \$1,095 to \$2,190 per year for a family of three—for the developing nations of Africa or Latin America (Ravallion 1996). In contrast, the 1998 United States, 'absolute' poverty threshold was \$13,003 for a family of three—about 6 to 12 times the World Bank's poverty

line—while one-half of median income, the preferred relative poverty standard, was another 25 percent above this poverty line or 8–15 times the poverty standard in poor countries. Moreover, as economic inequality has increased in most rich societies over the past 20 years, the study of relative deprivation and poverty has taken on a new life (Gottschalk and Smeeding 2000). The link between marginalization, relative poverty, and the globalization of trade is just beginning to emerge as a topic of prime interest among sociologists (e.g., Alber and Standing 2000).

In fact, cross-national comparisons of poverty in rich countries rely almost exclusively on a relative concept of poverty. Cross-national studies typically compare the percentage of persons living with income below some fraction, normally half, of the national median income. This kind of comparison is consistent with a well-established theoretical perspective on poverty (Townsend 1979, Sen 1983, 1992). However, some feel that such a standard is too low. For instance, the European Statistical Office Working Group on Poverty Measurement recently recommended using 60 percent of the national median income as a common poverty threshold for European Community poverty studies in the new millennium (Eurostat 2000).

2.2 *Alternative Measures of Resource Poverty*

Because there is no single commonly accepted way to measure poverty among sociologists, there is a desire to go beyond the popularly used income poverty definition. As a result, there exists a wide variety of additional poverty measures that substitute for or complement the preponderance of income-based measures used by quantitative sociologists and economists (e.g., Ruggles 1990, Haveman and Mullikin 1999, Boltvinik 2000). In principle, poverty is a multi-dimensional concept and should reflect several aspects of personal well-being. Forms of deprivation other than economic hardship can certainly be relevant to poverty measurement and to anti-poverty policy-making.

Even restricting consideration to economic poverty, measures other than annual income might be used to estimate household resources. For households with fluctuating incomes, annual income can provide a poor approximation for permanent or long-run average income. Some social scientists suggest that annual consumption represents a better proxy for permanent income and hence should be preferred over annual income for measuring household resources (Haveman and Mullikin 1999). However, broad-based consumption data are more difficult to come by than are income data. A number of authors have suggested that separate measures of needs ought to be developed for different goods and services (Aaron 1986). Housing and health care are often mentioned in this context, while the former is of much greater interest in the United Kingdom (DSS 1993).

2.3 Social Indicators

Social indicators present an entirely different method of poverty measurement. Researchers have a long tradition of using social indicators to measure both economic hardship and affluence. Analysts often define direct measures of deprivation, such as lack of food, heat, or access to health care (Bauman 1998, Mayer and Jencks 1993). Because each household's need is imperfectly measured by an income or consumption threshold, many households with incomes above the thresholds may still experience hardships, such as hunger, or face high rent payments or heavy medical expenses that prevent its members from buying enough food or fuel. Further, individual members of a household may suffer hardship because of unequal sharing of incomes within the household. In these cases, direct measures of material hardship might offer a useful indication of poverty, especially in a cross-national context, and many sociologists are therefore attracted to such measures (Mayer and Jencks 1993).

2.4 Time Poor

Finally, resources other than access to material goods might be important determinants of poverty. The literature in the 'time poor' has grown in recent years after a nascent period. The argument is that time is often the scarcest commodity in market work-oriented societies. Further, time spent on home production is often undervalued or not valued at all. The gender bias in time use is therefore at the heart of these types of analyses (Vickery 1997, Douthitt 1994). In particular, recent research has focused on the time crunch on single parents who must both earn a living in the labor market and care for their children (Folbre 1994, England and Folbre 1999).

3. Summary

Sociologists and other social scientists have used a variety of methods to define and measure poverty. Each approach has its strengths and weaknesses. Over the past few decades, income-based poverty measures using annual assessments of household income have provided the main statistics for tracking poverty over time, across nations, and across sub-populations within nations for sociologists and for other social scientists. They have also provided important tools for testing causal hypotheses concerning the explanations, causes, and cures for poverty, including place, space, race, gender, and other popular theories of poverty in sociology. They are complemented by social indicator-based measures of inadequacy, and by the adequacy of time for market work, home work, and the nurturing and care of family members. Sociological studies of

poverty have both a rich heritage and have become an important area of research in increasingly unequal rich societies.

Power in Society

Power has been seen as an 'essentially contested' concept (Lukes 1974). Some of the major recent contours of this contestation will be addressed in this entry.

1. Weber: Ideal Types of Rule and Power

At the core of modernism, according to Weber, lies the rationalization of various institutional arenas such as the market, technology, law, state, the growing pervasiveness of rational calculation in all spheres of life, and the disenchantment of more spiritual or superstitious forms of calculation. Disenchantment means exposure to a world in which meaningfulness is never

Table 1
Power/authority dynamics

	Versus tradition	Versus charisma	Versus rational-legality
Tradition	Rival dynasties	Dynasty confronting a revolutionary hero	Privilege ranged against rights according to law
Charisma	Princess Diana versus the British Royal Family	Hitler against Stalin during World War II	Nelson Mandela against De Klerk's Apartheid Government of South Africa
Rational-legality	Oliver Cromwell leading the Parliament against the monarch, Charles I	The Marcos Government in the Phillipines against Cory Aquino	Two governments disputing each others claim to the same territory, such as India and Pakistan over Kashmir

'given.' Instead, meanings clash, struggle against the resistance of others and are never wholly secure. Rational action consists precisely in the capacity to respond to the uncertainties of a world without meaning. Analytically, he conceived of three main types of rule around which rational action might revolve: principles of charisma, tradition, or rational legality. Each of these three types is a source of a particular type of *Herrschaft* (authority, or in better translation, domination).

In Weber's view, rationality had only a limited number of sources. It might derive from those few individuals who choose to impose value and meaning upon the world by confronting the world as something other than resolutely unyieldingly, absolutely and unbreakably cast in a mold. There were precious few such people in Weber's vision, other than charismatic leaders. Charisma is often identified with historical figures regarded as ordained with exceptional grace and a sense of calling that they were able to transmit and project to others, such as Jesus. Charisma is not a purely historical category, however, but it is only the rare charismatic leader, whose personal grace, sense of calling, duty, and devotion to some ultimate ideal is unshakeable, who would be able to impose such meaning on life. Hence, charisma was one of the key bases of authority that Weber identified. Charisma is typically something above the grubby theater of mundane political wheeling and dealing. In terms of modern life we might think of celebrities such as Princess Diana who were able to parlay their celebrity into a passionate social advocacy on behalf of the victims of landmines and in so doing, effect substantial changes in government policies. Here was a charismatic celebrity for the modern age—especially in her death. Clearly, in modern times, celebrity and charisma are closely related but by no means the same. Often they become confused: the cult of the personality that modern leaders like Mao, Stalin, and Hitler cultivated were deliberate attempts to use tight control of the state to fashion and stage-manage a celebrity that transcended the political sphere and which sought to invest them with charisma.

Tradition functions as another ideal type, best seen in claims to authority based on lineage or dynasty, in principles of 'blood and breeding' or exclusion from opportunities to claim authority because of the lack of such blood and breeding. The succession principles of monarchy, or inheritance rights attached to property, are prime examples of rule by tradition. Most pervasive, however, as a form of authority, was what Weber took as the quintessential modality of modern rule: rational-legal bureaucracy, where rule is conducted according to abstract principles. The dominance of what Weber referred to as the rational-legal does not overwhelm all other bases for rule and authority. However, its pervasiveness is often summed up today in a popular fear of 'economic rationalism,' referring to those situations where only a legally mandated economic calculus is applied to policy formulation (such as competition policy), without regard for other ways of accounting for the impact of such policies on the human spirit, communities, and the fabric of society.

Each principle of rule posits a particular type of authority and it is a simple matter to construct a matrix of these relations in order to generate some idea of what power might be. Weber defined power in terms of social action that is goal-oriented, even against the resistance of others. An evident example of power thus arises when there are cases of conflict between principles of rule (see Table 1). Here, power is seen in terms of the opposed principles or ultimate values.

2. Power as a Generic Concept

While Weber's definition of power is quite generic, the concept need not be premised on the conflict of rival, ultimate values, as per the examples of Table 1. Steven Lukes (1974), for instance, in one of the most influential books on the subject, regarded Weber's definition as essentially similar to the generic definition of power contained in the work of Robert Dahl (1957). Here power is defined as the situation that prevails when A gets a B to do something that they would not

otherwise do. This sounds a methodologically sparse and modern behavioral definition but it is one that reaches back into the earliest development of the modern era—to Thomas Hobbes's conception of power in a causal, mechanical world.

The Community Power Debate that formed around Dahl's (1961) work concerned the distribution of power in postwar USA. Dahl (1961) insisted that such questions could only be answered empirically, rather than through a broad ranging essaying of concepts that were then current, such as their being a 'military-industrial complex.' Additionally, he thought them better answered at the local, community level rather than at the national level. To determine the distribution of power required an operational definition for empirical investigation. For Dahl, power was indissoluble from its exercise: Someone had to be seen doing something to another for us to say that power had been exerted. Unlike Weber, he was not concerned with ultimate values but he did think it important that the exercise of power should be determined by competition over issues that people thought important. Basically, he sought to determine what the key issues were in a community and then establish the outcome of the politics surrounding these decisions, to see who gained or yielded power.

3. *Power, Real Interests and Hegemony*

By the time that Lukes (1974) published his book on *Power: A Radical View*, Dahl's approach had already been criticized by Bachrach and Baratz (1970) for leaving out of consideration 'what does not happen.' Nonissues, nondecision making, the construction of agendas, and the mobilization of bias through everyday routines, had all been introduced to show how power is accomplished through covert means, through inaction, rather than through overt exercise of causal power.

Lukes took the critique one step further. He argued that the critics had only sought to qualify Dahl's behaviorism rather than transcend it through radical critique. What was required, he argued, was a conception of how power worked not only against people's expressed and implicit preferences but also their 'real interests.'

The notion of real interests came from Marxist discourse—originally designed to address situations of 'false consciousness'—where a class of people were unable to recognize that the system within which they were embedded was the source of their entrapment. Lukes followed the Italian Marxist theorist, *Antonio Gramsci*, in introducing a 'cultural spin' with the notion of hegemony. Where people were deluded about what they wanted and what they might authentically be, because of their inability to think in concepts other than those of domination and the

dominated, then they suffered from hegemony. The basic idea was that they were subject to a 'ruling culture' disseminated through the media, the state, education, and other institutional arenas.

Theories of hegemony became variations upon the theme of working-class acquiescence secured through normative incorporation by dominant ideology (Abercrombie et al. 1980). The narrative was one of concealment: Marxist theory, in theory, should have provided revelation—but it did not. Only the theorist could see the truth of the mechanisms that, despite and even through resistance, secured and reproduced consent. The subjects of analysis had the nature of their real interests concealed from them. Western Marxism, the source of these insights, was impotent at best and at worst irrelevant, in lifting the veils of occlusion (Anderson 1976). In the West socialism became increasingly utopian (Bauman 1977); in the East increasingly dystopian (Fehér et al. 1983), as the collapse of 'dictatorship over needs' produced its implosion.

4. *The Discursive Turn*

The ideological arguments, with their fundamental denial of consumer sovereignty, receded in importance in the 1980s. One response to this situation within the Marxist camp came from Laclau and Mouffe 1985, who instead of thinking of hegemony as a state of mind regarded it as a set of practices. These practices were primarily discursive. Hegemony thus came to be seen not in terms of its substantive content but its form. Hegemony existed when the indefinite possibilities of signifying elements and their relations were strategically foreclosed (Laclau and Mouffe 1985). Again, the emphasis is on things that do not happen. Any stable set of articulations is thus hegemonic: Only permanent Cultural Revolution would not be—although the implications are not spelled out.

Real interests are what radical politics and theories claim to uncover and reveal. One way of doing this, suggested Haugaard (1998), might be to explain to actors the way in which their structured practices feed into the reinforcement of a regime of domination contrary to interests already known to them. What may be at issue are structural and institutional relations of domination rather than real but unknown interests. Once actors reflect upon their practical consciousness then they enjoy relative autonomy. Power thus consists not so much in the suppression of real interests but the denial of the relative autonomy required for reflection (Haugaard 1998, p. 141).

Haugaard (1998) notes that conceptions of interests form discursively, even to the extent that one can persuade some people that they have real but unrealized interests blocked by their present conditions of existence. Such discursive realities help shape them to

resist the sources of domination identified. Politics mobilize power and resistance through discursive expression of existing, past, or future conditions of existence. Thus, resistance is not endemic but depends on the practical consciousness of people and the categorical devices through which they lead their everyday lives in relation with the discursive consciousness proffered by various media of representation—parties, press, radio, television, the Internet, public intellectuals. Only in rare moments is such diversity represented or resisted in the name of some great unifying narrative or theme. Most probably these will be those relatively rare moments where a privileged identity is posited as a historical subject: the subject people, the subject party, the subject race, the subject nation, the subject church, the subject gender, the subject sexuality, the subject ecology, and so on.

A plurality of life-worlds, with interpretative resources, and translation devices for switching between them, minimizes the chances of hegemony. People from sophisticated cultures routinely have a multiplicity of interpretative horizons available to them, as a result of exposure to different life-worlds through various media, educational experiences, travel or migration, or interpersonal relations. Of course, to the extent that these experiences are compartmentalized, one way or another, then the ability to achieve critical distance from any posited identity is diminished.

The theorization of autonomy in terms of moves between interpretative horizons means that the ability of actors to transcend their social environments and structured context does not presuppose an ability to 'escape' the processes of socialization by adopting a neutral, culturally unbiased, position. Autonomy does not involve a flight into any transcendental realism of absolute Truth, nor does it involve the transcending of false consciousness. Critical faculty does not imply the objectivity of truth, nor does it entail an undersocialized concept of agency whereby autonomy is gained by transcending the basis of social culture. It requires only relative reflexivity on the part of subjects. Such a conception of the relation of power and knowledge, with its emphasis on conditions of relative autonomy, turns out to be a way of re-approaching the classical questions about power and community that were at the center of Dahl's work. The difference is that, this time, the approach has been through Foucault rather than Dahl.

5. Foucault and Power

Foucault provides a detailed history of some power practices and techniques that have characterized modernity in a way that is nonreductive and complements Weber (Dandekker 1991), although he understates the importance of Max Weber's (1978) argument concerning discipline. Nonetheless, there are common

themes (see Szakolczai 1998). Different emphases on power occur through the course of Foucault's work. First, there is his work on genealogy as the natural history of specific practices. Second, the work on the 'care of the self,' where histories are used to critique the present, by uncovering the constituted nature of what have been taken as the here-and-now; third, the discussion of government or 'governmentality.'

In Foucault's (1979) most influential genealogical model of 'surveillance and discipline,' power is constituted in an intimate relationship with liberty. Because the exercise of power presumes a free subject, in a well-known formula, there will always be resistance. Where liberty is extremely limited, because power is stable and hierarchical, then Foucault terms it domination. (The parallelism of this account with that of Weber's 1978 discussion of *Herrschaft*, is evident.) Two models of power are compared and contrasted: the repressive and the positive. (Foucault's 1979 concern with the facilitative and productive aspects of power relates to the kind of arguments made most clearly by Parsons 1963.) In general Foucault does not offer a critique of power: It would be impossible to do so because, to coin a phrase, power has no other: It is inescapable. Liberation from power is only a dream (or a nightmare). However, specific forms of power may and do change. The 'punitive' power of corporal excess may be contrasted with the 'positive' power of bureaucracy. However, there is no space outside of power, no knowledge that is pure truth. (In this way are utopia and dystopia avoided.) In reading Foucault it is necessary to uncouple a sociological from a philosophical question concerning truth. The former deals with what passes for truth rather than asking what is truth—with how truth-effects are produced, in the Foucauldian vernacular. It is the latter that concerns Foucault, rather than the former.

In Foucault's model of power relationships through government—the structuring of action through conduct—which he defines as the capacity of people to regulate their own behavior through various rationalities, his treatment of liberalism suggests that it is conditions of relative autonomy that define the nature of political community.

6. Community Politics after Foucault

Foucault suggests that democracy is neither an ideal with which to measure actual practice nor a method for producing utopias. It is the messy and politically expeditious ways of making sense of politics its participants routinely use. It is this fundamental approach that Flyvberg (1998) takes from Foucault. He provides a deeply documented, rich narrative of one complex set of issues and processes associated with the many ways in which political communities were constructed and deconstructed in the laborious

pursuit of local interests and issues surrounding a proposed traffic-plan for the city of Aalborg in Denmark.

Aalborg was not unusual in respect of its power relations: They were sufficiently asymmetric as to verge on domination. Here, the authority of technical rationality was a weapon of the politically weak—those without other resources at their disposal. Hence, not surprisingly, technically rational plans were constantly undercut and attempts at democracy secured on that technically rational basis proved weak. Neither a normative emphasis on democracy nor rationality proved sufficient to avoid domination by superior power. Such power defined reality and, not surprisingly, the rationality it accepted depended on power rather than legality. One of the main strategies of the dominant group was to use techniques of rationalization as power: Indeed, the greater the power the lesser the rationality. Thus, we might conclude that power is more ordinarily stable than conflictual and that its relations are constantly being produced and reproduced in process. Where power is stable then power relations are more characteristically rational.

7. Conclusion

In conclusion, we may note that in the genealogy of power that has been constructed here, power is not defined as only one thing, or in one set of terms. The terms shift with debate but there is a family resemblance among them. The emphases have changed with the values underlying scholarship. Lukes' importation of the Gramscian notion of hegemony seemed to take us a long way from the political communities that Dahl studied with such methodological scruples. Laclau and Mouffe's introduction of Foucault to the debate, somewhat surprisingly, brings debate back full circle to issues of political community because of the centrality, their conception of power placed on discourse and identity. The theme of the relative autonomy of political processes dominated the late work of Foucault and was taken up empirically by Flyvberg. Thus, nearly 50 years after the Community Power Debate first kicked off contemporary sociological interest in the conceptual relation of power and society, the concepts have come back to their empirical point of departure—but much richer and more sophisticated than when they first embarked on that journey.

Power: Political

Leading political theorists, such as Machiavelli and Hobbes, have devoted much attention to 'political power.' As Robert A. Dahl noted (1957), 'power' has a certain universality, whether it is called 'power, influence, control, *pouvoir*, *puissance*, *Macht*, *Herrschaft*, *Gewalt*, *imperium*, *potestas*, *auctoritas*, *potentia*,' etc. This article focuses on the concept of 'power' defined as a type of social causation.

1. Power as Causation

From 1953 to 1975, several leading political scientists developed the view of power as social causation, converging with an earlier viewpoint of Max Weber. After rejecting alternative definitions of 'power,' Herbert Simon (1953) cited a definition by Lasswell and Kaplan (1950): 'The exercise of influence (influence process) consists in affecting policies of others than the self.'

In the formulation best known to political scientists, Dahl stated (1957): 'My intuitive idea of power, then, is something like this: A has power over B to the extent

that he can get B to do something that B would not otherwise do.' James G. March (1955) stated: '... the set of all influence relations is here defined to be that subset of all causal relations such that the behavior of an individual appears as the terminal point in the causal linkage. Alternatively, we can say that two individuals are in an influence relation if their behaviors are linked causally.'

This leads to distinctions among different types of causal relations as they might relate to power. First, 'political power' refers to causal relations among humans, not to inanimate forces changing human behavior, as a hurricane might, for instance. Second, a distinction causing much confusion, one needs to distinguish situations in which the changed behavior reflects the intentions of the powerful actor. One might change the behavior of another in a way not intended, as when an incompetent lobbyist changes a legislator's vote to one different from that favored by the lobbyist. Some political scientists, such as March, are more comfortable with 'power' as causing changes in the direction intended by the powerful actor, and referring to the more general category of causing any changes as 'influence.' However, the seminal articles by Simon and Dahl do not restrict 'power' to intended changes in others' behavior.

Other examples of such causal relations would include power-as-suggestion: when A proposes a behavior change, B adopts the change without resistance. Another category of causal relations occurs when B resists, and A exercises rewards and sanctions, perhaps even force, to get B to change his or her behavior. This type of power may be called coercion (McFarland 1969).

In regard to power as coercive causation, John Harsanyi (1962) emphasized the costs of exercising power and also the costs of compliance with the exercise of power. For instance, a lobbyist might change a legislator's vote with little cost if it just means arranging a meeting with one of the legislator's staff. However, the cost is high if the lobbyist must mobilize hundreds of persons to petition the recalcitrant legislator. From the standpoint of the legislator, a vote may be 'cheap,' offending almost no one, or it may endanger victory in the next election. Still another causal situation occurs when A's preferences cause changes in B's preferences, causing B to act differently. This is widely known as 'anticipated reactions,' in which B, perhaps to please A and to avoid A's exercise of sanctions, changes behavior in line with an anticipation of what A wants him or her to do, even though A did not explicitly state such preferences (Nagel 1975).

An important, implicit aspect of defining power as causation is its link to empiricism. A statement of power then implies observations of instances of A changing B's behavior. It rules out defining 'power' in terms of the resources (wealth or force, etc.) used to get B to comply. One first has to observe the

causal relationship; then one analyzes how power was wielded.

Such resources were called by Dahl (1957) a 'power base,' and both he and Simon (1953) stated that the power base should not be confused with 'power' itself. In addition, Dahl stated that power-as-causation, to be an empirically useful concept, had to be used with four concomitant dimensions of power: base, amount, scope, and domain. *Base*, then, refers to the resources or means that A uses to cause changes in others' behavior. *Amount* refers to the idea that some instances of power refer to greater changes in behavior than others. A lobbyist exercises more power when he or she changes the legislator's vote from 'no' to 'yes,' for instance, than if the change is only from 'abstain' to 'yes.' The *domain* of an actor's power consists of those persons subject to the actor's power. The *scope* of power consists of the matters subject to the actor's power.

Dahl's major contribution to the study of political power is his insistence that the domain and scope always be clearly stated in discussions of power. Or to put it another way, an actor's power in one situation should not be immediately generalized to postulating equivalent power over other persons in other situations. The pharmaceutical lobbyist may have power over just one or over a score of legislators regarding the regulation of generic drugs. The same lobbyist might not have equivalent power over votes about Medicare payments for prescriptions; this lobbyist may have no power at all over any legislators in regard to civil rights or to gun control.

Scope and domain of power were key issues in the still widely remembered community power debate of the 1960s. Following the example set by Dahl in *Who Governs?* (1961), political scientists studied political power in localities by conducting case studies of public policy-making and charting which persons changed the course of events. Such studies normally found that the domain and scope of power was fragmented; different persons had power in different areas of policy. On the one hand, other social scientists—tending to be sociologists—followed a different conception of power, conceiving power to be possession of wealth or high social status. Such observers usually described inequalities of wealth and status and stated this as a finding of 'power' in a community. Political scientists, on the other hand, for the most part did not consider wealth and status to be 'power' itself, but instead to be resources that could be used to win political power, if such wealthy or high-status persons intended to do so. But such intentions are an empirical question, in this view, and must be observed in case studies.

This famous (or notorious) controversy extended for at least a decade and was expressed in scores of books and hundreds of journal articles before the frustrated debate participants, unable to persuade one another, for the most part went on to study questions other than community power (Polsby 1980).

Proponents of power-as-resource generally overlook a strong criticism of the power-as-causation model. Social causation is ordinarily very complex; case studies are not easy to do; power as causation thus is ordinarily complex, requiring a great deal of effort to study.

Such writers as Simon (1957), March (1955), Harsanyi (1962), and Riker (1964) left us with elaborate statistical models for studying power, models which require costly and difficult data collection. Jack Nagel (1975) wrote a concluding work in this line of analysis, in which power-as-causation was stated as path analysis, a form of statistics.

2. Power and Policy-making

March (1966) and Riker (1964) were both noted for asking the question in respect to political analysis: 'what is the power of power?' Political scientists answered this question, not by flocking to do more studies of the holders of wealth and status, but by stating models of power structure applicable to political systems, both national and local. Dahl (1961) had pressed forward the definition of power as causation in the course of his empirical refutation of the power elite model (Mills 1956), as applied by Floyd Hunter (1953) to the city of Atlanta. Such writers were among those who described power by describing characteristics and activities of an elite group, whose actual exercise of power usually went undemonstrated. Scholars such as Dahl became known as stating a *pluralist* model of power, finding power to be fragmented among various scopes and domains, as opposed to the concentration of power within a single elite.

Scholars such as Edelman (1964), McConnell (1966), and Lowi (1979) agreed with Dahl that political power in America is fragmented, but argued that stable, unrepresentative elites often controlled policy within specific scopes of power—such as setting grazing fees on federal lands, developing nuclear power plants, setting airline and interstate trucking schedules and fees, and so forth. Such analyses, which flourished briefly, were also based on case studies of policy-making, and constitute a school which might be termed *multiple-elitist*, finding not a single power elite but hundreds of elites, each specific to a particular scope of action and not subject to control by elected officials. But multiple-elitism in turn faced a revisionist interpretation, *neopluralism*, as found in studies by James Q. Wilson (1980) and Jack Walker (1991), for instance, who found that while power within specific scopes of policy was normally unequal, it was nevertheless shared by so many organized interest groups, politicians, and governmental agencies that even within narrowly defined policy scopes, stable and controlling elites are seldom found.

The power-as-causation model was developed from 1953 to 1975, and the examples cited in this literature were almost always of power among individual persons. But given the great difficulties in gathering such data, political scientists seldom conducted such studies, and instead the analysis of political power flourished with the development of models of public policy-making just cited. Such scholars saw no need to worry about possible criticisms of ignoring the power bases of wealth and status, and continued to conduct case studies of policy-making, following Dahl's example, even as many argued with Dahl's pluralist model. Such case studies were not conducted according to the canons of path analysis or other forms of statistics; instead researchers used historical materials, interviews, and current documents to ascertain which groups, leaders, and government agencies caused changes in the course of public policy. Relatively simple empirical methods, assuming power-as-causation, have been enough to generate interesting models of power structure, but perhaps more complex methods will be needed to resolve differences among various schools of political power analysis.

The study of political power has developed satisfactorily since Simon's seminal article in 1953, but a great theoretical difficulty remains—the problem of *hegemony*. Hegemonic writers stress the great importance of the power to determine which issues are on the political agenda of a political system (Lukes 1974). Community power theorists Bachrach and Baratz (1962) argued that there are 'two faces of power,' one of which is power over the formation of political issues, and the other is the overt activity studied by Dahl. In arguing for the understanding of hegemony, the Marxist Antonio Gramsci argued (1971) that capitalism maintained its political power through socialization of persons into supportive values and norms, as much as through the machinations of 'bourgeois government.' Social values shape the preferences of the actors in their search for political power, but how can the scholar make empirical statements about one set of values displacing perhaps hundreds of conceivable alternative value systems? This seems to presuppose a comprehensive theory of social relations. Hegemony can be distinguished from the power of *anticipated reactions*, power exercised when B anticipates A's intentions, and acts according to them, perhaps fearing the costs of A's overt coercion. Republican members of Congress may have considered blocking appropriations for a government department, but anticipating President Clinton's effective reactions, they think better of the idea and do little but discuss the matter. But since the matter received some discussion, the theorist of political power may make an empirical observation. Similarly, in international relations, we speak of the deterrent power of weapons, even if these are never used. From the behavior of those deterred, scholars can find evidence that some probability of warlike behavior by one

nation was deterred (a change of behavior) through the possession of weapons by the other nation.

Practical Reasoning: Philosophical Aspects

Practical reasoning is reasoning that aims to resolve the question of what one is to do. Such reasoning is practical in at least two senses. First, it is practical in its subject matter, insofar as it is concerned with human action. But it is also practical in its issue, insofar as reflection about action can itself directly move people to act. Reasoning of this kind raises two sets of philosophical problems. One concerns the question of how reflection can succeed in being practical in its issue. What assumptions must be made both about agents and about the processes of reasoning they engage in to make sense of the fact that such reflection can give rise to action? Can justice be done to this fact while preserving the idea that practical reasoning is genuinely a form of reasoning? A second set of issues concerns the content of the standards that are brought to bear in practical reasoning. Which norms for the assessment of action are binding on us as agents? Do these norms provide resources for critical reflection about our ends, or are they exclusively instrumental? Under what conditions do moral norms yield valid standards for reasoning about action? The first set of issues is addressed in Sects. 1–3, while Sects. 4 and 5 cover the second set of issues.

1. Practical and Theoretical Reasoning

Practical reasoning takes place from a distinctive standpoint. When agents deliberate about action, they think about themselves and their situation in characteristic ways. What are some of the salient features of the practical point of view?

One way to interpret this point of view is to contrast it with the standpoint of theoretical reflection. Theoretical reflection is sometimes understood as reasoning about questions of explanation and prediction. Looking backward to events that have already taken place, it asks why they have occurred; looking forward, it attempts to determine what is going to happen in the future. In these ways, theoretical reflection is concerned with matters of fact and their explanation. Furthermore it treats these issues in impersonal terms that are accessible (in principle) to anyone. The natural and social sciences can be viewed as giving paradigmatic expression to theoretical reasoning, so construed.

Practical reasoning, by contrast, takes a distinctively normative question as its starting point. It typically asks, of a set of alternatives for action, none of which has yet been performed, what one ought to do, or what it would be best to do. It is thus concerned not with matters of fact and their explanation, but with matters of value, of what is to be done. In practical reasoning

agents attempt to assess and weigh their reasons for action, the considerations that speak for and against alternative courses of action that are open to them. Moreover, they do this from a distinctively first-personal point of view, one that is defined in terms of a practical predicament in which they find ourselves (individually or collectively—people sometimes reason jointly about what they should do together; see *Joint Action*).

There is, however, a different way of understanding theoretical reasoning, stressing the parallels rather than the differences between the two forms of reflection. According to this interpretation, theoretical reflection is concerned with a normative rather than a factual question, namely with the question of what one ought to believe. It attempts to answer this normative question by assessing and weighing reasons for belief, the considerations that speak for and against the particular conclusions one might draw about the way the world is. Furthermore, it does this from a standpoint of first-personal reflection: the stance of theoretical reasoning in this sense is the committed stance of the believer, not the stance of detached contemplation of one's beliefs themselves (Moran 1997). Seen in this way, the contrast between practical and theoretical reflection is essentially a contrast between two different systems of norms: those for the regulation of action on the one hand, and those for the regulation of belief on the other.

Theoretical reflection, interpreted along these lines, addresses the considerations that recommend accepting particular claims as to what is or is not the case. That is, it is reasoning with an eye to the truth of propositions, and the reasons for belief in which it deals are considerations that speak in favor of such propositions' being true, or worthy of acceptance. Practical reasoning, by contrast, is concerned not with the truth of propositions but with the value of actions. The reasons in which it deals are considerations that speak in favor of particular actions being good, or worthy of performance in some way. This difference in subject matter corresponds to a further difference between the two kinds of reasoning, in respect of their consequences. Theoretical reflection about what one ought to believe produces changes in one's overall set of beliefs, whereas practical reason gives rise to action; it is, as noted above, practical not only in its subject matter, but also in its issue.

Two observations are in order about this side of practical reasoning. First, the contrast just drawn might suggest that there is a categorical difference in the effects of theoretical and practical reasoning, insofar as the former produces changes in our mental states, whereas the latter gives rise to bodily movements. But this would be misleading. Practical reasoning gives rise not to bodily movements *per se*, but to intentional actions, which are intelligible as such only to the extent they reflect our mental states. It would thus be more accurate to characterize the consequences of both

theoretical and practical reasoning as *attitudes*, noting that the former leads to modifications of our beliefs, whereas the latter leads to modifications of our intentions (Harman 1986, Bratman 1987). Second, in neither case do the modifications in question occur infallibly. There is room for irrationality both in the theoretical and the practical sphere, which in its strongest form involves a failure to acquire the attitudes that one acknowledges to be called for by the reasons one has reflected on. Thus a person might end up watching another hour of television, while judging that it would be better on the whole to go back to work. Practical irrationality of this latter kind is known as *akrasia*, incontinence, or weakness of will, and its possibility makes clear that practical reasoning is not automatically practical in its issue. A better way to represent the consequences of practical reasoning would be to say that it generates appropriate intentions to the extent an agent is rational (Korsgaard 1996; see *Irrationality: Philosophical Aspects*).

2. Naturalism and Normativity

The connection of practical reasoning with intentional action raises large questions about its credentials as a genuine form of reasoning. As noted above, intentional action is not mere bodily movement, but reflects a mental state of the agent's, viz. intention. To be in this kind of mental state is to have a goal or aim of some kind, which one seeks to realize through one's action. Intention seems in this respect to be strikingly unlike belief. The propositions that give the content of beliefs have a representative function; they aim to fit the way the world is, so that if one discovers that the world is not how one previously took it to be, one's belief will automatically be modified in the process. With intentions, however, matters are otherwise (Smith 1987). The intention to go shopping on Tuesday, for instance, is not a state that would or should be abandoned upon discovering that one has not (yet) gone shopping on Tuesday; rather the person with such an intention will ordinarily try to bring the world into alignment with the intention, by going shopping when Tuesday comes around. Intentions are in this way more like blueprints than like sketches of an already completed structure.

Reflection on this contrast between belief and intention has led some philosophers to ask whether practical reasoning might not be something of a misnomer. The concern, in a nutshell, is how processes of thought that count as genuine reasoning could by themselves generate states with the peculiar, nonrepresentative function of intentions. Reasoning seems to consist of cognitive operations, whereas intentions are distinctively noncognitive states insofar as they do not aim to reflect the way things happen to be in the world.

Expressivist accounts give voice to this skeptical attitude about practical reasoning. These accounts offer interpretations of the normative language that distinctively figures in practical reflection about action. As was seen in Sect. 1, such reflection is an attempt to assess an agent's reasons for acting in one way or another; conclusions about such reasons are characteristically expressed in claims about what it would be *good* to do, or about the actions that one *ought* to perform. According to the expressivist, however, such claims do not represent genuine cognitive achievements, judgments that are literally capable of being true or false. Rather they give expression to desires, sentiments, and pro-attitudes, the kinds of noncognitive state that motivate people to action. Only if normative assertions are understood in this way—so the expressivist contends—can sense be made of the capacity of practical reflection to generate states with the peculiar structure and function of intentions.

Expressivism in this form can be seen as a naturalistic interpretation of practical reasoning, one that is appropriate to the enlightened commitments of the modern scientific world view. It is naturalistic metaphysically, insofar as no assumptions need be made about the objective existence in the world of such questionable entities as values, norms, or reasons for action. If normative claims do not represent genuine cognitive achievements, then their legitimacy does not depend on our postulating a realm of normative facts to which those claims might correspond. It is also naturalistic psychologically, insofar as it promises explanations of intentional human behavior that are basically continuous with explanations of the behavior of nonhuman animals. In both the human and the nonhuman case, behavior is seen as the causal product of noncognitive attitudes, operating in conjunction with the creature's factual representation of how things are in its environment. The difference is just that humans have much more sophisticated linguistic methods for giving voice to their motivating noncognitive attitudes. Indeed, many contemporary expressivists would contend that these expressive resources are sufficiently powerful to explain the features of practical reflection that initially give it the appearance of a genuine form of reasoning (Blackburn 1998, Gibbard 1990).

Other philosophers remain unimpressed with these naturalistic explanations. One ground for dissatisfaction with them is the following. The expressivist strategy relies on an initial contrast between practical reflection and the genuine forms of cognitive activity characteristic of theoretical reasoning. There has to be some basic sense in which such discourse does not come up to the standards of authentic cognitive discourse in the literal sense, otherwise the contention that normative discourse is expressive rather than cognitive will lack any significant content. But the contrast between theoretical and practical reflection required for this purpose seems elusive. As was seen in

Sect. 1, theoretical reasoning is no less a normative enterprise than practical reasoning. It concerns itself with reasons for belief: the evidence and other considerations that speak for and against particular conclusions about the way things are in the world. In this respect, theoretical and practical reasoning would seem equally problematic from the naturalistic perspective—assuming, that is, that it leaves no place for such normative considerations as reasons. But if naturalism calls in question the credentials of theoretical reason, it thereby undermines the contrast between genuine reasoning and noncognitive normative discourse on which expressivists themselves rely (see *Emotion and Expression; Intentionality and Rationality: An Analytic Perspective*).

3. Reasons and Motivation

The capacity of practical reasoning to generate intentional action divides even those philosophers who agree in rejecting the expressivist strategy discussed above. Such philosophers are prepared to grant that there are reasons for action, and to accept the cognitive credentials of normative claims about such reasons. But they differ in their accounts of the truth conditions of these normative claims. Two approaches may be distinguished. The first of these, frequently referred to as internalism, holds that reasons for action must be grounded in an agent's prior motivations (Williams 1981). According to this position, a given agent *s* can have reason to do *x* only if *x*-ing would speak to or further some element in *s*'s 'subjective motivational set.' There must be some rational route that connects *s*'s *x*-ing with the subjective motivations to which *s* is actually already subject; otherwise the claim that *s* has reason to *x* must be rejected as false or incoherent. Behind this internalist position lies the idea that practical reasoning is practical in its issue. Internalists contend that sense can be made of the capacity of such reasoning to generate new intentions only if it is conditioned by motivational resources that are already to hand. Reasoning about action is a matter of working out the implications of the commitments contained in one's subjective motivational set; in this sense, motivation is prior to practical reason, and constrains it. Externalists reject this assumption, contending that one can have reasons for action that are independent of one's prior motivations. Most of them agree that practical reasoning must be capable of generating new intentional actions, and hence of giving rise to motivation. They agree, in other words, that if agent *s* has reason to do *x*, it must be possible for *s* to acquire the motivation to *x* through reflection on the relevant reasons. But they deny that such reasoning must in any way be constrained by *s*'s subjective motivations prior to the episode of reasoning. Prac-

tical reasoning is not exclusively a process of working out the implications of one's existing commitments; it is also an attempt to get clear about what it would objectively be good to do. Normative considerations of this kind are independent of one's prior motivations, and can open up new motivational possibilities (Parfit 1997).

Underlying this dispute are diverging approaches to the explanation of intentional action. Internalists are impressed by the differences between intentions and the cognitive states that figure in paradigmatic examples of theoretical reasoning. Pointing to these differences, they ask how practical reasoning can succeed in producing new intentions if it is not grounded in something of the same basic psychological type: a motivation or desire that is already part of the agent's subjective motivational equipment. Many externalists find this contrast between intentions and cognitive states overdrawn. They observe that we need to postulate basic dispositions of responsiveness to reasons to account for the capacity of theoretical reflection to generate new beliefs, and question why these same dispositions cannot explain the fact that practical reasoning is practical in its issue. Cognitive or not, intentions belong to the broad class of attitudes that are sensitive to judgments, and this may account for the capacity of practical reflection to give rise to new intentions (Scanlon 1998). A third possibility is that intentions are products of the will, a capacity for self-determination distinct from the dispositions that render theoretical rationality possible. Depending on how it is developed, the theory of the will may offer a different way of accounting for the practical consequences of practical reflection, without assuming that reasons for action are grounded in an agent's subjective motivations (Wallace 1999).

4. Instrumental and Maximizing Rationality

Among the substantive norms of practical reasoning, those of instrumental rationality appear least controversial. Instrumental rationality, in its most basic form, instructs agents to take those means that are necessary to achieve their ends. In the modern era, this form of rationality has widely been viewed as the single unproblematic norm of practical reasoning. The instrumental principle makes no assumptions about the prospects for rationally scrutinizing peoples' ends. Rational criticism of this kind would seem to presuppose that there are objective values, standards for assessment of ends that are independent from psychological facts about what people happen to be motivated to pursue. In keeping with the naturalistic attitude sketched in Sect. 2, however, it may be doubted whether such standards can be reconciled with the metaphysical commitments of contemporary scientific practice (see *Value Pluralism*). A world that is shorn of objective values or norms leaves no room for

rational criticism of people's ends, but only for Weberian *Zweckrationalität*: the rational determination of means to the realization of ends that are taken as given, as a matter of psychological fact.

It is important to bear in mind, however, that instrumental rationality is itself the expression of an objective normative commitment. The instrumental principle tells us that we have *reason* to take the means that are necessary to achieve our ends; if the principle is valid, then people are open to rational criticism to the extent they fail to exhibit this kind of instrumental consistency, regardless of whether they want to comply with the principle or not. If naturalism really leaves no place for objective norms or values, it may be wondered how an exception can possibly be made for the instrumental norm. The consistent naturalist should perhaps reject even *Zweckrationalität* in favor of a skeptical attitude towards practical reasoning in all its forms (Hampton 1998). Further questions can be raised about the plausibility of the instrumental norm as a self-standing principle of practical reason. The norm says that one should take the means that are necessary to achieve one's ends. But how can the fact that a given means is necessary, relative to some end, give a person reason to choose the means, if the end is not itself something it would be good to achieve in some way? The instrumental principle seems to function as a binding standard for practical reasoning only if it is taken for granted that there are additional, independent standards for the assessment of our ends (Korsgaard 1997).

One way to make room for the rational criticism of individual ends, without departing from the spirit of *Zweckrationalität*, is to expand one's view to encompass the totality of an agent's ends. Thus, even if there are no values that are ultimately independent of an agent's given ends, it would appear possible to criticize particular intrinsic desires by reference to others in the agent's subjective motivational set. An agent's desire for leisure, for instance, might be subordinated insofar as its satisfaction would frustrate the realization of other goals that are subjectively more important to the agent. Practical reasoning, it might be suggested, is a holistic enterprise, concerned not merely with the specification of means to the realization of individual ends, but with coordinated achievement of the totality of an agent's ends.

Many philosophers view this holistic perspective as the most fruitful way of conceptualizing the tasks of practical reasoning. It defines an important and difficult problem for practical reasoning to solve, without departing from the metaphysically modest assumption that there is no court of appeal for the rational criticism of an agent's ends that is independent of those ends themselves. The most sophisticated and influential expression of this holistic perspective is the maximizing conception of rationality. According to the maximizing conception, the fundamental aim of practical reasoning is to determine which course of

action would optimally advance the agent's complete set of ends. Thus it has been suggested that the rational action is the one whose subjective expected utility—reflecting both the utility of possible outcomes, from the agent's point of view, and the agent's beliefs about the probability of those outcomes—is the highest.

The maximizing conception of rationality finds its most complete expression in decision theory and in the theory of rational choice (as developed, for instance, in economics). These disciplines articulate with mathematical precision the assumption that one is acting rationally to the extent one does what is likely to bring about the best state of affairs, given both one's preferences and one's beliefs about the probable consequences of the alternatives that are open to one. Proponents of these theories often claim for them the additional advantage of empirical adequacy, contending that they are flexible enough to accommodate the full range of behaviors that human agents engage in, both within the marketplace and outside of it. Especially if one operates with the notion of 'revealed preferences'—preferences, that is, that are inferred solely on the basis of actual behavior—then virtually anything an agent might choose to do could be interpreted as an attempt to maximize expected utility. Decision theory, on this account of it, becomes an all-encompassing framework for the interpretation of human behavior, according to which agents are always striving to produce outcomes that would be optimal, relative to their preferences and beliefs (see *Rational Choice Explanation: Philosophical Aspects*).

If decision theory is interpreted in this way, however, then its relevance to the understanding of practical reasoning begins to seem correspondingly tenuous. Maximizing rationality initially looks to be a norm of practical reflection. In this guise, its appeal lies in the idea that there can be rational requirements on action, stemming from the totality of an agent's preferences and beliefs, even if it is not assumed that there are independent, substantive standards for the critical assessment of individual ends. But this normative understanding of maximizing rationality is tenable only if it is at least conceivable that individual agents might occasionally fail to comply with its requirements—an 'ought' that it is not so much as possible to flout is not really an 'ought' at all. Proponents of the maximizing approach need to be attentive to the latent tension between the empirical and the normative aspirations of their theory, for maximizing rationality cannot claim both perfect empirical adequacy and normative authority for practical deliberation.

Assuming this tension can be resolved, further questions arise about the plausibility of the normative requirement to maximize expected utility. Doubts have been raised, for instance, with regard to the assumption that it is necessarily irrational to fail to select that action that would be optimal, relative to one's preferences and beliefs. Perfectly rational agents

often seem to be content with states of affairs that are 'good enough,' from the perspective of their aims and desires, even when they are aware of alternatives that promise a higher return; they 'satisfice' rather than seeking to maximize the value of the outcomes that they bring about (Slote 1989). They also treat their past intentions and plans as fixed constraints on their decision-making, rather than attempting to maximize subjective utility anew in every situation they confront (Bratman 1987). Some contend that maximizing rationality is flexible enough that it can accommodate alleged counterexamples of these kinds (Pettit 1984). If not, however, there may be grounds for doubting that it represents a fundamental and uncontroversial norm for reasoning about action.

5. Specification, Expressive Rationality, and Moral Reasons

If maximizing rationality is not the unproblematic requirement of practical reasoning that it initially seemed to be, what are the alternatives to it? Consider the assumption that critical assessment of an agent's individual ends is off-limits. This apparently truistic assumption has been questioned by some philosophers, who point out that a great many of one's aims in life are rather inchoate; people want, for instance, to be successful in their careers, and loyal to their friends, without being entirely clear about what these ends require of them. To the extent one's ends are indefinite in this way, they will not provide satisfactory starting points for instrumental, maximizing, or even satisficing reflection. One will need to specify such ends more precisely before one can begin to think about which means they require one to pursue, or to generate from them a rank-ordering of possible outcomes. Here is a possible task for practical reasoning that does not fit neatly into the categories of *Zweckrationalität*, however broadly construed (Wiggins 1987, Richardson 1994).

Practical reflection about ends is not an easy or well-defined activity. There are no straightforward criteria for success in this kind of reflection, and it is not even clear when it has been brought to a satisfactory conclusion. These considerations are no doubt partially responsible for the assumption—especially widespread in the social sciences—that there is no reasoning about final ends. On the other hand, how is one supposed to clarify one's largest and most important ends, if not by reasoning about them in some way? Rather than exclude such reflection because it does not conform to a prior and possibly inappropriate paradigm of proper reasoning, perhaps the conception of practical reasoning should be expanded to make room for clarificatory reflection about the ends of action. To do so would be to acknowledge that practical reasoning can be both objective and subjective at the same

time; by working out the meaning and implications of such commitments as loyalty or success, for instance, agents also help to get clear the values that define who they are (Taylor 1985; see *Hermeneutics, Including Critical Theory*).

A different point at which to question received models of practical reasoning is the theory of value to which they are committed. Maximizing and satisficing models alike seem committed to a consequentialist account of the relation of action to value: the thesis that value inheres ultimately in states of affairs, and that actions are to be judged rational to the extent they produce valuable states of affairs. This thesis seems at odds, however, with intuitive ways of thinking about value. It appears a distorted understanding of friendship, for instance, to say that what friends value fundamentally are states of affairs (involving, say, joint activities with the friend); what people value as friends are rather the concrete persons with whom they are befriended. This suggests a different way of conceptualizing the rationality of action. What makes actions rational, it has been claimed, is not the production of valuable states of affairs, but rather their success in expressing the attitudes that it is rational to adopt toward the true bearers of intrinsic value: people, animals, and things (Anderson 1993). A supposed advantage of this approach is its ability to explain the rationality of behaviors that seem intuitively sensible, but that are hard to fit into the consequentialist scheme (such as commitments deriving from one's past involvement in an activity or project, which can look like an irrational weighing of 'sunk costs' to the consequentialist; compare Nozick 1993).

Morality provides an especially fertile source of examples and problems for the theory of practical reasoning. One of the defining questions of moral philosophy is the question of the rational authority of moral norms: to what extent, and under what conditions, are people rationally required to comply with the demands of conventional morality? Reflection on this question has produced some of the most far-reaching and illuminating philosophical work on the nature of practical reasoning. Two divergent tendencies within this body of work should be singled out. Some approaches to moral reasoning proceed by relating it to patterns of reflection familiar from other, nonmoral domains, particularly the maximizing patterns canvassed in the preceding section. Thus it has been argued that, though morality imposes constraints on the direct pursuit of individual utility, these constraints can be justified in terms of the values expressed by ordinary economic rationality; a strategy of constrained maximization is recommended on grounds of enlightened self-interest, and this in turn accounts for the authority of moral norms to govern the practical reflection of individuals (Gauthier 1986). Other philosophers have sought to make sense of morality as a source of rational norms by assimilating

it more directly to the maximizing conception. For instance, proponents of consequentialism as an ethical theory—the theory that agents are morally required to maximize the good, impartially conceived—consider it an advantage of this account that it represents moral requirements in terms of the maximizing conception of rationality familiar from other contexts (Harsanyi 1982; see *Consequentialism Including Utilitarianism; Economics and Ethics*).

A different approach stresses the discontinuities between moral and nonmoral patterns of reasoning. According to this approach, morality is a source of constraints (such as prohibitions on murder and deception) that cannot be represented accurately within the framework of maximizing rationality (for example, Scanlon 1998). If this is correct, then those who wish to make sense of moral requirements, as norms that appropriately govern the reflection of individual agents, will need to expand their conception of the forms and possibilities of practical reasoning (see *Ethics and Values*).

Practice: Anthropological Aspects

The word practice carries a clear meaning in everyday English. A practice is a convention or institution, and in anthropological discourse the word often appears in its ordinary sense. Tibetans follow the practice of sky burial or South Indians practice cross-cousin marriage. But the word also enters anthropological discourse in more theoretized ways.

1. Sources

The idea that human action takes place against a background—constituted or tacit knowledge, *inter-subjective meanings*, a form of life, or practice—has sources in Husserl, Wittgenstein, and Polanyi. But the notion has mostly influenced students of human behavior, from Merleau-Ponty to Michel Foucault and Pierre Bourdieu, by way of Heidegger's *Being and Time*. For Heidegger, the epistemological question—how do we know our understanding of the world matches the world itself—cannot be asked as Descartes did, by making the question of truth a matter of beginning with what a conscious subject can know of the world with absolute certainty and working from there. The Cartesian subject on Heidegger's account can know that he or she exists only because of the presence of a set of background practices which make knowing (or acting, judging, laughing, and so on) possible. The intelligibility of the world in other words depends on the actor's prior 'being-in-the world.'

Heidegger argues that understanding human action requires recognizing that it is practical twice over—it depends on this background of practices and it is purposive. In Heidegger's language *intentionality* is always practical rather than cognitive, but practices are purposive in an extended sense of the word. The actor may not have any purpose in mind because

being-in-the world is a skilled activity that goes on whether the actor is aware or not (1962, p. 405). Intrinsic to human activity is the actor's comportment with things in the world, and everyday being resides in his or her doing, intending, and coping. Human beings are socialized into these practices relative to their historical moment and culture, yet the practices themselves cannot be made explicit. If such is the case, the idea of practice challenges hopes for a scientific account of behavior.

Mainstream political science, for instance, assumes that the *actor's point of view* is a thing in itself. It consists of beliefs, attitudes, and evaluations. These states of mind are an objective social reality and capable of furnishing the brute data on which the political scientist constructs a science of politics. The problem is that the actor's point of view cannot be reduced to that which can be attributed to him as a belief, attitude, or evaluation if the content of consciousness depends on intersubjective belief or practices that stand behind these mental states and make them possible (Taylor 1971). The intersubjective beliefs Japanese villagers hold about reaching public consensus, Taylor says, must be understood as residing in the relationship between actors and the society they inhabit. Critics of *positivism* argue that no amount of questioning could elicit these intersubjective beliefs from the Japanese themselves because they are ineffable and depend on still other practices. Yet without accounting for the bottomless matrix of practices in which those beliefs, attitudes, and evaluations are embedded, no comparative science of politics is possible.

2. Habitus, Practice, and Time

Another example of Heidegger's influence is Bourdieu's use of the word practice in the sense of *praxis*, *action*, or *agency*. While Taylor reacts to the assumption that social action can be explained by focusing on an actor's consciousness, Bourdieu denies that it can be understood as consciousness reduced to rules and norms. In his view, action is relational, recursive, and reflexive. Behavior has a cultural referent, but is considerably more complicated than the execution of a blueprint. Bourdieu's attempt to accommodate strategy and innovation as part of an account of social behavior appeared as nearly as his *Algeria 1960* which he organized around the distinction between dispositions and economic structures (English trans. 1979). He theorizes that relationship in a full-blown way in his *Outline of a Theory of Practice* (1977). Dispositions, Bourdieu writes, have two parts—the *habitus*—the ensemble of dispositions towards action and perception that operates from within social agents—and the practice which the habitus generates. The habitus is 'the durably installed generative principle of regulated improvisations' (1977, p. 78). Those structured, objectively unified practices

are subjective and changing, but they follow from the habitus in the same way a jazz band improvises on a familiar melody.

Where a traditional anthropological account of kinship focused on genealogical rules and the constraints those rules exert on some activity such as marriage choice, Bourdieu saw genealogical forces in relation to other variables (1977). To regard Kabyle marriage as the realization of a parallel cousin rule for arranging a match is to remove one source of determination from the relationship in which it operates. Any calculation that an anthropologist might make of how often Algerians marry their parallel cousins depends on the extent of the social unit in relation to which the calculation is made. The size of that social unit is itself a strategic variable (1990, p. 15). Other variables pertain to the couple (age and age difference, previous matrimonial history, sibling order, relationship to the family authority-holder), but a great many more are family matters (the economic and social status of the families, their social affiliations, ability to defend themselves, as well as sheer numbers). For Kabyles the habitus includes parallel cousin marriage as one disposition among many, and the strategies that emerge from all of those dispositions—weighing each in relation to others—constitute practice.

Families strategize by considering all of these considerations, and as they learn more about the other side, their strategy evolves. Because human behavior is recursive as well as relational, its analysis must take *time* into consideration. Bourdieu insists that de-temporalizing science fails to understand what constitutes social behavior. Time gives behavior 'its form, as the order of succession, and therefore its direction and meaning' (1990, p. 98). Where Lévi-Strauss thought the gift exchange was organized according to deep principles unknown to the actor, Bourdieu argued that it was driven by 100 small calculations, idiomatic to actors who re-evaluate and change their strategies as the situation unfolds in time. Those calculations may be intuitive, but theory misconstrues its object when it takes the actor's agency as simply applicative.

There is a third part of practice where Bourdieu turns Heidegger in a sociological direction. Practices are *reflexive*. They carry with them their own interpretation, which means that they organize the relationship between individuals and society in a way that is circular. Heidegger puts the matter in distinctive language—existence is an understanding of being shared by individuals and society. Because practices are shared, they are the basis of mutual intelligibility, but this same condition means that there is never anything like a subjective inner sphere (1977, pp. 80–1). Individuals, whatever their self-conception, are social creatures. Individuality cannot be absolute, but a variant on the local class habitus and other dispositions.

In this sense Bourdieu blurs the distinction between the individual and society. 'The habitus—embodied

history, internalized as a second nature and so forgotten as history—is the active presence of the whole past of which it is a product. As such, it is what gives practices their relative autonomy with respect to external determinations of the immediate presence. This autonomy is that of the past, enacted and acting, which ..., makes the individual agent a world within a world' (1990, p. 56). *Symbolic interactionists* and *ethnomethodologists* assume that social action derives from individuals responding to immediate circumstances, and Bourdieu too wants to account for circumstances. But he does so by insisting that the actor's course is guided by a dialectic. He is always a social being subject to the orientations and limits of the habitus' 'operations of invention' as they develop amidst those objective structures (1977, p. 95).

That practices are reflective of larger social understandings (of what it is to be a person, a teacher, a woman) has implications for the way Bourdieu understands agency: 'it is because subjects do not, strictly speaking, know what they are doing that what they do has more meaning than they know' (1977, p. 77). It also has implications for the way Bourdieu understands agency as organized in time. He says that gift exchange is one of the social games that cannot be played unless the players ignore 'the objective truth of the game ... and unless they are predisposed to contribute, with their efforts, their marks of care and attention, and their time, to the production of collective misrecognition. Everything takes place as if the agents' strategies and especially those that play on the tempo of action ... were organized with a view to disguising to themselves and from others the truth of their practice, which the anthropologist brutally reveals simply by substituting the interchangeable moments of a reversible sequence for practices performed in time and in their own time' (1990, pp. 105–6).

3. Practice and Domination

The notion that the actor's point of view entails his or her misrecognizing the social game derives from a tradition of concern for consciousness that has affinities to both Marx and Heidegger. What Bourdieu takes from Marx (and what separates him from Heidegger) is the idea of structure, and specifically the economic structures in which actors act. The world is prior to the actor's agency in the world, but it bears on individuals relative to their position in the social organization of production. It is the objective character of social conditions that produces a class habitus, the harmony of dispositions, ethos, taste, and what he calls body *hexis*—while individuals are thoroughly social, they are related to society in ways appropriate to their peculiar identities.

Bourdieu has studied how relations of *domination* shake an actor's subjective aspirations in an extraordinary variety of contexts—from the Kabyles of

Algeria, peasants in the region of Bearn in south-western France, the academic establishment, systems of classification in educational settings, museums, class relations, sports, to high fashion and the production of other cultural goods in modern industrialized societies. In its most cunning form domination operates in systems of classification. Whether he turns his attention to anthropological concerns with kinship, ritual, calendars, and domestic space or more sociological matters such as fashion, taste, and educational systems of classification, Bourdieu dismisses Kantian and Lévi-Straussian assumptions. All such classifications are not folk epistemologies but ideological mystifications of political realities.

Because Bourdieu assumes the nondistinction of the material and the symbolic, he rejects 'the spurious alternatives of social physics and social phenomenology' (1990, p. 140). In the same way that charisma is not a particular form of power, contra Weber, but the condition of all power, meaning grounds all human action. In studying *taste* as a discriminating practice in modern France, Bourdieu draws the study of culture into the realm of culture understood anthropologically (1984). The endless conversion of economic capital into *symbolic capital* uses taste to enunciate class differences but requires the complicity of the entire society. That conversion is the condition which makes possible the continuation of domination, yet it 'cannot succeed without the complicity of the whole group ... As Mauss puts it, the whole society pays itself in the coin of its dream' (1977, p. 195).

4. Practice and its Applications

Seen against the background of anthropological theory, practice theory was a response to the profession's recent discontent with the notion of culture, especially its neglect of power and strategy. Seen against a Heideggerian background, it was another critique of the error with which Western philosophy began, objectivism (1962, pp. 41–9). Anthropologists found much to admire in Bourdieu's work—his even-handed concern for both the actor's point of view and structure, efforts to transcend the conventional antinomies, and recognition of temporality as figuring in social life. Exploiting practice theory as a way to tie together consciousness and structure, action and its temporal horizon, as well as Weber and Marx, theorists have applied Bourdieu's thinking to case studies that range from gift-giving, saving, and consuming to gender, sexual difference, class relations, and colonial encounters.

If one counted anthropologists invoking the importance of practice, temporality, or simply Bourdieu's name, his influence would be striking. Counting only scholars who fully pursue his research program, the number would shrink to people who

publish in the journal he founded, *Actes de la recherche en sciences sociales*, or work with him at the Centre de Sociologie Européenne in Paris. The most vibrant tradition occupying the space between these extremes are anthropologists who have seen practice theory as a vehicle for coping with history and temporality. Marshall Sahlins' work on Hawaii and Fiji carries on Bourdieu's interest in social reproduction, here fixed on situations where European actors intruded on South Pacific systems of domination. In accounting for the circumstances that surrounded Captain Cook's arrival in Hawaii, Sahlins characterizes events in a way that melds agency and structure, showing how mutual misrecognition created changes that look in retrospect entirely predictable (1985). In dealing with Hawaiians's initially worshipful attitude to Cook and his eventual murder, Sahlins pushes Bourdieu's commitment to agency and structure in a historical direction, arguing that those incidents evolved in a way better understood not as misrecognition and disaster, but the reproduction of culture—Hawaiians thought Cook was their god Lono—and its transformation. Sherry Ortner melds practice theory, structure, and history in characterizing the relationship of 'big' people and 'small' people and monks and nuns in Sherpa society and relations among that society, the Nepal state, and the British Raj (1989). Her confidence in the Bourdieuan project also organized her important article evaluating the state of anthropological theory (1984).

Arjun Appadurai's attempt to theorize globalization has even more inspirations, but Bourdieu's work is critical. Approaching consumer capitalism as a system as much symbolic as material, Appadurai extends the analysis in several directions. He understands consumption as a transnational phenomenon, which finds its locus at the level of body hexis, the individual, class, and nation-state. Stressing the way the media have unleashed the imagination, Appadurai argues that in the transnational world the habitus has been replaced by self-conscious choice, justification, and representation, often intended for far-flung diasporic communities and capitalist frontiers (1996, p. 44). But the role agency, strategy, and innovation play in Appadurai's account of local societies negotiating modernity would strike Bourdieu as the operations of the habitus under new circumstances.

Pragmatics: Linguistic

Pragmatics is the study of the relationship between the structure of a semiotic system (notably language) and its usage in context, and, along with semantics (see *Semantics*), forms part of the general theory of meaning. Within the theory meaning, pragmatics is concerned especially with implicit meaning, with inference and the unsaid, and with the way in which language structure trades on this background of the presumed and the inferred. Pragmatics has come to play an important part in general linguistic theory, partly because it has substantial intrinsic subject matter, partly because it promises explanations for other linguistic phenomena, and partly as a response to over-idealization in contemporary grammatical theory (see *Generative Grammar*). It has also become an area of interdisciplinary concern, with fundamental contributions from philosophy of language, linguistics, psychology, and the sociology of language.

1. History

The use of the term ‘pragmatics’ in modern semiotics derives from the philosophical work of C. S. Peirce and R. Carnap, reflected in Morris’s (1938) three divisions of semiotics, the study of sign systems: *syntax*, which investigates the relation of signs to signs; *semantics*, which investigates the relation of signs to the things referred to; and *pragmatics*, which studies the relation of signs to their users. Since then, the usage of the term has bifurcated into a broad use, which subsumes sociolinguistics (see *Sociolinguistics*) and discourse analysis (see *Conversation Analysis: Sociological, and Discourse, Anthropology of*), and a narrower use (associated especially with philosophy of

language and approaches to the study of meaning which derive from it) in which pragmatics deals with those aspects of meaning that are systematically context-dependent.

2. Scope

Contemporary linguistic pragmatics is focused on a number of special relations between linguistic meaning and context. On the narrower scope of pragmatics, concerned with context-dependent meaning, the following topics have come to be central: deixis, presupposition, speech acts, implicature, and conversational inference, which are discussed briefly in turn.

2.1 Deixis

Deixis, from the Greek word for ‘pointing or demonstrating’ (the equivalent philosophical term ‘indexicality’ is from the corresponding Latin) is the phenomenon whereby some linguistic expressions are systematically dependent on the context for their interpretation. Take, for example, the utterance ‘Put this book over there’—which book is being referred to, and in which place it is to be put, are determined by features of the context outside the utterance itself, here typically gestures: *this* and *there* act as place holders for contextually-specified parameters. A good test for whether an expression is deictic or not is whether an utterance in which it plays a part would be equally true (or false) regardless of speaker, addressee, time, or place of utterance: thus ‘The square root of nine is three’ has no obvious deictics, whereas ‘We are coming soon’ has only deictic expressions.

At first sight, deixis seems to be a simple phenomenon, a leftover from the direct ‘here and now’ relevance of animal communication systems. But the intersection of this context-dependence with the property of abstract symbolic representation in language (Hockett’s displacement feature of language design) leads to deep complexities, and the phenomena turn out to be very puzzling, both philosophically and psychologically, for deixis introduces context dependency into almost every utterance (in English, for example, nearly all sentences are tensed, and tense is deictic, as in ‘It is Tuesday’ where *is* locates the reference time as today). One of the central philosophical puzzles is that deixis makes possible self-reference in utterances, thus introducing, for instance, many paradoxes of the ‘Cretan liar’ type: ‘This sentence is false’ is true if and only if it is false. One of the central psychological puzzles is that deixis makes clear that there is a mismatch between what a sentence means and the thought corresponding to its utterance. For example, what exactly is the thought corresponding to the utterance ‘Today is Tuesday’? It is obviously not ‘Tuesday is Tuesday,’ nor (if the day of speaking is

31st December 2035) ‘31st December 2035 is a Tuesday’ since the speaker may have no idea of the date. Closer might be ‘The diurnal span in which I am now speaking falls on the calendrical second day of the week’—but now we have paraphrased one deictic term (*today*) in terms of others (*I, now*). And the puzzle goes on.

Languages incorporate deictic context-dependency in many different places in their grammars and lexica, but it is conventional to consider four main notional parameters.

First, there is *person deixis*, reflected in the traditional grammatical categories of first, second, and third person, where first and second person refer to members of the speech event (current speaker and current addressee, respectively) in contrast to the third person. These categories are reflected in pronoun systems, verbal agreement and elsewhere. Many languages make unfamiliar demands here: for example, in Southeast Asian languages such as Korean or Japanese have different word-forms for referring to entities such as kinsfolk, houses, or food, according to the relative status of speaker and addressee. Or in some Australian languages (such as Dalabon) pronouns make reference to whether the speaker and the referent, or the referents in the case of plural third person pronouns, are one vs. two generations apart genealogically. This encoding of the social relation between speaker, addressee, and third-party referents is often recognized as a separate deictic dimension, called *social deixis*.

A second important parameter is time. *Temporal deixis* is manifested directly in English in words such as *now*, and, as mentioned above, in tense. True tenses locate time relative to the moment of speaking, so that a past tense is used for events (or situations) preceding it, present for events including it, and future for events succeeding it. Not all languages have tenses (e.g., Malay or Chinese), and not all the grammatical categories that grammarians call tenses are truly deictic. Some languages (e.g., Bantu or Papuan languages) have up to six deictic tenses, however (specifying, for instance, that something happened the day before yesterday). There are many other manifestations of temporal deixis, from calendrical specifications like *yesterday* to more covert items like *ago* (as in *nine years ago*) or *Good night* which presumes that it is night and that the speaker is leaving.

A third parameter is *spatial deixis*, reflected in demonstratives such as *this* and *that*, or adverbs such as *here* and *there*, where spatial locations are indicated by reference to the place of speaking. Demonstrative systems vary greatly across languages, with some making distance from speaker primary, others making a contrast between ‘this near speaker’ vs. ‘that near addressee,’ and others invoking attentional issues, so that one has a contrast between, for instance, ‘this we are talking about’ vs. ‘that to which I want to draw your attention.’ Huge arrays of demonstratives are

found in some languages (e.g., Inuit) where these sorts of parameters intersect with, for example, the shape of things referred to. Languages often have pairs of verbs, such as *come* vs. *go*, *bring* vs. *take*, which are often interpreted according to whether the motion is toward or away from the place of speaking. Many other expressions in language are covertly place-deictic. For example, ‘the cat is behind the tree’ implies that the tree is between the speaker and the cat, and ‘Let’s go to the local pub’ implies that the pub is near to the place of speaking.

Lastly, *discourse deixis* involves the possibility of referring from one utterance backward or forward to others, as in ‘That was a good speech’ vs. ‘It made a sound like this: goooo.’ Discourse deixis grades into anaphora, the use of expressions such as pronouns to refer to entities introduced earlier, usually by fuller expressions. It is also closely related to *definiteness*, as in *the man* vs. *a man*, since all these phenomena rely on mental models of entities introduced into the discourse.

Considerable effort has gone into understanding how deixis works, and how it can be brought within a formal theory of meaning. But for the most part theoretical models underestimate the complexity and pervasiveness of deictic phenomena, and the richness of the contextual systems that support them. For example, good studies of actual deictic usage are rare, and the study of gesture is in its infancy (McNeill 2000).

2.2 Presupposition

Presupposition is a second major topic in pragmatics, and concerns the way in which propositions already presumed in a discourse context are usually not stated or questioned, but encoded in a more ‘background’ way. For example, ‘Has he stopped bothering you?’ presupposes the proposition that you and I know that he has been bothering you, and asks whether this has stopped. The classical test for presupposition is survival under negation: ‘He hasn’t stopped bothering me’ and ‘He has stopped bothering me’ both presuppose that he was bothering me. Languages have complex systems for foregrounding and backgrounding information in this way. Thus mental attitude verbs, such as *know* or *regret*, or change of state verbs such as *start* and *stop*, presuppose their complements, definite descriptions (such as ‘the King of Buganda’) presuppose the existence of the entities referred to, iteratives like *again* (as in ‘John did it again’) presuppose earlier occurrences, and so on. The phenomena and corresponding explanations are complex, and are dealt with in a separate article (see *Linguistic Presupposition*), but the relevance to pragmatics is that presupposition implies clearly that natural languages are built to trade on, and signal, the dependency of utterances on propositions already taken for granted.

The pragmatic aspects of the phenomena are often underplayed in semantic accounts of the phenomena. For example, consider the sentence ‘Sue cried before she finished her thesis’. This would normally presume that she finished her thesis, this being a presupposition from the *before*-clause. But the minimally different sentence ‘Sue died before she finished her thesis’ seems to make no such presumption, because of course we happen to know that the dead do not complete theses. This *defeasibility*, or cancelation of an inference in the context of contrary assumptions, is a hallmark of pragmatic inference.

2.3 Speech Acts

A third major topic in pragmatics concerns the general force or point of utterances, and is usually discussed under the rubric of speech acts. We can take a simple underlying proposition such as ‘The wine is (put) on the table,’ and we can embody it in utterances with different *illocutionary force* (in the terminology of the philosopher J. L. Austin). We can assert or vouch for the truth of the proposition, as in the assertion ‘The wine is on the table.’ We can ask whether it is the case, as in ‘Is the wine on the table?’ We can demand that the proposition be made true, as in ‘Put the wine on the table,’ and we can forbid anyone making it true, as in ‘Do not put the wine on the table.’ Languages typically indicate a handful of such illocutionary forces in the grammar of sentence types, as here in the English unmarked statement order, the marked inversion of yes–no questions, or the covert subjects of imperatives. Beyond statements, questions, and imperatives, most languages have in addition minor sentence types, e.g., exclamatives, as in ‘What a wonderful dress,’ or hortatives like ‘Let’s start,’ or imprecatives like ‘Damn you!’ and other more exotic types (e.g., special forms for blessings, curses, warnings). Thus the grammars of languages seem to presume a set of fundamental uses for language, and there has been some philosophical and theoretical interest in these categories. However, actual usage is much more complicated than this discussion would suggest. For example, one can use the statements ‘I suppose the wine is on the table’ to question whether it is, or ‘I would like the wine on the table’ to request that it be put there, or ‘The wine should not be placed on the table’ to forbid it. Some of these uses can be explained as secondary or derivative uses of one sentence type to perform a speech act prototypically associated with another. For example, *I would like ...* could be said to indirectly hint, rather than directly request, and can thus be described as an indirect speech act. What this discussion makes clear is that it is important to keep apart the grammar of sentence types from the illocutionary forces or speech acts they can be used to perform.

There has been much work on grammatical sentence types (and what the grammarians call *mood*), speech

acts, and indirect speech acts, and their relationship to one another. This is the subject of a separate article, but here one major point is that these phenomena indicate directly that natural languages are designed not just as abstract systems, but as tools for human communication, a point of view underlined in functional approaches to language structure (see *Grammar: Functional Approaches*). Speech acts can also be seen to be fundamentally context dependent. First, speech acts are dependent on, and contribute to, the context in which speech is taking place. One way of seeing this is to construe speech acts as operations on the context (conceived of as sets of propositions taken for granted): a statement adds a proposition to the context, a question requests whether such a proposition is to be added, a denial removes one, and so on. Note too how a permission presumes that a prohibition would otherwise be in force. Second, the interpretation of a sentence as performing a specific speech act is obviously context dependent. Consider the sentence ‘What are you doing tonight?’ in, say, the following discourse context where it has a straightforward informational query status:

A: ‘I can’t wait for this evening.’

B: ‘What are you doing tonight?’

Now compare its role in a different context:

A: ‘What are you doing tonight?’

B: ‘Oh I don’t know, not much.’

A: ‘Would you like to come to the movies?’

Here the utterance checks out a condition on an invitation, and in so doing can be seen as precluding such an invitation (a ‘pre-invitation’), which is then (given an appropriate response) expected to follow. Sequences of utterances thus set up specific expectancies, crucial in interpretation—a matter dealt with more fully below.

2.4 Conversational Implicature

So far we have considered ways in which the structures of languages build in presumptions of use, as in pronouns, demonstratives, verbs of presupposition, or sentence types as indicators of speech acts. In these cases, the semantics of the expressions trigger the pragmatic inferences, which are themselves subject to pragmatic resolution. But another very important aspect of pragmatics is concerned with inferences that are invited—or *implicated*—rather than required or triggered by the semantics: often, synonymous expressions will have different implicatures. The philosopher H. P. Grice noted that there are a number of different ways in which such invited meanings can be invoked, all of which point to a set of background assumptions about how language should be used, which he formulated as a set of maxims of conversation. He sketched four such maxims, with attendant sub-maxims: the maxim of Quality (‘Say what you believe to be true’); the maxim of Relevance (‘Make what you

say relevant and timely'); the maxim of Quantity ('Don't say more or less than is required'); and the maxim of Manner ('Be brief and clear'). Then he showed that if a speaker violates them overtly, the speaker is generally credited with some implicit, indirect meaning—for example, if it is raining, and the speaker says 'Thank God I didn't bother to bring my umbrella,' thereby clearly violating the maxim of Quality, an ironic interpretation is generated. (Any such interpretations which are suggested by reference to the maxims, Grice called *conversational implicatures* to distinguish them from logical implications). If on the other hand the speaker just seems to be following the maxims, then additional inferences are generated. For example, if you say 'There are five gallons in the tank,' I'll assume that there are no more than five gallons in the tank, because otherwise by the maxim of Quantity ('say as much as is required') you should have said so (note that if there are more than five gallons, then of course what you have said is certainly true, but is also misleading). Grice went on to note a number of interesting applications of his theory of implicature. For example philosophers had long disagreed about just how close the ordinary language words 'if,' 'or,' and 'and' are to their logical counterparts. Grice argued that the divergence between ordinary language and logic was due largely to the implicatures of language usage. For example, if I say 'Glenn was an astronaut or he was a senator,' I suggest that he was not both, but this does not mean that natural languages *or* is not equivalent to logical (inclusive) disjunction. That is because if I knew he was both, I should (following the maxim of Quantity) have said so; since I didn't, I imply that I believe he was one or the other, but not both.

Although modern versions of implicature theory use somewhat different 'maxims,' they follow Grice's idea that the presumption of background principles of language use can generate many detailed inferences that are suggested but not entailed by what has been said. There are two main branches of contemporary theory. One takes the line (following the trend in the cognitive sciences) that these background principles are innate cognitive mechanisms of information processing. The other branch follows Grice more closely, and argues that these principles follow from rational design characteristics of communication. The former line is more generally concerned with the nature of inference in communication, while the second 'neo-Gricean' line of argumentation has been developed more narrowly to give explanations of linguistic facts, and is thus of more direct relevance to linguistic theory, and so is the focus of the following remarks.

One central attraction of the Gricean approach is that it promises to simplify the kinds of meanings we attribute to expressions. For example, as mentioned above, English *or* seems normally to have an exclusive use (as in 'The book is either in the bedroom or the sitting room'), but obviously this is not always so

(consider 'I lent you my pen or my pencil, or both'). Grice's tactic is to avoid positing an ambiguity (between inclusive and exclusive *or*), by assuming that *or* has a wide, general meaning (e.g., the inclusive meaning), which is then specialized in context where appropriate by an extra pragmatic inference—namely the Quantity implicature 'not both.' By generalizing Grice's observations we can note, first, that any pair of expressions (such as *and*, *or*), where the use of one expression would entail the other (as in *p and q* implying *p or q*) but not vice versa, form a scale of informativeness—the use of *and* is more informative than *or*, because *p or q* allows not only for the circumstance that *p*, or that *q*, but also for the circumstance that *p and q*. In short, *p and q* rules out more alternative states of affairs. Then we can also note that, for any such pair of expressions, asserting the weaker or less informative member will implicate the inapplicability of the stronger expression (for if you had meant that, you should have said it). Hence asserting *p or q* implicates that one is not in a position to assert *p and q*. Now consider many other such ordered pairs, where each is of the form <strong, weak>:

<*and*, *or*>, <*all*, *some*>, <*certain*, *possible*>, <*four*, *three*>, <*must*, *may*>, <*hot*, *warm*>

For each of these, asserting the weaker, less informative expression will implicate that the stronger expression does not apply, as in 'Some of the students are punctual,' which, other things being equal, will implicate that not all of the students are punctual. Modern treatments of these so-called *scalar implicatures* are quite developed (Atlas 2000, Gazdar 1979, Horn 1989, Levinson 2000).

Many further systematic observations can be made. Consider the contrast between 'John could solve the problem' vs. 'John had the ability to solve the problem'—the first suggests that he did solve it, while the second suggests he didn't. The opposition is one between a direct lexical coding with the verb *can* and a more periphrastic expression *have the ability to*. More generally, the opposition is between any simple, direct encoding, which invites a rich interpretation to the stereotypical scenario, and a less direct, unusual, more prolix or *marked* expression, which suggests a complementary interpretation. Consider, for example, 'He went downtown and bought a coat,' which suggests a single complex action (a coat-buying expedition), vs. 'He went downtown and in addition he bought a coat,' which suggests two independent actions. These opposing tendencies of interpretation can be related to *iconicity* in language (see *Linguistics: Iconicity*), but what gives them reliability is mutual expectations between speaker and addressee—that is, that they follow from general principles or maxims.

Contemporary neoGricean theory recognizes two or three maxims: for example, a maxim of Quantity (or

Q-principle, giving us the scalar implicatures mentioned above); a maxim that maximizes information from direct, unmarked expressions (an Informativeness or I-principle); and a maxim of Manner or markedness (or M-principle) that curtails those informative interpretations (Levinson 2000). Three such principles suffice to capture many detailed inferences which interact closely with linguistic structure, and they can be thought of as stable heuristics which serve to amplify message content with default inferences.

In this way, Grice's ideas can be given both precision and generality. The description of many crucial aspects of meaning (for example, those associated with the natural language connectives, quantifiers, and modals) can be simplified and improved by taking into account these inferences which are closely associated with expressions by general principle, but not actually encoded in them. Such inferences have a default or presumptive character, and may be confused with the semantics and syntax of expressions.

These observations have considerable importance for linguistic theory. If they are pushed home, they imply a rather different view about the relation of language competence to nonlinguistic abilities than is usually assumed. For example, it turns out that pragmatics cannot interface with semantics in the way originally imagined: as a module or system of principles that, given the proposition coded in an utterance, would calculate additional noncoded inferences. The problem is that pragmatic inferences clearly play a central role in deriving the proposition in the first place. For example, in 'It is better to drive home and drink than to drink and drive home' the proposition expressed depends on the antecedent construal of *and* as temporarily asymmetrical (i.e., as 'and then'), which is a matter of implicature. Thus what is coded semantically and what is inferred pragmatically are often necessarily integrated in the extraction of propositional content. The implication is that there is a single level of representation to which quite different kinds of principles contribute—semantics and logical inference on the one hand, and pragmatics and presumptive reasoning on the other.

Another possible radical implication is that many correlations between form and meaning that have been attributed to syntax are more properly ascribed to pragmatics. For example, it is normally supposed that in a sentence like 'The chairman voted for him,' the chairman and the man voted for must be distinct by a rule of grammar. But in 'No-one else voted for the incumbent chairman—only the chairman voted for him' it is possible to understand the chairman as voting for himself. Arguably, this is because normally one would express such coreference by the reflexive *himself*, and the use of the nonreflexive pronoun thereby implicates a non-coreferential reading, unless there are other reasons to use it. Here there are such other reasons—'Only the chairman voted for himself'

would imply that everybody else voted for people other than themselves, and that may not be what is intended. Many such reductions of alleged syntactic patterns to general patterns in pragmatics may be possible (see Huang 1994, Levinson 2000).

2.5 Conversational Structure

Conversational inferences seem to be of two kinds: first the implicature type, which relies on general background presumptions or heuristics; and second, inferences that are tied to more specific details of conversational interchange. Conversation—or the normal, informal exchange of speech, where there is rapid alternation of speakers—can be contrasted with more formal, specialized types of speech exchange (as in chaired meetings, interviews, or religious services). Needless to say, conversation is the primary form of human verbal interaction, the context in which all primary language-learning is accomplished and many details of linguistic structure are tied to it intimately. For example, a primary property of conversation is rapid turn-taking, and with this turn-taking the deictic centering also alternates: what was 'I' is now referred to as 'you,' what was 'here' becomes 'there,' and so forth, an alternation that children initially find difficult.

The characteristics of turn-taking (and indeed conversation in general) have been studied primarily by sociologists (under the rubric of conversation analysis). In the model advanced by Sacks and Schegloff, conversational turn-taking is organized as a sharing system whereby the current speaker has rights only to the end of a sentential construction or turn-taking unit, at which point transition to another speaker is governed by an ordered set of rules—if the speaker has selected a next speaker, that party should speak next, if not, other speakers may start speaking, failing which the original speaker may continue. These rules explain many details of conversational patterning, such as just where overlaps occur (e.g., as competing starts). They also explain the differential significance of silence—if no-one decides to speak after a unit which selects no following speaker, silence is likely to be interpreted simply as a lapse in conversation, but after a next speaker is selected it is heard as a significant withholding of speech (Levinson 1983, p. 300, after Atkinson and Drew):

A: *Is there something bothering you or not?*

B: (1.0 second silence)

A: *Yes or no?*

B: (1.5 seconds silence)

A: *Eh?*

B: *No.*

Differential meanings attributed to silence eloquently make the point that the semiotic significance of utterances is very much conditioned by the locus in which they occur. Consider, for example, that after a

request, an acceptance or refusal is due, but these options are not equal: an acceptance is usually delivered immediately in simple form, whereas a refusal is typically delayed, indirect, and accompanied by excuses. Recollect too, that as noted above, many speech acts are preceded by an utterance that checks out whether the conditions for that action are met—thus one can hint at an upcoming request for an appointment by asking whether the addressee would be available at a certain time. Then we can readily understand the following, where a telephone caller C already interprets a two-second pause as a negative answer (from Levinson 1983, p. 320):

C: *So I was wondering would you be in your office on Monday*

(micro-second pause)

by any chance?

(2.0 second silence)

C: *Probably not*

Here the interpretation relies (a) on the asymmetry between what the conversation analysts call *preferred* and *dispreferred* responses to specific speech acts, and (b) on the understanding that the question is not idle, but functions as a prelude to a request.

The study of conversation thus shows that the attribution of meaning to utterances depends crucially on sequential location. Arguably, this is exactly what Grice had in mind by his maxim of Relevance, where the implicatures of an utterance would also derive from the expected goals of the speaker at a particular point in discourse. Goal-driven accounts of conversational understandings have been explored most thoroughly in artificial intelligence circles, where the construction of a machine that could enter into functional dialogues has been a long-term objective.

3. Conclusions

In addition to the topics reviewed here, there are pragmatic perspectives on many other phenomena, for example register, style, jargon, and other specializations of language, the contrastive use of languages by multilingual speakers (see *Code Switching: Linguistic*), and social constraints on the use of language (see, for example, *Politeness and Language*). From research on all these topics, an overall picture is emerging of the systematic relations between semiotic systems and their contexts of use. First, any sign system or language makes systematic provision for contextual features, as in deixis or presupposition. Second, what is actually coded in signs or linguistic expressions is only a small part of the meaning attributed in context, the remainder being generated by presumptions of use. Third, the coded meaning or semantics is usually specified much less fully than conventional wisdom implies. Consider a road sign depicting falling rocks—the depicted content is specific yet hardly conveys the full message: we must add the illocutionary force ('Beware!'), and the deictic inference ('in this vicinity'

or 'the next kilometer'). Such a sign contrasts with other warning signs—for instance, a simple exclamation mark—which indicates general danger but implies that the danger is other than rocks (since otherwise the rock sign would have been used). All such signs contrast with no sign, which implies no special foreseeable danger. In similar but much more complicated ways, pragmatic principles remain the essential basis for linguistic communication. Because lexical limitations and the bounds of learning and memory constrain natural language semantics deeply. In addition, the relatively slow articulation of speech compared with understanding processes puts a clear premium on pragmatic inference. A pragmatic perspective offers fundamental insights into both the structure and use of language.

S. C. Levinson

Pragmatism: Philosophical Aspects

Pragmatism is a US philosophical movement which began in the late nineteenth century and exerted significant influence until around the time of John Dewey's death in 1952. Pragmatism then fell from favor but began to enjoy a revival at the end of the twentieth century. The 'classical' pragmatists are C. S. Peirce, William James, and John Dewey. Their philosophies differed a good deal but all defended broadly empiricist views of knowledge which reject many traditional empiricist psychological views, and emphasize the role of thought in guiding action. Richard Rorty is the most influential contemporary figure who aligns himself with pragmatism.

1. 'Classical' Pragmatism

The most important pragmatist philosophers are C. S. Peirce, William James, and John Dewey. These three are often referred to as the 'classical' pragmatists. All three were born and worked in the USA. All were primarily philosophers but had strong interests in other disciplines. The views of the 'classical pragmatists' do have important common themes, but are also dissimilar in many ways.

Pragmatism is an empiricist view of thought and knowledge which rejects much of the psychological picture usually associated with empiricism. Pragmatists think traditional empiricism has had too passive a view of the mind, and pragmatists place great emphasis on the role played by thought in guiding action and solving practical problems. Pragmatism also rejects attempts to understand human knowledge by tracing its connections to some special set of

'foundational' beliefs. For pragmatism, both specific beliefs and methods of inquiry in general should be judged primarily by their consequences, by their usefulness in achieving human goals.

The nature of truth has been a central topic for pragmatists, and a source of much trouble for them. Pragmatists in general reject 'correspondence' theories of truth. Correspondence theories claim that a true belief or statement is one which represents the world as it really is. After rejecting correspondence, pragmatists have had a difficult time devising an alternative view of truth.

Pragmatism has an often complicated relationship with science, but it is fair to say that both Peirce and Dewey regarded science as a distinctive and superior way of acquiring knowledge. For both, the scientist is in some respects the model or ideal inquirer. Although pragmatists stress the role of knowledge in solving practical problems, it is definitely an error to see pragmatism as claiming that the direction of research in science, or choices between rival theories, should be guided solely by practical or commercial demands.

Pragmatists tend to argue that there is an important place in the universe for human choice and initiative; they oppose philosophical systems which regard the world as in some sense 'finished,' 'complete,' or impervious to the effects of human choice. This is a rather vague thing to oppose, but it is common for pragmatists to be constantly on the lookout for any hint of a denial of the significance of human choice. This concern pervades much pragmatist writing. Pragmatists also tend to hold generally 'humanistic' perspectives on matters involving morals and values, opposing both nihilistic views that reject all moral thinking as illusory, and views that locate moral and other evaluative facts outside the everyday world of human well-being.

2. Charles Sanders Peirce (1839–1914)

Peirce's career began well but ended very badly, without his ever having held a long-term academic job. Peirce never set out his ideas in an organized and systematic way. It is difficult and probably fruitless to try to form these ideas into a single coherent system. Peirce's most famous works are about the relations between doubt, inquiry, belief, and action. He also wrote a good deal about logic, the theory of signs (which he called 'semiology'), some speculative cosmological ideas, probability, measurement, and other topics in the philosophy of science.

Peirce argued that inquiry always begins with 'real and living doubt' which he distinguished from the feigned doubt of Descartes. Doubt prompts inquiry, which aims at belief. Peirce claimed that the essence of belief is the establishment of a habit of action. Alexander Bain had made this suggestion in the mid-

nineteenth century, within the framework of a more orthodox associationist psychology. Peirce and later pragmatists made this link between belief and action central to their theories of mind and knowledge.

Peirce believed that science is the most effective method for relieving doubt and acquiring useful habits of action. His defense of science stressed the social properties of scientific inquiry, especially the tendency scientific testing has to produce a 'convergence' of belief among people who start from different positions.

In his most influential paper, 'How to make our ideas clear,' Peirce argued for a principle which later became famous as 'the pragmatic maxim.' This principle is often seen as the single idea most central to pragmatism. Peirce said that to work out what the meaning of a 'conception' is, we should work out 'what effects, that might conceivably have practical bearings, we conceive the object of our conception to have. Then, our conception of these effects is the whole of our conception of the object.' This famous principle is quite obscure, and was later paraphrased by James, Peirce, and others in a number of conflicting ways. One reasonable view is to see the famous 'maxim' as expressing a fairly familiar empiricist view, that our concept of something is just our concept of its possible effects on our experience. Then the novelty in 'How to make our ideas clear' lies in Peirce's attempt to derive this empiricist principle from an unusual starting point—a theory of the role of belief in action.

In 'How to make our ideas clear' Peirce also gave a famous definition of truth. Peirce said that what we mean by the truth is the opinion which is 'ultimately fated to be agreed to by all who investigate,' or in a more modern formulation, the opinion that will be held at the limit of scientific inquiry. This is usually taken to be a novel *definition* of truth, in conflict with more familiar views such as the correspondence theory. In fact it is difficult to work out how Peirce intended his theory of truth to be taken. In some places it looks more like an expression of faith in the power of science to *find* the truth than an unorthodox philosophical theory of what it is for an idea to be true.

3. William James (1842–1910)

James made pragmatism famous, especially in his 1907 book *Pragmatism* (repr. 1979), which is the most widely read of all pragmatist writings.

James had a brilliant and influential career based at Harvard, in both philosophy and psychology. He wrote many important works before he began calling himself a 'pragmatist' and aligning his views with Peirce, in 1898. In these earlier works James argued that we have the right actively to choose sides on momentous, unresolved philosophical issues that will affect how we live our lives. Choices made on these issues will inevitably be strongly affected by our individual temperaments; we should not expect all individuals to find the same philosophies appealing.

Problems James applied this doctrine to include the existence of God, the freedom of the will, and the reality of moral facts. In this earlier period James also published a landmark work in psychology, his two-volume *Principles of Psychology* (1890, repr. 1950).

After 1898 James began to embed his characteristic themes within an overtly 'pragmatist' framework. Unlike Peirce, James took pragmatism to be continuous with the mainstream empiricist philosophies of English thinkers such as David Hume and J. S. Mill. James publicized pragmatism with great energy, and transformed it in ways that induced some distress in Peirce.

James presented pragmatism as a way to avoid the errors of the two key rival philosophies of his day—overly scientific materialism and empiricism on the one hand, and sentimental, over-optimistic religious idealism on the other. He saw pragmatism as a way of distilling the genuine human significance from obscure philosophical theories and debates. James also argued that there is an inevitable and appropriate role for values in choices about theoretical issues, defended the role of human choice as a factor in determining the ultimate nature and significance of the universe, and defended the legitimacy of individual religious experience.

James made pragmatism more 'practical' than Peirce did, linking it to problems of everyday life. James was a less scientific thinker than Peirce, and also more individualistic than Peirce or Dewey. James talked of assessing ideas in terms of their 'cash value,' an unfortunate phrase which led many to interpret pragmatism as vulgar and anti-intellectual. James also invited a stream of criticism through his tendency to discuss the nature of truth in a vague and simplistic way. He said at various times that true ideas are just those that can be verified, or those that are useful. Some of the criticisms of James rested on misinterpretations, but there is no question that he wrote in an imprecise way and was not the most consistent of philosophers. Despite this, James's writings have endured. His discussions of the role of individual temperament in philosophical choices never seem dated, for example. Another reason for James's continuing appeal is the way his attractive personality, imagination, and boundless energy seem to radiate from the pages of his work.

4. John Dewey (1859–1952)

Dewey's work is the high point of the pragmatist tradition to date. In the course of a remarkably long and productive career, Dewey published in virtually all areas of philosophy and in psychology, education, and politics. He wrote both popular, accessible works and dense, uncompromising ones. Dewey spent his most important years at the University of Chicago, where he worked in philosophy, education, and psychology, and after that at Columbia, where he

focused more on philosophy and was also active in politics.

Dewey's work went through several phases. Early in his career he accepted an idealist philosophy of the type influenced by Hegel, and also had strong Christian interests. Around the turn of the century he turned toward a more scientific approach to philosophy, influenced by Darwin and by James's *Principles of Psychology*. Around this time Dewey also dropped his commitment to Christianity, although his attitude to religious ideas and to the psychological and social role of religion remained complex.

The scientifically oriented philosophy Dewey developed was initially reminiscent of James's pragmatism. Later Dewey began to recast some pragmatist themes within a more 'naturalistic' framework—a framework which sets out from a biological description of living organisms and their relations to their environments. Dewey argued that intelligence is a means for humans to transform their environments, in order to deal with the problems posed by uncertainty and change in natural events.

In *Experience and Nature*, perhaps his greatest work, Dewey both defended this naturalistic view of mind and knowledge, and criticized the philosophical tradition for its postulation of false divides or 'gulfs' between mind and matter, thought and object, and so on. Dewey thought that the philosophical tradition is plagued by 'dualisms' which lead to pseudoproblems. The source of these dualisms is a 'split in being' established by the ancient Greeks, a split between the 'perfect, permanent, self-possessed' and the 'defective, changing, relational.' Dewey sought to replace these dualisms with a view based on various kinds of 'continuity,' between mind and nature, between organism and environment, and between cognition and simpler biological capacities. For Dewey, these natural continuities also provide the material needed to resolve other traditional oppositions such as that between the theoretical and practical, and between fact and value. Much of Dewey's later work is an unusual mixture of scrupulously careful system building based on assertions of 'continuity,' and sweeping historical surveys, tracing the histories of key philosophical errors back and forward through thousands of years.

Dewey also defended a social theory of mind, claiming that because thought is symbolic and symbolism is social, thought only exists within a language-using community. He argued that the primary role of science is to help human societies deal with problems and control their environments. But, like Peirce, Dewey thought that it was unscientific for scientists to direct their work according to *specific* practical problems. Rather, science is the study of a special class of properties of natural processes—relations and connections between things, which Dewey called 'instrumental' properties. Science is most successful in expanding our capacities for problem solving when it is directed on the study of the instrumental properties

of things in an open-ended way unconstrained by immediate practical applications.

Dewey thought that the proper role of knowledge is to enable humans to transform their situations in beneficial ways. This led Dewey to reject what he called the 'spectator theory of knowledge,' the view that the ideal knower is someone who registers what is going on but does not intervene. This also led Dewey into some of the same arguments James had with defenders of correspondence theories of truth. Dewey thought that theories of truth as correspondence were aimed at inventing magical relations between thought and the world in order to overcome what he saw as a nonexistent problem—the problem of how the mind and the external world could have any contact with each other. He also thought correspondence theories belong with a spectator theory of the role of knowledge.

Dewey wrote often of the role played by knowledge in 'transforming' or 'reconstructing' the world. This 'transformation' should not be understood as implying an idealist metaphysical view. Dewey thought that knowledge is a factor in changing things in the world because knowledge has a role in guiding *action*, which transforms things by means of ordinary physical relationships.

Dewey was a significant figure in US political and social thought. Here he defended a version of liberalism, and he wrote extensively about the proper structure of a democratic society. At various times he was attacked by both the right and the left. He hoped for a more 'democratic' economic order, but always kept Marxism and communism at arm's length. Dewey's best known political activity was his chairing of an international inquiry into Stalin's trial of Trotsky. The inquiry entitled its report 'Not guilty.'

At Chicago Dewey worked closely with George Herbert Mead, who became one of the founders of social psychology in the USA. Mead is sometimes grouped as a major pragmatist thinker (see, for example, Scheffler 1986, Joas 1993). Mead argued that human individuality is a product of social embedding; that cognition in general and specific mental developments such as a sense of self emerge as products of various kinds of symbolic behavior within a community. Dewey also wrote about art and took a lifelong interest in education. When he was at Chicago he established an experimental school. Dewey favored problem solving as an approach to all types of learning. His ideas remained influential in education for many years while his name had almost dropped out of mainstream English-speaking philosophy.

5. After Dewey

Dewey's ideas, and pragmatism in general, subsided from philosophical discussion for several decades after Dewey's death in 1952. A primary reason for this was

the growing focus on formal logic and the philosophy of language in US philosophy after World War II, prompted especially by the immigration of European philosophers and logicians who defended a rigorous 'analytic' style of philosophy. After Peirce, the pragmatists had not taken an interest in formal logic. Dewey also had idiosyncratic and rather opaque ideas on the philosophy of language, which rapidly came to seem dated.

More recently, interest in pragmatism has revived. In part, this has been due to the influence of Richard Rorty, who has both revived some of Dewey's ideas and become a significant pragmatist thinker in his own right. But aside from Rorty's explicit advocacy, quite a number of the key figures in mid- to late twentieth-century English-speaking philosophy have some connection with pragmatism. W. V. O. Quine is sometimes seen as a pragmatist, because of his opposition to foundationalist projects in epistemology, and his view of rational thought as a matter of making adjustments to a 'web of belief.' For Quine, these adjustments to the web are made in whatever ways seem to work best in dealing with experience; no beliefs are in principle immune to revision. In the closing sentences of his immensely influential paper 'Two dogmas of empiricism' (1953), Quine refers to these adjustments made to beliefs in the face of evidence as 'pragmatic.' But Quine's theory focuses on the role of beliefs in prediction, and does not discuss the link between thought and action in the detail associated with classical pragmatism.

Hilary Putnam is another influential defender of some broadly pragmatist ideas. Putnam's early work defended a strongly 'realist' set of views about the relation between thought and the external world. But Putnam changed his mind, and defends a position he calls 'internal realism,' which rejects the correspondence theory of truth and which Putnam sees as continuous with the pragmatist tradition. Putnam has defended views about truth which resemble (one reading of) Peirce's view, for example. Donald Davidson, another giant figure in late twentieth-century philosophy, is occasionally classified as a pragmatist, largely because of his opposition to some standard doctrines about the representational properties of language and thought, and his opposition to some versions of the correspondence theory of truth. But Davidson's connection to classical pragmatism is tenuous.

Rorty's work has carried the influence of pragmatism outside of philosophy into neighboring humanistic disciplines. Rorty views himself as carrying on the tradition of Dewey, and to a lesser extent James. Rorty is an 'antiessentialist' about traditional philosophical concepts such as truth, knowledge and justice. Antiessentialism in this sense holds that the only theory there can be of truth (etc.) is a theory of how the term 'true' functions in ordinary discourse; it is an error to give a philosophical analysis of truth that

goes beyond this. The degree of continuity between Rorty's ideas and Dewey's is a matter of controversy. As outlined above, Dewey's mature work includes a mixture of sweeping historical stories aimed at dissolving philosophical problems, and careful system building of his own. Rorty endorses the historical dissolving but not the system building. However, it can be argued that Dewey's critical points and his attempts to 'get over' standard debates tend to depend on his positive philosophical theories. And James used pragmatism to breathe new life into metaphysical problems, not to deflate them. As Rorty's views on traditional philosophical questions are so focused on dissolving and deflating, it is in some ways more appropriate to associate Rorty with the later work of Ludwig Wittgenstein rather than with pragmatism.

In recent discussion, the term 'pragmatist' has come to be used in a very loose way, to signify endorsement of any one of a wide range of ideas that are taken to have a connection with Peirce, James, or Dewey. These ideas include holism about justification, opposition to correspondence theories of truth, opposition to representationalist theories of thought and language, opposition to traditional views about logic and rationality, and almost any kind of emphasis on the practical, action-guiding side of reasoning and belief. Contemporary writers who identify themselves with 'pragmatism' often have very little in common. These loose uses of the term have led to confusion. Perhaps any contemporary 'pragmatism' should hold, at a minimum, that the role of thought in guiding action is of central importance to the philosophy of mind and epistemology, and as a consequence of this there is a need to rework standard views about knowledge and inquiry. But any summary one might give runs into the problem that even 'classical' pragmatism was a diverse and shifting collection of ideas.

Pragmatist Social Thought, History of

Pragmatism is the name usually given to the classical philosophical movement in the USA. It emerged in the last decades of the nineteenth century and achieved a certain hegemony in the country's intellectual life during, and immediately after, the so-called Progressive Era (1896–1914). From the 1930s, and even more after 1945, it was largely displaced by other currents of thought in philosophy, the social sciences, and public political discourse. American pragmatism also attracted considerable attention in Europe, especially around 1910, though exposition and critical discussion of pragmatism displayed widespread misunderstandings and the tendency to depreciate it by reducing it to an expression of alleged American national characteristics.

1. Pragmatism Defined

The everyday sense of the term 'pragmatic' certainly contributed to these misunderstandings, connoting as it does a kind of 'muddling through' which is oriented to immediate requirements, disregards theoretical or moral principles, and treats the given features of the

situation simply as part of a calculation. The term pragmatism has the same Greek roots as praxis, practical, etc. The founder of pragmatism, Charles Sanders Peirce (1839–1914), coined the term as a result of his reflections on Kant's use of the terms 'pragmatic' and 'practical.' Peirce's lectures and writings around 1878 are now regarded as the original documents of pragmatism. These first became known only to narrow circles of intellectuals in Cambridge, Massachusetts, and did not achieve wider notice until some 20 years later, when William James (1842–1910) referred to them in some lectures, but above all through his lectures on 'Pragmatism' published in 1907. Peirce came to distance himself from James's pragmatism and to call his own philosophy 'pragmaticism.'

Along with Peirce and James, the inner core of pragmatism is usually taken to include John Dewey (1859–1952) and George Herbert Mead (1863–1931). The differences between all these thinkers were so evident, not least to the 'pragmatists' themselves, that their subsumption into a single school or movement has constantly been questioned. The most widely accepted view, however, has been that despite the differences there is enough of a core of shared views to justify speaking of 'pragmatism' as a distinct philosophical orientation.

What are the basic themes of pragmatism? Peirce's approach starts from his critique of Descartes' methodological principle of radical doubt and the resultant program of making the thinking ego's certainty of itself into the firm foundation of a new philosophy. The pragmatist questions the meaningfulness of Cartesian doubt, not in order to defend unquestionable authorities against the emancipatory claim of the thinking ego, but arguing for a more substantial doubt, that is, the grounding of cognition in real problem situations. In pragmatism, the guiding idea of the doubting ego is replaced by the idea of a cooperative search for truth in order to overcome real problems of action. Real doubt occurs in action, conceived as a cyclical succession of phases. Thus every perception of the world and every action in it are anchored in an unreflective belief in self-evident conditions and successful habits. But these habitual ways of acting constantly come up against the resistance of the world, which is seen to be the source of the destruction of unreflective expectations.

The resultant phase of real doubt leads to a reconstruction of the interrupted context. Perception must grasp new or different aspects of reality; action must attach itself to other elements of the world or reorganize its own structure. This reconstruction is a creative accomplishment by the actor. If he or she succeeds, via a change in perception, in acting differently and thus getting going again, then something new has come into the world: a new way of acting which can be institutionalized and itself become an unreflectively followed routine. Thus pragmatists see all human action in the opposition between un-

reflective habits of action and creative accomplishments. This also means that creativity is seen here as characterizing achievements in situations which demand a solution, rather than the unconstrained creation of something new without a constitutive background in unreflective habits.

From this basic model of pragmatism, in which action and cognition are combined in a particular way, we can derive the other central claims of pragmatism. In the metaphysics of pragmatism, reality is not deterministic: rather, it enables and demands creative action. In the epistemology of pragmatism, knowledge is not the reproduction of reality but an instrument for dealing with it successfully. The semantics of pragmatism locates the meaning of concepts in the practical consequences for action resulting from their use or their difference from other concepts. Thus in pragmatism's theory of truth, the truth of sentences can only be determined by way of a process of agreement on the success of action based on them, and not on, say, their correspondence with an uninterpreted reality. The misunderstanding of pragmatism as principally a movement aiming at the destruction of the ideal of true knowledge resulted primarily from the isolation of individual sentences, such as some of William James's statements about truth, from the whole complex of pragmatist thought.

2. Main Variants of Historical Pragmatism

The leading representatives of pragmatism contributed to different fields of inquiry. Peirce was primarily interested in developing a general theory of scientific knowledge and a broadly conceived theory of signs of semiotics. His multifaceted work, which does not deal with questions of social theory, includes important thoughts on the intersubjective use of signs and on the creative production of hypotheses ('abduction'). This theory of signs, particularly in its emphasis on the 'discourse' of scientists in an experimental community, has become very influential.

William James at first worked mainly in psychology, in which he saw the prospect of a way out of the dilemma between a religiously based belief in the free will of the moral agent and the scientific image of the world as a universe governed by causal processes. The solution, for James, lay in the functionality for the survival of the human organism in its environment which he saw in the human capacity to pay deliberate attention to perceptual impressions and to choose between alternative courses of action. A 'functionalist' psychology could proceed by understanding all mental achievements in terms of their function for the organism's active mastery of its environment.

James elaborated his antideterminist stance in an influential article on *The Will to Believe*, in which he defended the legitimacy of religious experience against scientific skepticism. This essay also became the point of departure for his wide-ranging study of the varieties

of religious experience, in which he founded the empirical study of religion not on religious institutions or theological doctrines, but on the phenomenology of religious experience. In his last years, he began to use the phenomenology of experience as a guideline for the elaboration of a pluralist, nondeterminist metaphysics.

John Dewey, whose thought at first developed rather independently of the first pragmatists, abandoned his earlier neo-Hegelian approach during the 1890s and linked up with the logical and psychological aspects of pragmatism as developed by Peirce and James. He constructed a philosophy which extended the core ideas of pragmatism into all the traditional domains of philosophy (metaphysics, logic, ethics, aesthetics), but also and in particular the fields of educational theory, social and political philosophy. He gave more explicit emphasis than the others to a radical version of democracy as the normative core of pragmatism. Taking part in a great number of political controversies, he became one of the most influential American intellectuals ever and *the* representative thinker of the United States.

George Herbert Mead, a friend of Dewey, did most to develop James's strategy of the translation of pragmatist themes into the program of a biologically based empirical social science. His decisive contribution to social theory consists of his theory of the specific features of human communication and hence the attempt to thematize the constitution of personality structures in the dynamics of interpersonal relationships. Mead attacked the assumption of a presocial substantial self and replaced it by a theory of the genesis of the self in which even the interaction of a person with himself or herself is conceptualized as the result of social structures. Mead also pursued this line of thought in the direction of problems of cognitive development, such as the constitution of permanent objects in experience and the constitution of structures of time. His ethical theory and antideterminist philosophy of history remain rather neglected.

Thus it can be said that pragmatism has never been a clearly delimited school of thought with a fixed research program; it shows, however, the characteristics of an intellectual movement or, at least, constellation with the common elements of anti-foundationalism, the fallible nature of truth, the social nature of the self, the importance of inquiry in all fields of human life, and (metaphysical) pluralism (see Bernstein 1992). During the first decades, pragmatism exerted a considerable influence on a variety of disciplines in the United States (functionalist psychology; institutionalist economics; educational reform; law; theology; political theory; the Chicago school of sociology). After the 1930s this influence clearly waned, reaching a nadir in the 1950s and 1960s. (An indicator of this development is probably the fact that the 1968 edition of this encyclopedia did not contain an entry on pragmatism.) One of the few currents

which kept the heritage of pragmatist social thought alive was the school of symbolic interactionism in sociology, which produced a rich amount of empirical work mostly on interpersonal relationships, processes of emergence and definition of deviant and sub-cultural behavior, social movements, and the division of labor in professional organizations. There are other main figures of American sociology at that time in whose work pragmatist orientations can easily be detected (C. Wright Mills, Philip Selznick).

3. Contemporary Pragmatist Thinking

Since the late 1970s a renaissance of pragmatist philosophy has been underway. Apart from thinkers like Richard Bernstein and John Smith, who had continuously pursued a pragmatist agenda, two thinkers have probably contributed most to this renaissance. One is Richard Rorty who had for a long time tried to articulate pragmatist motifs within the tradition of analytical philosophy before breaking (more or less) with it and proposing a variant of postmodern thinking he calls pragmatism. Though Rorty is a perceptive social critic, he has no social theory and actively repudiates the need for it. His philosophy has sparked a vast critical literature and reappropriation of the historical pragmatists; his main rival in these debates is Hilary Putnam in whose work one can find a thorough and significant restatement of pragmatist philosophy.

The other main originator of this renaissance is Jürgen Habermas. Together with Karl-Otto Apel, these two German thinkers gave a new twist to the winded history of the European reception of pragmatism. From the beginnings of the twentieth century on, very diverse schools of European thinking had used elements from American pragmatism for their own purposes (e.g., French Catholic Modernism; Italian proto-Fascism; German Philosophical Anthropology; and others). Other European thinkers came close to pragmatism in some aspects of their work (e.g., Max Scheler, Arnold Gehlen, Martin Heidegger, Ludwig Wittgenstein) without spelling out their relationship with it. Peirce's ideas about the 'discourse' of scientists has been of decisive importance for the 'discourse ethics' developed by Apel and Habermas. Mead's understanding of symbolically mediated interaction has been crucial for the 'Theory of Communicative Action' by Habermas; he declares Mead the main inspiration for 'the paradigm shift from purposive to communicative action' which he proposes in sociological theory.

Habermas' faithfulness to the pragmatist heritage has been disputed almost as much as Rorty's. There are obviously other possibilities for pragmatist social thought than his combination of a theory of communication with systems theory or than his restriction of the tasks of moral theory to the program of discourse ethics. One can claim (Joas 1996, 2000) that the

most fundamental contribution of pragmatist social thought lies not in its emphasis on communication, but in its specific understanding of the creativity of human action. This understanding distinguishes pragmatist social thought from approaches focusing on either rational action or normatively oriented action, or from a systems theory or structuralism which disconnect the dynamics of human action from the development of social wholes. On the basis of pragmatism understood as a theory of the 'situated creativity' of human action, it becomes possible to reconceptualize rationality and normativity and to develop a theory of macrosocial processes and social change prepared by the political theory and philosophy of history in the works of the classical pragmatists.

Precautionary Principle

The precautionary principle is an intuitively appealing concept that has risen to prominence over the past decade. The most well-known definition of the principle is contained in the Rio Declaration of the 1992 United Nations Conference on Environment and Development (UNCED). Principle 15 of the Declaration states that 'Where there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation' (Cameron 1994, p. 269). The principle has been invoked so often in international environmental resolutions that it is considered by many to be a fundamental normative principle (Cameron 1994, Costanza and Cornwall 1992). Unfortunately, there is no consensual definition of the principle and few practical guidelines for its implementation in national and international environmental policy.

The precautionary principle's rapid rise to prominence can be attributed to several factors. First, the notion of precaution is intuitively appealing, perhaps because we have been told from an early age that 'an ounce of prevention is worth a pound of cure.' Second, with the growing realization that human activities are creating global problems, such as global warming, the depletion of the ozone layer and the reduction in biological diversity, such admonishments have become all the more urgent. As the scales of the problems we face have grown, so too have the stakes. The higher the stakes, the less we can afford to take chances with the future. Third, as the size and complexity of the problems have grown, so too have the uncertainties. Thus, traditional science is unable to provide unequivocal answers. Given the stakes involved and absent clear solutions, it seems only prudent to err on the side of safety and take action now rather than later. If we wait for clear scientific proof of harm, it may be too late to do anything.

The term precautionary principle (*Vorsorgeprinzip*) was first used explicitly with regard to environmental policy in the former Federal German Republic in the 1970s (O'Riordan 1994, p. 306, O'Riordan and Jordan 1995, p. 193, Boehmer-Christiansen 1994). Subsequently, the precautionary principle was incorporated into many national and international environmental policies and protocols. The earliest use of the precautionary principle in an international agreement was in the Ministerial Declaration of the Second International Conference on the Protection of the North Sea in London in 1987. This declaration stated

that 'in order to protect the North Sea from possibly damaging effects of the most dangerous substances, a precautionary approach is necessary which may require action to control inputs of some substances before a causal link has been established by absolutely clear scientific evidence' (Cameron 1994, pp. 267–8). In 1989, the Nordic Council's Conference on Pollution of the Seas called for a precautionary approach 'eliminating and preventing pollution emission when there is reason to believe that damage or harmful effects are likely to be caused, even where there is inadequate or inconclusive scientific evidence to prove a link between emissions and effects' (Cameron 1994, p. 268). In 1992, the precautionary principle was boosted to prominence by its incorporation as Principle 15 in the United Nations Conference on Environment and Development (UNCED). Similar language was used in the 1992 United Nations Framework Convention on Climate Change, and the 1992 UNCED Biodiversity Convention (Cameron 1994, p. 269). Many other similar definitions have been proposed. For example, a group of academics and environmental activists called the Wingspread Group have concluded that there is compelling evidence of harm from toxic substances, global warming, ozone depletion and nuclear materials, and that existing environmental regulations are inadequate. The group proposed that 'When an activity raises threats of harm to human health or the environment, precautionary measures should be taken even if some cause and effect relationships are not fully established scientifically' (Risk Policy Report 1998).

The precautionary principle comprises three core ideas. First, it is necessary to take protective actions in advance of clear scientific proof, because scientific proof is unlikely to be forthcoming in the near future, and delay in action may ultimately prove more harmful and more costly to correct after the fact. Advocates of the precautionary principle argue that the uncertainties inherent in problems such as global warming and ozone depletion necessitate taking action prior to clear scientific proof. Because the uncertainties are inherent, traditional scientific methods can never eliminate them, so waiting for clear scientific evidence is foolhardy. Wynne (1992) identifies four kinds of uncertainty—risk, uncertainty, ignorance and indeterminacy. He proposes that a precautionary approach that recognizes these uncertainties and the limitations of traditional scientific methods is necessary. Funtowicz and Ravetz (1992) argue that the nature of environmental problems changes as the decision stakes and levels of uncertainty increase. Applied scientists and professional consultants (such as engineers) are able to provide adequate solutions for environmental problems with moderate to low decision stakes and levels of uncertainty. As we move into the realm of problems such as global warming, the stakes and the uncertainties are so high that a new kind of science is necessary. Post-normal science relies on the use of 'extended facts' and an extended peer community for

review. Thus, advocates of the precautionary principle call for greater use of civic science based on negotiation, quasi-formal predictions and evaluations, and more attention to the process rather than the content of the analysis (O'Riordan and Jordan 1995, Hunt 1994).

Second, traditional methods of economic analysis, such as the use of discount rates and cost benefit analysis, are inadequate because of the nature and likelihood of the harm, the extent of uncertainties, and the delay before the harm becomes evident (Perrings 1995). Traditionally, economists assume that the growth in capital resulting from current investments will more than compensate future generations for possible harm. Unfortunately, this means that little value is placed on impacts 25 years or more in the future, and it remains unclear what the impacts will be on natural capital. Advocates of the precautionary principle argue that the likelihood, nature and magnitude of the future costs of environmental problems, such as global warming or biodiversity loss, are unknown and cannot be calculated using traditional economic methods (O'Riordan and Jordan 1995).

Third, there is a need to shift the burden of proof to the 'developer' to show that the technology or activity is 'safe.' Under many current legal and policy frameworks, the presumption is that a technology or activity is 'innocent until proven guilty.' The precautionary principle would change this to presume that a technology or activity is 'guilty until proven innocent' (O'Riordan and Jordan 1995, O'Riordan 1994).

O'Riordan and Jordan (1995) identify several other elements that characterize precautionary approaches. These include the need to: (a) maintain proportionality between the likely harm and the cost of preventive measures; (b) take preventive measures to safeguard 'ecological space' to prevent pushing natural systems beyond thresholds that result in irreversible change; (c) recognize that natural systems have intrinsic value and there is a moral imperative to protect them; (d) shift emphasis to meso-term planning (i.e., 25–100 years); and (e) pay for the ecological damage caused by those who were less than cautious in the past.

The precautionary principle has been criticized on several fronts. O'Riordan and Jordan (1995, p. 192) fear that the principle runs the risk of following the 'dangerously successful pathway pioneered by sustainability.' The principle has broad intuitive appeal but lacks rigorous consensual definitions, and while it has been adopted widely as a laudable goal for environmental policy there are no clear guidelines for its implementation. Like sustainability, the precautionary principle is neither a well-defined principle nor a stable concept. It has become the repository for a jumble of adventurous beliefs that challenge the status quo of political power, ideology and civil rights. Neither concept has much coherence other than it is captured by the spirit that is challenging the authority of science, the hegemony of cost-benefit analysis, the

powerlessness of victims of environmental abuse, and the unimplemented ethics of intrinsic natural rights and intergenerational equity (O'Riordan and Jordan 1995, p. 191).

Bodansky (1994) argues that the precautionary principle underlies many of the environmental laws enacted in the 1970s in the US, but that its impact has often been contrary to the intent of the framers of these laws. He argues that the precautionary approach of the original Clean Air and Clean Water Acts led to delays in the promulgation of regulations. He also suggests that shifting the burden of proof to the proponent of a technology or activity may do little to enhance safety, since harmful impacts are often discovered only belatedly, as in the case of DDT and CFCs. Furthermore, shifting the burden of proof may actually exacerbate harm by discouraging the introduction of beneficial technologies. Bodansky questions whether it is feasible to establish guidelines that determine what levels of harm and scientific certainty are necessary to trigger the precautionary principle, and whether we should always err on the side of safety even if the social costs are very high. Bodansky (1994, p. 225) concludes 'Simple rules promise simple answers. But, in the end, there may be no practical alternative to the imperfect, difficult, often dissatisfying task of muddling along.'

Perrings (1995) and Costanza and Cornwall (1992) are more optimistic about the practical application of the principle. Perrings (1995, p. 159) believes that in the absence of better (i.e., more certain) information the precautionary principle 'leads to a sequential approach in which the decision maker reserves judgment about the uncertain outcomes of each activity, assuming the worst-case outcome until evidence is provided to the contrary'. Thus, the decision-maker assigns worst-case values to the uncertain outcomes of current activities and attempts to minimize the maximum environmental costs. The pragmatic problem becomes choosing a plausible worst-case for decision-makers.

Costanza and Cornwall (1992) propose combining the precautionary principle with the polluter pays principle to develop an environmental deposit-refund or assurance bonding system. Under this system, an 'assurance bond,' equal to the best estimate of the largest potential future damages, would be levied on the proponent of the technology or activity. Portions of the bond would be returned as and when the proponent could show that the suspected damages had not occurred or they would be used to repair or compensate for any damages resulting. Costanza and Cornwall believe this system would shift the burden of proof and the cost of uncertainty from the public to the proponent or developer. The bond would also serve as an incentive for businesses to conduct thorough, publicly accessible research on the environmental impacts of their activities and to look for ways to minimize pollution. Unfortunately, many questions

about the practical value of such a system remain unanswered: who determines the worst-case scenario and the size of the bond, especially since there is so much uncertainty about the future environmental impacts of so many activities? Who decides if and when the bond should be returned, and how? Is it practicable to think of dealing with myriad environmental problems in this fashion? How would this be implemented at an international level?

In conclusion, the precautionary principle has enormous intuitive appeal and has become an integral part of many international environmental agreements. The future success of the principle, however, rests on the development of clear practical guidelines for its implementation at both the national and international levels.

Prefectorial Government

Governments must govern their territory and ensure that decisions reached in the national capital are implemented throughout the country. Different political traditions emphasize policy coherence and uniformity across their territory to differing degrees, and therefore invest varying levels of political and administrative resources into controlling subnational governments. For countries more concerned with uniformity (such as France and countries that have adopted the French administrative tradition) prefects are crucial instruments for central governments. France and several other countries utilize these administrative officials as one component of their attempts to control policy implementation through subnational units of government, and also exercise control over the field staffs of other ministries in central government.

Prefectorial government refers to the utilization of central government officials—the prefect or *prefet*—to monitor and control policy within the area of the country for which each is responsible. For example, each department in France has a prefect, along with several *sous préfets* and other administrators responsible for controlling policy within the department. These officials are employees of the Ministry of the Interior and must review actions taken by both field services of most other ministries, as well as many decisions of department and commune officials. The relationships between the prefect and field staffs may be rather complex. For example, the prefect has little control over the pedagogical activities of the Ministry of Education, but does control construction of new schools.

The office of prefect has a long history, in France being derived from royal intendants in the *ancien* regime, and having persisted in one form or another since the Napoleonic era. As the office was developed during the Napoleonic era, it was seen as the means of creating a common nationhood in the face of substantial internal diversity within the country. The office briefly was called Commissioner of the Republic during the early stages of decentralizing reforms during the 1980s but the traditional title soon was restored to reflect the power of the State. Also, the creation of the regional planning system and regional governments with limited powers during the 1960s produced another level of government at which there is a need for prefectorial control in France, with some analogous development in other systems. Also, the

continued decentralization and deconcentration of policymaking in France (and other countries) means there is an additional necessity of integrating and coordinating policies at the implementation stage (Dupuy and Thoenig 1985, Thorval 2000). The system has been copied, with predictable variations, at various times in numerous other countries such as Italy, Greece, Spain, and Japan, as well as continuing to be utilized in several former French colonies. Few of the systems copied from the original have provided these officials with the potent regulatory functions characteristic of French administration.

Formally prefects exercise substantial powers within their department. They can reverse decisions made by other officials within their department and impose their own decisions in place of those decisions they consider inappropriate, or at least refer the issues involved back to Paris for final determination. Given the strong tutelary and control functions exercised by prefects, they rarely if ever are natives of the territories within which they work. In addition, the prefect has tended to have a virtual monopoly over communication between the department and the central government in Paris, so that the field staffs of most ministries have been channeled through the prefecture. This monopoly of communication constitutes a major source of power for prefects, given that the field staffs responsible to other ministries might have few independent avenues for complaining about the decisions of the prefect. In addition to the powers over national ministries, prefects frequently are directly involved with local government and have been in essence the chief executive for local governments. With reforms in the administrative system these local governments have been given increased powers but the prefect still has numerous tutelary powers.

The French prefect, much as the President of the United States, can be conceptualized as fulfilling a number of functions (Bernard 1992):

- (a) The guarantor of the heritage of the nation and of the continuation society;
- (b) The guardian of public order, with ultimate responsibility to preserve security and safety;
- (c) The representative of the State within the geographical area, and the guarantor of equality of citizens;
- (d) The promoter of regional economic development and (increasingly) the link of the region with the European Union; and
- (e) The promoter of social consensus and cooperation within the region.

The political climate favoring decentralization and enhanced local autonomy has minimized the central position of prefects in most political systems, but the office remains an active component of administration in political systems that remain concerned about creating uniformity, including France. Indeed, the role of the prefect as a coordinator of local services may be even more crucial with the substantial deconcentration

of policymaking. The range of powers available to prefects is becoming more constrained, and local communities are more likely to assert their own policy and political concerns. Even with the increase in local democracy, prefects remain powerful actors in local government, preserving their political power in part through alliances with local political leaders. With the creation of regional governments concerned primarily with economic development there is now a new level of prefectorial government in France, although the degree of control available to these officials is substantially more limited. Further, the role that the prefect plays in the distribution of funds coming from the European Union has also enhanced the central role of the prefect in subnational policy-making.

All administrative systems that utilize this variety of administrative mechanism for control over local areas are not called prefectorial. For example, the governors appointed by central government in Scandinavian countries have lost much of their authority over local authorities, although there are some vestigial powers of that sort. Even local mayors in some administrative systems (Finland and the Netherlands) may be in effect central government officials responsible for ensuring policy delivery in the face of potentially recalcitrant local political forces.

Authoritarian governments also have employed a variety of administrative mechanisms to control local governments and policy implementation, often using party officials rather than administrators to exercise the same control functions exercised by prefects.

Likewise, all administrative systems that are called prefectorial do not function in the same ways. Fried (1963), for example, distinguished between integrated and unintegrated prefectorial systems, with the former being exemplified by the French model and the latter by the Italian. The Italian prefectorial system is substantially less restrictive than the French version of exercising administrative control through prefects. For example, Italian field staffs from line ministries have had their own lines of contact with the government in Rome without being dependent upon the prefect. Also, Italian prefects have not exerted direct control over local governments in as overt a manner as they might in France, nor have they supplied accounting and other managerial services to the local governments. The prefect in Italian (and most other) administrative systems is more of a monitor than an effective regulator of subnational governments.

There are in many ways two prefects existing simultaneously in the office, and there is a great deal of ambiguity in the role as it has evolved (de Montricher 2000). On the one hand, much of what has already been described reflects the legal version of the prefectorial role. This official is the formally powerful representative of the authority of the State, resplendent in their gold-braided uniform, playing a central part in local ceremonies to demonstrate the involvement of central government in those activities. On the

other hand, the prefect is a bureaucratic politician who must build coalitions with local officials in order to be successful in governing. Although prefectural systems originally were designed to exercise central control over subnational policies and administration, in practice local governments also have a great deal of political influence over the prefect, and may convince that official to promote their own local interests, rather than simply being forced to accept what they are being instructed from the center.

The prefect generally does not have to be persuaded very much to help the local community in pressing its demands on central government. The prefect is a career administrative official, generally coming from the very summit of the career structure. These officials naturally want to build a successful career, and prefects are also subject to removal from office more readily than are other civil servants. One measure of success for the prefect would be the ability to administer central policies without complaints from the localities, complaints that might be expressed through local political notables. Further, if prefects can construct a workable coalition with political elites in the localities over which they have responsibility they may be able to build an even more effective administration and thereby improve their career chances even more. Various examinations of the politics of these administrative relationships undertaken in France demonstrate that influence and control circulate in both directions and that most final policy decisions are the products of negotiation and bargaining rather than imposition of authority through the prefect (Crozier and Thoenig 1976, Worms 1966). Further, prefects engage in a number of consultation and consensus-building operations within their departments to both enhance the quality of the decisions made and improve the involvement of local citizens in their own government. In France the power of local politics is enhanced by the *cumul des mandats* through which the same politician will hold office at both the central and local levels.

Prefectoral control may appear almost quaint in the contemporary era that stresses local democracy and accepts greater diversity among policy outcomes. Further, prefectural administration may appear anti-democratic, given that this instrument of governing substitutes administrative controls for the judgment of locally elected public officials (Behar and Estebe 1996). The overwhelming concern with uniformity and control also may limit the capacity of local and regional governments to innovate, while there is growing evidence of the efficacy of policy innovation at lower levels of government. In addition, uniformity in policy and administration may not conform well to managerialist ideas devolving authority to lower echelons of organizations.

Prefectoral policymaking systems are concerned strongly with centralized control and can be contrasted with federal systems that tend to involve states or

provinces for implementation without the direct monitoring and control, and that are willing to accept wider disparities in policy. The prefectural systems may also be contrasted with other types of unitary government that rely on the functional field staffs of central ministries to provide sufficient uniformity throughout their territory. Those functional administrative systems do not consider it necessary to impose an extra level of oversight, at least not to impose *ex ante* controls. Thus, the choice of this form of governing reflects some fundamental choices about the way in which laws are to be implemented and the extent to which uniformity is a requirement for justice.

B. G. Peters

Preference Models with Latent Variables

1. Introduction

Much of human behavior may be viewed as successive choices among more or less well-defined options or alternatives. In some situations, choices are made over a continuum of possibilities; for example how much of a particular resource to allocate for a task or how much to work. In other situations, choices are made among a finite (discrete) number of options. Familiar instances are a citizen deciding whether to vote and if so for whom, a shopper contemplating various brands of a product category, or a couple weighing marriage. Frequently, these decisions are made in a sequential manner. Examples include choice of employment, domicile, transportation mode and investment. With an emphasis on discrete types of choice problems,

research on preference and choice has revolved about the development of mathematical models that predict how both observed and unobserved attributes of decision makers and of choice options determine decisions. By treating the unobserved attributes as latent (random) variables, these preference models focus mainly on choice outcomes and to a lesser extent on the underlying decision processes. As a result, the main purpose of preference models with latent variables is to summarize the data at hand and to facilitate the forecasting of choices made by decision makers facing possibly new or different variants of the choice options.

The prevalence of behavioral models with their objective of choice prediction originated with the work of Thurstone (1927). By invoking the psychophysical concept of a sensory continuum, Thurstone explained the observation that choices by the same person may not be deterministic under seemingly identical conditions. He argued that options should be represented along this sensory continuum by random variables that describe the options' effects on a person's sensory apparatus. The choice process is then reduced to selecting the option with the greatest realization. One may question the use of randomness as a device to represent factors that determine the formation of preferences but are unknown to the observer. However, because, in general, it is not feasible to identify or measure all relevant choice determinants (such as all attributes of the choice options of the person choosing, or of environmental factors) the question of whether the choice process is inherently random or is determined by a multitude of different factors may be of little relevance in at least one aspect: either position arrives at the same conclusion that choices are best described in terms of their probabilities of occurrence.

Thurstone's early conceptualizations gave rise to an extensive body of methodological and empirical research, mainly in economics and psychology. Surveys about developments in choice theories (e.g. see *Decision and Choice: Random Utility Models of Choice and Response Time*; Luce's Choice Axiom; *Ranking Models, Mathematics of*, Marley 1992, Suppes et al. 1992) and choice modeling (Amemiya 1985, Fligner and Verducci 1993, Manski and McFadden 1981, McFadden 1984) indicate that the merging of the literatures in these two disciplines produced a flexible and powerful framework for the structural investigation of choice data. In particular, this framework has proved to be useful for analyses of individual preference differences at a particular point in time and over time, multidimensional representations of choice alternatives, and the incorporation of variables that describe choice options and decision makers. Each of these areas of research is outlined in the following sections. Because emphasis is on conceptual issues, more technical topics such as sampling, estimation and inference will not be discussed (Albert and Chib 1993).

2. Theoretical Framework

We define a population $\mathcal{P}$ of decision makers ($n \in \mathcal{P}$) and a finite set $\mathcal{C}$ of choice alternatives ($j \in \mathcal{C}$). For each decision maker n and choice alternative j , a vector $\mathbf{x}_{nj}$ of observed variables is available that partially describe the pair (n, j) . The underlying momentary utility of option j to person n is denoted by u_{nj} and a function of the observed and unobserved attribute values. Distributional assumptions are made to capture the variation of the unobserved attribute values and taste differences among the decision makers. In combination with a decision rule for selecting an option, the utilities determine the options' choice probabilities. As a result, the choice probabilities can be represented by an a priori specified member of a family of functions which is partially determined by the distributional assumptions about the unobserved attribute values and utility variations and indexed by a parameter vector θ .

Choice data may be collected in a variety of formats. For example, the *paired comparison* technique is the method of choice in laboratory settings. In large scale surveys or panel interviewer studies, incomplete and/or partial *rankings* or *preference ratings* are frequently collected because of their time-efficiency. In conjoint measurement studies (e.g., see *Measurement Theory: Conjoint*), the constant-sum technique is often used. In recurrent choice studies, we observe how often each choice option is selected within a certain time period. Each data type requires a different treatment to both investigate how decision makers differ in their preferences for choice options and to accommodate the distinct psychological processes that are specific to each choice task.

Consider, for example, a ranking experiment with the choice set $\mathcal{C} = \{i, j, k\}$ but without any attribute information. The first three columns of Table 1 represent the six possible ranking outcomes. Each number corresponds to one of the ranking positions of an option. For instance, the ranking outcome $\{2, 1, 3\}$ indicates that options i, j and k are ranked second, first and third, respectively. Here the rankings are obtained based on the ordering (from largest to smallest) of the underlying options' utilities. The remaining columns of Table 1 depict these orderings of the utility values

Table 1
Outcomes of a ranking experiment

Ranks			Ordering of utilities
i	j	k	
1	2	3	$u_i \geq u_j \geq u_k$
1	3	2	$u_i \geq u_k \geq u_j$
2	1	3	$u_j \geq u_i \geq u_k$
3	1	2	$u_j \geq u_k \geq u_i$
2	3	1	$u_k \geq u_i \geq u_j$
3	2	1	$u_k \geq u_j \geq u_i$

(without the subscript n) for each of the six ranking outcomes. For instance, $u_j \geq u_i \geq u_k$ indicates that the utility of j is larger than the utility of i which, in turn, is larger than the utility of k . The probability of observing this ranking outcome can be written as $\Pr(j \geq i \geq k | \theta) = \Pr((u_j - u_i) \geq 0 \cap (u_i - u_k) \geq 0)$. If the individual utilities follow a multivariate normal distribution with mean vector $\mu = (\mu_i, \mu_j, \mu_k)'$ and covariance matrix

$$\Sigma = \begin{bmatrix} \sigma_i^2 & \sigma_{ij} & \sigma_{ik} \\ \sigma_{ij} & \sigma_j^2 & \sigma_{jk} \\ \sigma_{ik} & \sigma_{jk} & \sigma_k^2 \end{bmatrix}, \quad (1)$$

then probability of observing this ranking can be computed by evaluating the cumulative distribution function of the bivariate normal density with upper integration limits $(\mu_j - \mu_i)/(\sigma_j^2 - 2\sigma_{ij} + \sigma_i^2)$ and $(\mu_i - \mu_k)/(\sigma_i^2 - 2\sigma_{ik} + \sigma_k^2)$ and correlation coefficient $(\sigma_{ij} - \sigma_{jk} - \sigma_i^2 + \sigma_{ik})/[(\sigma_j^2 - 2\sigma_{ij} + \sigma_i^2)^{1/2}(\sigma_i^2 - 2\sigma_{ik} + \sigma_k^2)^{1/2}]^{-1}$. It is important to note that because the ranking probabilities are based on the differences between the options' utilities, it is not possible to uniquely identify the underlying mean and covariance structure.

When relating attribute information to individual utilities, it is useful to distinguish between systematic and random sources of influence. Random sources of influence include (a) attributes of the choice options that are unobserved but influence preferences, (b) measurement errors, and (c) unobserved variables that account for taste variations among the decision makers (Manski & McFadden 1981). Systematic components of influence include the effects of the measured person and option characteristics x_{nj} . The implication of this view is that u_{nj} can be written as $u_{nj} = \mu_{nj} + \varepsilon_{nj}$, where μ_{nj} and ε_{nj} represent the effects of observed and unobserved determinants, respectively, of an option's utility. Without prior information, we can only determine the distribution of the unobserved values across the population of decision makers.

2.1 Modeling μ

The specific functional relationship between μ_{nj} and known option and person characteristics may depend on the particular application. For example, in situations where the measured attributes of the choice options are of a 'more-is-better' type, a linear function may prove sufficient to describe the attributes' effects. This is the case for the *vector model* (Carroll and DeSoete 1991) which assumes that a decision maker combines the attribute values in a linear fashion. In contrast, when the systematic utility component is a *single-peaked* function of the measured variables, an *ideal-point* representation is more appropriate (Coombs 1964).

The attribute effects may vary from person to person in a systematic fashion, for example, by being related

to such person-specific variables as age, gender, and educational achievement. However, in many cases reference to demographic variables is not sufficient to explain heterogeneity in preferences among individuals. Because psychological or economic theories provide little guidance about the role person-specific variables play in the formation of preferences, a random regression approach is required. Thus, it may be postulated that the attribute effects follow some a priori specified distribution. In particular, latent structure models are useful in capturing individual differences in the attribute effects by introducing the fairly unrestrictive assumption that individual variations can be described by a small number of 'prototypical' effect vectors (Böckenholt and Böckenholt 1991). Individual differences are accounted for by assigning each person to a preference class such that members of a preference class exhibit the same or similar attribute effects. For example, when preference data are collected by the method of first choices, a latent-class choice model is given by the following equation

$$\Pr_n(i|\theta) = \sum_{s=1}^S \pi_n(s) \Pr_n(i|\theta_s) \quad (2)$$

where

- $\Pr_n(i|\theta)$ = probability of person n choosing alternative i , and θ is a parameter vector;
- $\pi_n(s)$ = probability of person n belonging to class s ;
- $\Pr_n(i|\theta_s)$ = probability of person n choosing alternative i given n belonging to class s .

The latent classes may represent (a) different *decision rules* adopted by the individuals; (b) variable choice sets considered by the individuals; or (c) subgroups of the population with varying tastes or, sensitivity to the options and their attributes.

2.2 Modeling ε

Attributes that influence the utility of an alternative but are not measured are represented by ε_j . The distribution of ε_j is frequently specified to be multivariate normal with arbitrary covariance matrix. This specification is useful in analyzing *similarity* relationships between choice options that are introduced by the unmeasured attributes. Because the estimation of the elements of the covariance matrix is computationally complex, more restrictive representations are also of interest. For example, Stern (1990) proposed a family of choice models based on independent gamma random variables which includes Luce's (1959) choice model as a special case.

Careful checks are necessary to determine whether the independence assumption is valid or whether unobserved attributes may contain information useful in identifying systematic sources of individual differences and option characteristics. If respondents per-

ceive a common set of latent attributes but differ in the weights they assign to the attribute values, the covariances of ε_j can be decomposed according to a linear *factor-analytic model* (Takane 1987). Other possibilities include the application of ideal-point models which are based on the assumption that individuals choose the option that is closest to their ‘ideal option’ where closeness is a function of the distance between the choice option and the person-specific ideal option (Coombs 1964). Distance may be defined in various ways, for example, by an Euclidean distance in a continuous latent attribute space or by a latent tree structure in which both choice and ‘ideal’ options are represented by nodes. However, in all of these cases, the interpretation of taste differences is much simplified provided the assumption is correct that decision makers use the same set of attributes in assessing the choice options.

2.3 Modeling Preferences Over Time

When collecting time-dependent choice data, it is important to take into account that individuals not only differ in their preferences at a particular point in time but also in the way they change their preferences over time. For instance, current preferences may depend on such diverse factors as previous choices, *interchoice times*, or the length of time a particular preference state has been occupied. Decision makers may also differ in their familiarity with features of the choice options with the result that some decision makers are stable in their preferences over time while others may change their preferences according to some learning process. A complicating factor in this context is that choice environments outside a laboratory setting are rarely stable. Typically, attributes of choice options (e.g., price) and decision environments (e.g., changing tax code) vary over time and influence choice behavior.

The development of time-dependent choice models requires significant modifications of the statistical framework for cross-sectional choice data. However, because choice processes are inherently dynamic and are studied best by taking their temporal nature into account, approaches that focus on these aspects are more likely to lead to important insights about decision making. Conceptually, it is useful to distinguish between *heterogeneity* and *state dependence* in the analysis of recurrent choice data. According to the ‘heterogeneity approach,’ individual choices are assumed to be conditionally independent given the person-specific parameters. For example, *latent structure choice models* represent time-dependent individual differences by switches among latent preference states. If preferences are stable, membership in a latent preference state is time-homogeneous. In contrast, systematic choice variability over time may indicate changes in the perception of (some of) the choice options. Stability and shifts in preference states (for,

say, three equidistant time points) can be investigated by extending Eq. (2) to

$$\Pr_n(i_{t-1}, j_t, k_{t+1} | \theta) = \sum_{a=1}^S \sum_{b=1}^S \sum_{c=1}^S \pi_n(abc) \Pr_n(i_{t-1} | \theta_a) \Pr_n(j_t | \theta_b) \Pr_n(k_{t+1} | \theta_c), \quad (3)$$

where

- $\Pr_n(i_{t-1}, j_t, k_{t+1} | \theta)$ = probability of person n choosing alternative i at time point $(t-1)$, j at time point t , and k at time point $(t+1)$; and

- $\pi_n(abc)$ = probability of person n belonging to classes a , b , and c at time points $(t-1)$, t , and $t+1$, respectively.

Special cases of (3) are obtained by imposing constraints on $\pi_n(abc)$ to describe the switching process among the latent preference states (Böckenholt and Langeheine 1996).

Although time-varying taste heterogeneity is perhaps the single most important source of dependency in recurrent choice data, the assumption of conditionally independent decisions may require the estimation of a large number of preference states in order to be satisfied. A more parsimonious approach for modeling state dependency is obtained by considering the outcomes of previous choices as possible explanatory variables for current choices. For example, if only the choice outcome at $(t-1)$ influences the current choice, the state-specific choice probabilities are specified as $\Pr_n(j_t | i_{t-1}, \theta_s)$. This approach has been shown to be fruitful in capturing such psychological phenomena as habit persistence, learning, or variety seeking (Manski and McFadden 1981). Further generalizations are also possible by allowing for several sets of preference states, where each set follows a different switching process over time.

3. Conclusion

The formulation of choice models in terms of latent utilities has a long tradition in biometric, econometric, psychometric and sociometric disciplines. The numerous applications and further developments in each of these areas have led to many improvements in the statistical apparatus necessary for estimating and validating choice models. However, the unifying principle remains valid that observed individual choice behavior is an imperfect reflection of the underlying preferences of a person. This viewpoint leads to a probabilistic representation of the relation between the manifest and latent levels of choice analysis taking into account both the process by which an individual arrives at a choice and the factors that influence this process. Some of these factors are unobservable (such as the processed information about the choice alternatives), while other factors are known and measurable. By separating these two sources of influence due to measured and unobserved attributes at the individual level, a powerful modeling approach is obtained that

facilitates the identification and isolation of the net effects of choice option characteristics, individual characteristics, and interactions of option and individual characteristics as separate choice determinants.

Modifications of this choice modeling approach are necessary when the choice set is large or when a simultaneous presentation of the choice options is not feasible. In these cases, one may argue that decision makers tend to rely on *satisfying* rules and the idea of an *aspiration level* may be more appropriate than the principle of utility maximization (Simon 1957). In contrast to the large number of possible satisfying rules, however, only a few mathematical representations have been proposed. Perhaps the most popular model is due to Coombs' (1964) analysis of the 'pick any/m' task and Thurstone's (1959) work on the method of successive categories. In the 'pick any/m' task it is assumed that choice options are selected when their utilities exceed some specified minimum value. Thus, the underlying choice process is scalar valued and based on a binary comparison between the option's utility and a threshold value. More specifically, according to Coombs' (1964) unidimensional unfolding approach, the utility of item j for person n is given by the distance between two parameters representing j and n on a unidimensional continuum. This idea has been incorporated in several psychometric models by making the simplifying assumption that the perception of the item-specific parameters does not vary from person to person (Andrich 1997). In general, results of the *maximization* and 'aspiration level' hypotheses are not directly comparable because in the latter case we model the probability of belonging to some category (i.e., 'above the threshold') and in the former case we model order relations among the choice options.

In recent years, stochastic choice models have come under criticism because, frequently, they cannot capture context-sensitive behavior (Tversky and Kahneman 1991). For example, the models' underlying assumption that the assessment of an option's utility does not depend on comparisons drawn between it and other available alternatives has received little support in laboratory studies. Moreover, the deliberation process from the onset of the choice task to the final selection has been shown to play an important role that should be taken into account by the next generation of choice models (Busemeyer and Townsend 1993). Clearly, the latent utility approach has proved to be most useful in providing parsimonious descriptions of how judges differ in their preferences at a particular point in time or over time. However, by emphasizing interindividual differences, this approach can render only limited insights about cognitive processes influencing a choice.

Prefrontal Cortex

The prefrontal cortex is the cortex of association of the frontal lobes. It plays a major role in the temporal organization of behavior, reasoning and language.

The underlying mechanisms are not fully understood, but are known to support at least two cognitive functions of temporal integration that are essential to that role: active short-term memory and preparatory set.

1. Anatomy

In evolution and in individual growth, the prefrontal cortex develops more slowly, yet further, than most other brain structures, in both size and weight (Fig. 1). Phylogenetically and ontogenetically, it is one of the last regions of the cortex (neocortex) to develop (Brodmann 1909). The human prefrontal cortex does

not reach full structural maturation of cells and connections until young adulthood. In the adult human, the prefrontal cortex constitutes almost one-third of the totality of the neocortex. For reasons that are not well understood, this region of the cortex, which is one of the latest to develop, is also one of the most vulnerable to involution and pathological aging (Raz 2000).

The primate prefrontal cortex (Petrides and Pandya 1994) is composed of three major parts or regions (Fig. 2): the dorsolateral prefrontal cortex, that is, the cortex of the dorsal and lateral convexity of the anterior portion of the frontal lobe (Brodmann cytoarchitectonic area 46, and lateral parts of areas 8, 9,

Figure 1
The prefrontal cortex (shaded) in six animal species

Figure 2

The three major regions of the prefrontal cortex in the human, with cytoarchitectonic areas numerated according to Brodmann's map

10, and 11); the medial and cingulate prefrontal cortex, which is nearly flat and faces the medial surface of the contralateral frontal pole (areas 12, 24 and 32, and medial parts of 8, 9, 10, and 11); and the inferior orbital prefrontal cortex, slightly concave and located directly above the orbit (areas 13, 47, and inferior parts of 10, 11, and 13).

Of the three regions, the dorsolateral develops last and most. This region is bordered posteriorly by the premotor cortex (area 6); the medial and orbital prefrontal cortices (often considered together and designated orbitomedial prefrontal cortex) are anterior and adjacent to the corpus callosum and to limbic structures (piriform cortex and amygdala, cingulate cortex, septum, and hypothalamus). In terms of cellular architecture, the posterior orbitomedial cortex is transitional, with features of both the limbic cortex and neocortex.

2. Functional Connectivity

The functions of the prefrontal cortex can be best understood as components of a general role of frontal cortex in the representation and execution of the actions of the organism. In its totality, the frontal cortex can be considered motor cortex in the broadest

sense. It represents and coordinates actions in all domains of adaptation of the organism to its internal and external environment. In order to coordinate such a wide gamut of activity, the prefrontal cortex receives inputs from, and sends outputs to, many other parts of the brain.

Each of the three principal prefrontal regions has its own set of fiber connections mostly reciprocal and topologically organized—not only with the other two prefrontal regions, but with other cerebral structures, cortical and subcortical. Especially noteworthy for their number and functional implications are the connections of the three prefrontal regions with the thalamus, limbic structures, the basal ganglia, and other parts of the cortex. The orbital and medial prefrontal regions are well connected with the medial and anterior nuclei of the thalamus, the piriform cortex, the hippocampus, the amygdala, and the hypothalamus.

This connectivity with the thalamus and limbic structures falls into three major categories: (a) gustatory and olfactory inputs for the processing of information on taste and olfaction; (b) inputs from the internal milieu of the organism, notably from the hypothalamus, related to motivation, visceral functions, and affective states; and (c) efferent outputs to thalamic and limbic structures for the control of

instinctual, emotional, and social behavior, as well as certain visceral functions.

The dorsolateral prefrontal cortex, on the other hand, is extensively interconnected with other areas of the frontal lobe, homolaterally and contralaterally (through corpus callosum), with the hippocampus, and with several areas of the neocortex of the temporal and parietal lobes, in the posterior aspects of the cerebral hemisphere (Pandya and Yeterian 1985). All this cortical connectivity is essential for cognition. It serves the integrative and associative functions that support the cardinal role of the prefrontal cortex in executive memory and in the temporal organization of behavior. In addition, the dorsolateral prefrontal cortex sends important efferent fibers to the basal ganglia, including caudate nucleus, and the cerebellum. This connectivity serves the motor output functions of the prefrontal cortex through structures that are involved in skeletal and ocular motilities.

3. Physiology

Drive, emotional behavior and visceral actions, as well as their affective connotations, are the physiological purview of medial and orbital prefrontal areas. The medial prefrontal cortex plays an important role in basic motivation, though this role is still poorly understood.

In the human, large lesions of this medial cortex lead to apathy, inattention, and lack of spontaneity in speech, behavior, and ideation (Cummings 1985). The orbital prefrontal cortex, on the other hand, seems essential for the inhibitory control of internal drives. Animals or humans with lesions of this cortex often manifest disinhibition of eating, sex, and aggression, in addition to related abnormalities of social and emotional behavior. The human subject with orbitofrontal damage commonly shows uninhibited instinctual behavior, impulsivity, reckless risk taking, coarse and tasteless humor, and poor moral judgement (Stuss and Benson 1986, Damasio et al. 1994). Oftentimes he or she runs into conflict with the law. Further, because internal impulse control is necessary for steady attention and normal goal directed behavior, the orbitomedial prefrontal cortex serves the general role of the prefrontal cortex in the organization of behavior and cognition.

The dorsolateral prefrontal cortex is involved in both the representation and the enactment of temporally organized behavior and of cognitive operations, which are required in language and logical reasoning (Luria 1966, Fuster 1997). These representations fall under the general category of motor or executive memory, which includes the representations of complex schemes of temporally organized action, such as plans, programs, or scripts of behavior and cognition. The qualifications of novelty and complexity should be emphasized because, after its acquisi-

tion and consolidation, routine behavior is no longer represented or enacted by the prefrontal cortex, but by neural structures at lower stages of the motor hierarchy (e.g., motor and premotor cortices, basal ganglia).

A subject of much debate is the functional specialization of areas within the dorsolateral prefrontal cortex. Given that this cortex can be anatomically subdivided into a number of cytoarchitectonically distinct areas (Petrides and Pandya 1994), each with a separate set of connections (Pandya and Yeterian 1985), the functional specialization of its areas can be, in principle, reasonably assumed. Accordingly, some single-cell studies with monkeys support a degree of seemingly modular commitment of various dorsolateral areas to the representation of different categories of sensory information, such as spatial location or visual configuration (Goldman-Rakic 1995). Other single-unit studies, however, point to the essentially associative character of all dorsolateral prefrontal areas.

In the pursuit of behavioral goals, dorsolateral prefrontal cells associate sensory information across modalities (e.g., sight and sound) and across time (Fuster et al. 2000). Furthermore, some cells associate sensory stimuli with subsequent motor actions (Rainer et al. 1998). These associative properties of dorsolateral prefrontal cells point to their essential temporal integrative functions. Thus, the apparent sensory or motor specificity of certain dorsolateral areas may be related to the specificity of their predominant inputs from sensory systems or outputs to motor systems. In any case, that specificity of areas—thus far fragmentary, and far from established—seems secondary to their basic integrative functions at the cognitive level. Those functions (see later) are crucial for the temporal organization of behavior.

It is likely, though not proven, that the connectivity of the prefrontal cortex with the hippocampus is essential for the formation of executive memory, including the schemas of behavioral and cognitive action. Once they have been formed, the executive memory networks of the cortex of the frontal lobe appear hierarchically organized. Represented in primary motor cortex, the lowest stage of that organization, are the simplest motor memories, elements of motor action defined by specific movement and muscle group (i.e., innate or phyletic motor memory). Immediately above, in the premotor cortex, are representations defined by trajectory and goal of movement. At the summit, in the dorsolateral prefrontal cortex, are representations of complex schemas and sequences of goal-directed action. In a manner still unknown, this cortical region represents the broad schemas of action and, in addition, is critically involved in the enactment of those schemas. A consistent component of the dorsolateral frontal-lobe syndrome in the human is the inability to formulate and to enact plans of action.

4. Temporal Structuring of Action

The main function of the dorsolateral prefrontal cortex is the temporal organization of behavior, language and reasoning. This cortical region appears to secure the orderly and timely execution of all new goal-directed sequences in those three domains of activity. As a precondition for its enactment, however, a new or recently learned sequence of acts is presumably represented in prefrontal networks in the form of a schema or plan of action (executive memory). The execution of that sequence is a highly complex process of temporal integration that probably engages many cortical and subcortical brain regions. The dorsolateral prefrontal cortex seems to orchestrate the functions of many other parts of the brain. It does so with the purpose and end-result of structuring behavior and cognition in time, of forming temporal gestalts (or melodies of action) toward the attainment of biological and cognitive goals.

In as much as intelligence is manifested and tested by performance of logical goal-directed directed tasks and sequences of behavior and language, it is reasonable to assume that the dorsolateral prefrontal cortex is an important component of the neural substrate of intelligence. Indeed, it has been argued on the basis of empirical data from the human, that this cortex is the foundation of general intelligence, as measured by Spearman (Duncan et al. 1996). This psychological metric reflects the proficiency of a subject in performance of a large variety of tests, all of which require the temporal integration of behavioral, verbal or cognitive contents.

Towards the end of the twentieth century, evidence has been accumulating for two temporally integrative functions of dorsolateral prefrontal cortex providing the neural and cognitive support to the process of temporal organization. Those two functions are temporally symmetrical and mutually complementary. The first is a temporally retrospective function of short-term memory; the second, a temporally prospective function of preparatory set. Both together help the organism to bridge time between sensory and motor events, and thus to mediate cross-temporal contingencies of behavior. Both seem to share the same or overlapping networks of dorsolateral prefrontal cortex. Both depend on the coordination of neural activity between this cortex and the association cortices of the posterior regions of the cerebral hemispheres.

4.1 Short-term Memory

Short-term memory is commonly conceptualized as the temporary retention of information before it becomes permanent or long-term memory. Recently, however, cognitive psychology has developed a different concept of short-term memory: the temporary

retention of information, old or new, for the execution of an action in the short term, as is required for the performance of complex behavior or the solution of problems. This kind of short-term memory has been called working memory (Baddeley 1986). There is considerable evidence that both types of short-term memory share the same cortical neurons and networks, and that working memory consists in the sustained activation of a wide cortical network representing information to be used prospectively in the near term. That information may be newly acquired or may be an item of long-term memory reactivated for the short term as the occasion demands. As that memory contributes to form a temporal structure of behavioral or cognitive action, the neurons of dorsolateral prefrontal cortex are part of the activated memory network. There is conclusive evidence that the dorsolateral prefrontal region is critically involved in all forms of active short-term memory toward a goal, or working memory (Fuster 1997).

The evidence comes chiefly from two methodologies, selective cortical lesion (or inactivation) and single-cell recording, in the nonhuman primate performing short-term memory or delay tasks (e.g., delayed response, delayed matching). In these tasks, the animal is presented on successive trials with an item of sensory information—which varies from trial to trial—and is required to retain it in memory for electing and executing the appropriate motor response a few seconds or minutes later. Each trial amounts to a specific selection from a set repertoire of actions, a selection that depends on the sensory cue that has preceded it by seconds or minutes. The relative novelty of the relevant sensory-motor association for that particular trial, and the need to retain a sensory item temporarily in memory, place both the trial and the memory under prefrontal control. Monkeys with lesions of dorsolateral prefrontal cortex perform poorly in delay tasks. They seem unable to keep the working memory of the stimulus for each trial. In a normal animal performing a delay task, neurons of that cortex fire persistently—and often in stimulus-specific manner—during the delay (memory period) of every trial.

These observations denote the importance of cellular dynamics in dorsolateral prefrontal cortex for working memory and the temporal organization of behavior. Recent neuroimaging methods have provided further evidence, at a more global level, of the involvement of the dorsolateral prefrontal cortex in working memory (Smith and Jonides 1999). Unlike microelectrode studies, however, and because of its constraints of temporal and spatial resolution, neuroimaging does not yet reveal the dynamics of neuronal populations of this cortex in working memory. What defines prefrontal memory in the active state, or working memory, is the teleological quality of that memory, which is mobilized for the construction of future action. As noted in Sect. 3, one source of

Figure 3

Cortical anatomy of the perception-action cycle depicted around a lateral view of the human brain. Unlabelled regions represent sub-areas of labelled regions or intermediate areas between them. All the arrows represent connections that have been demonstrated in the monkey

apparent areal specialization in dorsolateral prefrontal cortex is the nature of sensory inputs leading to associated action (visual, spatial, etc.). The other is the nature of the associated actions themselves (skeletal movements, ocular movements, etc.). Sensory- or motor-specific cell groupings and areas within that cortex are probably components of teleological associations, and thus the paths to prospective action. In any case, the integrative functions of dorsolateral cortex, namely memory and set, are supramodal and transcend the sensory or motor properties of any given prefrontal area.

4.2 Set

Also from the teleological character of the temporal structuring of action derives the prefrontal function of preparatory set. Setting receptors and effectors for prospective actions is the temporal mirror image of active short-term memory. This second integrative function, preparatory set, is the other side of the coin

of the superordinate prefrontal function of temporal organization. It prepares the organism for anticipated percepts and actions (memory of the future) that will complete the bridging of a cross-temporal contingency. Although the mechanisms of set are not yet known, they probably include the priming of sensory and motor structures via efferent prefrontal connections. In the monkey and the human, the activation of dorsolateral prefrontal cortex in preparatory set is manifested by a progressive increase of cell discharge and slow surface-negative potentials before a stimulus-contingent act. The cellular evidence indicates that memory and set occur largely at the same time. Both seem to be processed simultaneously in the period between two mutually contingent events.

While some prefrontal cells engage in working memory of the cue, others in the same region do it in the preparation of the upcoming behavioral response. The activity of those cells shows that, while the representation of sensory information tends to wane over a delay, the representation of the prepared response tends to increase (Quintana and Fuster 1999).

The choice of one motor act among alternatives is, on the motor side, the equivalent of focusing sensory attention. Thus, preparatory set, the second cognitive function of the dorsolateral prefrontal cortex, can be rightly considered attention, the focusing of attention on a motor act to ensure its prompt and efficient execution.

In summary, the symmetry of the two temporal integrative functions of prefrontal cortex, memory and set, is paralleled by a symmetry of attentive processes, one sensory and the other motor. Active short-term memory is attention focused on the representation of a recent sensory event, whereas preparatory set is attention focused on a consequent and subsequent act. Although attention—especially perceptual attention in the human—is usually associated with consciousness, neither of the two temporal integrative functions of the prefrontal cortex—active memory or set—need be conscious.

5. Perception–Action Cycle

The organization of new and complex behavior commonly requires a continuous succession of temporal integrations of percepts and actions. In this succession, each integration depends to some degree on previous ones. Each act produces changes in the environment that will determine and modify subsequent perceptions, and these will determine and modify subsequent acts. The continuous operation of this cybernetic cycle of interactions of the organism with its environment is a basic principle of biology, the so-called perception–action cycle.

As complex new behavior evolves toward a goal, percepts and acts that are mutually contingent are often separated by time and by other intervening acts and percepts. Further, the pursuit of that goal requires the intervening attainment of lesser or subordinate goals. Thus, the temporal organization of the behavior requires a continuous mediation of contingencies across time. To mediate those cross-temporal contingencies is a function of the biological substrate of the perception–action cycle. The dorsolateral prefrontal cortex is at the apex of that substrate, which basically consists of two parallel hierarchies of neural structures, one sensory and the other motor, extending from the spinal cord to the cerebral cortex. Corresponding levels of each hierarchy are reciprocally interconnected, while each structure in either hierarchy is reciprocally interconnected with the one above and the one below. Figure 3 shows the cortical stages of those hierarchies. The contingencies of automatic and routine behavior (e.g., walking, reflex acts) are mediated at lower, subcortical, stages of the neural organization of the perception action cycle.

Complex new behavior, however, engages the cortical stages of the cycle neural hierarchies. Because this kind of behavior usually contains multiple and complex contingencies across time, the highest neocortical

stages are called into action for its implementation, in particular the dorsolateral prefrontal cortex. This cortex, in functional coordination with the sensory association cortices of the posterior hemisphere, mediates cross-temporal contingencies at the top of the cycle. The prefrontal cortex supports that mediation across time through its two temporal integrative functions of active memory and preparatory set. Both require the functional interaction of prefrontal with posterior cortices, as suggested by combined use of behavioral, cortical-cooling and cell-recording methods (Fuster et al. 1985).

The understanding of the mechanisms of that interaction will lead to more precise knowledge than we now have of the functions of the prefrontal cortex in the temporal organization of behavior. For a number of empirical and theoretical reasons, the role of this cortex in the organization of language and reasoning is probably based on similar functions and mechanisms.

Prefrontal Cortex Development and Development of Cognitive Function

Prefrontal cortex (PFC) is by far the largest cortical area in the human brain (see *Prefrontal Cortex*). It appears to be required when a task is novel or complicated and thus requires concentration. An example would be when you need to guide your actions by information you are holding in mind, and must pay attention so that you act according to that information and not your natural inclination. Its period of maturation is particularly protracted. PFC shows significant developmental changes as early as the first year of life, but does not reach full maturity in humans until young adulthood. In this article, developmental periods are broken up into 0–1, 1–3, 3–7, and 7–22 years. For each period, changes in cognitive abilities thought to depend on PFC are briefly described, as is evidence of maturational changes in PFC.

1. Behavioral Evidence of Improvements in Cognitive Functions that Depend on PFC During the First Year of Life

Piaget's 'A-not-B' task has been widely used to study infant cognitive development (Wellman et al. 1987). Under the name 'delayed response,' the almost identical task has been widely used to study the functions of a subregion of PFC in rhesus monkeys (Goldman-Rakic 1987). The subregion is dorsolateral PFC (DL-PFC). A participant watches as a reward is hidden to the left or right in one of two identical hiding places. A few seconds later the participant is encouraged to find the hidden treat. The participant must hold in mind over those few seconds where the treat was hidden

and, over trials, must update his or her mental record to reflect where the treat was hidden last. The participant is rewarded for reaching correctly by being allowed to retrieve the treat. In this way, the behavior of reaching to that location is reinforced and hence the tendency to make that response is strengthened. When the reward is then hidden at the other location, the participant must inhibit the natural tendency to repeat the rewarded response and instead respond according to the representation held in mind of where the reward was hidden last. Hence, this task requires an aspect of working memory (holding information in mind) plus inhibition of a prepotent action tendency (the tendency to repeat a positively reinforced response).

By roughly 7½ to 8 months of age, infants reach correctly to the first hiding location with delays as long as two or three seconds (Diamond 1985). When the reward is then hidden at the other hiding place, however, infants err by going back to the first location (called the 'A-not-B error'). Infants show marked improvements in their performance of the A-not-B/delayed response task at 7½ to 12 months of age. For example, each month they can withstand delays approximately two seconds longer, so that by 12 months of age delays of roughly 10 seconds or longer are needed to see the A-not-B error (Diamond 1985).

In a transparent barrier detour task called 'object retrieval' (Diamond 1991) a toy is placed within easy reach in a small, clear box, open on one side. There is a very strong pull to reach straight for the toy through the side one is looking, which must be inhibited when an infant is looking through a closed side of the box. At 6 to 8 months of age, infants reach only at the side through which they are looking. They must look through the opening, and continue to do so, to reach in and retrieve the toy. As they get older, the memory of having looked through the opening is enough; infants can look through the opening, sit up, and reach in while looking through a closed side. By 11 or 12 months of age, infants do not need to look along the line of reach at all. Infants progress through a well-demarcated series of five stages in performance of this task from 6 to 12 months of age (Diamond 1991).

Although the A-not-B/delayed response and object retrieval tasks share few surface similarities, human infants improve on these tasks during the same age period (6–12 months) and so do infant rhesus monkeys (1½–4 months; Diamond 1991). Despite wide individual differences in the rate at which infants improve on these tasks, the age at which a given infant reaches 'Phase 1B' on the object retrieval task is remarkably close to the age at which that same infant can first uncover a hidden object in the A-not-B/delayed response paradigm (Diamond 1991).

There is no behavioral task more firmly linked to DL-PFC than the A-not-B/delayed response task (Goldman-Rakic 1987, Fuster 1989). This is one of the strongest brain-behavior relations in all of cognitive

neuroscience. DL-PFC lesions in the monkey also disrupt performance on the object retrieval task (Diamond 1991). MPTP (1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine) injections, which reduce the level of dopamine in PFC, also produce deficits on the task (Taylor et al. 1990, Schneider and Roeltgen 1993). (MPTP also affects the level of dopamine in the striatum, but lesions of the striatum do not impair performance on the object retrieval task (Crofts et al. 1999).)

Human infants of 7 to 9 months, infant monkeys of $1\frac{1}{2}$ to $2\frac{1}{2}$ months, adult monkeys in whom DL-PFC has been removed, infant monkeys of 5 months in whom DL-PFC was removed at 4 months, and adult monkeys who have received MPTP injections to disrupt the prefrontal dopamine system all fail the A-not-B/delayed response and object retrieval tasks under the same conditions and in the same ways (Diamond 1991). In human infants, changes in the pattern of electrical activity detected by electroencephalogram (EEG) over frontal cortex and in the coherence of electrical activity detected by EEG over frontal cortex and parietal cortex (A-not-B: Bell and Fox 1992, object retrieval: N A Fox, personal communication 1992) correlate closely with developmental improvements on the A-not-B/delayed response and object retrieval tasks. This does not prove that developmental improvements on these tasks rely in part on maturational changes in DL-PFC, but it is consistent with that hypothesis.

2. Anatomical and Biochemical Evidence of Maturational Changes in PFC During the First Year of Life

Nerve cells consist of axons, dendrites, and a cell body. Dendrites, which branch off from the cell body, represent the largest part of the receptive surface of a neuron. In humans, the period of marked growth in the length and extent of the dendritic branches of pyramidal neurons in layer III of DL-PFC is $7\frac{1}{2}$ to 12 months (Koenderink et al. 1994), exactly coinciding with the period when human infants are improving on the A-not-B/delayed response and object retrieval tasks. Pyramidal neurons of this PFC region have a relatively short dendritic extent in $7\frac{1}{2}$ -month-old infants. By 12 months of age, they have reached their full mature extension. The surface of the cell bodies of these neurons also increases between $7\frac{1}{2}$ and 12 months (Koenderink et al. 1994). The level of glucose metabolism in DL-PFC increases during this period as well, and approximates adult levels by 1 year of age (Chugani et al. 1987).

Dopamine is an important neurotransmitter in PFC. During the period that infant rhesus monkeys are improving on the A-not-B/delayed response and object retrieval tasks (1.5–4 months), the level of dopamine is increasing in their brain (Brown and

Goldman 1977), the density of dopamine receptors in their PFC is increasing (Lidow and Rakic 1992), and the distribution within their DL-PFC of axons containing the rate-limiting enzyme (tyrosine hydroxylase) for the production of dopamine is changing markedly (Rosenberg and Lewis 1994).

Acetylcholinesterase (AChE) is an enzyme essential for metabolizing another neurotransmitter, acetylcholine. In humans, the pattern of AChE staining in DL-PFC changes dramatically during the first year of life (Kostovic et al. 1988).

3. Behavioral Evidence of Improvements in Cognitive Functions that Depend on PFC From Age 1–3 Years

This is the period for which we know the least about changes in PFC anatomy or in cognitive functions dependent on PFC. Kochanska et al. (2000) report that the ability to inhibit a prepotent response in order to perform a modulated or different response improves markedly from 22 to 33 months of age and that the consistency across their various measures of inhibition also increases between 22 and 33 months.

Using a lazy susan to bring a toy within reach requires relating the lazy susan and its movement to the toy and its movement. It also requires inhibition of trying to reach on a direct line of sight (as the younger children try to do) and inhibition of the tendency to push the lazy susan in the direction you want the toy to go (you must push left to get the toy to approach on the right). Children improve in their ability to do this between 12 and 24 months (Koslowski and Bruner 1972). Case (1992) similarly reports marked improvements on a simple balance beam problem between $1\frac{1}{2}$ and $2\frac{1}{2}$ years.

4. Evidence of Maturational Changes in PFC From Age 1–3 Years

Almost nothing is known about changes in prefrontal cortex during this period. AChE reactivity of layer III pyramidal neurons begins to develop at this time (Kostovic et al. 1988), but that is surely not the only change in prefrontal cortex between 1 and 3 years of age.

5. Behavioral Evidence of Improvements in Cognitive Functions that Depend on PFC From Age 3–7 Years

Clear improvements in tasks that require holding information in mind plus inhibition are seen between 3 and 7 years of age. Three-year-olds make an error reminiscent of infants' A-not-B error, but with a more difficult task. On this task, 3-year-olds sort cards

correctly by the first criterion (whether it is color or shape: Zelazo et al. 1995), just as infants and prefrontally lesioned monkeys are correct at the first hiding place, and just as adults with PFC damage sort cards correctly according to the first criterion (Wisconsin Card Sort test: Milner 1964, Stuss et al. 2000). Three-year-olds err when they must switch to a new sorting criterion, e.g., when cards previously sorted by color must now be sorted by shape, just as infants of 7½ to 9 months and prefrontally lesioned monkeys err when required to switch and search for the reward at the other location, and just as adults with PFC damage err when required to switch to a new sorting criterion. Although 3-year-old children fail to sort by the new sorting criterion, they can correctly state the new criterion (Zelazo et al. 1996), as is sometimes seen with adult patients who have sustained damage to PFC (Luria and Homskaya 1964, Milner 1964). Infants, too, sometimes indicate that they know the correct answer on the A-not-B task, by looking at the correct well, although they reach back incorrectly to the well that was previously correct (Hofstadter and Reznick 1996).

Another example of apparently knowing the correct answer, but not being able to act in accord with it is provided by work with 'go/no-go' tasks (Tikhomirov 1978, Livesey and Morgan 1991). Here, the participant is to respond to one stimulus but do nothing when shown another. Children between 3 and 4 years old repeat the instructions correctly, but they cannot get themselves to act accordingly; they respond even to the 'no-go' stimulus. By 5 years, they perform well on the card sort and go/no-go tasks.

The problem on the card sort task appears to be in (a) integrating two dimensions of a single stimulus (e.g., if children are used to focusing on whether stimuli are red or blue, they have trouble refocusing and concentrating instead on whether the same stimuli are trucks or stars) and (b) inhibiting the tendency to repeat their previously correct response. Similarly, children of 3 years have difficulty with 'appearance-reality' tasks (e.g., Flavell 1986) where, for example, they are presented with a sponge that looks like a rock. Three-year-olds typically report that it looks like a rock and really is a rock, whereas children of 4 or 5 years correctly answer that it looks like a rock but really is a sponge. The problem for the younger children is in relating two conflicting identities of the same object (e.g., Rice et al. 1997) and in inhibiting the response that matches their perception. Manipulations that reduce perceptual salience, by removing the object during questioning, enable children of 3 or 4 years to perform much better (e.g., Heberle et al. 1999).

'Theory of mind' and 'false belief' tasks are other tasks that require holding two things in mind about the same situation (the true state of affairs and the false belief of another person) and inhibiting the impulse to give the veridical answer. Here, as well, manipulations that reduce the perceptual salience

of the true state of affairs aid children of 3 to 4 years (e.g., Zaitchik 1991). Carlson et al. (1998) reasoned that pointing veridically is likely to be a well-practiced and reinforced response in young children, and that children of 3 to 4 years have trouble inhibiting that tendency when they should point to the false location on false belief tasks. Carlson et al. (1998) found that when they gave children a novel response by which to indicate the false location, children of 3 to 4 years performed much better.

Many of the advances of Piaget's 'preoperational' child of 5 to 7 years over a child of 3 to 4 years, who is in the stage of 'concrete operations,' similarly reflect the development of the ability to hold more than one thing in mind and to inhibit the strongest response tendency of the moment. For example, children of 3 or 4 years fail tests of liquid conservation (they do not attend to both height and width, attending only to the most perceptually salient of the two dimensions) and they fail tests of perspective-taking where they must mentally manipulate a scene to indicate what it would look like from another perspective and must inhibit the tendency to give the most salient response (i.e., their current perspective). By 5 or 6 years, they can do these things. Since part of the difficulty posed by Piaget's liquid conservation task is the salience of the visual perception that the tall, thin container contains more liquid, placing an opaque screen between the child and the containers before the child answers enables younger children to perform better (Bruner 1964).

In the 'delay of gratification' paradigm, when faced with the choice of a smaller, immediate reward or a later, larger reward, children of 3 to 4 years are unable to inhibit going for the immediate reward although they would prefer the larger one. By 5 or 6 years of age, children are better able to wait for the preferred reward (Mischel and Mischel 1983).

Between 4 and 5 years of age children show improvement on several tests in the CANTAB battery that are designed to assess frontal lobe function (Luciana and Nelson 1998). For example, their improved ability to retain temporal order information in memory is demonstrated by better performance at 5 years on (a) a test of spatial memory span that is similar to the children's game, Simon, or the Corsi block task (the child must touch boxes displayed on a computer screen in the order in which he or she just saw them change color); and on (b) a spatial self-ordered pointing task where the child must keep track of which squares he or she has already touched.

The 'day-night' task (Gerstadt et al. 1994) requires that children hold two rules in mind and inhibit the tendency to say what the stimuli really represent; instead they must say the opposite ('Say "night" when shown a white card with a picture of the sun, and say "day" when shown a black card with a picture of the moon and stars'). Children of 3½ to 4½ years find the task very difficult; by 6 or 7 years it is trivially easy. If

abstract designs are used as the stimuli, even children of $3\frac{1}{2}$ have no difficulty correctly saying 'day' to one and 'night' to the other (Gerstadt et al. 1994). Hence, the need to learn and remember two rules is not in itself sufficient to account for the poor performance of young children on the task.

Luria's 'tapping' test (Luria 1966) also requires (a) remembering two rules and (b) inhibiting a prepotent response, making the opposite response instead. Here, one needs to remember the rules, 'Tap once when the experimenter taps twice, and tap twice when the experimenter taps once,' and one needs to inhibit the tendency to mimic what the experimenter does. Adults with large frontal lobe lesions fail this task (Luria 1966). Children improve on the task over the same age range at which they improve on the day-night task (Diamond and Taylor 1996). Moreover, performance on the two tasks is correlated so that children whose performance on the day-night task is delayed or accelerated show a corresponding delay or acceleration in their performance on the tapping task (Diamond et al. 1997, Diamond 2001).

The 'counting span' and 'spatial span' tasks of Case (1972) require finding target stimuli, counting them or remembering their locations, holding that information in mind while finding target stimuli in new arrays, and keeping track of the answers computed on each trial so that they can be repeated back in order at the end. Thus, these tasks require temporal order memory and resisting interference from prior and interpolated activity. A meta-analysis of 12 cross-sectional studies revealed strong linear improvements on both tasks between $4\frac{1}{2}$ and $6\frac{1}{2}$ years (Case 1992). Performance on these tasks is highly correlated with performance on Piaget's 'balance beam' task, 'Raven's matrices,' and 'concept acquisition.' On the balance beam and Raven's matrices tests, 4-year-olds tend to answer accordingly to what is perceptually salient. By 7 or 8 years of age, they are able to take two dimensions, or two perspectives, into account and relate one to the other. They can mentally manipulate, combine, recombine, order, and reorder information.

6. Anatomical Evidence of Maturational Changes in PFC From Age 3–7 Years

The density of neurons in human DL-PFC is highest at birth and declines thereafter. At 2 years of age it is 55 percent above the adult mean, but by 7 it is only 10 percent above adult levels (Huttenlocher 1990). Thus there is a dramatic change in neuronal density in DL-PFC between the ages of 2 and 7. The synaptic density of layer III pyramidal cells in DL-PFC increases after birth and reaches its maximum at about 1 year of age; by 7 years of age the decrease in synaptic density is significant, though not yet down to adult level (Huttenlocher 1979). Another change during this period is a marked expansion in the dendritic trees of

layer III pyramidal cells in human DL-PFC between 2 and 5 years of age (Mrzljak et al. 1990). In addition, the density of neuropeptide Y-immunoreactive neurons in human DL-PFC increases between the ages of 2 and 4 years and 6 to 7 years (DeLalle et al. 1997).

7. Behavioral Evidence of Improvements in Cognitive Functions that Depend on PFC From 7 Years to Adulthood

Some abilities dependent on DL-PFC appear to reach their adult levels by about 11 years of age. The Wisconsin Card Sort test is one of the classic tests for studying PFC function in adults (Milner 1964, Stuss et al. 2000). Here, the participant must deduce the rule for sorting cards, which can be sorted by color, shape, or number. Children do not begin to reach adult levels of performance on this task until they are about 11 years old (Chelune and Baer 1986). Continuous, marked improvement is seen on the counting and spatial span tasks through age 8, and then improvement is less steep until performance asymptotes around 10 or 11 years of age (Case 1972, 1992). Pascual-Leone's tasks (the compound stimulus visual information and the digit placement tests) show similar developmental progressions (Pascual-Leone 1970, Case 1972). Hale et al. (1997) report that resistance to interference improves from 8 to 10 years, when it approximates adult levels.

Other abilities dependent on PFC continue to show improvement into adulthood. Zald and Iacono (1998) report that spatial working memory improves from 14 to 20 years of age. They found that 20-year-olds were significantly more accurate than 14-year-olds at indicating the location of an object in space using memory even after brief delays of only half a second. (There was no age difference in the ability to accurately indicate an object's location using visual feedback.) The improvement with age was in the ability to accurately get the information into working memory, not in the ability to hold it in mind for a longer period. Indeed, they found little difference over age in the rate of degradation of the memory.

Another task that requires precise spatial memory is the pattern span task (Wilson et al. 1987). On any given trial some of the squares in a grid pattern are filled and some unfilled. After a quick look, the participant is presented with the grid with one change; the participant is to find that change. Performance on this task improves dramatically between 5 and 11 years, when it reaches adult levels (Wilson et al. 1987).

Several bodies of work indicate that the ability to inhibit a prepotent response tendency continues to improve until early adulthood. In the 'directed forgetting' paradigm, participants are directed to forget some of the words they are shown and to remember others. Even children as old as roughly 11 years show more intrusions of the to-be-forgotten words than do

adults (e.g., Harnishfeger and Pope 1996, Lehman et al.). The 'anti-saccade' task requires the participant to suppress the tendency to reflexively look to a visual stimulus in the periphery, and instead look away in the opposite direction. It depends especially on the frontal eye fields, and the supplementary eye fields and DL-PFC (O'Driscoll et al. 1995, Luna et al.). Performance on the task improves continuously from 8 until about 20 to 25 years of age (Munoz et al. 1998, Luna et al. (in press)). Luna et al. (in press) report that while activation in the frontal eye fields, supplementary eye fields, and DL-PFC increased during anti-saccade performance in participants of all ages, increased activation of the thalamus, striatum, and cerebellum was seen only in adults, suggesting that the circuit connecting PFC with subcortical regions might mature late.

8. Anatomical Evidence that PFC is not Fully Mature Until Adolescence or Early Adulthood

One of the functions of glial cells is to provide an insulating sheath, called myelin, around the axons of neurons, which increases the speed of transmission of communication between neurons and which acts as an electrical insulator, decreasing lateral transmission and interference, thus improving the signal:noise ratio. Myelination of PFC is protracted and does not reach adult levels until adolescence (Huttenlocher 1970, Giedd et al. 1999). For example, using MRI and following the same children longitudinally, Giedd et al. (1999) were able to show that the amount of white matter (i.e., myelinated axons) increased linearly in frontal cortex from 4 to 13 years of age.

Portions of the neuron that are unmyelinated, such as the cell body, have a gray appearance. In their longitudinal study, Giedd et al. (1999) found that gray matter in frontal cortex increased until adolescence, reaching its maximum extent at 12 years of age for males and 11 years for females. However, in cross-sectional volumetric studies, Jernigan et al. (1991) and Sowell et al. (1999a) report *reductions* in gray matter volume between childhood and adolescence, with the most dramatic changes occurring in dorsal frontal and parietal cortex. Sowell et al. (2001) related these gray matter changes to cognitive performance and found that, between 7 and 16 years of age, gray matter in frontal cortex (which included in their analyses not only PFC, but motor cortex, and all cortex in between) decreased in size, and the ability to accurately remember which words had and had not been presented earlier (i.e., the ability to remember which words had been seen in the present context and to discriminate them from other familiar words) improved. Impressively, gray matter thinning in frontal cortex was significantly correlated with this source memory, independent of age. Indeed, while the relation between frontal cortex gray matter thinning and this ability

remained significant controlling for age, the relation between age and source memory was no longer significant controlling for frontal gray matter changes.

Synaptogenesis occurs concurrently with myelination. Huttenlocher (1979) reports that the synaptic density of layer III pyramidal cells in DL-PFC increases until about the age of 1 year, and then decreases, finally reaching adult levels at about 16 years of age. Huttenlocher and Dabholkar (1997) report that the formation of synaptic contacts in DL-PFC reaches its maximum after 15 months of age, and synapse elimination occurs late in childhood, extending to mid-adolescence for DL-PFC.

Developmental changes in PFC continue into adulthood. Sowell et al. (1999b) report a reduction in the density of gray matter in frontal cortex between adolescence (12–16 years) and adulthood (23–30 years). Kostovic et al. (1988) report that acetylcholinesterase (AChE) reactivity of layer III pyramidal cells in DL-PFC, which begins to develop after the first postnatal year, reaches its peak intensity in young adults.

A. Diamond

Prehistoric Art

As far as we know, people have been making objects, forms and images that we consider to be ‘art’ for at least 35,000 years and perhaps even longer. Some

claim that evidence of red ochre, as a kind of coloring material, indicates human engagement with artistic activities (such as body painting) for more than 200,000 years. Others have pointed to individual objects, dated to even earlier than that, which they are convinced were modified by ancient humans with an intent to represent something, suggesting that ‘art’ has long been a part of the cultural repertoire of humans, even of different biological species than we anatomically modern humans. And when most lay people learn that they are talking to an archaeologist, they inevitably ask, ‘What is the most fantastic thing you have ever found?’, hoping we will be able to tell them about a gold decorated necklace, a carved figurine, or magnificent painted jar: they want to know about ‘prehistoric art.’

1. Definitions

The very term, ‘prehistoric art,’ is difficult to define. Technically speaking, it refers to the ‘art’ made by prehistoric peoples; that is, by people in those societies without, and usually before the development of, written texts. There have in recent times been human societies without writing systems (nonliterate) and with what might be called ‘the arts,’ but these are more likely to be what we call ‘ethnographic arts’ because they are still ‘living’ arts and can be described ethnographically. There are some problems with the way in which the term ‘prehistory’ is used, including the implication that, without writing systems, prehistoric groups have no history, and experienced little change. But we know this is not the case at all, and that there are myriad ways other than in writing by which ‘history’ is reckoned, transmitted, and experienced. Also, in relation to the idea of ‘prehistoric art,’ there are some archaeologically known societies, such as the Maya or Egyptians, who had writing systems, but whose ‘arts’ are sometimes referred to as prehistoric or, more often, as ancient art. In fact, it is perhaps better to think of the arts that we are interested in as the archaeological arts, rather than prehistoric ones. With such a term, we realize we are dealing with the art(s) from past human societies that we study by using the wide range of archaeological methods, theories, and techniques.

Then there is the term ‘art,’ which is itself notoriously difficult to define. Furthermore, it is a term that has had differing meanings even within the last two centuries of Western scholarship and culture. Since the nineteenth century, ‘we’ in the Western tradition have associated the term, ‘art,’ with aesthetics and aesthetically-pleasing attributes; as something that is usually produced by specialists who are often considered to be gifted individuals with admirable degrees of creativity, and who are often separated from real-life, everyday activities. Our present-day notions of art include the idea that art is to be held in awe while, at the same time, the production

and products of art are embedded in the capitalist system, with economic as well as cultural value; art objects function in their own domain, that of high culture and aesthetics.

However, all this is unlikely to be applicable to the art-making and art images and forms that we are concerned with in prehistoric and archaeological contexts. It is a well-known truism in anthropology that in most cultures which have been studied ethnographically, there is rarely a word, or even a concept, equivalent to our word and concept, 'art.' It is not really possible to try to separate out 'art' from other aspects of cultural life, such as art as something distinct from religion, social relations, and/or politics. And yet there are images, forms, and cultural practices in other cultural contexts, both ethnographic and archaeological, that we acknowledge unproblematically as 'art,' mostly because, if they were produced by our own culture, we would classify them readily as art: cave and rock paintings, sculpted figurines or statues, decorated bronze goblets, and the like.

Is there a better term: visual culture? Material culture? Images? Representations? Material symbols? The term or label we use, such as 'art,' is not itself the real problem; what is more of an issue is that if we use such a term in our own sense, without recognizing its historical specificity, then what we mean by it is often left unexamined, and the analysis or interpretation of the phenomenon is led in certain directions because of the label. If what we have is 'art,' then there must be artists and aesthetic meanings. However, as Morphy (1999) has so eloquently noted: we need to develop a concept of art that 'neither distances the objects of other societies from Western cultures nor appropriates the object to European categories.'

Books that treat the topic of 'prehistoric art' as a single entity are rare; most book-length treatments are concerned with the art and imagery of specific regions (e.g., Keyser 1992; see also *Sub-Saharan Africa, Archaeology of*), time periods (e.g., Leroi-Gourhan 1967) or in specific media (Dowson 1992). In 1966, Powell authored an overview of prehistoric art, which was divided into four chapters: the art of the hunters, that of the cultivators, that of the metalworkers, and what he called the 'art of a barbarian nation,' referring to the Celts of Europe (Powell 1966). His coverage was limited to Europe, and he treated each 'kind' of art by apparent categories of 'lifestyle,' but it is just as much a book about the 'progress' of art from the Paleolithic period (the hunters), through the Neolithic (the cultivators), the Bronze and Iron Ages (the metalworkers), to the 'archaic state' (Celts). As such, he presents a now-problematic evolutionist view, a view of 'progress' through different chronocultural periods. Indeed, for much of the nineteenth and twentieth century, the ethnographic (and archaeological) arts have been embedded in a progressivist notion (Errington 1998); we used to talk unquestioningly of 'primitive art' (Price 1989).

More recently, Bahn (1998) has authored an illustrated history of prehistoric art, but it is almost exclusively about 'rock art,' with a short chapter on 'body art' and one on 'objets d'art,' or portable art (items that could circulate). He returns again and again to a baseline of the Ice Age imagery of Europe, although this book is an important source for appreciating that rock art—paintings, engravings, and petroglyphs on rock surfaces, rock shelters and in caves—is truly global in its distribution. Bahn's map of sites is a map of the world, while Powell's is one of Europe. This is indicative of a real shift of scope in our understanding and treatments of 'early art' and/or rock art from all times. As we will see below, the search for the earliest art has been one of the major preoccupations of many who study 'prehistoric art.'

2. How to Study Prehistoric Art

First, it is always important to recognize that the corpus of materials that we consider as 'prehistoric art' is certainly only a sample of what was made in the human past. There is always the problem of preservation, and that what we have in the present is only a sample of past artistic production. It is no coincidence that rock art, ceramic sculpture and decorated pots, metal objects, and images made out of ivory, bone, antler, shell, and beads of various sorts are some of the primary forms of prehistoric art. The wood, hide, basketry, cloth, netting and twining, feathers, and body art are rarely, if ever, preserved. If the arts of ethnographic groups are any indication, we have an impoverished archaeological sample of prehistoric visual and material culture.

But given the preservation of at least some portion of prehistoric artistic production, how do we then go about studying it? First, we need some theoretical or conceptual frameworks within which even to think about what the images and forms might be about, especially if we cannot directly apply our own notions of 'art,' artists, and aesthetics. Much of this has to come from related fields, such as the anthropology of art, the ethnographic arts, and art history. We need to draw on understandings of what visual and material representation is all about (e.g., Gombrich 1961, Bryson 1983), of symbolism (e.g., Geertz 1983), and of humans as materialists and symbolists (Conkey 1993); of how technology and materials are integral to the artforms (e.g., Lechtman 1984), of style (Conkey and Hastorf 1990); and of the social contexts and production of art (e.g., Wolff 1981), and of the 'social life of things' (e.g., Appadurai 1986). Studies of 'art' in ethnographic contexts (e.g., Morphy 1991), general overviews of the anthropology of art (e.g., Layton 1981), and ethnoarchaeological studies (see *Ethnoarchaeology*) provide important resources.

Second, we need to recognize the importance of the archaeological context of the so-called art forms, and

we need to take context into consideration when we try to interpret or understand the meanings, uses, or even the making of the art. Do the preconceptions that female figurines—from about 7,000 years ago from sites in such places as southeast Europe—are objects of worship and a female-centered world change when we recognize that some, if not many, of the figurines have been recovered from trash deposits, often broken? Are the Ice Age paintings of southwestern Europe found deep in caves, away from daylight, comparable to those found on daylight shelters? Is there a difference in the uses and meanings between objects found in everyday places and living sites, and those found in architectural structures that are so different in size, form, and location that they must be other-than-'houses'? The individual images and objects may well take their specific meanings from the locations where they were made and/or found, or from the other artifacts or structures with which they are associated.

We can use the most up-to-date techniques and methods, especially those of materials science, to make inferences about the images and objects: we can identify the sources of the raw materials, such as clay, stones, or pigments, which in turn can inform on trade, exchange, circulation of goods, and the social relations that effect such practices. We can identify different ways in which pigments were processed by Ice Age cave 'artists' in Europe (e.g., Clottes 1993), and therefore suggest the social relationships that must have obtained in order to have images in different sites made by the same pigment 'recipes.' We can show how certain fibers were used to apply pigment in Australian rock paintings (e.g., Cole and Watchman 1992). We can infer the stages of manufacture of metal earspools (e.g., Lechtman 1984) and how these stages resonate with other cultural principles and practices. We can use infrared photography to 'see' color and images that have long since faded away. We can use high powered microscopic analysis to detect the precise strokes of a stone tool on the surface of a bone object; from such analyses have come the suggestion that lunar calendars may have been made at least 15,000 years ago (Marshack 1991). These are just a few examples of how our increasingly sophisticated methods of materials science that are common in the analysis of other archaeological materials can be applied to the study of prehistoric art images and objects.

Both of these approaches—knowing the archaeological contexts of the art, and the application of scientific techniques—have featured prominently in the increasing ability to date many objects and images. It has long been the case that objects that are found in stratigraphic context—that is, in the geological/archaeological layers of an archaeological site—can, if excavated and recorded carefully, be attributed to at least a relative date (see *Chronology, Stratigraphy, and Dating Methods in Archaeology*). They can also be given more secure dates if other artifacts or materials

in the same stratigraphic layer are suitable for some of the many techniques of archaeological or chronometric dating (see *Archaeometry and Chronology, Stratigraphy, and Dating Methods in Archaeology*). However, many art forms, such as rock art or objects that are unfortunately out-of-context, cannot be dated in this associative manner. And many of these images themselves cannot be dated at all, although recent advances have changed this somewhat. Earlier generations of scholars, for example, dated all the cave art of Europe or the varying rock art styles of Australia by means of stylistic criteria, often based on assumptions as to what 'ought' to be earlier image-making and what 'ought' to be later. At the same time, many researchers were reluctant even to consider the art as a subject worthy of archaeological study, primarily because it could not be dated (see Whitley and Loendorf 1994).

That much art cannot be dated has, in combination with the fact that the interpretation of art is never straightforward (if only because it is the product of symbolic cultural practices that are not easily comprehended through the usual archaeological methods), led many archaeologists to dismiss art and images as viable archaeological data. This has been the case especially when it comes to objects and images from many thousands of years ago, where there are no real historic links between the archaeological 'cultures' and those known ethnohistorically or ethnographically, where there is no direct historical method that can be applied (see *Theory in Archaeology*). Some have suggested that the recent explosion of interest in the global study of rock art is due, in part, to new dating methods that have allowed researchers to begin to date imagery with more security. For this genre of prehistoric art—rock art—the most important new technique has been the development of accelerator mass spectrometry (AMS) carbon-14 dating, which can be done using a very minute sample of material, thus not destroying a painting or image, although it can only be used if there are organic materials in the pigments, such as charcoal (see *Archaeometry*).

3. Some Major Questions

At least two major questions come to mind when we sit down to address the subject of prehistoric art: first there is the question of the origins or the 'birth' of art; second, there is the challenging issue of how we can interpret the art and approach what it might mean. Until recently, it was thought that the cave paintings and other arts of the Upper Paleolithic period (c. 30,000–10,000 years ago) in Europe comprised the 'first' art, even though images from ancient cultures had been found all over the globe (see Bahn 1998 on the 'discovery' of prehistoric art). This was a compelling idea because there were many different caves

with images and many other objects and art forms; because it seemed to be associated with the earliest evidence for anatomically modern humans—our own species, *Homo sapiens*; and because it was in Europe, which allowed for the idea of a continuous tradition of art—a crucial essence of what it means to be human—from deep prehistory up into the twenty-first century.

However, work during the last few decades of the twentieth century has undermined seriously the idea that there is any single ‘birthplace’ of art: both southern Africa and Australia have yielded rock art images that can be attributed to the same general time period as the European Paleolithic imagery. And there are those who point to more isolated finds (see Bahn 1998, pp. 86–7), although many are debated hotly as being ‘art’ or intentional representations at even earlier dates. And we now recognize that anatomically modern humans have a deeper history, perhaps as much as 200,000 years longer, than previously thought (see *Sub-Saharan Africa, Archaeology of*). However, the exact nature of the relationship between being anatomically modern and the appearance of representational and/or symbolic imagery is hardly resolved, but the fact that this kind of imagery appears in multiple locations, in varying forms and amounts, calls for a more contextual approach: what is it about life and social relations at these times that set a context within which ‘art’—at least in more durable forms that have been preserved—became a part of cultural practices? While the search for ‘the origins’ of many phenomena in the human past is always a seductive question, as far as prehistoric art is concerned, it is now clear that there was no single ‘center’ for art-making, but that the preserved evidence around the globe attests the engagement of ancient humans with materials, images, and technologies (of working stone, of coloring materials, etc.) for cultural purposes that still elude us.

And thus, the final, but most difficult question is the interpretive one: how can we infer some (if any) of the meanings of prehistoric art? This question is both the most difficult and most complex question, and what everyone wants to know. Since all of archaeology is interpretive, while drawing on as much empirical evidence as possible, and since human behavior is so multivocal, with so many potential meanings and ambiguities, it is unlikely to expect a single answer, a single interpretation. Even in known or ethnographic contexts, the so-called meaning of art-making or of the art itself is ever-shifting, contextual, and multiple, dependent upon viewers, users, makers, and situations. Do we assume that prehistoric peoples were somehow ‘simpler’ and therefore a (simple) single account can suffice?

Despite the complexity of the challenge, there are some things that we can say about interpreting prehistoric art. In some instances, we can infer information clearly about clothing from human depictions, about activities as depicted in ‘scenes,’ preferred

symbols or forms, and what kinds of object were traded or used in certain contexts. In other instances, we can advance general theories, such as the role of shamans in making images that derive from their visions (e.g., Lewis-Williams and Dowson 1989, Turpin 1994), such as the ways in which ritual landscapes were created with artforms and megaliths, such as the idea that some arts appear to be ‘about’ interpersonal social relations, whereas other arts appear to be ‘about’ maintaining the corporate entity (e.g., Layton 1985). While we are unlikely ever to fix, with certainty, what a particular picture or object ‘meant,’ recent past decades have witnessed enormous gains, thanks to the application of scientific techniques, the innovative and expanded theories for interpretation, and a more widespread recognition that the archaeological arts are just as crucial to our understanding of past societies as are other kinds of archaeological data.

M. W. Conkey

Prejudice in Society

Prejudice is defined as cognitive beliefs, affects, and discriminatory behaviors towards members of a group on account of their membership to this group. When race, other groups, sex, or sexual preferences, for instance, are the targets of prejudice, it will be labeled racism, ethnocentrism, sexism, or homophobia. Many authors add that prejudice relies on undue generalizations and is irrational. Such addition implies that one knows what the objective truth is. It also overlooks the sophisticated ways that prejudice can take.

1. Classical Explanations

Personality was one of the first explanations to be proposed. After World War II, researchers explained fascism, ethnocentrism, and antisemitism by socialization (Adorno et al. 1950). Because children were obliged to obey parental authority blindly and to repress their hostile ideas, they later had to find scapegoats as a source of catharsis and represented the world into simplified categories: the good and the bad ones. This 'right-winged' authoritarian personality later was expanded to include all dogmatisms (Rokeach 1960). Whether authoritarian or dogmatic, personality cannot explain rapid changes in prejudice. Moreover, it is unable to account for regional differences in prejudice and it is mute about why certain groups, but not others, are the targets of prejudice.

Other psychologists influenced by behaviorism and psychoanalysis proposed a general theory of aggression that focused on situations (Dollard et al. 1939). According to them, aggression was a necessary consequence of frustration, and frustration was the neces-

sary and sufficient antecedent of aggression. Applied to prejudice, this theory predicted that socio-economic factors (e.g., the price of cotton) would be determining in eliciting aggressive discriminatory behaviors (e.g., lynching of Blacks in the US). Besides being unfalsifiable, this theory is not better than personality ones in order to predict which group will be selected as a scapegoat.

Lack of contact was a third explanation (Allport 1954). It played a crucial role when the US Supreme Court ruled segregation in schools illegal. Socio-psychological experts testified that prejudice was due to lack of contacts between the groups. These psychologists were not naive to the point of thinking that contact *per se* was sufficient to eliminate prejudice. They listed a series of conditions under which contact would be effective. Unfortunately, in everyday life, these conditions are sometimes difficult to meet, such as contact restricted to atypical members of the stigmatized group and collaborative institutional environment. That will be discussed under different headings later on, but lack of contact is still a predominant explanation of prejudice. Sherif (1966) was one of the opponents to the contact hypothesis. For him, life is a competition for scarce resources and mere contact will render competition even harder. In order to be successful, Sherif argued, reduction of tension depends on supra-ordinate collaboration, that is, a collaboration that needs the efforts of the two otherwise competing groups.

In reaction to Sherif's conceptualization, proponents of Social Identity Theory stressed the fact that resources need not be real to induce conflict (Tajfel 1981). Symbolic resources may suffice. For these theoreticians, mere categorization into groups will lead to ethnocentrism, also called in-group favoritism bias, if the latter brings out a positive social identity to the discriminators.

2. Modern Forms of Prejudice

Prejudice or at least its expression has decreased over the years. When the measure of stereotypes, that is, measure of general beliefs about groups' behaviors and personality, was discovered in the early 1930s, it was a good thing for white Americans to express negative stereotypes about African-Americans. Whites gave more negative stereotypes about African-Americans when responding publicly than when answering anonymously. Now, the targets of open prejudice or stereotypes become rarer although they still exist (e.g., integrists). Such a situation does not mean that prejudice has disappeared. According to the authors, it is either the form or the conditions of expression that have changed. Here, we review briefly the different conceptualizations (see Dovidio and Gaertner 1986).

The most pessimistic view is probably the one of symbolic racism. For its proponents, prejudice has

remained the same but its expression has become subtler because of the pressure from the society. The most optimistic view is represented by regressive racism, which suggests that prejudice has decreased but that it comes again to the surface in stressful situations. Between these two extremes, aversive racism defends the idea that people persuade themselves that they are not prejudiced and try to rationalize what could be considered prejudiced in their behavior. Under the label of ambivalent amplification racism, other theoreticians hypothesize that people have ambivalent feelings about others. According to the circumstances, these ambivalent feelings are amplified either towards the absence of prejudice or towards its expression.

In fact, prejudice itself may take ambivalent forms. To the same extent that sociability and competence are the two dimensions organizing person perception, they may also guide the perception of groups. Groups may be perceived as likeable but incompetent (e.g., housewives) or they may be considered competent but unlikable (e.g., feminists). Competence would be triggered by the status of the group in the society (e.g., feminists are perceived as intellectuals). Likability, on the other hand, would result from the outcome dependence between the dominant and the dominated groups in society (e.g., the males 'need' housewives). Because of these differences in the perception of groups, people will try to explain them. The most radical explanation is to attribute them a different (genetic, cultural, linguistic, religious) essence. Because group members are all and foremost concerned with their in-group, they will attribute to it the human essence. It follows that they will attribute an infrahuman essence to 'others.' This infrahuman essence is characterized by a lack of typically human attributes. According to the circumstances, these deficient attributes can be the intelligence, the language, some typically human emotions such as love or sorrow, etc. (Leyens et al. 2000).

Finally, to the same extent that lack of contact was thought to reduce prejudice, many authors have argued that lack of cognitive resources may facilitate the expression of prejudice. All people know the negative stereotypes held by different groups and many do not share them. However, when they are overloaded by a demanding environment and in need of cognitive capacities, they may let prejudice leak. Such perspective makes a clear distinction between beliefs or stereotypes, on the one hand, and prejudice on the other (Devine 1989). It is obvious that, in normal circumstances, the attribution of an infrahuman essence is only possible under lack of cognitive control. In war times, on the contrary, this attribution often constitutes a conscious strategy.

Besides their differences, these different conceptualizations share one common point. Increasingly, prejudice is considered less a reaction against some other groups of individuals but more a measure of

protection of the in-group. In general, people are less concerned by the other groups than by the well being of their own group.

3. *Implicit and Explicit Measures of Prejudice*

Prejudice typically was measured by questionnaires. To give but one example, the 'social distance scale' proposed different items of the form: 'I would accept a member of X (the group concerned) in the country, in the street, at work, as a friend, as a member of my family, etc.' A response at one level (e.g., at work) implied acceptance of the lower levels (e.g., country and street). As the expression of prejudice changed, its measures had to be adapted. From being blatant, questionnaire items have become more subtle but it is still easy to guess their purpose and, therefore, to control one's answers. These questionnaire measures are called explicit.

Some behaviors are obviously a more valuable source of information than questionnaires. Prosocial behaviors in the street or hiring rates in high-status positions on the job market may be taken as valid indicators of nonprejudice.

Laboratory implicit measures have also proliferated. Some of these measures have the advantage that the participants to the studies are not at all aware of what is measured. For instance, participants have to decide whether the string of letters they see on the screen of a computer is a word or a nonword. Among the words there are some positive or negative words. Before the presentation of some of the words, a social category is primed subliminally. The typical finding of such procedure is that the reaction times will be shorter for positive words when the social category is liked and for negative words when the social category is disliked.

The problem still to be solved concerns the correlations between these different measures. The questionnaire measures usually correlate highly between them. They rarely correlate, however, with behaviors and implicit measures. Also, different implicit measures do not necessarily correlate between themselves, which means that they probably measure different aspects of prejudice.

4. *Automatic and Controlled Prejudice*

The pervasive expression of prejudice and the development of implicit measures have launched an important and provocative debate about automatic vs. controlled behavior. One is reminded here of the unconscious in psychoanalysis.

Not long ago, most social psychologists believed that people made errors in their social judgments and, therefore, showed prejudice because they were unmotivated or incompetent to attend correct infor-

mation. Intelligence (or information) and effort were thought to be able to counterbalance these 'errors.' At present, some researchers do not hesitate to claim that people's first reactions are automatic and that neither abilities nor motivation can help. Automaticity does not imply inevitability of prejudice. It only means that people with prejudice will show it in their first reactions no matter how hard they try not to.

Automatic behavior will also depend on what is activated. A Black person is not only Black; she may also be tall, attractive, a physician, a woman, etc. The activation of the concept 'woman' may induce seduction. The activation of 'physician' may lead to help-seeking behavior. Among many persons, however, there is a limit to this flexibility. A lot of individuals will see a physician when this Black physician brings good news, and they will see a Black person when the physician is the bearer of bad news.

This link between a category and its attributes has implications. Active suppression of a category (e.g., skinhead) may, paradoxically, lead to a rebound effect. Stated otherwise, people who are instructed not to think of someone as a skinhead may, later on, perceive him as more prototypical of a skinhead. Indeed, by an ironic process, the monitoring of 'not-thinking-skinhead' activates attributes pertaining to the category. When the suppression is abandoned, all the activated attributes pop up; it is the rebound effect.

Up to now, we have reasoned as if activation of a category and of its attributes always led to an assimilation process (i.e., prejudice). It is true that people who are primed with the concept of professors do better at a Trivial Pursuit game than those who have been primed by the concept 'hooligan.' Priming specific exemplars of a category, like Einstein, may lead to a contrast effect. Indeed, everyone realizes that they are not Einstein and far from resembling him. This example leads us naturally to the attempts at reducing prejudice.

5. Reduction of Prejudice

One can distinguish between two approaches in the studies that looked at the reduction of prejudice. One approach focuses on information about individuals and the other concentrates on categorical representation of the world.

5.1 The Focus on Individuals

This approach relies mostly on the intellectual (and somewhat emotional) abilities to take into account evidence contradictory with one's prejudice. Three models have been proposed as possible ways to reduce prejudice:

5.1.1 The conversion model. According to this model, which could also be called the Sidney Poitier or Mandela model, the encounter with a very atypical member of a disliked category could provoke a conversion that would generalize to the whole category. Although anecdotal evidence is not lacking in favor of this model, no experimental demonstration has yet succeeded.

5.1.2 The book-keeping model. For the proponents of this model, people would integrate the different pieces of information that they receive from various members of the stigmatized group and that contradict their beliefs. Reduction of prejudice would be proportionate to the contradicting information. Empirical evidence in support of this model exists but it is not overwhelming.

5.1.3 The subtyping model. When confronted with contradicting information, people would try to subcategorize the exceptions in order to maintain their representation of the whole category intact. 'These women are unemotional; but they are not real women, they are businesswomen.' Needless to say that this strategy is often used.

5.2 The Focus on Categories

It is not surprising that this approach has been more elaborated than the previous one by psychologists because it goes back to the definition of prejudice, that is, reaction against individuals because of the category they belong to.

5.2.1 Decategorization. The early proponents of the contact hypothesis were members of the human relations movement and believed that solutions to conflicts would come from considering anybody as an individual rather than part of a given category. In spite of the disaster brought up by the compulsory desegregation of schools in the US, decategorization can be effective in eliminating the in-group favoritism bias.

5.2.2 Recategorization. It is often unrealistic to transform group members into mere individuals. Supporters of recategorization inspired themselves of Sherif's (1966) superordinate goal. This goal could only be achieved when all parties put their forces together and create some kind of new entity. Re-

categorization also eliminates the in-group favoritism bias, but it does it differently and more advantageously than decategorization. Whereas decategorization brings the attraction to the in-group down to the level of the out-group, recategorization carries the attraction of the out-group up to the level of the in-group. Recategorization transforms the 'we' and 'they' into 'us.'

5.2.3 Cross-categorization. It is said that Belgium never had bloody conflicts despite its history of linguistic problems because language was not the only divider in the country; religion and political orientations also played a role. Language cross-cuts religion and ideology. The problem with cross-categorization is that some people will find similarities with the other side, but that others will be completely different.

5.2.4 Harmonious differentiation. European researchers especially are aware that it may be neither feasible nor desirable to get away with categories. Some of them defend a blend of decategorization while at the same time proposing means to respect existing categories. This stream of research is still in need of convincing results.

6. The Targets' Reactions to Prejudice

Members of stigmatized group may suffer from prejudice and react to it in different ways (Crocker et al. 1998). When treated badly, for example, some may prefer to attribute the situation to discrimination rather than to their misconduct. Such a solution preserves their self-image. Others prefer to condemn their own behavior because this behavior can change whereas they will remain forever in their stigmatized group. The conditions that stir up the first or the second reaction are not yet well known.

Another solution is to find innovative ways to affirm a valuable identity. A typical example is the case of the African-Americans who invested in sport when the slogan 'Black is beautiful' lost its momentum. Simultaneously to this investment in a new domain, members of stigmatized groups may disengage themselves from goals that are denied to them. School or work may become unimportant for some of them. Indeed, very often, immigrants' children do poorly in school and their peer group is likely to disavow those who do well.

Besides the lack of social support, the atypical members of stigmatized groups suffer an additional burden in competitive situations like exams or job interviews. Not only do they feel the anxiety linked to the situation, but they have the additional anxiety to demonstrate that they are atypical of their group. It is,

for instance, the case of women and mathematics, or of children from poor families and school achievement in general. In a way, it is a fulfilling prophecy.

Pre-motor Cortex

The frontal lobe of primates is formed by two large regions, a rostral region involved in cognitive functions (prefrontal lobe) and a caudal one devoted to motor functions. Histologically, the caudal region is

characterized by the absence of granular cells. It is referred to also as the agranular frontal cortex (AFC). The AFC consists of two main sectors: area 4 (the primary motor cortex) and area 6. Recent data showed that area 6 is neither anatomically nor functionally unitary, but is formed by a mosaic of independent 'premotor' areas (see He et al. 1993, Rizzolatti et al. 1998). The aim of the present article is to review the general organization of the premotor areas in monkeys and to discuss in detail the operations of two of them. A comparison between the monkey and human premotor cortices will be made in the last section.

1. The General Organization of the Premotor Area: Classes and Connectivity

The existence of a cortex with motor functions lying rostral to the primary motor cortex (the 'premotor cortex') has been postulated since the beginning of the twentieth century. However, following the stimulation studies of Woolsey and Penfield, the prevalent view was that AFC functionally consists of two large motor areas: the 'primary motor cortex' located on the lateral brain convexity (MI) and the 'supplementary motor area' (SMA) located on its mesial surface (see Porter and Lemon 1993). Anatomical and functional evidence collected from 1980–2000 showed that this view is incorrect. The AFC is formed by seven independent areas (F1–F7). F1 corresponds to the Brodmann area 4 (the 'primary motor cortex'); the other areas are located within the Brodmann area 6 (the 'premotor areas'). This new subdivision of the AFC is shown in Fig. 1.

The premotor areas can be subdivided into two main classes: areas that receive their predominant cortical input from the parietal lobe (parieto-dependent premotor areas) and areas that receive their predominant cortical input from the prefrontal and the cingulate cortex (fronto-dependent premotor areas). Areas F2, F3, F4, and F5 belong to the first class, areas F6 and F7 to the second (Rizzolatti et al. 1998).

The organization of corticospinal projections is in accord with this subdivision (He et al. 1993). The parieto-dependent areas have direct access to the spinal cord, whereas the fronto-dependent areas send their output to the brain stem. Furthermore, the parieto-dependent areas have direct connections with F1, whereas the fronto-dependent areas lack this link.

Within the parieto-dependent group of premotor areas, each area is the target of a different set of parietal areas. Typically, each premotor area receives strong afferents from one parietal area. Conversely, each parietal area projects predominantly (but not exclusively) to a single premotor area. Thus, the parietal and premotor areas form a series of ana-

Figure 1

Frontal lobe of the monkey brain. The mesial and the lateral surfaces are shown in the upper and lower part of the figure, respectively. Dotted lines indicate the borders between the various areas forming the agranular frontal cortex (F1–F7). Area F1 roughly corresponds to area 4 of Brodmann. Some authors refer to areas F2 and F7 as caudal and rostral dorsal premotor cortex, respectively. Areas F4 and F5 are also collectively referred to as ventral premotor cortex.

tomical circuits largely independent one from another. The functional correlate of this anatomical organization is that each parieto-premotor circuit is dedicated to a specific sensorimotor transformation (see Rizzolatti et al. 1998). The result of this operation is the generation of a 'potential motor action,' that is of a representation of an action that may or may not be executed.

The fronto-dependent premotor areas (F6 and F7) have only weak connections with the parietal lobe. F6 is mostly connected with the prefrontal area 46 and the rostral cingulate cortex (area 24c). F7 is richly connected with the dorsal sector of the prefrontal cortex. The functions of prefrontal and cingulate areas are much less known than those of the parietal cortex. There is consensus, however, that these areas are not involved in the analysis of sensory stimuli, but rather

play a role in cognitive functions such as working memory, temporal planning of actions, and motivation. It is clear, therefore, that the functions of the fronto-dependent premotor areas ought to be different from those of the parieto-dependent ones. The hypothesis presented here is that the fronto-dependent premotor areas relay information on the individual's motivations, long-term plans, and memory of past action from the prefronto/cingulate cortex to the parieto-dependent premotor areas. On the basis of this information, the potential motor actions, formed in the posterior premotor areas, are either executed or not.

2. The Parieto-dependent Premotor Areas (Fig. 1: F2, F3, F4, and F5)

As a model of information processing of the parieto-dependent areas, the functional properties of one of them (area F5) will be reviewed in some detail (see Rizzolatti et al. 1999). The properties of the other parieto-dependent areas will only be dealt with in short.

2.1 Area F5

Area F5 occupies the rostroventral part of the AFC (Fig.1). Its electrical stimulation evokes hand and mouth movements. F5 neurons typically discharge in association with goal-directed motor actions, such as object grasping, holding, tearing, and manipulating. The neuron firing correlates with specific actions (e.g., grasping) or action segments (e.g., hand opening, hand closure during grasping) rather than with the individual movements forming the action. Most of the F5 neurons code specific types of hand prehensions such as precision grip or whole-hand prehension.

A considerable part of F5 neurons respond to visual stimuli. Visually responsive F5 neurons fall into two classes: 'canonical neurons' and 'mirror neurons.' Canonical neurons discharge to the presentation of 3-D objects. Typically, their response is also present when there is no subsequent action on the presented object. Most canonical neurons are selective for one or a small set of visual objects similar in size and shape. Typically, the visual selectivity is congruent with the motor selectivity. A neuron that is selective for precision grip responds also to the presentation of small, but not of large objects. Mirror neurons do not discharge in response to object presentation but to action upon objects (see Sect. 2.2).

The parietal area that predominantly sends its input to area F5 is the anterior intraparietal area (AIP). Neurons of this area have been subdivided into three main classes: 'motor dominant,' 'visual dominant,'

and 'visual and motor' neurons. 'Motor dominant' neurons are functionally similar to F5 motor neurons. Like F5 neurons, their discharge is associated with actions rather than individual movements. Often they are selective for object size, shape, and/or orientation. 'Visual dominant' neurons are active only when the task is performed in light, but not in dark. They respond also to object presentation in the absence of movements. Many of them are selective for size, shape, and/or orientation of 3-D objects. 'Visual and motor' neurons discharge in both light and dark, but less in the last condition. Like F5 canonical neurons, 'visual and motor' neurons show congruence between their visual and motor properties (Sakata et al. 1995).

From this summary of the AIP neuron characteristics, it is clear that the AIP and F5 have many functional properties in common. There are, however, also some important differences between the two areas. First, in F5 there are no 'visual dominant' neurons. Second, purely motor neurons are much more frequent in F5 than in the AIP. Third, most AIP neurons discharge during the whole action leading to the grasping of objects, being active often also during object holding. By contrast, most F5 neurons are active only during a specific phase of the grasping/holding action, not during the whole action.

On the basis of these findings and inactivation data, it has been proposed that areas AIP and F5 form the key elements of a circuit that transforms visual information on intrinsic (physical) properties of objects into grasping movements (Jeannerod et al. 1995). The following model has been proposed to explain how this transformation occurs.

AIP neurons code visual information on the object's intrinsic features. This information is then sent to specific sets of F5 neurons that transform the received information into potential hand movements appropriate to the size, shape, and orientation of the presented object. In turn, F5 neurons transmit this information to F1 (and the spinal cord) for movement execution. The movement occurs, however, only if there is a concomitant 'go' signal coming from the fronto-dependent premotor areas.

Objects can be grasped in different ways according to the use one wants to make of them. Because different AIP neurons are selective for different object features, F5 receives a multiple descriptions of each seen object from the AIP. The decision on how to grasp that object is determined by the motivations of the acting agent. This decision comes from the fronto/cingulate cortex and reaches the AIP via F5. Thus, a corollary discharge from F5 activates the AIP. In this view, the AIP 'visual and motor' neurons are memory neurons that maintain the representation of the selected object feature active during the entire execution of movement. Finally, the 'motor dominant' neurons would represent an intermediate stage in the transmission of F5 corollary discharge to the AIP 'visual-and-motor' neurons.

2.2 Mirror Neurons

F5 mirror neurons are neurons that discharge when the monkey makes a specific hand action and when it observes another individual making a similar action. The simple presentation of 3-D objects does not activate them. Similarly, the observation of actions that are not directed toward an object, or the observation of actions made using tools, fail to activate them (for a review, see Rizzolatti et al. 1999).

The visual and motor properties of mirror neurons are usually congruent. A neuron that discharges when the monkey grasps an object discharges also when the monkey observes another individual making the same action. In some neurons the way in which the object is precisely grasped does not matter (broad congruence). Other neurons fire only if the observed action is identical to that coded by that neuron (e.g., executed precision grip and observed precision grip; strict congruence).

There is evidence that mirror neurons are mostly located in the caudal part of F5. This sector is anatomically connected with parietal area PF, where, unlike in area AIP, there are neurons with mirror properties. It appears, therefore, that mirror neurons are part of a parieto-premotor circuit separate from that of canonical F5 neurons.

The discharge evoked by the observation of actions is most likely, as in the case of canonical neurons, not a pictorial description of the stimuli, but the motor representation of the action coded by the neuron. However, while canonical neurons use this representation to guide successive motor actions, this is not true for mirror neurons. This, obviously, raises the question of what this motor representation is for. Monkeys, unlike humans, are unable to imitate hand actions. Thus, the imitation hypothesis can be ruled out (at least for hand F5 neurons). The most accepted interpretation of mirror neuron activity is that it is used for action understanding. The assumptions underlying this hypothesis are: (a) individuals understand actions made by other individuals because they are able to react to them internally; and (b) the individuals know the outcome of their actions.

In conclusion, mirror neurons data indicate that the parieto-premotor circuits intervene in higher order cognitive functions and, very interestingly, that the same mechanisms that are at the basis of sensorimotor transformation underlie cognitive functions.

2.3 Areas F2, F3, and F4

Area F2 forms the caudal part of superior area 6 (Fig. 1). F2 receives a rich somatosensory input from area 5. Its ventro-rostral sector also receives visual information from the parietal areas MIP (medial intraparietal area) and V6A (see Rizzolatti et al. 1998). The dorsal part of F2 is related to hind limb movements, whereas the ventral part is related to forelimb

movements. Single neuron studies of the arm field showed that some F2 neurons discharge during the preparation of reaching movements, others during movement execution. F2 neurons code the direction of reaching movement rather than a specific position in space (Weinrich et al. 1984). It is likely that F2 uses information on limb position in order to organize (and/or control) appropriate limb trajectories.

Area F3 (or SMA proper) is located on the mesial cortical surface. Its main input originates from somatosensory parietal areas (mostly mesial area 5). F3 contains a complete representation of body movements, with a prevalence of axial and proximal, arm and leg, movements. Electrical stimulation of F3 frequently evokes complex movements, involving both proximal and distal joints. Single joint movements are rarely evoked (Luppino et al. 1991). It has been proposed that F3 uses the knowledge of actual limb position to prepare the posture necessary for the incoming movements, thus playing a fundamental role in predictive postural adjustments. SMA also appears to contribute to the initial stages of the learning of motor sequences improving their performance (Hikosaka et al. 1999) and, according to others, in the execution of certain motor sequences (Tanji 1994).

Area F4 forms the caudal part of inferior area 6. F4 receives its main input from the ventral intraparietal area (VIP), a parietal area that contains visual and bimodal, visual and tactile, neurons. Electrical stimulation of F4 evokes mostly head and proximal arm movements. One of the most interesting characteristics of F4 is the presence of neurons with tactile and visual receptive fields. The tactile receptive fields are typically large and located on the face, arms, and chest. The visual receptive fields are limited in depth and are located in the space immediately around the animal. They are registered with the tactile fields. The visual receptive fields remain anchored to the tactile fields regardless of the eye and the body part position. These properties show that the F4 visual receptive fields are coded in egocentric coordinates. It has been suggested that F4 plays a crucial role in reaching movements, transforming spatial locations coded in egocentric coordinates into movement directed toward those locations (Graziano et al. 1994, Fogassi et al. 1996).

3. The Fronto-dependent Premotor Areas (F6, F7)

3.1 Area F7

Very little is known on the functional properties of area F7, except for its dorsal sector where eye movements are represented (supplementary eye field, SEF). The SEF is connected with the frontal eye field and other centers controlling eye movements. In contrast to the SEF, the F7 ventral part is linked to the premotor areas controlling body movements. In both

the SEF and ventral F7 many neurons respond to visual stimuli. The precise role of F7 in motor control is unknown.

Interestingly, joint ablation of F7 and (rostral) F2 determines a profound deficit in learning arbitrary stimulus-movements associations. This finding stresses once more that the premotor areas are involved in cognitive, as well as motor functions (Passingham 1993).

3.2 Area F6

Area F6 (or pre-SMA) corresponds to the rostral part of the SMA of Woolsey and Penfield. Motor responses can be evoked from it only with rather high current intensities. Typically, they consist of slow, complex arm movements (Luppino et al. 1991). Visual responses are common in F6, while somatosensory responses are rare. F6 neurons, recorded during active arm movements, show frequently a long leading activity preceding movements (Tanji 1994).

Studies carried out in a naturalistic condition where monkeys interacted with objects presented close to and far from them, showed that F6 neurons exert a global control on arm actions, rather than firing in association to specific, distal (like F5), or proximal (like F4) actions. Some discharge at visual presentation of graspable objects independent of their location, but increase their firing as the stimulus moves toward the monkey. Others, on the contrary, are inhibited at the presentation of the graspable objects, but start to discharge as soon as an object is brought close to the monkey. Summing up: there are several facilitation/inhibition combinations that characterize different F6 neurons. What appears to be constant is the modulation of the neuron discharge according to whether an object can or cannot be grasped (see Rizzolatti et al. 1998).

Recent data showed that F6 plays an important role in the early stages of motor learning, precisely when the cognitive aspect of the procedure to be learned is acquired. This conclusion is based on the behavior of single neurons and on inactivation experiments showing that the number of errors for learning new sequences increases after muscimol injections of this area. In contrast, the performance of learned sequences is not affected by pre-SMA inactivation (Hikosaka et al. 1999).

The data reviewed above suggest that F6 plays a double role in motor control. A first role consists in controlling the posterior premotor areas. Normally, even when the posterior areas are activated, movement does not start. Only when external contingencies and motivational factors allow it, F6 renders the movement onset possible. A second possible role of F6 is more cognitive. It consists in the control of visuomotor associations underlying the declarative phase of motor learning.

4. The Premotor Cortex in Humans

Data from brain imaging studies indicate that the organization pattern of the AFC in humans is similar to that of non-human primates. As in monkeys, there is a multiplicity of premotor areas in humans. Some of them become active during the execution of simple movements (Fink et al. 1997); others require more complex tasks.

The distinction between premotor areas that elaborate sensory information for action (parieto-dependent areas) and areas that control action execution (fronto-dependent areas) appears to hold true also for humans. For example, recent data (Binkofski et al. 1999) showed that in humans there is a specific circuit for hand-object interactions. As in the monkeys, this circuit includes a parietal area—the probable homologue of monkey area AIP—and a ventral premotor area, area 44, the probable homologue of monkey F5. Conversely, data on the pre-SMA (F6) indicate that this premotor area is involved in humans, as it is in the monkey, in complex actions, rather than in the execution of simple movements (Picard and Strick 1996, Hikosaka et al. 1999).

G. Rizzolatti and G. Luppino

Prenatal and Infant Development: Overview

Infancy extends from birth through 2 years of age. It has long been regarded as a special period of life in which numerous important transformations of structure take place, and the essential processes of information exchange with the world are laid down. Over this period, the infant is transformed from a condition of utter dependence on the caregiver for survival to a condition of relative independence or life-preserving agency—a transformation accompanied by marked physical, behavioral, and cognitive changes. While no characterization of this transition is entirely satisfactory, several elements set the infant apart from children of other ages. Despite disclaimers that what happens very early in life can be reversed or improved upon, most developmental psychologists celebrate the very considerable and enduring influence of early experience. This article paints a broad picture of infant development, its prenatal antecedents, and its relation to the behavior of older children and adults.

1. Prenatal Development

1.1 Physical and Cognitive Development

The ‘prenatal period’ extends from conception to birth. During the ‘germinal stage’ (fertilization–2 weeks) and ‘embryonic stage’ (2–8 weeks), the fertiliz-

ed egg rapidly divides and attaches to the uterine wall, the major organs and systems of the body differentiate, and interconnections form between the developing components of the central and peripheral nervous systems. During the fetal stage (8 weeks–birth), the organism grows rapidly and the physical features that identify it as human become increasingly apparent.

During the prenatal period, the mechanisms that will facilitate the organism’s adaptation postnatally become functionally mature. Infants born prematurely, for example, who readily learn responses that increase the amount of quiet sleep, reveal this anticipatory maturation. The characteristics of the mother’s voice are also learned during the prenatal period. After birth, hungry infants orient and root in the direction of their mother’s voice, thereby increasing their efficiency of breast-feeding irrespective of whether the mother is holding them on the left or right. Newborns will also learn to activate a tape-recording of their mother’s voice—but not of another woman’s voice—by sucking non-nutritively on a modified nipple. Moreover, ‘prenatal learning’ is highly specific: newborns will suck harder to listen to their mother reading a Dr. Seuss passage that she had read aloud daily during the last 6 weeks of gestation than to hear her reading a novel Dr. Seuss passage (DeCasper and Spence 1986). This specificity continues postnatally throughout the first half year. Similar learning prenatally familiarizes organisms with the linguistic environment into which they eventually will be born.

1.2 The Jacksonian Principle

The development and dissolution of prenatal motor function is described by the ‘Jacksonian principle,’ which states that the last reflexes to develop are the first to disappear when the organism undergoes demise, whereas the first to develop are the last to disappear (Jackson 1884, cited in Taylor 1958). The contralateral (avoiding) reflex, which moves a stimulated site away from a tactile stimulus, is supplanted weeks later by an ipsilateral reflex (Hooker 1952). This sequence is reversed by fetal anoxia. The reversion occurs because reflexes that develop first are well practiced and require less oxygen to be initiated than reflexes that are more recent. Similarly, the order in which sensory functions develop (tactile, vestibular, thermal, chemical, auditory, and visual) is subsequently reversed during injury, disease, or aging.

2. Mileposts of Infant Development

2.1 Zero–6 Months

Birth marks the organism’s transition from a parasitic, waterborne existence in a thermally constant environment with constant access to nutrition to an in-

dependent, land-dwelling existence in a desiccating and cold environment with discontinuous access to food. The occasion of birth is unremarkable, important primarily for triggering the onset of the 'regulatory mechanisms' (respiration, blood flow, digestion) that are critical for this transition. These regulatory arrangements and their interactions are the major constraints on the newborn's behavior and the environmental conditions it can tolerate (Adolph 1968). The evolutionary requirement of all newborn mammals is to grow, which necessitates maximizing energy intake and minimizing energy expenditure. Not surprisingly, therefore, newborns primarily eat and sleep. Early postnatal learning also reflects this necessity: Newborns readily learn where and when food is accessible. Also, because full-term newborns do not physiologically thermoregulate before 4–9 weeks of age, they will not learn energetically costly responses that compete with behavioral thermoregulation.

Over the first 3 months of life, the birthweight of the infant doubles. During this period, brain development is very rapid and influenced appreciably by the kinds of experience to which the infant has been subjected. While most information about dendrite proliferation, the directionality of neuronal connections, cell death, and the effects of deprivation on neural and behavioral development comes from mammals other than humans, the universality of the effects described by neuroanatomists and neuropsychologists is impressive.

In the period following birth, much of the infant's behavior is reflexive, that is, specific stimuli call forth specific reactions (e.g., touches to the mouth elicit rooting and mouthing, abrasions of the skin elicit retraction of the injured body part). This early behavior is principally under the control of the subcortical portions of the brain, and the elicited behaviors are typically swift and obligatory.

Between 2 and 4 months of age, cortical maturation—especially dendritic proliferation—is increasingly evident, and neonatal reflexes disappear or weaken. Also during this period, activity undergoes a major transition from elicited to voluntary. The developmental sequence in which reflexes emerged during the prenatal period is recapitulated during this transitional period, and the sequence in which the postnatal reflexes appear is similarly reversed when the organism is challenged (Humphrey 1969). The postnatal repetition of fetal activity sequences is again due to the lower oxygen requirement of more primitive, hence more practiced, reflexes. Practicing neonatal reflexes reduces their oxygen requirement and speeds the transition.

The transitional process has been implicated in the sudden infant death syndrome (SIDS). McGraw (1943) characterized the period when reflexes are neither reliably elicited nor under voluntary control as a period of 'disorganized behavior.' The transitional period of the respiratory occlusion reflex corresponds

to the time when SIDS is most likely to occur (95 percent of all crib deaths occur between 2–5 months). By 6 months, the occlusion reflex has come under cortically mediated voluntary control, and the infant is once again able to defend successfully against respiratory occlusion (Lipsitt 1979).

Also, over the first 3 months of age the behavioral repertoire of the infant sharply expands. Infants can acquire both classically conditioned and operantly conditioned responses at birth and can remember what they have learned for a surprisingly long time (Lipsitt 1969). An eyeblink reflex that is classically conditioned at 10 days of age, for example, is remembered for at least 10 days. Newborns can habituate to a repeatedly presented stimulus and discriminate it from others that they have not previously encountered. Imitation, a particularly efficient form of learning, can be demonstrated within hours of birth. Not only can newborns imitate an adult's facial gestures immediately after they were modeled, but by 6 weeks of age, infants can imitate facial gestures after a 24-hour delay. Piaget (1962) described early facial imitation as stimulus-bound and reflexive and hypothesized that it disappeared along with many other neonatal reflexes. However, it was later shown not to disappear (e.g., Meltzoff and Moore 1994). Infants' early imitation of facial expressions foreshadows their later dyadic interactions with adults and siblings.

By 3 months of age, infants can acquire arbitrary categories, learn the serial order of an arbitrary list, and pick up incidental information about events in their visual surround—including information about correlated features ('what goes with what'). Although some aspects of visual processing (e.g., accommodation and convergence, and feature search) are adult-like by 3–4 months, others (e.g., visual acuity and conjunction search) do not achieve adult levels for 1 year. Infants can detect depth by 2–3 months but do not fear depth until they begin to crawl. They can also recognize faces of live adults after 24 hours by 6 weeks of age and can recognize them from photos by 5 months.

Observers often remark that infants blossom into 'social creatures' between 2 and 4 months of age, cooing and smiling widely at individuals who interact with them, reaching to other persons, and intensely watching the behavior of others. By their fourth month, infants follow conversations between adults with their eyes, differentiate social from nonsocial objects (which they previously did not), and imitate vocalizations. Not surprisingly, social stimuli are highly effective in establishing and maintaining behavior at this time. The features that define a stimulus as social, however, change with age. Although newborns differentiate between facial expressions and prefer to look at faces than at other visual stimuli, this preference is not based on a social dimension but on contrast and movement—critical features of the human face which influence infants' scanning patterns over the

first 8 weeks. By 4 weeks of age, however, infants display greater pupillary dilation to social than non-social stimuli; by 6 weeks, they display differential cardiac responses to mothers and strangers; and by 12 weeks, they display differential pupillary responses to them and smile more frequently at the mother than at a stranger.

2.2 Six to 12 Months

During the second half-year, a normal infant becomes a walker, a speaker, and a social being who responds emotionally to parents and differentially to familiar persons and strangers. The simultaneous appearance of strong attachment to caregivers and wariness of unfamiliar individuals at 9–10 months of age is one of the most consistent benchmarks of this period (Ainsworth 1979). At the same time, infants begin to look at the target of a pointing finger rather than at the finger *per se* and begin to exhibit social referencing—a strategy by which infants assess the emotional valence of a new situation or person by checking how the caregiver has responded and responding in kind.

For a half-century, another developmental benchmark was attainment at 10 months of object permanence—the concept that an unseen object or person continues to exist. In the classic object search task, infants younger than 10 months consistently failed to retrieve an object they had just watched an adult hide. New paradigms using looking instead of reaching measures, however, have now revealed that even 3-month-olds can locate where an object was hidden.

The types of learning of which infants are capable and their understanding of the physical world rapidly expands over the last half-year. Infants can individuate objects, solve problems requiring causal reasoning, form learning sets ('learning how to learn'), comprehend some spoken speech, repeat a couple of syllables and perhaps produce a word, plan and execute a detour, and track objects through occlusion—a finding that has fueled heated debate over whether infants can count. Before infants begin to crawl (7–9 months), they have already learned what happens in what places. Once infants can locomote, they begin to form a cognitive map or representation of the spatial relationships between these places, which facilitates navigation from one place to another.

2.3 Twelve to 24 Months

Over this period, infants' linguistic, motoric, and cognitive skills continue to improve and broaden. Between 12 and 18 months of age, for example, infants can use landmarks to locate objects instead of using their own body as a reference point, and between 18 and 24 months, they can use geometric cues in the

environment to reorient. Although 18 months was set as the minimum age for deferred imitation of actions on an object (Piaget 1962), the use of tasks particularly suited to younger infants has lowered this age to 6 months. Still, infants' ability to imitate televised demonstrations lags well behind their ability to imitate live demonstrations. The same live demonstration that 6-month-olds can imitate after 24 hours cannot be imitated from television before 18 months, although 15-month-olds can imitate some televised actions after 24 hours if the viewing conditions are more naturalistic. Generally speaking, the pervasiveness of reports that infants' cognitive and motoric performance is superior in natural settings calls into question most if not all minimum age limits that have been imposed by laboratory tests.

Within the last five years, research on the ontogeny of memory has revealed that retention increases linearly over the infancy period, and reminders protract retention even longer. At all ages, a single reactivation or reinstatement reminder, for example, doubles the life of a memory—a remarkable result given that memories of older infants are initially so long. The finding that a few reinstatements can maintain a memory acquired at 6 months through 2 years of age reveals that early experiences can be enduring and raises new questions about infantile amnesia (adults' inability to recollect experiences from early childhood). The two memory systems (declarative, non-declarative) found in older children and normal adults are also functional by 3 months (Rovee-Collier et al. 2001).

3. Risk Factors and Individual Differences

In recent years, advances in the successful delivery and survival of very small and premature babies, often born in jeopardy, have fueled new debate over the importance of early experience. Because the lower threshold for survival is very new, it is inevitable that time must pass before the numerous longitudinal studies, now under way, will yield critical information about the relation between specific prenatal deficits and neonatal hazards and particular developmental outcomes. Such investigations are unlikely to rule out the possibility that some affected infants will be indistinguishable from their age-matched peers in developmental competencies. It is a question of proportions and resiliency.

Although infants born 38 weeks after conception are, on average, less mature than those born at 40 weeks are, the level of physiological maturity can vary among infants born at 40 weeks by as much as 3–4 weeks. Sex differences are also present at birth, with girls being 1–2 weeks ahead of boys in neurological maturation. In normal infants, some of this variability disappears by the end of the first year, but many

individual differences persist, the full range and significance of which are not yet fully appreciated.

Early attempts to predict later intellectual performance from infant behavior focused on sensory and motor abilities and was unsuccessful. Modest-to-good correlations have now been found between measures of information processing beginning at 5–6 months (e.g., habituation rate, novelty preference, 1-week retention ratios) and scores on various intelligence tests at 3–5 years. The Fagan Test of Infant Intelligence (Fagan and Detterman 1992), which correlates later intelligence with infant novelty preference scores, is sensitive to early exposure to environmental toxins, substances of abuse, and nutritional deficits and supplements, as well as to maternal HIV infection, intraventricular hemorrhage, bronchopulmonary dysplasia, genetic anomalies, and various neurological abnormalities.

4. Past Trends and Future Trajectory

The origins of research on infant development can be traced to baby diaries published by Darwin and Preyer in the late nineteenth century. Over the first half of the twentieth century, detailed diaries of their own children's behavior stimulated Morgan, Stern, Guillaume, Valentine, and Piaget to propose theoretical accounts of early cognitive development (Wallace et al. 1994). At the same time, Pavlov's seminal studies spawned longitudinal studies of classical conditioning with infants in Russia and other Eastern-block countries. These early studies provided the first systematic data on infant learning and documented the sequential onset of sensory function from the age at which stimuli from different modalities became effective conditioned stimuli. During this period, Western researchers produced only scattered reports of infant conditioning and retention, emotional development, activity, and color vision.

In 1958, federal funding of a long-term prospective study of infant development ushered in the era of modern infancy research. Using sophisticated apparatus and innovative methods, researchers at 12 sites across the US began to systematically document the infant's basic sensory and learning abilities. These initial inquiries sparked subsequent generations of research on all aspects of perceptual, cognitive, and behavioral development across the entire span of infancy. By the end of the twentieth century, a large amount of developmental data was amassed on infant attention, perception, cognition, motor skills, and the sequelae of many early risk conditions.

The twenty-first century will witness intensive research that elaborates this knowledge and challenges other long-held beliefs about infant development. Also in this century, advances in cognitive and behavioral neuroscience should facilitate attempts to relate de-

velopmental changes in infant cognition to specific changes in the developing brain. This effort will require the development of new, noninvasive techniques and the adaptation of current ones (e.g., functional magnetic resonance imaging, positron emission topography) for use with very young infants. Finally, methodological advances should allow new insights into prenatal development and its contribution to postnatal development.

Presidency: United States

1. Meaning

The term 'presidency' is applied to several distinct perspectives on the office of the President of the United States. Most commonly, and in its narrowest sense, it is employed as a label to refer to the incumbency of one particular President, as in the presidency of Abraham Lincoln or the presidency of Franklin Roosevelt. More broadly, the term applies to the historical development and legacy of a succession of presidencies since the office was established in 1789. In a more precise constitutional sense, the presidency is that branch of government established by Article II of the Constitution of the United States encompassing a set of constitutional and statutory powers and duties of the President together with additional 'implied' or 'inherent' powers and responsibilities not specifically enumerated in the Constitution or statute law. Finally, the term 'presidency' is used to denote the institutional structure of the office of President embracing the Executive Office of the President—a collection of staff units, originating from proposals contained in the Brownlow Report of 1937, that provide the President with the capacity to manage the work of the executive branch of government and to liaise with the principal constituents of the President, namely the Congress, the media, and interest groups.

These different usages of the term present no significant analytical difficulties. In the literature on the US presidency, the context is usually sufficient to clarify the sense in which the term is being employed and in none of its various forms is it conceptually or theoretically problematic. This is partly because the academic study of the presidency has not been encumbered by rigid theoretical or conceptual frameworks—a matter of concern to some presidency scholars who wish it were so, and a relief to others who see value in the broad, disparate, and eclectic approach that has characterized the study of the presidency to date.

2. Intellectual Context

The academic study of the US presidency has essentially been the preserve of historians and political scientists. Historians have generally confined their attention to individual presidents and presidencies whereas political scientists have traditionally concentrated on the constitutional and political power of the presidency and its institutional structure and development over time. Few historians, with some notable exceptions (see, e.g., Schlesinger 1973, McDonald 1994) have focused on the broader institutional development of the American presidency and only a handful of political scientists (see, e.g., Milkis 1993, Skowronek 1993) have borrowed from the discipline of history to further what political science has had to

say about the presidency. Given the vast amount of scholarship on US presidents and the presidency produced by historians and political scientists, there has been little significant cross-fertilization between the two disciplines and it would not be unfair to say that the study of the US presidency, as distinguished from the study of US presidents, has been dominated by political scientists.

Until the publication in 1960 of Richard Neustadt's seminal work, *Presidential Power*, scholarship on the US presidency had primarily focused on the constitutional and statutory powers of the President, the various roles and functions of the President, and its relationship to the other branches of government as exemplified in the classic texts of Edward S. Corwin (1957), Clinton Rossiter (1956), and Wilfred Binkley (1962). There has also been a strong normative tradition in the literature the presidency, but this has produced various and divergent diagnoses of the weaknesses of the presidency and no uniform prescription for change, although the British system of cabinet government or variants of it has tended to be among the more popular reform proposals.

Neustadt's *Presidential Power* brought the study of the presidency into contact with the behavioral revolution in postwar political science. Neustadt defined power in terms of the president's persuasive or bargaining ability derived from his 'professional reputation' and 'public prestige.' Asserting that 'powers are no guarantee of power,' he proceeded to show that the leadership ability of presidents was not inherent in the office but was highly personal and dependent on the President's own capabilities as a seeker and wielder of effective influence upon others involved in governing the country. Neustadt's immediate impact was to shift the concerns of presidency scholars away from the formal, legal, and institutional boundaries of presidential power toward a more behavioral and theoretical effort to locate the reality of power and leadership in the White House.

While Neustadt's work was a major break with the tradition of presidency scholarship it did not represent a departure from the basic values of the leading presidency scholars who were firm in their belief that the presidency was and ought to be the center of action in American politics and who advocated a strong and dominant presidency as the only institution capable of responding to the social and political problems facing the country. They represented a generation reared during the presidency of Franklin D. Roosevelt and who made FDR, or what was often referred to as 'the New Deal presidency,' the normative model for their scholarship.

3. The Changing Focus of Presidency Scholarship

Notwithstanding Neustadt's impact, the political science of the American presidency lagged behind the behavioral revolution for much of the 1960s and 1970s

and not until the 1980s did the community of presidency scholars begin to exercise the kind of introspection and self-criticism on which behavioralism in America had thrived. That introspection produced a clear but belated appeal for the study of the presidency to connect with the basic tenets of the behavioral revolution—a more rigorous scientific methodology, the need for quantitative measures, and a greater concern for the conceptual and theoretical underpinnings of presidency scholarship (see, e.g., Edwards and Wayne 1983). That appeal did result in a redirection of the focus of presidency scholars and, since the mid-1980s, the political science of the US presidency has taken a quantum leap theoretically, methodologically, and conceptually.

The fundamental values of presidency scholars also changed around the same time. The combined effect of the Vietnam War and Watergate led to a significant reassessment of the New Deal model of presidential power and even those who continued to advocate strong presidential leadership became more sensitive to notions of accountability and restraint. By the end of the century, presidency scholarship had launched an assault on what Mark Peterson called the ‘presidency-centered perspective’ on American government (see Peterson 1990, also Jones 1994), a timely shift in a new era of divided government.

4. Current Theory and Research

The epistemological transformation of presidency scholarship from the mid-1980s could not properly be called a revolution because it did not succeed in displacing older, established approaches entirely. The ‘public law’ tradition, e.g., has flourished during the last two decades partly because of the practical relevance of issues such as the war power, the legislative veto, impoundments, presidential nominations, and impeachment. Scholars following in the footsteps of Corwin (see, e.g., Fisher 1995) have made significant contributions to the study of the presidency that have not been dependent on theoretical sophistication or quantitative methodology. Similarly, the ‘institutional’ school has also been reinvigorated by political developments in recent times. Watergate and the Iran-contra affair, for example, acted as a catalyst for substantial research on the role of the presidential staff and the structure and organization of the Executive Office of the President (see Burke 1992, Hart 1995, Walcott and Hult 1995) and, although much of this work is theoretically and conceptually grounded, it also builds on the descriptive and empirical approach that underlies the ‘institutional’ tradition in presidency scholarship.

The breadth of current research on the US presidency would be difficult to categorize. In addition to those areas mentioned above, it encompasses the study

of presidential psychology and character, leadership style, decision-making processes, popularity, professional reputation, bargaining and persuasion, media management, rhetoric, the impact of public opinion on presidents, the impact of presidents on public policy, and much more.

Current research also embraces a variety of approaches and techniques which, when combined with the range of subject-matter, makes presidency scholarship a broad, diverse, and pluralistic area of study open to the criticism that it lacks coherence in focus and methodology. But it would also be true to say that much current research on the presidency builds upon and extends the seminal research of the past and, while there may not be a single, coherent approach to the political science of the American presidency, there is continuity of research concerns co-existing with a willingness to utilize new methodological and theoretical developments.

Rational choice theorists, however, have staked a claim for the comprehensiveness of their approach and suggested that it may offer presidency scholarship the analytical and theoretical coherence it presently lacks. Applications of rational choice theory to the study of the presidency are still few in number but recent work by rational choice theorists, particularly in the field of presidential–congressional relations, has made a significant impact (see especially Krehbiel 1998, Cameron 2000) and laid the foundations for an extension of that approach to other hitherto less theoretically receptive aspects of the presidency

5. Methodological and Theoretical Problems

Although the cutting-edge of presidency research is in the hands of the rational choice theorists and their close companions, the new institutionalists, their approach has been contested by other presidency scholars who are less convinced of its general utility across the spectrum of presidency scholarship and who question the desirability of imposing a conceptual and methodological uniformity on future research. The debate is exacerbated by the tendency of the new institutionalists to distinguish between the ‘institutional’ and the ‘personal’ presidency, rejecting the latter in the interests of parsimony and theoretical clarity. While it is true that behavioral studies of the ‘personal’ aspects of the presidency, as exemplified by James David Barber’s pioneering work on presidential personality (Barber 1972), revealed how difficult it is to theorize on the basis of a large number of complex variables, that has yet to be accepted as a sufficient argument for ignoring the complexity of the US presidency.

A more longstanding methodological problem for presidency scholars is the lack of access to their subject of study. Presidents of the USA generally do not

give interviews to political scientists, nor do they respond to questionnaires, nor, for the most part, can they be observed at work, neither do their memoirs or papers usually provide the kind of data that presidency scholars require. This is a principal reason why the study of the presidency has lagged behind other branches of the US government in terms of scientific rigor and why the gaps in the state of knowledge about the presidency are still quite substantial.

6. Future Directions

During the last 20 years, research on the presidency has been driven in large measure by the behavior of presidents themselves and the imperatives of the political science profession. In all probability, these two forces are likely to determine the direction of presidency research in the foreseeable future.

Presidency scholars have often been caught unprepared by the behavior of recent presidents and the events surrounding their presidencies. The Vietnam War was a catalyst for substantial research on the war power. The growth and expansion of the presidential staff system was barely studied before Watergate. The weakness of Jimmy Carter as President provided the impetus for Polsby's (1983) landmark study of the reformed presidential nomination process and its impact on the nature of the presidency. Ronald Reagan's public popularity prompted numerous studies of 'going public' strategies of presidential leadership (see especially Kernell 1986). As long as occupants of the White House continue to surprise scholars of the presidency they are likely to influence the range and nature of future research.

Similarly, the professional emphasis on theoretical sophistication and scientific rigor is likely to determine the priorities of future research on the presidency as it has done in the past. The danger is that such imperatives may overwhelm and marginalize those aspects of presidency scholarship where theory and quantitative methods are less applicable and less suitable to the object of study.

Presidential Government

Democratic governance takes two basic forms: parliamentarism and presidentialism; some people would add semipresidentialism, leaving aside the very unique Swiss institutional structure. Each of them presents a variety of forms that lead to question the dichotomy. There are a few defining characteristics from which many consequences can be derived. Each is identified with a paradigmatic case: the British Westminster parliamentarism, US presidentialism and the semipresidentialism of France. However, as Sartori (1994) notes, parliamentarism takes a variety of forms like the German Federal Republic—the Kanzler democracy—and the assembly parliamentarism of the Third and Fourth French Republics, and contemporary Italy.

Presidential systems are based on an executive with considerable powers in the constitution, and generally with full control of the composition of the cabinet and the administration, elected by the people (directly or by an electoral college elected for that purpose) for a fixed period of time, and are not dependent on a formal vote of confidence by the democratically elected representatives in a parliament. The president is not only the holder of executive power, but is also the symbolic head of state who cannot be dismissed between elections except in rare cases of impeachment.

Two features stand out in presidential systems:

(a) Both the president, who controls the executive and is elected by the people (or an electoral college elected by the people for that sole purpose), and an elected legislature (unicameral or bicameral) enjoy democratic legitimacy. It is a system of 'dual democratic legitimacy.'

(b) Both the president and congress are elected for a fixed term, the president's tenure in office is independent of the legislature, and the survival of the legislature is independent of the president. This leads to what we characterize as the 'rigidity' of the presidential system.

Most of the characteristics and problems of presidential systems flow from these two essential features. Some other nondefining features of presidentialism are often associated with it, such as term limits or no re-election, automatic succession by a vice-president, more or less extensive rule making, and emergency powers. One characteristic, so normal that it can be included in the definition, is that the presidency is a unipersonal office. There have only been two cases of directly elected pluripersonal 'presidencies': the two-person Cypriot administration (1960–1963) and the Uruguayan Colegiado (which governed twice — 1918–1933 and 1952–1967).

The basic characteristic of the president is the full claim to democratic legitimacy. The claim very often has strong plebiscitary components, although sometimes it is based on fewer popular votes than are received by many prime ministers in parliamentary systems heading minority Cabinets. The presidency gives the incumbent, who combines the qualities of head of state representing the nation and the powers of the executive, a very different aura and self-image, and creates very different popular expectations than those redounding to a prime minister with whatever popularity he might enjoy after his party receiving the same number of votes.

The most striking fact is that in a presidential system, the legislators, particularly when they represent well-organized, disciplined parties that constitute real, ideological, and political choices for the voters, also enjoy a democratic legitimacy, and it is possible that the majority of a legislature might represent a different political choice from that of the voters supporting a president. Who, on the basis of democratic principles, is better legitimated to speak

the name of the people: the president, or the congressional majority that opposes his policies? Since both derive their powers from the vote of the people, a conflict is always latent and sometimes erupts dramatically; there is no democratic principle to resolve it, and the mechanisms that might exist in the constitution are generally complex, highly technical, legalistic, and therefore of doubtful democratic legitimacy for the electorate. It is no accident that in some of those situations the military intervenes as 'poder moderador.'

It could be argued that such conflicts are normal in the USA and have not led to serious crisis. It would exceed the limits of this essay to explain the uniqueness of American political institutions and practices that have limited the impact of such conflicts, including the unique characteristics of the American political parties that lead many American political scientists to ask for a more responsible, disciplined ideological party system (Riggs 1998).

In a unipersonal presidency there is only one winner who gains full control of the executive. It has been argued that in a Westminster parliamentary system a party winning an absolute majority is also (or even more) a 'winner take all' while in a presidential system it is less likely that a president will have an absolute majority in congress for the entire period of his mandate. However, it is a president, one person that wins control of the executive rather than a party, and that person gains that power irrespective of the size of his plurality or in a runoff in a narrowed competition in which necessarily one candidate will have a majority. The loser in a presidential election ends with no public office in contrast to the leader of a defeated party in a parliamentary election likely to hold a seat in Parliament. Part of the unipersonal election is, in many presidential systems, the succession by a vice-president chosen by the nominee using criteria that would not have been those of the electorate or a party leadership.

The plurality rule remains the most common method for electing presidents. However, the fear of a president being elected by a small plurality has led to introduce a majority runoff election among the two leading candidates (when no candidate has received a majority). The plurality rule (Shugart and Carey 1992) favors a two-party competition or at least the formation of broad pre-election coalitions and discourages candidates from minor parties. The runoff election, on the other hand, encourages a larger number of candidates in the first run, either in the hope to make it to the runoff (even with a modest number of votes) or place themselves in the condition to bargain for their support by one or the other of the two front runners.

Each procedure can have negative consequences. The plurality rule in a fragmented party system can lead to the election with the support of a small minority. The runoff in addition to encouraging party

fragmentation in the first run, can create false coalitions (which will not hold after the election), or mortgages the candidate with allies which may exact a price or distort his image. It also generates in the winner the feeling that he represents the majority of the people, though in the first run he had weak support and his opponent might have been ahead.

In a multiethnic society the fear that a candidate from a populous state could be elected against those from other ethnic-religious communities, has led to a complex system of concurrent pluralities, to assure the election of a president with appeal across ethnic groups (as in Nigeria).

There are a few instances in which the popular vote, in the absence of a decisive majority, does not determine the winner. In Chile, before 1973, the Congress chose the president in the event that no candidate received a majority of popular votes among the top two contenders. Traditionally the one with the largest plurality was elected. In the USA, when in the nondeliberative electoral college no candidate obtains the vote of the majority of electors at the first count, the decision goes to the House of Representatives.

The fixed term of office of both presidents and congress introduces a particular rigidity. A failed president cannot be (normally) forced to relinquish power, but is obliged to continue governing, and he cannot (constitutionally) dismiss a congress committed to oppose his policies. A failed parliamentary prime minister can lose a vote of confidence, be replaced by another leader of his party or coalition, and if he feels that the opposition is wrong, call for an election hoping to discipline his party or coalition and/or revalidate his authority. The rigidity and the length of some presidential mandates leads to the frequent rule of no-reelection, or of no continuous reelections.

The dual legitimacy resulting from separate election of president and the legislature and their mutual independence can lead to 'divided government.' The congress and the presidency may be controlled by different parties (or factions of the same party) creating an impasse. How to govern?

Ackerman (2000) has developed three scenarios. The first emphasizes accommodation, based on bargaining, they may be called the Madisonian hope. Fiorina (1996) argues that American voters desire a divided government because they are uncertain about endorsing an ideological direction offered by either party. Mayhew (1991) argues that divided government has not impeded major legislation. The second involves constitutional breakdown, in which one or another power assaults the system and installs itself as a single lawmaker. A situation of this type is in Latin America, where traditionally the military as 'poder moderador' intervened temporarily, or more recently assuming complete power. Referring to my analysis (Linz 1994), Ackerman calls this breakdown the 'Linzian nightmare.' A third less dramatic alternative

is backbiting, mutual recrimination, and partisan deadlock, which he calls 'crisis of governability.' To the use of constitutional or extraconstitutional decree powers, emergency legislation, patterns described in detail by Carey and Shugart (1998) and their collaborators in a chapter significantly entitled 'Calling Out the Tanks or Filling Out the Forms,' I would add a fourth alternative that explains the absence of recorded conflicts: the application of the 'rule of anticipated reactions.' The avoidance of conflict by not initiating policies is likely to lead to conflict even when desirable, necessary, and proposed by the president at the time of his election.

The disjunction between the image of the voters and the president himself as an initiator of major policies, reforms, and change, and the gridlock, mutual blaming, and/or of a frustrated president or congress confronted with *decretazos*, an avalanche of decrees as *faits accomplis*, reducing the legislature to impotence, does not contribute to political efficacy and the legitimacy of either or both institutions. The breakdown of democracy and the turn to unconstitutional rule or authoritarianism is only one possible outcome. 'Formal' democratic continuity, particularly in recent crises in Latin America (or the ex-USSR countries) is no proof that the system works.

The situation that Ackerman calls of full authority, when the presidency, the House and Senate are controlled by the same party and there is a favorable majority in the Supreme Court is rare and may last a short time. The result is a burst of legislation, law-making initiatives that will be strong in symbolic statement and difficult to change afterwards, with less concern about implementation. In a parliamentary system, where laws can more easily be changed with electoral defeat, governments are more interested in statutes framed in mid-sized concepts keyed to operational realities, to make them work.

Although the separation of executive and the legislative power, more accurately separate institutions sharing powers, implies that the bureaucracy (and the military) are the domain of the presidency, the fact is that they have two masters. Congress is perhaps increasingly adept to intervene in details of public administration and defense thanks to the prerogative of 'oversight,' of financing departments and programs, the long-standing freedom to investigate. A result is the dependence on both the presidency and the congress and indirectly the separation from both, and subordination to neither. A response to this situation has been 'politicized professionalism': the growing number of political appointees, the large number of in-and-outers, and the short tenure of those appointed who prefer to move to the private sector (and consequently the lack of accumulated experience and continuity in policies). The president turns to 'loyalists' rather than experienced civil servants who would be concerned about their relations with powerful congressmen or women.

In the ongoing debate over the success or failure of presidentialism it is important to distinguish:

(a) The basic theoretical issues derived from the defining characteristics of presidentialism (Linz 1994, Shugart and Carey 1992).

(b) The problems for presidentialism not derived from the basic characteristics; like no reelection, tensions with vice-presidents, mid-term congressional elections, etc.

(c) The problems with presidentialism and the actual breakdowns of presidential compared to parliamentary systems. A comparison plagued by a number of methodological problems; time period covered, regional comparisons, level of economic development (OECD vs. developing countries), and increasingly formal stability with 'defective' democracies (some actually authoritarian regimes) (Stepan and Skach 1994, Shugart and Carey 1992, Thibaut 1996).

(d) The absence of a possibility of a transition to parliamentarism and therefore the limited relevance of a theoretical comparison and the need to consider 'improvements,' modifications of presidentialism that correct some features contributing to some of its failures (Nohlen and Fernandez 1991).

(e) The need to keep the problems of semi-presidentialism, offered as a more viable alternative to presidentialism, separate. In this case, the lack of consensus on which countries are semipresidential and the small number of cases (at least before the new postcommunist regimes), makes an analysis like (c) difficult.

The basic argument for the separation of powers is that it provides mutual checks, enhancing freedom, preventing the concentration of power enjoyed by a British prime minister. Mutual checks, the greater difficulty in enacting policies, the opportunity for all interests to be heard and taken into account, the slowing down of the process, and the opportunity for vetoes, generate weak executives and block many of their initiatives, and this is presumably what the voters want when they split their vote for congress and the president. Perhaps this is an advantage in a society that works well independently of public policies, in a wealthy market economy with no major need for redistributive policies, or with independent nonpolitical agencies, but is unlikely to fit societies facing serious problems of underdevelopment and social injustice, requiring more effective government action.

Among the positive aspects of presidentialism its advocates list:

The separation of powers of congress and the executive allows the 'representatives' to act as representatives of interests, particularly of those with a geographical basis, since they are not bound to support the policies of the executive and no party discipline is needed to support a government. In the absence of proportional representation, they enjoy considerable independence from the party leadership and are more likely to represent interests rather than broad policy or

ideological alternatives. All politics become local. As Sartori (1994, p. 84) writes: three factors 'ideological unprincipledness, weak and undisciplined parties and locality centered politics, contribute to the working of US presidentialism.'

The separate election, particularly mid-term elections, and the limited influence of the president in many cases in the nomination or the making of lists of candidates (especially in federal systems) and in their electoral success, makes the representatives independent. Even their own partisans will owe them almost nothing and often doubt their usefulness in the elections. The selection by primaries has probably reinforced that tendency. This makes members of congress, compared to parliamentarians, better representatives of interests of their constituents but less reliable in supporting a party (and presidential) policy program. In fact, that 'representative' function is seen (Shugart and Carey 1992) as one of the positive aspects of presidentialism.

One presumed advantage is the identifiability of presidents, compared to the incertitude of who will head the government in some parliamentary systems based on coalition-making among multiple parties after the election. However, in many parliamentary systems the voter knows well who will head the government if the party he votes for wins. Although presidential candidates identify themselves with certain policy goals, they are less bound to a program than a party and the prime minister it supports, or minor parties that make their coalition support dependent on certain demands (for example, national minority parties).

Shugart and Carey (1992, p. 44-45) consider the personal identifiability the basis for greater accountability. This might be true, except when reelection is barred and for the blaming game between the president and congress (particularly in the case of divided government).

Presidential elections allow the citizen to choose one individual to put his trust in—on account of real or perceived qualities and commitments without the mediation of complex institutions: a party, a legislature, or a plurality of actors like parties forming a coalition. That personalization simplifies the choice. It also permits outsiders, not identified with a party, who may not have held any office before, to appeal personally and directly to the voter: Collor, Fujimori, Tyminski, Perrot. That appeal requires access to the media, which in turn may involve access to funding—in some cases personal wealth—and considerable misunderstanding of what is necessary to govern. It may also appeal to 'being above parties,' perceived as divisive, somewhat like a monarch. The election of military leaders: Mannerheim, Hindenburg, De Gaulle, Eanes, even Eisenhower, reflects this desire. TV is particularly congruent with these patterns.

Latin American presidents greatly vary in terms of their constitutional powers, both reactive (veto power,

for example) and proactive (decree legislation) and in terms of their partisan support in congress. The possible combinations (Mainwaring and Shugart 1997, pp. 40–54) are too complex to summarize here.

The difficulties with presidentialism in Latin America have generated two opposite responses: attempts to curtail the powers of the president out of fear of the abuse of power and authoritarian predispositions and efforts to strengthen the presidency as an answer to the weakness of the presidency, particularly in relation to congress.

Many presidential systems have a vice-president, with limited functions except when he has to step in to succeed the president for reasons of death, resignation, impeachment, or incapacity. He generally is not elected independently but on a ticket with the presidential candidate, chosen by him, often for electoral or personal reasons without concern about his or her qualifications. The frequent destructive conflicts between presidents and vice-presidents have led to recent constitutions to not include that office.

1. Semipresidentialism

Semipresidentialism as a distinctive form of organizing democratic political life, gained importance as a constitutional model and political reality with the consolidation of the French Fifth Republic defined by Sartori (1994, p. 132):

(a) The head of state (President) is elected by popular vote—either directly or indirectly—for a fixed term of office.

(b) The head of state shares the executive power with a Prime Minister, thus entering a dual authority structure whose three defining criteria are (c) to (e).

(c) The President is independent from parliament, but is not entitled to govern alone or directly and therefore his will must be conveyed and processed via his government.

(d) Conversely, the Prime Minister and his Cabinet are president-independent in that they are parliament-dependent: they are subject to either parliamentary confidence or no-confidence (or both), and in either case need the support of a parliamentary majority.

(e) The dual authority structure of semipresidentialism allows for different balances and also for shifting prevalences of power within the executive, under the strict condition that the ‘autonomy potential’ of each component unit of the executive does subsist.

Shugart and Carey (1992) prefer to call this system ‘premier presidentialism’ and distinguish it from ‘presidential parliamentary’ (which others include under semipresidentialism) on the basis of the constitutional position of the president.

Since its inception in the constitution of the Weimar Republic (1918) and the Finnish Constitution, it has been the object of considerable dispute. Different

terms were used to characterize it: bipolar executive, parliamentary presidential, and Duverger established the term semipresidentialism. The ambiguities surrounding it lead some authors to treat it as a variant of presidentialism, while others see it as a form of parliamentarism. This author, as Sartori, considers it a form *sui generis* distinct from both presidentialism and parliamentarism.

Bartolini (1984) has shown that semipresidentialism was introduced in countries that achieved independence and sought a symbol for the new nation (Ireland, Iceland, and earlier in Finland). In Portugal, it was an attempt to overcome the uncertainties of a transition to democracy.

The French semipresidentialism of the Fifth Republic after the introduction in 1962 of direct presidential election is a two-headed system. It makes possible the alternation—according to some authors—between presidential and parliamentary phases depending on the party or parties of the president having a majority in the chamber. Sartori, rightly, prefers to speak of ‘oscillation,’ since, in the case of split majorities—described by the French as ‘cohabitation’—the president retains some specific powers, particularly in foreign affairs and is not reduced to the status of a president head of state in a parliamentary republic. Nor can a president cum government, that has to govern with and through another body, be assimilated to a ‘pure’ president that governs alone, that is the government. The oscillation assures considerable flexibility and until now ‘cohabitation’ has worked relatively well.

Elgin (1999, p. 14) lists countries that he considers semipresidential: 6 in Western Europe: France, Finland, Portugal, Austria, Iceland, and Ireland; 5 in Central and Eastern Europe: Poland, Bulgaria, Romania, Croatia, Macedonia, and Slovenia; 11 in the former USSR: Russia, Ukraine, Lithuania, Moldavia, and Belarus (of them in the Asian belt: Armenia, Azerbaijan, Kazakhstan, Kyrgyzstan, and Uzbekistan; 5 in Asia and the Middle East: Lebanon, Maldives, Mongolia, South Korea, and Sri Lanka; 3 in America: Dominican Republic, Guyana, and Haiti; and 11 in Africa. A total of 42 countries, among which only 18 in 1999 were rated from 1 to 3 on the Freedom House index of political rights; 6 in Western Europe, 4 in Central and Eastern Europe, 1 (Lithuania) in the ex-USSR; 2 in Asia; 1 in the Americas; and 4 in Africa.

The conclusion about regimes that from a formal constitutional perspective and definition can be classified as semipresidential is that the material constitution (the actual working over time) varies enormously. In some, the president, although popularly elected and with considerable legal powers, acts more like a president in parliamentary regimes. One difficulty is that a large number of countries that have adopted semipresidential institutions are new democracies, and are politically unsettled (and doubtful democracies), and it is premature to characterize those

politics. Moreover, much depends on the personality and political goals of the founding presidents and their successors.

Though all conceptual classification of forms of government cover a wide range of variations, this is even truer about semipresidential given the ambiguities in the constitutions about the powers of presidents and prime ministers, the role of leadership and personality, and the fact that the extended list of such regimes includes many countries dubiously democratic.

On the basis of the long-time actual working of formally semipresidential regimes, Linz (1994) has excluded Austria, Ireland, and Iceland from the list and he and Sartori (1997) would also exclude Portugal after 1982.

The dual legitimacy resulting from the separate direct election of president and parliament persists in semipresidential regimes, but the principle that a prime minister requires the confidence of a majority in the parliament reduces—perhaps even eliminates—the conflicts derived from ‘divided government.’ The French constitutional practice in the situations of ‘cohabitation’ supports that interpretation, though one might still ask to what extent it reflects a long tradition of parliamentarism (in addition to other favorable conditions).

We might add to the complexity (and perhaps confusion) a distinction between formally semipresidential regimes in which the president exercises significant powers (and is expected to do so) and those where he has not done so (and is not expected to do so). We obviate the argument that the formal institutional structure is not irrelevant, and that in fact it might at some point become politically relevant. The formally but not materially semipresidential regimes on that account are not parliamentary though they may work as parliamentary. More complicated is the issue—not considered in the earlier studies of this regime type—of the president enjoying such formal and actual powers that the prime minister and his cabinet are fully dependent on the president and the parliament, though formally empowered to question that dominance, is unable to do so. Should such regimes be considered presidential rather than semipresidential? The question can be raised about Russia and Sri Lanka. Again, the complex constitutional rules cannot be ignored but so can the actual working of the system under Yeltsin not be fitted into a ‘semipresidential mode.’ With such a narrowing down we still would have a number of working stable pure semipresidential regimes.

Presidents generally are identified with a political party, a leader of a party, or after winning the nomination of a party become its leader (yet when defeated lose that position). However, in Russia, Yeltsin, though elected with the support of the parties, opted for not identifying with a party and the constitution formally forbids the president from being

a party member. The same is true for other post-communist presidential or semipresidential constitutions.

The idea of president above party, not identified with a party and not campaigning for a party, is likely to make it more difficult for a president to have party support, and does not contribute to the building of strong parties.

Semipresidentialism can work well when the presidential majority and the majority in parliament are of the same party or coalition and when, without being the same, there is a majority in the chamber, supporting a prime minister of a different party (the French ‘cohabitation’). The system becomes more problematic as Kaltefleiter (1970) has analyzed in detail when the parliament is unwilling or unable to provide support to the choice of prime minister or of the president but is also unable to support someone of its own choice. This can be the case of a highly fractioned parliament or of a polarized pluralism in which the extremes make it impossible for the center to govern. Parties might be ready to tolerate weak presidential cabinets (abdicating their responsibility) and the president governing by decree. The president, on the other hand, having the power of dissolution, may be tempted to call for elections to solve the impasse and construct a majority. Repeated elections in a climate of crisis might deepen the crisis and contribute to strengthen the antisystem disloyal or semiloyal oppositions. These patterns developed in Germany under the presidency of Hindenburg and his presidential cabinets, contributed to the breakdown of the Weimar Republic.

Presidential Personality

The structure of the American constitutional system and the realities of American politics combine to make it a virtual certainty that the personal qualities of the chief executive will have significant consequences for the nation and the world. The Constitution accords the president coequal status with the legislative and judicial branches of government. Barring impeachment by the House of Representatives and conviction by the Senate, he (and at some possible point she) is entitled to remain in office until the end of his term. Because the occupant of the Oval Office has power to veto legislation and is his nation's chief diplomatic officer, the commander and chief of its armed forces, and the administrator of its laws, he is a force to contend with even when his standing with the public and Congress is at low ebb.

One could imagine a nation in which the highest political leader had great formal powers but was of little personal consequence, because that individual was merely the agent of a powerful political party or some other extra-governmental force. That is emphatically not the case in the USA, where the political parties are highly decentralized and there are many centers of power. American presidents have placed their stamp on public policy since the founding of the Republic, but for much of American history the president tended to defer to Congress for the initiation of policy, the federal government played only a modest part in the lives of citizens, and the nation was inactive in global affairs. Then came the Great Depression,

World War II, and the incisive response to these challenges of Franklin D. Roosevelt. During the three terms and three months of the Roosevelt presidency, the USA became a world power and a nascent welfare state, and the presidency itself underwent a metamorphosis. The president replaced Congress as the principal source of legislative proposals; presidents began to make an increasing amount of public policy by executive action; and the Executive Office of the President was created, providing the chief executive with the organizational support needed to carry out his obligations.

The qualities that distinguish one chief executive from another have their greatest potential impact in the realm of national security, where the president is custodian of a vast nuclear arsenal. No president other than Harry S. Truman has employed nuclear weapons, but there have been many presidentially-initiated conventional military commitments, the largest of which have been in Korea in the 1950s, Vietnam in the 1960s and 1970s, and the Persian Gulf in 1991. The president also is a major domestic force, not only because of his formal powers, but also because his great political visibility places him in a unique position to seek public support for his policies.

The two most influential efforts to identify the personal qualities that shape presidential performance are Neustadt's *Presidential Power* (1960), and Barber's *The Presidential Character* (1972). Neustadt's book, which has been described as the American equivalent of Machiavelli's *The Prince*, is an exercise in political psychology with the emphasis on the political. Taking it as his premise that the American political order places severe constraints on the chief executive, Neustadt argues that a president can best overcome the constraints on him by using his formal powers as levers for bargaining and persuasion and making it evident to the other members of the policy-making community that he has the support of the public and is a skilled, determined political operator. From this it follows that an effective president should be well grounded in the ways of American politics, sensitive to power relations, and self-assured about the merit of his policies and his ability to direct his nation.

Barber's book is a study of political psychology with the stress on the psychological. Barber identifies five broad determinants of a president's White House performance. Two relate to the political context—the contemporary *power situation* (e.g., the partisan balance in Congress) and *climate of expectations* (e.g., the state of public opinion). The other three bear on the president's inner characteristics—his *political style* (habitual way of carrying out his responsibilities), *world view* (political beliefs and assumptions), and *character* (the deeper layers of his psyche). In principle, this is an excellent framework within which to analyze presidential personality, in that it reminds the analyst that a president's actions will be a joint function of his personal predispositions and his political context

(Greenstein 1969). In practice, however, Barber's focus is virtually exclusively on character, which he classifies in terms of whether a president is active or passive in the conduct of his responsibilities and positive or negative in the feelings he invests in politics.

In the resulting four-part classification, the two passive types parallel David Riesman's distinction between other- and inner-directed personalities. (Reisman 1950). These are the *passive-positive* presidents, who take their clues from others, and the *passive-negative* presidents, whose motivations for public service are grounded dictates of their consciences. Neither type, Barber argues, is well suited for the activist demands of the modern presidency. Barber's two active types echo another important distinction. The *active-positive* presidents are marked by what Lasswell (1951) refers to as the democratic character structure, which is to say that they are free of emotional perturbations that impede their leadership. The *active-negative* presidents are of a piece with the class of politicians Lasswell identifies as emotionally troubled power seekers—those for whom politics is a means of venting inner insecurities. As Barber puts it, the active-negative presidents channel great energy into their political actions, 'but it is an energy distorted from within' (Barber 1972, p. 9). Examples of such distortions include Woodrow Wilson's stubborn refusal to make the modest compromises that would have permitted the ratification of the Versailles Treaty and Lyndon Johnson's persistent escalation of the war in Vietnam, despite mounting protest at home and lack of success in the field.

Barber performs a valuable service by directing attention to the deeper strata of presidential personality, but his assumptions about human motivation are overly simple. Indeed, the very dichotomies that determine Barber's typology fail to account for important complexities. Rather than being either positive or negative in their feelings about politics, presidents may be subject to mood swings, as was the case of Theodore Roosevelt and Lyndon Johnson. Rather than being either active or passive, they may be active in some spheres and passive in others. Thus, Ronald Reagan was a tireless public communicator but had a hands-off approach to the internal workings of his presidency.

Barber's taxonomy is an example of what A. L. George and J. L. George (1998) characterize as a 'file drawer' approach to personality analysis. As an alternative, they propose elucidating presidents and other political figures in all of their complexity, drawing on existing clinical typologies as sources of hypotheses about a subject's inner dynamics. Theirs is the strategy taken in the most persuasive presidential psychobiographies, including their own sharply etched portrait of Woodrow Wilson (A. L. George and J. L. George 1956), Glad's (1980) subtle account of Jimmy Carter, and Renshon's richly psychoanalytic interpretation of Clinton (Renshon 1996).

A related track can be found in Greenstein's *The Presidential Difference* (2000), in which each of the eleven presidents from FDR to Clinton is characterized on his own terms but also compared with the others on the basis of six criteria: *public communication ability, organizational capacity, political skill, policy vision, cognitive style, and emotional intelligence*. A number of instructive patterns emerge. Only three of those presidents prove to have been consistently outstanding public communicators, Roosevelt, John F. Kennedy, and Reagan. In each case the president's effectiveness was much enhanced by his rhetorical prowess. Organizational capacity proves to have been even less common than eloquence, but it is at least as important. The most dramatic example of what can result in its absence is the chaotically organized Kennedy administration's failed effort to land anti-Castro insurgents at Cuba's Bay of Pigs.

The presidency of Jimmy Carter illustrates the critical importance of political skill for presidential effectiveness. Carter displayed impressive political ability in his rise to the White House, but upon becoming president he resisted the standard reciprocities of Washington politics, with negative results for the success of his program. The presidency of Lyndon Baines Johnson offers a complementary illustration. Between November 1963 and the end of 1965, Johnson displayed prodigious political skills, presiding over a tidal wave of legislative enactments. But in 1965 Johnson also embarked on an open-ended military intervention in Vietnam, using his skill to minimize public debate and controversy. What Johnson lacked was a realistic policy vision, at least in international affairs. He failed to establish the precise goals of the intervention, its probable duration, and the likely troop requirements. By 1968 there were a half million American troops in Vietnam at which point Johnson halted further troop increases, entered into negotiations with the communists, and withdrew himself from contention for a second elected term.

The cognitive and emotional qualities of presidents also are central of their leadership. One way presidents differ in their cognitive styles is in their capacity for abstract thinking. Jimmy Carter, for example, had an impressive ability to master specifics, but was unable to embed them in a larger rationale. Richard Nixon, by way of contrast, had an outstanding capacity to envisage broad patterns and possibilities. Before taking office, Nixon established three major international policy goals: extricating the nation from the fighting in Vietnam, arriving at an accommodation with the Soviet Union, and establishing relations with the People's Republic of China. By the end of his first term he had accomplished them all. But during the same period Nixon initiated the program of domestic political espionage and sabotage which led to the destruction of his presidency.

Nixon was one of several modern presidents who had outstanding cognitive strengths, but lacked what

has come to be called emotional intelligence (Goleman 1995), a term that captures the ability to manage one's emotions constructively, rather than being under their domination. Others include Johnson, Carter, and Clinton. Nixon and Johnson presided over Vietnam and Watergate—two of the unhappy episodes in American history. The presidencies of Carter and Clinton were not marked by comparably dire events, but each of them suffered from the character flaws of the chief executive.

The American political system is said to be one of institutions rather than individuals. But it was not the institution of the presidency that authorized the use of the atom bomb against Japan or led the USA into Vietnam. It was Harry S. Truman and Lyndon B. Johnson. American history is replete with episodes in which presidents took actions that might not have been taken by another White House incumbent, some of them of momentous significance. It follows that the qualities that distinguish one president from another demand close and continuing attention.

F. I. Greenstein

Presidential Popularity

A president's 'popularity' consists of the public's affection for him and endorsement of his policies. Popularity becomes significant to the extent that it can be used by a president to achieve his policy goals. For much of the twentieth century, commentators discussed the 'mandate' that a president has received in an electoral victory for him and his party in Congress. A more recent development has been the attempt to analyze and measure a president's popularity, defined as a resource enabling him to pursue goals that were not a product of that mandate. It is this latter point on which most recent scholarship has been focused following the publication of Richard Neustadt's *Presidential Power*, arguably the most influential book on studies of the presidency. Neustadt stated that a president's standing with the public, along with his professional reputation, was the base on which his influence and success would lie.

The need that White House officials have shown to organize and mobilize a president's popular standing stemmed from significant changes in the political environment during the second half of the twentieth century. Previously, the most important talent a president needed to gain support in the political system was to be able to bargain and negotiate with the independent political powers of Congress, the political parties, and the states. Without this collective mobilization of resources he did not have the ability to frame government policy. Important exceptions to this constitutional weakness of the office occurred during declared international wars such as World War I, when President Woodrow Wilson was able to direct policy without the normal deliberations and specific legislative powers granted by Congress, and during the extreme internal threat of the Civil War when President Lincoln asserted similar plenary authority.

The changes that led observers of the presidency to recognize the importance of his popularity as a major political resource occurred because of the erosion of hierarchy and authority among those in the political system whose support he needed to achieve his goals. After 1960, the fragmentation of institutional power led presidents and their advisers to try to gain and maintain the allegiance of a majority among the politically involved portions of the public. The diminished ability of a president to make arrangements within the small sphere of those who continuously engaged as primary actors in the political system required that he seek public support for almost all-important domestic policies before they could be instituted.

Beginning with the Administration of Richard Nixon, the White House established and continued to develop institutions at the service of the president so that he could maintain continuous support for his conduct of the office, could gather public support for

his policy direction, and combat his adversaries in the political system and the media whose activities weakened the president's status with the public. As Nuestadt elucidated, presidential power was now dependent not only on his professional prestige among national political influentials but on his popularity and prestige among the public at large.

Changes in technology have also played a central role in the importance of presidential popularity as a major foundation on which a president depends. Until the third decade of the twentieth century, however, a president had no way of reaching a national audience whose attention he could command directly and simultaneously. This changed dramatically with the arrival of radio, film with sound in the ubiquitous newsreels in the third and fourth decades of the twentieth century, and the establishment of television as the primary universal channel of communication and news in the fifth and sixth decades, when a president could sell his policies directly to an audience made up of large segments of the public, an audience that could increase his influence with formal apparatus of power in the system.

An early prediction of the importance of presidential popularity may be found in the pre-presidential work of Woodrow Wilson. In series of lectures delivered in 1908 while still in the academic world, Wilson stated that the president 'is the one person about whom a definite national opinion is formed, and, therefore, the one person who can form opinion by his own direct influence and act upon the whole country at once' (Wilson 1961, p. 127.) Other major commentators on the presidency through the 1950s put little or no emphasis on the issue of popularity. Among the best-known authors of texts on the presidency during this era, Clinton Rossiter provided only passing mention of the consequences for a president of his standing with the public (Rossiter 1954). Rossiter did suggest that communication with the public is an important tool of presidential leadership. Edward Corwin, author of the most widely used text on the presidency, made no mention at all of popularity (Corwin 1989).

By the 1960s and 1970s, political scientists, journalists, and other observers recognized that there was an important relationship between what a president had been able to accomplish and his personal support among the public. Especially after the end of the Cold War in the late 1980s, a president could no longer use his prestige as defender against a recognized adversary to gain support for his efforts.

Studying these phenomena, however, proved both difficult and elusive. What exactly was a president's popularity? Did it stem from his personal skills in presenting himself, or from the benefits the public believed could be attributed to him? Did events drive his popularity up or down, or did his popularity enable him to undertake difficult and risky objectives, which, if successful, would make him loved and respected by

the public? Furthermore, although you could show statistical correlations between the president's standing with the public as measured by polls, surveys, and particular events of his administration, causal links would be much harder to establish. Attempts to analyze the hows and whys of the level of popular support a president received during his term in office did not necessarily establish the consequences of this support.

The issue of presidential popularity now consists of a body of work divided here into two categories:

(a) The first encompasses research into how to define and measure presidential popularity, and how to explain changes in that popularity over time. Some variables that are commonly offered as potential explanations for changes in presidential standing with the public are presidential actions, the president's abilities as a communicator, news events, and the presentation of the news by the media as well as the general level of stability and prosperity in the nation.

(b) The second category includes work that addresses the question of how presidential popularity serves as a resource or constraint on a president in his dealings with other political actors. In particular, researchers in this area focus on a president's institutional and personal efforts to use his popularity to garner support from other institutional and political supporters in the system.

1. *Measuring Presidential Popularity*

Efforts by scholars to measure and obtain data on the public's perception and approval of a president have relied on polls, particular those published by the Gallup organization, which has provided results since the 1930s. From 1975 through 2000, Richard Brody provided the most prolific and important analysis summarizing public attitudes toward the president (Brody 1991; this book provides the best bibliographic source on works by Brody and others through 1991). In particular, Brody looked for correlations in the popular standing of the president, and public support for the president's ability to handle economic, social, and international situations. Following the course of a president's popularity during several administrations, he found that 'news events are dynamic ingredients in the processes of opinion change.' Further, 'evidence of policy success and failure contained in daily news reports in the mass media' are the basis on which the American people form and revise their collective evaluation of the president. (Brody 1991, p. 9)

Students of presidential popularity have paid a great deal of attention to the so-called 'rally phenomenon,' first put forward by John Mueller in 1970 (Mueller 1985). He suggested that poll data indicated that presidents received a significant boost in their popular rating from a public affected by patriotism when news events suggested that an international

crisis could involve the safety of the nation or its military forces. The widespread dissemination of this theory during the Cold War led to the political charge that a president might undertake military action deliberately to distract the public from other failings. Subsequent research, however, has indicated that a president receives such a boost in support only if there is no counterelite opposing his action. Since the end of the Cold War, many international events have been greeted with debate rather than support by the opposition and the rally phenomenon seems much more ephemeral.

A continuing problem of this research has been the difficulty of determining the proximate causes of fluctuations in a president's popularity. For example, although one can point out that a particular level of popularity was measured at the same time as certain events occurred, it is not clear whether there was support for a president's policy because he was popular or because the public endorsed the policy. Further, as suggested by Paul Gromke and Brian Newman, poll standing may reflect an 'aggregation of personal preferences' rather than the 'preferences of aggregates' (see Gronke and Newman 2000; this paper contains an excellent bibliography of recent works in the field.)

2. The Fabric of Presidential Popularity

The second line of study involves descriptive research emphasizing the action and/or statements of a president and his entourage as they attempt to bolster his standing with the public. Using interviews, observations, and reviewing documents, these researchers present a portrait of the importance of popularity as a factor determining a president's status in the political system. In particular, they have focused on the methods the White House employs to enhance a president's success in gaining approval for his administration. They also examine the activities of those in politics or working for news organizations who provide an alternative and frequently critical version of what is going on.

In *Going Public*, Samuel Kernell describes the process by which presidents have needed to gain public support in a political universe where persuading Congress or the bureaucracy involves approaching them with a powerful backing (Kernell 1997). In a study of the relationship between news organizations and the White House, Michael Grossman and Martha Kumar describe the institutionalization of White House operations designed to maximize the presi-

dent's standing through the news media and the efforts by news organizations to present an independent and alternative viewpoint (Grossman and Kumar 1981). In *Congress and the Presidency*, Nelson Polsby (1976) describes the difficult problem a president has in converting his public support to a body that has its own connection with the public: 'It is hard for a President to change all this while explaining the intricacies of a particular issue over television. He can, however, communicate his concern about the issue ... and, to a certain extent, set the terms in which it will be debated' (p. 187).

Researchers of this type also have a problem determining whether a president's standing is due to their efforts or other factors in the political environment. In spite of this lack of generally applicable tools of measurement, however, all researchers agree that what they have found has provided important information about how a president's standing affects his success.

Pri

Primary Elections

One of the major functions that political parties perform in democratic political systems is the recruiting and selection of candidates for public office. In most democracies, this task is performed by a small number of official party members, meeting together as a caucus, committee, or convention. In the USA, by contrast, candidate selection is done almost entirely by party primaries: preliminary elections, held under governmental auspices, in which virtually every interested voter is allowed to participate, regardless of their past or current support for the party and its purposes.

1. History and Development

From the 1830s through the early 1900s, American political parties nominated their candidates for public office through a multitiered system not unlike those still used in most other democracies. The system began with gatherings of the party membership in small local units such as towns, wards, or precincts, which would select delegates to county or district conventions. These county and district conventions would nominate some candidates themselves and might also select delegates to participate in a state convention.

In the first decade and a half of the twentieth century, however, this system was almost entirely abandoned, as most states enacted legislation requiring the major political parties to nominate their candidates through primary elections. The rapid and widespread adoption of primaries was the confluence of two distinct trends within the American political system. The first was a movement to subject the parties to a greater measure of legal regulation. Though parties clearly played a major role in electoral politics, they were, in the beginning, regarded as entirely private entities, such that fraud, intimidation, and corruption in party conventions was seen as a purely internal matter. As Key (1958) put it, 'it was no more illegal to commit fraud in the party caucus ... than it would be to do so in the election of officers of a drinking club.' Shortly after the Civil War, however, a number of states began passing laws aimed at outlawing bribery and fraud and preserving some measure of order and procedural integrity in party affairs. By the end of the nineteenth century, almost every state had enacted some legislation of this kind (for a detailed discussion of this development, see Merriam 1908).

Even as this trend was sweeping the field, however, a second demand was being made: that the parties needed to be 'democratized.' To quote Key again, 'through the history of American nomination practices runs a persistent attempt to permit popular participation in nominations and thereby to limit or to destroy the power of party oligarchies.' In the early 1900s, this viewpoint had a particular resonance with the Progressive movement, which saw popular government as being threatened by an alliance of party machines and powerful economic interests. The push for party 'democracy' was given further impetus by the increasing sectionalism of the American party system. By the late 1890s, many parts of the country had become so completely dominated by one party or the other that receiving the major party's nomination was tantamount to being elected.

Though a number of southern Democratic parties had already used primary elections on their own initiative, and other states had made them available on a voluntary basis, the first comprehensive, mandatory, statewide primary law was adopted by Wisconsin in 1903. Wisconsin's example was quickly emulated in a number of other western and midwestern states, and then spread to the rest of the country. By 1917, 'the direct primary had been adopted for most nominations in all save a handful of states' (Key 1958). A small number of states resisted the trend, but the tides of historical circumstance were clearly against them. The last holdout was Connecticut, which finally enacted a primary law in 1955. As of the early twenty-first century, primary elections are clearly the dominant way of making nominations throughout the USA.

It is perhaps worth adding that most state election laws require nomination by primary election only for so-called major parties (usually defined as parties that received some minimum percentage of the vote in the last election). Minor and third parties, such as the Libertarians or the Socialists, still generally use a caucus-convention process to nominate their candidates for public office.

Students of comparative politics have generally regarded primary elections as a uniquely American institution, strikingly different from the nomination systems employed in every other democracy (see, for example, Ranney 1981). While this still holds true as a generalization, there are some signs that other countries are beginning to experiment with primaries. In 1999, for example, the PRI in Mexico nominated its presidential candidate through an open, national primary. In these other countries, however, the de-

cision to use a primary is generally made by the party itself; only in the USA is the primary imposed upon the major parties by law.

2. Presidential Primaries

The trend toward primaries also partially transformed the presidential nomination process. Since the 1830s, both major parties in the USA had nominated their presidential candidates at national conventions, to which each state sent its own delegation. These state delegations, in turn, were selected at state party conventions or by state party committees. Beginning in 1912, however, a sizable number of states started using primary elections to choose their national convention delegates. Some Progressives (including President Woodrow Wilson) wanted to go further, scrap the national conventions entirely (at least as a device for making nominations), and choose the parties' presidential candidates through a national primary.

Yet, for a variety of reasons, primaries never became as thoroughly institutionalized in the presidential nomination process as they did in making state and local nominations. Proposals for a national primary never came close to being enacted; and while 25 states had passed presidential primary legislation by 1916, over the next 15 years eight of them repealed these statutes. The result, when all the dust had settled, was a distinctive system for conferring presidential nominations that modern scholars generally call the 'mixed system.' Under the mixed system, about one-third of the states selected their national convention delegations via presidential primary, while the remaining two-thirds used state conventions or state party committees. National conventions thus had a partly popular, partly organizational basis, and remained significant decision-making bodies, though the presidential nomination itself was increasingly decided in a single ballot (the best account of presidential primaries during this period is Davis 1967).

The mixed system came to an end in the early 1970s. In 1968, at a remarkably divisive and chaotic national convention, the Democrats voted to create a commission to re-examine their presidential selection process. In just four years, this Commission on Party Structure and Delegate Selection (often called the McGovern-Fraser Commission, after the two men who served as its chairmen) completely rewrote the party's rules governing delegate selection—so much so that most scholars see the years since 1968 as constituting a new era in presidential nominations, often referred to as the plebiscitary system. While the plebiscitary system differs from the old, mixed system in a variety of ways, one of the most important differences has been a huge increase in the number of presidential primaries. Where the 1968 election fea-

tured 17 Democratic presidential primaries and 16 Republican primaries, by 2000 there were 39 Democratic primaries and 43 Republican primaries. Under the mixed system, it was quite possible for someone to win a presidential nomination without contesting a single primary; under the new system, the nomination essentially goes to whichever candidate wins the most primaries (on these points, see Hagen and Mayer 2000). Though both parties still hold national conventions, they are increasingly empty affairs, put on for the benefit of television, in which all the important questions have already been decided.

3. Who Can Participate?

Since primaries are a product of state rather than national legislation, primaries vary across states in a host of major and minor ways. One of the most important differences, for both its practical and theoretical consequences, concerns who is allowed to vote in the primaries. At one extreme are the so-called closed primaries, in which every registered voter is asked if they are supporters of or affiliated with any particular party, and then only those who have expressed an affiliation with a party in advance are allowed to vote in that party's primary. (Even in this 'extreme' case, it should be noted, the level of commitment required from the voter is exceedingly light. Voters are only asked to affirm a kind of general, psychological tie to the party; they are not required, in any state, to show that they have performed any previous service for the party or to make a binding promise of future support.)

A somewhat more permissive regime, that might be called semiclosed primaries, prohibits registered Democrats from voting in Republican primaries and vice versa, but allows unaffiliated or independent voters to vote in either party's primary. A related provision, found in many state statutes, allows voters to change their party affiliation when they show up at the polling place on election day. More permissive still are what might be called declarative systems, where there is no party registration and any voter may vote in either party's primary simply by asking for that party's ballot.

Declarative systems at least ask the voters to state publicly that they wish to participate in the Democratic or Republican party primary. Open primaries, by contrast, relieve the voters of even this encumbrance. In open primaries, each voter is, in effect, given a ballot for both parties and then allowed to make his or her decision about which primary to participate in in the privacy of the voting booth. Since open primaries at least require a person to vote in only one party's primary on any given election day, a number of western states have recently sought to remove even this last imposition on the long-suffering voter. So-

called blanket primaries allow voters to participate in both party's primaries on the same day, casting a vote in, say, the Democratic primary for the US Senate, the Republican primary for the US House, the Democratic primary for state representative, and so on. (In June 2000, the US Supreme Court declared the California blanket primary law unconstitutional.)

States frequently change their primary legislation in large and small ways, and many of the systems that emerge are not easily placed in one of the categories listed above. But according to a recent analysis by Jewell and Morehouse (2001), 11 states had closed primary laws, 15 used semiclosed systems, 10 had declarative systems, 10 used open primaries, and 3 (including California) had opted for the blanket primary. As has already been suggested, none of these systems demand very much from the voter in the way of past or future support for the party, and none except the closed primaries even do much to prevent members of one party from helping select the other party's candidates.

Does it matter what type of participation standard a state chooses to adopt? Much of the concern about having open or declarative primaries originally focused on the possibility of party 'raiding': cases where large numbers of persons affiliated with one party would vote in the other party's primary, with the deliberate intention of nominating the weakest candidate. But there is little evidence that this sort of thing occurs: it is difficult enough to get most American voters to the polls at all, much less to convince them to carry out a complicated strategic maneuver. A more likely consequence of open primaries is that they make it more difficult for the parties to present a cohesive ideology and set of candidates. Independents and members of the opposition party tend to be less committed to a party's core symbols and principles, and thus more willing to support a candidate who is out of step with large segments of his or her own party.

4. *Who Does Participate?*

In numerical terms, voter turnout in primary elections is substantially greater than the turnout at local caucuses (where these are still held), but smaller than the turnout at general elections. The best venue for comparing turnout rates is presidential elections, for besides having reliable data on the number of votes cast in presidential primaries and in the November general election, there are, as noted earlier, still about 10–15 states that continue to select their national convention delegates through a caucus-convention procedure. In general, contested presidential primaries attract about 20–35 percent of a state's voting age Democrats or Republicans, compared to a 50–55 percent turnout in the general election and a participation rate of just 1–3 percent in the presidential caucuses. In addition, there is far greater variation in

primary election turnout rates, depending on how many seriously contested races are on the ballot.

One major exception to these generalizations occurred in the South when that region was still a one-party enclave. Since winning the Democratic nomination virtually guaranteed a candidate's triumph in the general election, southern Democratic primaries regularly drew a far larger turnout than the general elections that followed.

It was once widely believed that the people who voted in a party primary were not very representative of the party's typical voter or identifier. More recent research, however, suggests that this fear has been exaggerated. While there are some differences between primary voters and general election voters (the former are, for example, somewhat older and better educated), the differences are relatively small and do not appear to have much effect on either the type of candidate who gets nominated or the ideological views that get expressed.

5. *Consequences*

The widespread use of primary elections as a nominating device has had several major consequences for American politics. First, it greatly weakened party organizations by taking away from them the single most important function they once performed. Prior to the Progressive Era, it was very difficult for a candidate to get nominated by claiming to be an 'outsider' or insurgent, running in avowed opposition to the party establishment. Since the adoption of the primary, however, such candidacies have become quite common. This is not to say, of course, that candidates endorsed or supported by the regular party organization invariably lose primaries; but primaries have greatly increased the odds that a non- or anti-organization candidate will be successful.

Primaries also greatly lengthen the public phase of American election campaigns, since they generally guarantee that, in one party or the other, there will be two distinct campaigns: one for the nomination and one for the general election. Primary campaigns are also more expensive than those required in a caucus-convention system, since they must be targeted at a much larger and less attentive audience.

Though the point is disputed, there is also a long-standing concern that primaries make it more difficult for the parties to present a united front during the general election. According to this argument, often referred to as the 'divisive primary' hypothesis, primaries require the parties to air all their grievances and divisions in public, rather than settling them behind closed doors. In some cases, indeed, candidates may go out their way to create or emphasize divisions, as a way of distinguishing themselves from the other contenders in a primary. Primaries, it is further argued, may be good at assessing the first choices of party

voters, but are not very good at discovering compromise candidates that are acceptable to a variety of factions, or at promoting 'balanced tickets' that offer some measure of reward or recognition to a diverse set of interests. Other scholars, however, claim that primaries do not so much create divisions as reveal the ones that already exist (for a review of these issues, see Mayer 1996). At the very least, one can say that sharp intraparty conflict was certainly not absent from the days when American parties selected their candidates through caucuses and conventions, and that the primary has not prevented most Republican and Democratic candidates from receiving a substantial majority of the votes cast by their fellow partisans.

Primary School Education

1. Introduction

The primary grades are the first few grades of elementary school, in which students aged approximately 5–8 are socialized into the student role and taught basic tool skills. Evolving views on what constitutes appropriate curriculum and instruction during these grades have been influenced by developments in theory and research on the needs, interests, capabilities, and other characteristics of children in this age range. Emphasis has shifted from maturation

of generic stages of cognitive development to learning of domain-specific knowledge networks, so that readiness to learn is now seen as dependent more on relevant prior knowledge and experience than on age or developmental level.

2. From Generic Developmental Stages to Domain-specific Learning

The term 'primary school education' refers typically to the first two or three grades of elementary school, in which curriculum and instruction emphasize basic literacy and numeracy skills. These grades also emphasize socialization into the student role: teaching children to pay attention to lessons and to work persistently on assignments; to follow prescribed conventions for participating in whole-class activities (e.g., raise hand and wait to be called on); to collaborate productively with peers in pairs and small groups; and to take good care of personal possessions and classroom equipment. In many countries, formal schooling in the primary grades is preceded by a transitional year (called kindergarten in the USA). It is a year in which students are oriented to school routines, engaged in activities that feature artwork and other multisensory representations that call for listening, speaking, counting, building vocabulary, making visual discriminations, exercising fine motor skills, or in other ways developing readiness for the more formal academic learning emphasized in subsequent grades.

At all levels of schooling, curriculum development involves negotiating a reasonable balance among four general approaches: (a) equipping students with knowledge that is lasting, important, and fundamental to the human experience (emphasizing but not limited to the academic disciplines), (b) following the natural course of child development by matching content to students' interests and learning needs at each grade level, (c) meeting society's needs by preparing students to assume adult work roles and citizenship responsibilities, and (d) combating social injustice and promoting social change by addressing social policy issues (Kliebard 1994). The principle of meeting children's developmental needs and interests has special relevance for the primary grades because substantial cognitive development occurs during these years. Children aged five–eight (especially five–six) are often considered to be not merely less knowledgeable, but qualitatively different in several respects from older children and adults. Philosophers traditionally have maintained that children reach the *age of reason* at about age seven, when developments in their understanding of cause-and-effect relationships, reciprocity and the Golden Rule, and other key concepts and principles enable them to distinguish right from wrong and engage in principled moral reasoning. Researchers studying children's cognitive development speak of a

developmental shift that occurs between ages five and seven as children become less like animals and infants and more like older children and adults in their performance on a broad range of perceptual and cognitive tasks (Sameroff and Haith 1996).

Jean Piaget (1983) described children aged two–seven as egocentric in purview and unstable in their cognitive structures and thought patterns. Within his comprehensive stage theory of cognitive development, such children were labeled as preoperational because they had not yet acquired reversibility of thinking, conservation, classification, seriation, and other *concrete operations* that stabilize older children's cognitive structures, and enable them to engage in systematic reasoning (see *Cognitive Development: Child Education*). Piaget's work implied that progression from the preoperational to the concrete operational stage was determined primarily by maturation and thus not open to significant acceleration through educational interventions. Consequently, primary schooling models influenced by his ideas tended to emphasize play, exploration, discovery learning, and sensorimotor activities over more formally academic and verbally mediated instruction. Ideas drawn from Arnold Gesell, Maria Montessori, and others who emphasized developmental stages or the presumed special needs and characteristics of young children similarly led to early childhood and primary-grade education models that emphasize short and varied activities, hands-on learning, concrete and integrated topical units rather than systematic treatment of disciplinary content, and attempts to be responsive to children's learning initiatives rather than to move them through preplanned curricula in lock-step fashion. Contemporary notions of developmentally appropriate practice continue this tradition (NAEYC 1991), as do the British Infant School model and the Italian Reggio Emilia model.

In recent years, the predominant theoretical emphasis in developmental psychology has shifted from the stage theory of Piaget to the sociocultural learning theory of Lev Vygotsky (1978), and research on children's cognition has shifted emphasis from general developmental stages to domain- and situation-specific learning. Findings indicate that many aspects of cultural learning, including much of what is taught in elementary school, can be acquired through instruction, in which teachers provide modeling and explanations for students and coach and 'scaffold' their learning efforts. Instead of emphasizing limitations in cognitive capacity, pending the unfolding of genetically programmed maturation of internal structures, contemporary thinking emphasizes connecting with and building on students' prior knowledge in the domain. Instruction focuses on the *zone of proximal development*: the range of knowledge and skills that students are not yet ready to learn on their own but can learn with help from teachers (Tharp and Gallimore 1988).

A related notion is that instead of being organized into hierarchical levels, knowledge is organized within networks structured around key ideas. This implies that, instead of having to begin with the lowest cognitive level (knowledge) and proceed systematically through successively higher levels (comprehension, application, analysis, synthesis, and evaluation), instruction can begin anywhere in the network and develop understandings from there. Initial possibilities will be limited by the extent of learners' prior knowledge in the domain, but in principle, learners can accomplish any domain-related learning goals if they experience whatever instruction and learning opportunities may be required (without having to wait for supposed maturation of cognitive structures to occur).

Studies of children's domain-specific knowledge have verified that children's knowledge and learning capacities in many areas are much more advanced than previously suspected, although children find certain concepts difficult to grasp and certain misconceptions are commonly developed (e.g., that the sun rotates around the earth instead of vice-versa). It appears that Piaget's notions about children's learning capacities were too pessimistic and that his stage concepts are more applicable to developments in children's mathematical and scientific thinking than to developments in their thinking about issues addressed in the humanities and social sciences. Children are able to understand historical and literary content that is encoded within narrative structures built around the goals and motives of central characters, as well as cultural comparisons or other social science content that focuses on food, clothing, shelter, transportation, or other cultural universals with which they have had personal experience (Downey and Levstik 1991).

Research supports the following generalizations about difficulty level of curriculum content: (a) difficulty increases with the number of items that must be addressed simultaneously (it is harder to compare or interpret three things than two things); (b) abstract content is more difficult than more concrete content; (c) fine distinctions are more difficult than gross ones; (d) learning from print alone is more difficult than learning from multiple media; (e) it is easier to develop skills in thinking about matters that students see as closely related to their own lives than about other matters; and (f) providing structure, cues, and props makes thinking easier (Fair 1977).

In summary, much of what Piaget claimed about stage-related limitations in children's cognitive capacities is incorrect or limited to certain knowledge domains. However, Piaget was correct in suggesting that young children are qualitatively different from older children and adults in certain respects, so that it is not possible (or at least, not cost effective) to teach them some of the more abstract and complex aspects of each school subject. Primary-grade children appear to be ready for certain forms of systematic instruction that go well beyond what usually are described as

‘developmentally appropriate practices,’ but not yet ready for discipline-based courses that emphasize abstract content organized conceptually.

3. Curriculum and Instruction in the Primary Grades

Children show the capacity for operational thinking at five or six, but usually do not become functionally operational (use operational thinking most of the time) until a year or two later. Thus, in effect, the preoperational period extends until second or third grade for most students. Preoperational students are ready to learn about familiar experiences and observable phenomena, especially through exploration and manipulation of concrete objects. They also learn basic literacy and mathematics skills and those aspects of content area knowledge that can be linked to their experience base. Instruction in basic skills should connect with knowledge about language, print, counting, and numbers that children develop through their preschool experiences. These tool skills should be taught in an integrated way that stresses explanations for meaningful understanding and opportunities for authentic applications (Adams 1990, Hiebert and Carpenter 1992, Hooper and DeFraim 1980). Execution of basic skills should gradually become automatized, but these skills should be learned as strategies, so that procedural knowledge (about what to do and how to do it) is developed in connection with related propositional knowledge (about the nature and purposes of the skill) and conditional knowledge (about when and why to use it).

Primary-grade students require demonstration and explanation of skills, guided practice with feedback, and frequent opportunities to develop mastery through application. Good demonstrations and visual aids provide concrete models for children to watch or imitate, so that they do not have to struggle to follow purely verbal instruction. Complex tasks are broken into subtasks that children can master in sequences that gradually connect until the ultimate task is learned. When they work on their own, they may need cues, reminders, or other learning *scaffolds* that will help them overcome their limited attention spans and difficulty in following spoken or written directions. Models of completed tasks can be placed in learning centers and worksheets can include features such as spacing and lines to keep things separate; boxes or arrows to indicate where responses should be placed or where to go next; and division of assignments into modular units that can be presented, reviewed, and discussed separately.

Teaching in subject areas other than basic skills should either emphasize familiar content or make the strange familiar by using concrete props or other media. Actual objects are best, but substitutes such as videos or photos are also useful. Because young

children have limited experience and major gaps in their vocabularies, they may need such props to enable them to understand what the teacher is talking about. They are most likely to have difficulty when content is organized around the conceptual structures used in the academic disciplines rather than around their own emerging knowledge structures. Children tend to learn specifics first and build up abstract generalizations only gradually as they accumulate experience; they have trouble following the logical patterns (flowing from general rules to specific examples) that adults find helpful. They are predisposed to learn in various domains, and although they are inexperienced, they reason facily with the knowledge they have (Bransford et al. 1999). However, it is important to focus instruction on familiar and observable events, or at least events that are easily assimilated into the students’ existing schemes. For example, children have an intuitive sense of the past and an interest in people that can provide a basis for instruction in history and social studies. However, such instruction has to reach the operative level rooted in students’ concrete experiences, e.g., by having them investigate their own family histories, explore the geography of the neighborhood, or examine photos and artifacts from another culture. If the instruction stays at a purely figurative level (associating tipis with Native Americans, sombreros with Mexicans, etc.), it will have little meaning or potential for inclusion in networks of knowledge structured around powerful ideas (and will engender stereotypes, rather than layered understandings).

There has been noteworthy cross-national variation in the age at which children begin school and in the scope of the primary-grade curriculum. As more has been learned about children’s knowledge and learning capacities, the trend has been towards earlier school initiation and more demanding curricula. Kindergarten classes in the USA, for example, now feature less sensorimotor play and more verbally mediated instruction than in the past. Even so, primary-grade teachers tend to be nurturant individuals who are oriented more toward teaching children than teaching subject matter, and who are concerned about supporting their students’ personal development and adjustment to school, along with meeting their academic learning needs. Subject matter specialization usually does not begin until at least the fourth grade, so primary-grade teachers tend to be generalists who stay with their home-room class all day and teach all subjects.

Some schools even use looping arrangements that keep intact classes together for two consecutive years with the same teacher, as part of a larger effort to provide emotionally safe and supportive classroom environments for young learners. The children often work in learning centers or sit together on a rug instead of always sitting at desks or in chairs. Teacher aides, adult volunteers, or older students often assist the teacher by working with individuals or small

groups. Assessment is mostly informal, without emphasis on tests or grades. Curricula often present an idealistic and optimistic view of the world, sanitized to eliminate disturbing or depressing content, in an effort to 'preserve childhood innocence' by delaying confrontation with threatening realities. In general, most primary education approaches focus on orienting young children to school and equipping them with basic knowledge and skills, but within a relatively informal and highly supportive learning community. This ethos has persisted through developments from penpals to KIDSNET; from mathematics flash cards to number lines and manipulables; from penmanship drills to authentic writing and publishing; from fixed desks to flexibly arrangeable children's chairs and tables, etc., apparently because it is well-suited to the educational needs and capacities of young students.

Primate Behavior: Significance for Understanding Humans

Interest in the behavioral similarities between human and nonhuman primates can be traced to Huxley's (1863) assertion of a phylogenetic relationship between humans and African apes. From the outset, primate studies have been incorporated into diverse fields of inquiry, including biology, ecology, psychology, and anthropology. Physical anthropologists were intensely interested in the degree to which primate behavior could be viewed through an interpretive lens for insights into the behavior and mental capacities of ancestral humans. Contemporary primate studies continue to inform a broad array of fields in both the human and nonhuman behavioral sciences; this integrative approach contributes to our understanding not only of human evolution, but of the behavior of extant humans as well. In this article we briefly outline the history of primate behavioral studies within the field of physical anthropology, discussing past uses of primatology for building hypotheses of human evolution. We then discuss changes in the theoretical approach to the study of primate behavior and their effect on the understanding of social systems. We conclude by presenting current issues in primatology as they relate to the study of human social evolution and behavior.

1. Early Primate Models of Ancestral Hominin Behavior

Early primate models for the behavior of ancestral humans were based on either: (a) assumptions of similarity in ecological adaptation between extant savannah-living primates and ancestral humans, or (b) shared behavioral traits within the clade of African hominoids (including humans). Raymond Dart, the discoverer of the *Australopithecus* specimen at Taung, popularized the hypothesis of a saltatory shift to human bipedalism, tool use, and hunting as a result of moving from forests to savannahs (Dart 1957). Dart drew explicit parallels to baboons as contemporary savannah-dwellers that might share behavioral similarities to early humans. Brief field studies of wild baboons revealed distinct differences from modern humans. Nonetheless, early descriptions of baboon sociality, which emphasized male dominance and

aggression as important influences on social structure, were used to typify the human condition (Kinzey 1987). The historical prejudices and methodological weaknesses that gave rise to these models have received considerable critical scrutiny (Cartmill 1993). Despite their methodological weaknesses, these early studies planted the seeds for future primate field studies by asking the following questions: (a) In what way do ecological parameters shape social systems? (b) What were the relevant ecological parameters that shaped early human evolution?, and (c) What can extant primates tell us about human behavior and social evolution?

While ecological affinities led to the baboon model, phylogenetic affinities between human and nonhuman apes prompted field studies of chimpanzees, gorillas, orangutans, and bonobos (Hamburg and McCown 1979). Taking a comparative approach, Louis Leakey sponsored well-publicized field studies of three great ape species. Anthropologists focused most attention on the common chimpanzee, the closest living relative to humans (Sibley and Alquist 1987). Behaviors observed in both humans and chimps were assumed to be phylogenetically conservative and therefore likely to have been expressed in our shared common ancestor. Tool use, hunting/meat eating, and the savannah/woodland habitat of chimps at Gombe reinforced the confidence of some anthropologists in the importance of this suite of characters for the evolution of humans (Kinzey 1987).

Contrary to expectation, these studies revealed that, neither baboon nor chimpanzee models have strong explanatory power in reconstructing the behavior of ancestral humans. First, extant species evolved under unique selective pressures and are not satisfactory typological specimens of ancestral species. Second, there is significant intraspecific variation in the behavior of chimpanzees and baboons, with no adequate criteria for selecting which behaviors are applicable to models of ancestral humans. Third, if behaviors common to chimpanzees and humans are assumed to be phylogenetically conservative, there are significant problems with interpreting morphological evidence from the fossil record that is not shared by either modern chimpanzees or humans (see Potts, in Kinzey 1987).

These criticisms apply to the assumptions and methods employed by these modeling approaches and not to the usefulness of primate behavioral studies *per se* in elucidating past and current human behavior. Past mistakes have served to refine the approaches by which primate studies are conducted and applied. At the beginning of the twenty-first century, few primate studies make explicit use of typological models. Contemporary studies of primate behavior emphasize a comparative approach in which the functions of behaviors are investigated under different ecological and social conditions. The next section presents important conceptual changes in the study of

primate behavior and their influence on the application of primate models to the understanding of human behavior.

2. Conceptual Shifts in Primate Behavior Studies

During the same time that primate behavior was being used to construct models of ancestral hominines, it was also an active area of interest in the zoological sciences, particularly in the subfield of behavioral ecology. Behavioral ecology investigates behavioral adaptations to ecological and social conditions. Although behavioral ecologists directly observe phenotypic traits, they use these observations to test falsifiable predictions generated within an evolutionary framework which states that individuals act in ways that increase their inclusive fitness. For example, studies testing optimal foraging theory use economic cost-benefit models to generate predictions of behavioral responses to ecological conditions that affect an individual's energy budget. Other studies, particularly those that focus on reproductive behavior such as mating and offspring care, examine an individual's decisions when situated in a particular social milieu (Krebs and Davies 1991). This approach to the study of primate behavior is distinctly different from that which was used previously in two important ways: (a) its goal is to test and further develop general evolutionary principles for behavior rather than create models of specific extinct species, and (b) comparative outgroups can be taken from all animals rather than those restricted to the primate order.

Within the field of anthropology, human behavioral ecologists applied evolutionary concepts to test economic models of the ecology of contemporary human hunter-gatherers. Human behavioral ecologists focused on contingencies that had been found to be important in non-human primates: predation, reproductive opportunities, and the distribution and predictability of resources. However, the application of primate studies to the interpretation of human behavior encountered significant difficulties following the publication of E. O. Wilson's *Sociobiology* (1975). Criticism of early sociobiological theory is well documented and expressed two main concerns. First, the effusion of speculations on the application of sociobiological principles to human behavior was untestable and therefore unfalsifiable (Caro and Borgerhoff Mulder 1987). The second body of criticism, which objected to sociobiological depictions of humans as inflexible executors of the interests of selfish genes, stemmed from a poorly explained differentiation between genotypic determinism and the plasticity of behavioral phenotypic expression. Suites of behaviors resulting from complex socioenvironmental conditions (e.g., 'rape') were incorrectly treated as simple units of evolutionary analysis (Sunday and Tobach 1985). Disagreement over the application of

sociobiological theory to the study of human behavior resulted in a division between cultural anthropologists, who emphasized human uniqueness, and those biological anthropologists who studied primate behavior with an eye toward understanding that of humans. While it is a truism that genetic make-up influences behavior, and genetic relatedness influences to whom particular behaviors may be expressed, genetic determinism has no place in behavioral ecology.

The contemporary use of primate behavior within anthropology has shifted from the use of primates as typological models of human origins to field studies and experiments that test predictions developed within a behavioral ecology framework. Significant methodological changes have accompanied this theoretical shift. First, standard methods for the collection of quantifiable data facilitate interpretable statistical tests of predictions and comparison across primate studies (Altmann 1974). Second, more primate species are studied, thereby providing a larger and more diverse sample for comparison. Third, long-term field studies provide information on seasonal and inter-populational variability in behavior, the ontogeny of and change in relationships among individuals, and the causes and consequences of demographic processes in long-lived species. Fourth, a more diverse representation of scientists expands the field of inquiry to include aspects of social life previously assumed ancillary to social organization, particularly female reproductive strategies and the energetics of offspring care (Altmann 1980, Hrdy 1999). Analyses of the resulting data sets demonstrate rich intra- and inter-specific variability in behavior and relationships that parallel the intraspecific variability observed in humans.

3. Current Primate Studies in Anthropology

3.1 Social Behavior

Two general principles are commonly invoked to explain group size and composition in birds and mammals. First, female reproductive success is limited primarily by the availability of ecological resources, particularly food. With whom females form groups, and the competitive regime between females within those groups, is a function of the distribution of ecological resources in space and time (Wrangham 1980, van Schaik 1989). Male distribution, on the other hand, is patterned upon that of females (Andelmann 1986). The diversity of grouping patterns observed among primates across a range of environments supports this general framework.

Whether of the scramble or contest type, competition for resources underlies this ecological model (Krebs and Davies 1991). Competition, however, can be expressed in multiple ways. Aggression between group members certainly occurs, and individuals

obtain inclusive fitness benefits by aiding kin in contests, but not all competition results in direct conflict. Unrelated individuals also engage in cooperative and affiliative behaviors, and reconciliation often occurs after conflicts (de Waal 1983). Several benefits accrue from affiliative interactions with non-kin. First, individuals who engage in post-conflict reconciliation experience more rapid reductions in stress response than those that do not (Aureli 1992). Second, initiating affiliative behaviors garners favor with powerful group members and develops relationships with potential future allies (de Waal 1983). Third, males who invest in nonsexual affiliative behavior toward females obtain future matings with their 'friend' (Smuts 1985). 'Peaceful' interactions are essential to the social cohesion of groups and provide an alternative means of exerting influence and eliciting support. Long life spans and the opportunity for repeated encounters between known individuals provide the conditions under which individuals can predicate present behavior on anticipated future social interactions (Byrne and Whiten 1988).

The study of behavioral ecology in humans is likewise concerned with the tactics employed by modern humans to survive and reproduce within a particular socioecological context. Using principles developed in the field of animal behavior, human behavioral ecologists collect data from modern hunter-gatherers to test predictions derived from ecological optimization models (Winterhalder and Smith 2000). Human behavioral ecologists are able to measure directly the economic results of behavioral traits thought to be important to human evolution such as the intersexual division of labor, long juvenile dependence, and females' lengthy post-reproductive life span. The results of such studies have led to important challenges to the primacy of hunting in human history, suggesting instead that the economics of female provisioning and care of offspring provide a more parsimonious explanation for the evolution of human social systems (Hawkes et al. 1997, O'Connell et al. 1999).

Because of their general applicability, the use of behavioral ecology models raises the question of whether primate studies in particular are any more informative than studies of other taxa. Several lines of evidence combine to produce a positive answer. While studies of all taxa, particularly social mammals, serve to test theories that may be relevant to humans regarding the causes and consequences of social systems, the complex nature of social relationships observed in nonhuman primates make them particularly useful as comparative species for understanding the function of human social relationships. In addition, the use of nonhuman primates as comparison species controls for traits more phylogenetically conservative than behavior that may influence behavioral options (e.g., life history parameters, functional morphology, and physiology). Confining the study of

behavioral ecology to humans within the field of anthropology limits the perspective from which to understand human behavior. Cross-cultural studies can demonstrate intraspecific variation, but they do nothing to reveal which traits or behaviors are uniquely human. Interspecific comparative studies among primates reveal the extent and degree to which certain behavioral patterns are confined to humans. Primate studies therefore both focus and expand the field of vision in the study of human behavior.

3.2 Functional Morphology

Anatomists have a rich tradition of inferring the behavior of extinct species based on fossil skeletons, and tooth morphology figures prominently in the reconstruction of hominin diets (Jolly 1970). Interpretation of fossils is only possible, however, with studies of analogous structures and their function in extant species. Recently, anatomists have teamed up with primate behavioral ecologists to combine direct observations of primate feeding behavior with dental morphology. This partnership helps refine the techniques used to determine ancestral diet and feeding patterns. For example, field studies of the feeding ecology of four sympatric Sumatran primates allowed Ungar (1996) to test whether incisor size corresponds with diet. His finding that incisor size and shape best reflect the mode of ingestion rather than diet *per se* resolves some conflicts in interpretation of the fossil record. Dental microwear analyses can reveal more detailed information about diet than can analysis of gross dental morphology. Recent field studies examine primate feeding behavior, measure the physical properties of foods, and cast the teeth of wild primates in order to better understand the relationship between food type, mode of ingestion, and microwear (Teaford 1994). Similar studies are being conducted on humans (Ungar and Spencer 1999). With further refinement of this new technique, analysis of dental microwear can play an important role in the reconstruction not only of the diet of ancestral hominines, but the use of teeth for non-feeding functions as well (Teaford 1994).

Studies of positional behavior investigate the relationship between postcranial musculoskeletal anatomy and locomotion. The means by which wild great apes travel in their natural environment reveal the function of bone and muscle in the limbs (Fleagle 1999), and comparative anatomy between great apes and fossil hominines provides a basis for inferring locomotor behavior in hominines. This approach has shown that bipedal hominines descended from an arboreal primate that moved primarily by climbing rather than brachiating (Fleagle 1999). Likewise, *Australopithecus afarensis*, the hominin most likely responsible for the famous Laetoli footprints (Leakey 1987), probably spent a good proportion of the day moving arboreally as well as bipedally (Stern and Susman 1983). Field observations also provide clues

to possible sex differences in behavior. In apes, sexual dimorphism corresponds with differential use of arboreal and terrestrial substrates for moving, with males spending more time on the ground than females (Doran 1996). If the sexually dimorphic *A. afarensis* moved on the ground and in the trees, sex differences in substrate use may have likewise occurred.

3.3 Intelligence/Cognition

The comparative study of intelligence and cognition among nonhuman primates in the laboratory spans over half a century (Russon et al. 1996). The discovery of tool manufacture and use in wild chimpanzees (Goodall 1968) put to rest concerns that the development of the cognitive capacities necessary to use tools by laboratory primates was an artifact of intensive interaction with humans. Wild orangutans also manufacture and use tools with considerable complexity (Fox et al. 1999). In contrast, the proficiency with which capuchin monkeys use tools in both field and laboratory settings is significantly lower than that of great apes (Visalberghi and Trinca 1989). Great apes have crossed the line into a domain of intelligence once postulated to be uniquely human; furthermore, the intelligence required for ape-level tool use and manufacture evolved before the orangutan–African ape split (van Schaik et al. 1996).

Tool use behavior, however, is only one demonstration of intelligence. The decision-making processes required for large-bodied apes to travel arboreally is another (Povinelli and Cant 1995). Complexity in social interactions such as deception evinces cognition as well (Byrne and Whiten 1988). Primate studies provide empirical proof that many purported aspects of human uniqueness, such as intelligence and culture, are unique to humans only insofar as they are defined as such (Cartmill 1990). The corpus of work in this field demonstrates that, broadly defined, intelligence has evolved by degrees rather than as a result of a single selective pressure on early hominids. Diverse levels and types of cognitive capacities in an array of primates elicit two questions about humans: (a) is the higher intelligence demonstrated in humans an added *degree* of intelligence or is it a difference of *kind*, or both? and (b) what selected for human-level intelligence? Language is an obvious difference between humans and nonhuman primates, and it will undoubtedly figure prominently in answering these questions.

4. Future Directions in Research

Although most primates live in groups, a group is comprised of individuals with interests that often differ from those of their group-mates. In addition, those interests change as individuals grow to maturity, reproduce, and then, in some species, shift to a post-

reproductive phase of life. Building upon earlier research, future studies are needed to investigate the complexity of factors that influence individual decisions within the context of group life, in particular: (a) the strategies that individuals employ to satisfy their reproductive interests, even when those interests conflict with other group members, and (b) reproductive decisions that incorporate not just matings or fertilizations, but offspring survival as well.

Male aggression or threat of aggression toward females is observed among most species of primates, including humans (Smuts 1992, Smuts and Smuts 1993). Some of this conflict is with current or potential mating partners. However, significant variation in rates of sexual aggression occurs between and within species. For example, woolly spider monkey females copulate without aggression from their mates or other males, while male sexual aggression in rhesus macaques occurs frequently. In baboons, particular males develop 'friendships' with females while others do not (Smuts and Smuts 1993). There is even variation in individual males: some human males with pair-bonded mates force copulations with other females, and some pair-bonded males alternately exhibit affiliative and aggressive behavior toward their mate (Ellis 1989). Despite the seemingly widespread occurrence among primate species, however, extreme forms of direct sexual aggression in the form of forced copulations are uncommon in primates other than humans and orangutans. Some hypotheses to explain this striking contrast have been proposed and deserve further exploration.

What is the function of male sexual aggression? Under what conditions does it occur? Feminist scholars and biological and social scientists have long recognized that conflict between female and male reproductive interests influence individual behavior and shape the social systems in which individuals live (Hrdy 1977, MacKinnon 1989). Theoretical treatments of intersexual mating conflict in human and nonhuman primates provide a basis for predicting the conditions under which male sexual aggression, and conversely female countertactics to thwart males, occur (Smuts 1992, Smuts and Smuts 1993). Recent studies provide some preliminary basis for comparison (Smuts and Smuts 1993), but to strengthen the comparative method more studies conducted across a greater spectrum of primates are necessary. Of particular importance is quantifying the costs of sexual coercion, such as reduced foraging efficiency, in addition to infant or female mortality. New non-invasive hormonal assay techniques for field-collected samples are starting to be used (Whitten et al. 1998) and will allow researchers to measure endocrine response by females who are subject to male sexual aggression. Using these techniques, research can reveal the degree to which male aggression produces physiological effects that may negatively impact female fecundity.

Little is understood about why females resist mating by some males but not others. Equally little is known about female tactics to circumvent male attempts to restrict female reproductive choice. More studies are needed to determine the degree to which females select mates based on variation in quality among males (direct mate choice) or whether other factors, including male aggression, sufficiently constrain females to result in facultative, or indirect, female mate choice (Gowaty 1992, Wiley and Poston 1996). Whether for genetic quality, the quality of services, or constraints placed by males, with whom a female mates has an important reproductive outcome. Females are therefore predicted to exercise tactics, including sperm selection, that optimize their ability to retain control over reproductive choice and the timing of reproduction. Techniques for genetic analysis using non-invasive sampling methods have recently been developed (Borries et al. 1999) and will in the future facilitate evaluation of the success of both male and female reproductive strategies.

Variability among male reproductive decisions is likewise important. In contrast to the previously pervasive view within evolutionary studies and behavioral ecology, a recent shift recognizes that the acquisition of multiple mates is not the sole factor motivating male reproductive decisions. Whether they are excluded by other males, fail to attract mates, or are constrained by the need to allocate time to nonmating activities, male primates are limited in the number of females with whom they can actually mate and produce successful young. Males therefore optimize reproductive effort within operating constraints. While limitations on male mating opportunities have traditionally been viewed in terms of male-male competition and male mating aggression toward females, this is not always the case. Male choosiness for mates is likely to be one important tactic in species that have long periods of infant and juvenile dependency (Altmann 1997). Differences in female fertility, for example, may guide males away from young females as mates. Furthermore, in primates conception and birth are merely the first steps to reproductive success. Offspring must survive into adulthood in order to reproduce, since reproductive success is most accurately measured in the second generation (Clutton-Brock 1988). Offspring survival is critically dependent on maternal competence, including mothers' ability to obtain access to resources necessary to rear young. Males are therefore predicted to prefer as mates those females who are higher ranking, older, and experienced (Altmann 1997).

Females with insufficient resources to rear young may abandon current offspring in order to invest in future reproductive opportunities. Alternatively, in order to meet the demands of rearing offspring, mothers in some species share the task of offspring care. Fathers sometimes significantly assist females, and the need for paternal care constrains male prom-

isculity in some primates as it does in many species of birds (Clutton-Brock 1991). Likewise, related or unrelated individuals sometimes assist mothers. Related individuals gain inclusive fitness benefits resulting from the survival of grandchildren, sisters, and cousins, while both related and unrelated individuals may gain needed experience necessary for the survival of their future offspring (Hrды 1999). Long juvenile dependency and the need for assistance in rearing offspring play an important role in the lives of extant hunter-gatherers, and it figures prominently in models of human social evolution (O'Connell et al. 1999). The function of extended juvenile dependency, how mothers meet the demands of extensive infant care, and the consequences for reproductive success are among the most fascinating questions of human and nonhuman primate life-history. Yet because primate life spans are so long, these questions are also among the hardest to study. As data from uninterrupted long-term field studies become available, questions concerning the fitness advantages to variation in parental and alloparental care can be addressed.

Primate Families, Structure of

We often talk about animal ‘families’ when referring to the breeding units of animals. The word ‘family’ however, is derived from the Latin word for ‘household’ in which a man controls the resources of his wife and offspring. Such entities seem absent in non-human primates. In contrast, most female primates and their

dependent offspring forage largely independently of the males. Furthermore, mating and breeding occur in a large variety of ways. Biologists use the term ‘mating system’ to describe the patterns of behavior related to mate choice and reproduction. Such mating systems are intimately linked to the social system in which the animals live, but these systems are not identical. Mating partners include, but need not be restricted to, social partners. A key characteristic of female primates is their monthly ovulation. Breeding seasons do exist in many primates, but overall periods of female fertility are more frequent than in other mammals. Accordingly, sexual behavior is frequent and has acquired additional functions in many primates.

1. Diversity of Primates and Their Mating Systems

1.1 Types of Mating Systems

Primates include two hundred species ranging in size from mouse-sized prosimians and pigmy marmosets weighing less than 100 g to orangutans and gorillas with males weighing over 200 kg. Most primates are tree-dwelling but some, such as gorillas and baboons, are terrestrial. While some of the prosimians (a group of relatively ‘primitive’ primates such as galagos, pottos, lorises, and lemurs) are nocturnal and mostly solitary, the vast majority of primates are diurnal and extremely social. In fact sociality and sexuality are key primate adaptations. Primate mating systems represent a wide spectrum ranging from polyandry, where a single female mates with several males (South American tamarins), to monogamous pairs (owl monkeys, gibbons), to multi-male, multi-female groups (chimpanzees, spider monkeys, red colobus monkeys, and baboons) to harem type groups where a single male has exclusive reproductive access to multiple females (gorillas and langurs). Single-male groups can experience temporal visits by groups of bachelor males (Guenons) and solitary males and females can temporarily gather (orangutans). Size differences between males and females (called sexual dimorphism) seem to correlate with the degree to which males of a given species are polygamous. The males and females of the (serially) monogamous gibbons are the same size but males of the polygamous gorillas and mandrills can weigh more than twice as much as females. Primate mating systems are far more flexible and dynamic than previously thought. The same species may show different mating systems in different locations or at different times in the same location (Dunbar 1988). Changes in resource distribution or social changes can cause animals to alter the ways in which they find and choose mating partners.

1.2 Reproductive Costs for Male and Female Primates

Sexual reproduction refers to the process by which male and female germ cells fuse and produce individuals with unique combinations of genes. The germ cells carry half of the reshuffled genes that the parents inherited from the grandparents. Female germ cells (ova) are large and costly to produce whereas male germ cells (sperm) are tiny and much cheaper to produce. In animals with internal fertilization and gestation, this discrepancy in reproductive effort is exaggerated. Female mammals bear an even more disproportionate cost of reproduction because of lactation (the physiological cost of which is higher than gestation itself). Male investment often ends with successful insemination, after which males can look for further mates. The average number of offspring born to male and female species is roughly the same for both sexes, but the variance is much higher in males, where some highly successful males sire large numbers of offspring and many others none at all.

Biologists have repeatedly pointed at the imbalance between male and female reproductive costs to explain why males have a natural tendency to be promiscuous while females tend to be coy and choosier (Hrdy & Williams 1983). This caricature of male emphasis on quantity and female emphasis on quality is in part responsible for the fact that students of animal behavior have long overlooked the importance of female choice and multiple paternity (Gowaty 1992). Females, much rather than just being passive resources, for which males compete, are pursuing their own reproductive interests very actively. Their strategies are often less conspicuous and may involve long-term patterns, which explains why they have so often been overlooked.

Male primates can undoubtedly increase their lifetime reproductive success by maximizing the number of matings with fertile females. In primates, where mating often has more functions than simple fertilization, there may be strong advantages to multiple matings for females as well. Primates have long periods of development and infants are very dependent on parental assistance. Parental care is crucial to primate reproduction and is mostly the responsibility of mothers, though, in many cases males are also involved. The tamarins of the Amazon forest even have cooperative paternal care for twins born to the female. The young of many primates benefit from the protection and care from males with whom their mothers associate. Infant baboons and gibbons are often carried by males and chimpanzee males are known to adopt orphaned male youngsters. Wherever male help with the rearing of offspring is needed and there are several males present in the group, uncertainty of paternity can cause males to assist offspring that they did not sire, resulting in a strong motivation for females to mate with many different males. Too much

uncertainty about paternity is potentially dangerous, as males can be a threat to offspring that they perceive as not their own.

1.3 Sex as a Social Tool

In bonobos, apes known for their frequent sexual interactions, sex is directly used to reduce tension in the group and is often exchanged for food. Chimpanzee females often exchange sex for meat that tends to be controlled by males, which do most of the hunting and use prey as a social currency. A female chimpanzee will copulate more than six thousand times with a very large number of males (10 to 30) while she can only produce a maximum of six surviving offspring. Similarly, the high frequency of same-sex sexual contact in bonobos plays important, entirely social roles. In fact, bonobos appear to be the one species of primates, where frequent female–female sex facilitates the existence of strong female alliances which are strong enough to keep male aggression in check.

1.4 Sexual Advertising in Multi-male Groups

Females in many species with multi-male groups exhibit conspicuous pink swellings of their genital area during several days around the time of their ovulation. These swellings are known as estrous swellings and they represent a formidable ‘tool’ for female primates. A female with a swelling becomes the focus of attention of all males in the group. Her social status increases and males will compete for access to her. Several females can have estrous swellings at the same time, thus making it virtually impossible for any given male to monopolize access to all of them. Estrous swellings appear to play an important role for species where females disperse and join new social groups after they become sexually mature. Swellings are a kind of ‘social passport’ which greatly facilitates a female’s acceptance by unfamiliar males. There is evidence for certain amounts of disconnect between the advertising of fertility and actual time of ovulation. Such a disconnect could work to the advantage of the female because she could escape the controlling efforts of certain males and exert a freer choice of paternity for her offspring. The topic of ‘concealed ovulation’ takes on considerable importance as many scientists have suggested that humans have attained a stage of perfectly concealed ovulation (concealed even from a large proportion of women themselves). To what degree the inability of human males to detect the moment of peak fertility in women has played a role in leading to the high frequency of (serial) monogamy in our species is a much-debated issue.

Some primates use vocalization as a way to attract mates. Notable cases are the orangutan, gibbons, and

siamangs. In the orangutan, an interesting case of multiple male mating strategy includes sexually mature but small males, that do not sing to attract females but rather rely on forced matings between several males and a very reluctant female. Female criteria for choosing their mates remain poorly understood. Females can certainly learn about future social partners through their yearlong interactions with males, but for detecting 'good genes' they must rely on indirect signs such as body symmetry and relative absence of disease and parasites.

2. Determinants of Sociality in Primates

2.1 The Need for Social Grouping

The distribution of resources and the presence of predators play key roles for the distribution of individuals across space. When resources are clumped, groups of animals can live around a particular cluster of resources and defend a certain territory. Such groups can form cohesive social units. When resources are few and very dispersed, no single cluster of resources can be defended even by large groups of animals. Such environments tend to harbor animals living in much smaller groups or as dispersed individuals. Even highly social populations of chimpanzees are known to scatter into much smaller sub-groups during periods of low food abundance. The solitary orangutans on the other hand can gather in large numbers during periods of plenty (mast fruiting).

There are many good reasons for living socially. More eyes can see better and more ears can hear better. Living socially facilitates the search for food and the detection of predators. Another advantage is the phenomenon of the 'selfish herd' where the presence of other individuals spreads the risk of predation, as any of the others is as likely to be preyed upon as oneself. Also, cooperation in anti-predator defense is only possible in groups. Obviously, social life facilitates finding mates, even if it will increase the competition for them. Animals in groups can cooperate in defending resources against competitors. Such cooperative resource defense, when done by males, may have the added benefit of attracting females to the group, which may represent unwelcome competition to the females already resident in the group. Finally, the presence of individuals possessing different capabilities (such as hunting, raiding beehives, remembering the time and place certain foods can be harvested) in a group will benefit all group members. Unique individual experience and history shape large-brained, long-lived organisms such as primates. The mating strategies within a social group can vary dramatically between individuals. Some males, for example, may not show any ambition with respect to the dominance hierarchy. They spend their

whole life as subordinate males. Their affiliative behavior and friendship with certain females in the group may in the end translate into numerous offspring. Certain females may be much more successful at forming social bonds with dominant males. Sheer force can allow a male to ascend in the dominance hierarchy, but the majority of animals in his group may not follow him. The cognitive capacities of primates appear to have coevolved with their tendency for sociality. Long-lasting relationships with many group members require good memory and social intelligence.

2.2 Costs of Living Socially

There are multiple costs to sociality. Competition between males can create social instability and conflict. Such conflict is often violent and can lead to harm to bystanders or even infanticide by males hoping to remove the offspring of competitors and gain rapid access to fertile females (the loss of an infant causes lactating females to resume ovulatory cycles). Competition occurs not only between males for access to females, but also between females for access to males, access that may lead to support (shared resources) and male protection during social conflicts. Competition between female may be the factor that precludes the formation of strong female coalitions against males in many species. Infanticide perpetuated by females has been observed in some wild primate groups and may represent the darkest side of female-female competition for resources. The study of female dominance hierarchies in natural primate populations is still in its infancy. Such hierarchies tend to be more subtle, nevertheless, female social rank can play an important role for reproductive success and change the way females invest in sons or daughters. Finally, higher risk of infection by pathogens and parasites is an important cost to sociality.

2.3 Most Primate Groups are Female Bound

In most primates, females and their female relatives remain in their native groups while most males disperse to other groups when they reach sexual maturity. Some notable exceptions to female residence are found in colobus and spider monkeys and in our closest living relatives, chimpanzees and bonobos, where females disperse upon reaching sexual maturity and males remain in their natal communities. The driving force behind dispersal is thought to be inbreeding avoidance and/or competition with animals of the same sex (Moore & Rauf 1984). Sexual mimicry in white-cheeked gibbons, where adolescent females look like males, and in red colobus, where young males have pseudo-swells, indicates that same-sex competition is important in those species. The mechanisms

underlying inbreeding avoidance are poorly understood. Whether primates are able to recognize their paternal kin by features inherited from the father or whether they simply avoid mating with individuals from the same age cohort is still unclear (Alberts 1999). In humans, close proximity at an early age seems to be the crucial mechanism that triggers avoidance as sexual partners.

2.4 Do Males Follow Female Spacing?

The way females deploy themselves across time and space tends to determine how males can space themselves around females. Only if the ecosystem is capable of feeding a large number of females with enough tolerance for each other can males attempt to control such groups, either as the solitary reproductive male in a harem or as a group of males cooperating in female and territory defense and sharing the reproductive access to those females. All multi-female groups create the potential for female–female competition over access to resources and access to males and the support they may provide. Competition between potential mates may create the opportunity to enhance the visibility of positive traits or weaknesses. Because competition involves stress and stress is known to impact an animal's immune system, competition can exaggerate the visible differences in male quality. If female choice incites increased male competition, then female choice may indirectly lead to an increased size difference between males and females. Because strong and assertive males can be more successful at guarding resources that they share with females, females may favor the evolution of such males. Females need male protection from unwanted attention of other males, including, in the extreme case, forced copulation, as well as against the threat of male infanticide; both are part of male mating strategy in many primate species (Smuts 1993). Strong and protective males by the same token will be more successful at restricting the independence of females.

3. The Importance of Genes

3.1 The Benefit of Multiple Paternity to Females

Mating with multiple males can be advantageous for a female in various ways. As mentioned above, confusing paternity of her offspring can effectively protect them from male infanticide. She may gain support from her mating partners, both in terms of social support during conflicts with other group members and in terms of material support in the form of shared resources. More recently, the possibility of a genetic benefit has been proposed and some evidence is starting to accumulate (Zeh & Zeh 1996, 1997).

Because the primate fetus develops inside the mother, the female and the fetus need to achieve a type of 'immunological détente.' That is, the fetus must not be rejected by the mother's powerful immune system but, at the same time, the demands of the fetus must be kept in check, not allowing it to exact too high a toll on maternal resources. Multiple paternity will produce more diverse offspring. Such diversity may have much to do with defense against disease. The vertebrate immune system is an immensely sophisticated and very costly system, in order to allow long-lived organisms such as primates to survive in a world in which very short-lived, rapidly evolving parasites and pathogens (ranging from worms and protozoa to bacteria and viruses) are a constant threat.

The immune system relies on genetic variation present in all populations, as well as generated anew in each individual in order to produce a flexible repertoire of molecular probes (antibodies and T-cell receptors) which detect specific intruding pathogens. It seems critical that each fetus inherits genes coding for two rather different immunological 'tool kits' in order for the offspring to be well equipped for its countless future encounters with pathogens. Conceiving offspring with different fathers would allow females to produce sets of offspring with more variation in their immune repertoires, strongly reducing the risk of losing all or most offspring to the same disease. The same obviously applies to males as well. Furthermore, paternal and maternal genes have to work in harmony in order to produce healthy offspring. Some combinations may simply fail to work and yet others may work but put the offspring at a disadvantage from the beginning. The detection of embryos with strongly limited immune repertoires (i.e., two almost identical sets of multi-histocompatibility complex or 'MHC' alleles) inherited from both parents, can cause spontaneous abortions in many mammal species including our own. Because of the importance of compatibility between genomes, the most promising genes for each female are found in different males. Finally, multiple paternity may allow females to reduce inbreeding where females cannot recognize close kin.

3.2 Molecules and Behavior

Ova and sperm engage in intense molecular dialogue, a process which is important for creating reproductive barriers between species but which is also suspected to involve an additional level of (post-mating) female choice. Female primates are known to produce a large quantity of antibodies against sperm in their genital tracts, a process which strongly favors diversity in paternity as the antibodies would be formed against the sperm of the 'usual' mating partner leaving sperm from unknown males at an advantage. The role of chemoreception (pheromones) in regulating some primate behavior remains very poorly understood.

The fact that primates may be able to smell important immune molecules (MHC) points towards potentially important roles of such molecules and their detection in mate choice and sexual behavior (Wedekind & Furi 1997).

3.3 Post-mating Female Choice and Sperm Competition

Certain sperm may be more likely to be taken up by the egg as they approach it. Such cryptic female choice would represent a choice of individual sperm, possibly based on the genes carried by that sperm. Certain genes of crucial importance in early embryonic development are known to be expressed on the surface of sperm. Males can compete for fertilization of females via a process called 'sperm competition.' When females mate with many males within a short period of time, the sperm of different males will be available for fertilizing her egg. This exerts pressure on males to produce larger quantities of sperm in order to succeed in preference to other males. In chimpanzees, where multiple matings with many males give rise to strong sperm competition, males have conspicuously large testicles and produce large amounts of sperm. They even produce 'copulatory plugs,' a gelatinous mass blocking the entry to the uterus. In gorillas, on the other hand, where silver back males face very little competition in their harems, males have very small testicles. Female-female competition may take place via the depletion of sperm supply for other females.

3.4 Genomic Conflicts

Because different males can sire subsequent offspring, a conflict of interest can arise between the paternal and the maternal genes. A female will spread her total reproductive efforts across all her subsequent offspring. Males are likely to have sired offspring with other females and thus are spreading their reproductive effort across several females. Paternal genes in the embryo are likely to cause each embryo to be over-demanding from the point of view of the mother. Such paternal genes will increase the male's reproductive success at a detriment to each female, who will have invested too much in that particular offspring. It is this conflict which seems to be at the root of a phenomenon called 'imprinting.' Imprinting occurs when, among the two variants of each gene present in the embryo (the paternal and maternal alleles), only one of the two is expressed. Often, only the allele inherited from the mother is expressed, while the paternal allele appears to be silenced. Imprinting may have several functions but one of them may be female control of over-demanding genes from the father (Mochizuki et al. 1996, Spencer et al. 1998).

Primate mating systems represent the outcome of a delicate balance between various constantly changing forces. These include:

- (a) ecological factors such as the distribution of resources and pressure by predators;
- (b) female foraging and mating strategies, including the need to find multiple fathers of high genetic quality and good genetic compatibility and one or more supportive social partners;
- (c) male mating strategies that may entail the access to the largest number of fertile females often in severe competition with other males; and,
- (d) the need for parental care of infants and juveniles.

Compromises between male and female strategies seem to occur at every level, from gene expression to behavior. The existence of life-long friendships between adult primates of both sexes introduces an additional dimension, that of emotional attachment and trust between individuals.

4. Future Directions

Long-term field studies of primates in their natural habitat are being complemented by powerful molecular methods of analysis. Genetic analyses are providing detailed information on pedigrees and kinship, while hormone studies can provide knowledge of female reproductive state. Studies of hormones, such as oxytocin and vasopressin and their receptors, which seem to have dramatic effects on male social attachment behavior, are likely to produce new insights (Young et al. 1999). The study of genomic conflicts and imprinting is in its infancy. Similarly, further insight into the determinants of genetic compatibility and the maximizing of immune repertoires will produce much badly needed knowledge. The large number of longitudinal studies of natural primate communities under way is bound to reveal additional ways in which males and female primates strike compromises and successfully reproduce in ever-changing environments. Understanding mating systems is not only essential if one wants to understand evolution, because many primates are facing extinction, such an understanding is also crucial for conservation efforts in the wild and in captivity.

P. Gagneux

Primate Socioecology

Sociality is the primary behavioral adaptation of the anthropoid primates, the monkeys and apes. All of the anthropoid primates, except orangutans, spend most of their lives in stable groups of familiar individuals. However, the social organization among the anthropoid primates encompasses great diversity, ranging from the pair-bonded groups of gibbons and owl monkeys, to the polyandrous groups of tamarins; one-male groups of howlers and blue monkeys; multimale, multifemale groups of cebus monkeys and baboons; and fission-fusion communities of chimpanzees and spider monkeys. This great diversity in social organization shapes the behavioral options available to males and females and profoundly influences the evolution of social behavior and reproductive strategies in both sexes.

1. The Evolution of Social Organization

The great diversity in primate social organization has prompted researchers to ask a number of related

questions: Why do primates live in groups? How should groups be structured? How big should groups be? These questions were first raised in the 1960s and 1970s by primatologists who conducted comparative analyses searching for broad ecological correlates of social organization (reviewed by Janson 2000). These comparative efforts yielded some consistent associations between diet, home range size, group size, body weight, and group composition. But the analyses were unsatisfying because they could not account for much of the observed variation in social organization among primates. Moreover, while these studies revealed a number of robust associations among various ecological variables, they did not produce much insight about the causal processes underlying these correlations. Finally, these comparative studies did not consider the possibility that some of the similarities between species were the result of common phylogenetic history, not independent adaptations to ecological conditions, a problem that has become a central methodological concern in comparative studies in behavioral ecology.

In the 1980s researchers returned to these questions, equipped with the theoretical and methodological tools of contemporary behavioral ecology (Krebs and Davies 1993). Behavioral ecologists try to explain how evolutionary processes shape behavior in particular ecological contexts. Sociality is presumed to reflect a dynamic balance between the advantages and disadvantages of living in close proximity to conspecifics. Sociality is beneficial because animals who live in social groups are better able to acquire and control resources or less vulnerable to predators. On the other hand, sociality is disadvantageous because group-living animals may face more competition over access to food, become more vulnerable to disease, and become more susceptible to cuckoldry, infanticide, and cannibalism. The size and demographic composition of the groups that we see in nature reflects a compromise between the costs and benefits of sociality for individuals who occupy particular ecological niches.

1.1 Why do Primates Live in Groups?

For primates, the primary advantages of sociality are thought to be enhanced access to resources, reduced vulnerability to predation, or some combination of both these factors. Many primates feed on foods, such as fruit, that occur in patches large enough to feed several individuals at the same time. Taking note of this fact, Wrangham (1980) suggested that primates aggregate because groups are more successful in defending access to resources than lone individuals, an argument that has also been applied in other taxa. Thus, the potential for between-group competition over resources favors sociality.

van Schaik (1983, 1989) questioned Wrangham's explanation of the evolution of sociality, arguing that the benefits accrued in between-group competition would be offset by the costs incurred from increased within-group competition. Instead, van Schaik argued, grouping evolved as a defense against predators. Primates are preyed upon by a variety of predators, including leopards, raptors, snakes, and other primates. Grouping provides safety from predators for three reasons. First, levels of vigilance are higher because there are more individuals scanning for predators. Second, groups are more effective in actively mobbing or deterring predators. Third, any single individual is less likely to be caught in a group if predators strike at random. Thus, primates aggregate to obtain protection from predators, and within-group competition for food or safe positions is an unavoidable side effect of sociality.

Initial efforts to evaluate the relative importance of between-group competition and predation among primates provided some support for both models (Janson 2000). Thus, the between-group competition model was supported by evidence that hostile intergroup interactions are common among primates, and larger groups are typically able to supplant smaller groups in intergroup encounters. In some populations, large groups are better able to defend higher quality home ranges than smaller groups. However, within-group competition seems to reduce foraging efficiency consistently in gregarious species (Janson 1992).

The predation model was supported by evidence that group sizes are reduced when predators are absent and that members of large groups spend less time scanning for predators and detect predators sooner than members of small groups do (Janson 1992). Nonetheless, vigilance levels do not decline monotonically as group size increases (Janson 2000), suggesting that groups are larger than needed for predator defense.

1.2 *The Nature of Competition and Female Social Relationships*

As researchers continued to debate the role of resource competition and predation in the evolution of sociality, they also began to think more carefully about the effects of competition on primate females. The distribution of food resources determines the distribution of females, and this in turn determines the distribution of males. Females come first in this scenario because female fitness depends mainly on their nutritional status (Wrangham 1980), while male fitness depends primarily on their ability to obtain access to fertile females.

Wrangham (1980) hypothesized that variation in the extent of intergroup competition would produce two distinct kinds of social arrangements. When resources were clumped and abundant enough to feed

more than one individual, females would benefit from banding together to collectively defend access to them. Coalitionary alliances among kin are expected to be more beneficial than alliances among nonkin because kin share a common genetic interest (Hamilton 1964); thus females were expected to form nepotistic alliances. Female philopatry preserves matrilineal networks, and strong affiliate bonds strengthen alliances. Thus, female-bonded kin groups are expected to be associated with between group competition over resources. On the other hand, if resources are not clumped or occur in patches that are too small to feed several individuals, then the collective defense of resources will not be profitable. Nepotistic alliances will not enhance females' access to resources. In this situation, selective pressures favoring female philopatry and strong female bonds will be relaxed. When there is little between-group competition, non-female-bonded groups are expected to occur. Wrangham linked dietary specializations to social organization, arguing that fruit occurs in discrete patches that are often large enough to make collective defense profitable. He predicted that female-bonded groups would be mainly frugivorous.

Although it was rather easy to classify primate species as female-bonded or non-female-bonded, a number of empirical and theoretical objections to Wrangham's model were raised. However, all subsequent efforts to link ecology and social behavior have relied on Wrangham's insight that resource competition among females drives the evolution of social organization among primates.

van Schaik (1989) considered how the distribution of resources influences the nature of competition among females. Scramble competition occurs when individuals cannot effectively monopolize access to resources, and consequently do not compete over them directly. Contest competition occurs when resources are limited and can be monopolized profitably, generating direct confrontations over access to them. van Schaik suggested that within group contest competition (WGC), within group scramble competition (WGS), and between group contest competition (BGC) would have different effects on social organization (Table 1). (Between group scramble competition is assumed to be an automatic consequence of population density, but is not expected to influence social relationships directly).

When females compete over access to resources with group members, access to resources will be a function of individual dominance rank. Van Schaik predicted that WGC would be associated with strict linear dominance hierarchies. Since dominance rank influences female access to resources and ultimately affects their fitness, females will provide coalitionary support to their kin in order to enhance their dominance rank. This will lead to matrilineal dominance hierarchies and create strong selective pressures favoring female philopatry. Nepotistic support will also enhance the

Table 1

Effects of competitive regime on social organization and behavior

	Competitive regime			
	WGC only	WGC + BGC	WGS + BGC	WGS only
Characteristics of dominance hierarchy	Strictly linear	Moderately linear	Egalitarian	Egalitarian
	Nepotistic	Nepotistic	Individualistic	Individualistic
	Very stable	Fairly stable	Unstable	Unstable

stability of dominance hierarchies by dampening the effects of temporary variations in individual fighting ability. Affiliative interactions with coalition partners will reinforce alliances, so females are expected to form close and well-differentiated social relationships.

When WGS is the primary form of resources competition, female reproductive success will depend on the size of the female's social group, not her own rank. This means that there will be little incentive to aid relatives in disputes with other group members, and dominance hierarchies will not be nepotistic or strictly linear. If WGS is combined with strong BGC, females will rely on coalitionary support in intergroup encounters from all group members. Because females benefit more from supporting kin than nonkin, female philopatry will be favored. Since females' fitness depends on collective group action, females are expected to cultivate social ties with all other group members. Thus, females are expected to form relatively poorly differentiated social relationships.

If WGS is associated with weak BGC, then selective pressures favoring female philopatry will be relaxed. Female residence in social groups should reflect the balance between the benefits of living in groups of particular sizes and the costs of emigration from groups of suboptimal size.

1.3 Testing Socioecological Models in the Field

In the 1990s, many researchers set to work testing the predictions derived from socioecological models. This body of work confirmed many of the predictions derived from socioecological models. For example, Sterck et al. (1997) showed that coalitionary support,

linear dominance hierarchies, and female philopatry are linked in a sample of 27 primate taxa. Others have compared closely related species, that differ in key features of their ecology. For example:

(a) Mitchell et al. (1991) compared two closely related species of squirrel monkeys in Costa Rica and Peru that had similar diets, formed groups of similar sizes, and experienced similarly high levels of predation. The two species differed mainly in the extent of within-group competition over access to food resources. As predicted by socioecological models, the species that experienced high within-group competition also formed stable, linear dominance hierarchies, kin-based coalitions, and exhibited strict female philopatry. In the species that experienced low levels of within-group competition, a dominance hierarchy was not detected among females, female coalitions were not observed, and females sometimes left their natal groups.

(b) Barton et al. (1996) compared the behavior and ecology of baboons at two sites. In Laikipia, Kenya, where within-group competition for food and predation pressures were high, groups tended to be large, females formed strong bonds with one another, and females rarely transferred from their natal groups. In the Drakensburg Mountains of South Africa, food was more evenly distributed and predation pressure was relaxed. There, groups were typically smaller, bonds among females were weaker, female dispersal was more common, and bonds between females and males were strengthened.

(c) Isbell and her colleagues have examined the relative importance of phylogeny and ecology in shaping the behavior of female monkeys in two closely related species, patas (*Erythrocebus patas*) and vervets

(*Cercopithecus aethiops*). If phylogeny is the primary factor influencing social organization, then patas and vervets should be very similar. However, if ecological factors are crucial, then patas and vervets should differ because their diets differ. Patas rely more heavily than vervets on arthropods and other food items that require little handling time and are consumed very quickly. On the other hand, vervets rely more heavily than patas on foods, such as gums, seeds, and fruits, that have longer processing times and take longer to eat. Patas have less linear dominance hierarchies than vervets do, and dominance rank has a less pronounced effect on nonagonistic behavior tightly linked to ecology (such as ranging, diet, and activity budgets) among patas than among vervets (Isbell et al. 1999).

(d) Koenig et al. (1998) compared two populations of Hanuman langurs (*Presbytis entellus*) living at different sites in India. The langurs of Ramnagar relied heavily on just three food plants. These plants were low in abundance and clumped in their distribution, conditions that are expected to lead to contest competition. The langurs of Kanha relied on a larger array of plant foods, and one of their most highly preferred foods is superabundant, conditions that are expected to lead to scramble competition. The langurs of Ramnagar behave much as expected when WGC is strong: they have linear dominance hierarchies and females are philopatric. The langurs of Kanha have poorly developed dominance hierarchies and females frequently emigrate from their natal groups.

1.4 Distribution of Males

In socioecological models, males generally play a secondary role. Ecological factors shape the distribution of females, and males go where females are (Kappeler 2000). Social factors are generally thought to be more important than ecological factors in determining the distribution of males because intrasexual competition over access to females contributes more to variation in male reproductive success than intrasexual competition over access to food. When females live in groups, they become a defensible resource for males. The more females there are, the more difficult it is for a single male to monopolize them. This difficulty is compounded if females are widely dispersed or if females become receptive simultaneously. Comparative analyses indicate that the number of males in primate groups is generally correlated with the number of females present and with the extent of synchrony in female receptivity (Mitani et al. 1996, Nunn 1999).

The availability of females explains some, but not all of the variation in the number of males in social groups. This raises the possibility that the distribution of males is also influenced by other factors, including ecological pressures. Comparative analyses suggest

that the distribution of males in social groups is directly linked to predation pressure. Hill and Lee (1998) conducted a systematic survey of the Old World monkeys in an effort to assess the effects of predation risk on the distribution of males. They found that predation risk consistently influenced group size, as groups that faced the highest risks of predator attacks lived in the largest groups. In single-male groups, high predation risk was associated with an increase in the number of females, but in multimale groups predation risk influenced the number of males in social groups, but not the number of females. Thus, the distribution of males may be a joint product of the distribution of females and the intensity of predation pressures.

2. Beyond Socioecology

Socioecological models of primate social organization gained considerable currency in the 1990s. However, in the last few years, socioecological models of social organization have been subjected to a new set of empirical and theoretical challenges (Janson 2000). Not all the observed variation in social organization and behavior fit predictions derived from socioecological models. For example the comparison of squirrel monkeys by Mitchell et al. was complicated by subsequent observations of squirrel monkeys in Suriname (Boinski 1999). There, monkeys face intense WGC, but females have weak bonds with one another and do not form coalitions with other females. Comparative evidence indicates that males generally go where females are, but it has been surprisingly difficult to explain why individual males move from one group to another. Male baboons do not always enhance their access to females when they emigrate (Altmann 2000).

The role of environment in shaping social organization was challenged by new comparative studies which took phylogeny explicitly into account (di Fiore and Rendall 1994). Selected pairwise comparisons of closely related primate species provide support for socioecological models, but these comparisons may not be representative. Most of the characteristics associated with WGC, including linear dominance hierarchies, nepotistic alliances, and female philopatry are found in almost all of the extant Cercopithecae species, even though they now occupy an extremely diverse range of habitats. Di Fiore and Rendall's analysis indicates that there is considerable inertia in social evolution. The social systems categorized by socioecologists may represent different peaks in the adaptive landscape (Pope 2000). If so, this seriously constrains the possible paths for change in social evolution.

Socioecological models assume that ecological factors play a primary role in shaping social organization, but a strong case can be made that demographic and social factors may also shape social systems. A

growing body of evidence suggests that the risk of infanticide may affect primate social systems (van Schaik 2000). There is compelling evidence that infanticide is an evolved reproductive strategy in many animal taxa. In many primate species, males selectively kill infants whose deaths enhance their own reproductive prospects (van Schaik and Janson 2000). The presence of multiple males in social groups throughout the year may be linked to infanticidal risks faced by females (van Schaik 2000).

In summary, present evidence suggests that a broad range of ecological, historical, demographic, and social factors influence the evolution of primate groups. It was probably naïve to expect simple models to explain the full range of variation in primate social organization and behavior. It is, however, essential to begin with simple models before constructing more elaborate ones. The task now is to elaborate and extend socioecological models to accommodate new data and ideas about why primates live in groups.

Primates, Evolution of

The Primates, one of 20 extant orders of placental mammals, are of special interest because they include the human species (*Homo sapiens*). It should be noted at once that tree shrews, included in the Primates for most of the last hundred years, are now generally thought to have only a distant connection (if at all) and are hence allocated to their own order Scandentia. A recent review (Rowe 1996) portrayed 238 living primate species (excluding tree shrews) and the number is now some 250 and rising, partly reflecting the discovery of entirely new species but also following subdivision of existing species because of new information, notably molecular evidence. This is a dramatic increase over the 150 species listed in a leading

Figure 1

Geographical distribution of living nonhuman primates (excluding tree shrews). Shaded areas indicate the approximate ranges of the five natural groups, with the exception of the loris group (which occupies most but not all of the range occupied by Old World monkeys and apes)

handbook in the 1960s (Napier and Napier 1967). The order Primates also includes almost 450 fossil species (also progressively increasing), documenting the evolution of this group.

The evolutionary history of primates is a striking example of adaptive radiation, in which descendants from an original common ancestor with a particular set of characteristics diverged and adapted to occupy different geographical areas and ecological niches. Following Darwin's *Origin of Species*, this evolutionary radiation was reconstructed initially almost entirely from morphological (anatomical) features, but the comparative framework has been expanded gradually to include physiological, behavioral, ecological, chromosomal, and molecular characters.

1. Living Primates

The logical starting point for reconstruction of primate evolution is the array of living species, partly because recognition of the group arose from the study of living representatives, and partly because many features (notably chromosomal and molecular characters) are not fossilized. Known fossil relatives of living primates can be included subsequently in the overall framework, providing the benefit of a geological timescale.

Later inclusion of fossil species in a preliminary phylogenetic tree based on living forms also permits use of palaeontological evidence to test its validity.

Living nonhuman primates can be divided into five 'natural groups', each with a restricted geographical range (Fig. 1). As geographical isolation plays a fundamental part in evolutionary divergence, these groups are inherently likely to reflect basic subdivisions within the primate tree. Indeed, they are recognizable immediately in all widely accepted phylogenetic reconstructions and classifications. The first such group contains the Madagascar lemurs (infraorder Lemuriformes). These are the only primates present on that island, and document a substantial local radiation (Tattersall 1982). There are at least 35 living species and the modern array also includes at least 17 subfossil species that died out over the last few millennia, following the first human inhabitation of Madagascar. The second group contains the lorises and bushbabies (infraorder Lorisiformes). They are distributed widely in Africa, South Asia and South-east Asia, but the total number of species (about 20) is smaller than for lemurs, representing only a limited radiation. This applies even more drastically to the third group, containing the five closely related tarsier species of the South east Asian archipelago (infraorder Tarsiiformes). The fourth group contains the

monkeys of South and Central America (infraorder Platyrrhini), which are the only New World primates. This is a relatively large group of some 80 species, divided into claw-bearing marmosets and tamarins (family Callitrichidae), and true monkeys (family Cebidae), again documenting a major local radiation (Kinzey 1997). The fifth group, containing the Old World monkeys and apes of Africa, South Asia and South east Asia (infraorder Catarrhini) is the largest, with approximately 105 species. In fact, humans also belong to this group, but have expanded far beyond this original geological range. Within this fifth group, which is most directly relevant to human evolution, there is a clear division between Old World monkeys (superfamily Cercopithecoidea) and apes and humans (superfamily Hominoidea), despite extensive overlap in geographical distribution.

The first three natural groups of primates (lemurs, lorises and bushbabies, tarsiers) have remained relatively primitive and are collectively labeled prosimians (literally 'before the monkeys'). They are comparatively small (modal body weight approximately 500 g) and most species are nocturnal. Diurnal species (certain relatively large-bodied members of the families Lemnidae and Indridae) occur only among the lemurs. In fact, some lemurids (species of *Eulemur* and *Hapalemur*) show a highly unusual cathemeral pattern (Tattersall 1988), involving a mixture of nocturnal and diurnal activity. This is just one example of the great diversity of special adaptations found among the lemurs of Madagascar.

By contrast, members of the fourth and fifth natural groups of primates (monkeys, apes, and humans) share a distinctive set of advanced features in their dentitions, jaws, brain, and reproductive system, and can be labeled collectively simians. They are comparatively large (modal body weight approximately 5 kg), and virtually all species are diurnal. The only nocturnal simians are the New World owl monkeys (*Aotus*). The tenfold difference in modal body size between simians and prosimians, undoubtedly connected with the general distinction between nocturnal and diurnal habits, is just one indication of the pervasive importance of body size in primate biology. Availability of a compilation of body weights for almost all primate species, very largely derived from wild animals, therefore deserves special mention (Smith and Jungers 1997). Overall, living primates cover a 300-fold range of body sizes, extending from 40 g for the smallest of the mouse lemur species (*Microcebus*) to 120 kg for an adult male gorilla.

2. Definition of Living Primates

It is often stated that living primates represent a graded series, ranging from relatively primitive to very advanced, and that it is therefore difficult to demarcate them from other orders of mammals (notably Insecti-

vora). However, this view was influenced heavily by the inclusion of tree shrews in the order Primates. Reexamination excluding tree shrews revealed that there is in fact a substantial set of characteristics shared by all living primates, which separates them fairly clearly from other placental mammals, leading to the following definition (Martin 1986):

Primates are typically arboreal inhabitants of tropical and subtropical forest ecosystems. Their extremities are essentially adapted for prehension, rather than grappling of arboreal supports. A widely divergent hallux (big toe) provides the basis for a powerful grasping action of the foot in all genera except *Homo*, while the hand usually exhibits at least some prehensile capacity. The digits typically bear flat nails rather than bilaterally compressed claws; the hallux always bears a nail. The ventral surfaces of the extremities bear tactile pads with cutaneous ridges (dermatoglyphs) that reduce slippage on arboreal supports and provide for enhanced tactile sensitivity in association with dermal Meissner's corpuscles. Locomotion is hindlimb-dominated, with the center of gravity of the body located closer to the hindlimbs, such that the typical walking gait follows a diagonal sequence (forefoot precedes hindfoot on each side). The foot is typically adapted for tarsi-fulcrimation, with at least some degree of relative elongation of the distal segment of the calcaneus, commonly resulting in reverse alternation of the tarsus (calcaneo-navicular articulation).

The visual sense is greatly emphasized. The eyes are relatively large and the orbits possess (at least) a postorbital bar. Forward rotation of the eyes ensures a large degree of binocular overlap. Ipsilateral and contralateral retinofugal fibres are approximately balanced in numbers on each side of the brain and organised in such a way that the contralateral half of the visual field is represented. Enlargement and medial approximation of the orbits is typically associated with ethmoid exposure in the medial orbital wall (though there are several exceptions among the lemurs). The ventral floor of the well-developed auditory bulla is formed predominantly by the petrosal. The olfactory system is unspecialized in most nocturnal forms and reduced in diurnal forms. Partly because of the increased emphasis on vision, the brain is typically moderately enlarged, relative to body size, in comparison to other living mammals. The brain of living primates always possesses a true Sylvian sulcus (confluent with the rhinal sulcus) and a triradiate calcarine sulcus. Primates are unique among living mammals in that the brain constitutes a significantly larger proportion of fetal body weight at all stages of gestation.

Male primates are characterised by permanent precocial descent of the testes into a postpenial scrotum; female primates are characterised by the absence of a urogenital sinus (i.e. urinary and reproductive tracts entirely separate). In all primates, involvement of the yolk-sac in placentation is suppressed, at least during the latter half of gestation. Primates have long gestation periods, relative to maternal body size, and produce small litters of precocial neonates. Fetal growth and postnatal growth are characteristically slow in relation to maternal size. Sexual maturity is attained late and life-spans are correspondingly long relative to body size. Primates are, in short, adapted for slow reproductive turnover.

The dental formula exhibits a maximum of 2.1.3.3/2.1.3.3. The size of the premaxilla is very limited, in association with the reduced number of incisors, which are arranged more

transversely than longitudinally. The cheek teeth are typically relatively unspecialized, though cusps are generally low and rounded and the lower molars possess raised, enlarged talonids.

In fact, an additional distinctive feature should be added to this definition (Sussman 1999): all living primate species live in fairly elaborate social networks. Although nocturnal primate species have commonly been labeled 'solitary,' numerous field studies have shown that they have well established patterns of social interactions based on shared ranges, communal nesting, and regular encounters during the night. There are no immediately recognizable social groups of the kind found in all diurnal primates except the orang-utan, but there are nonetheless long-lasting associations between individuals. The pronounced social tendency now recognized for all primates is presumably linked to the high investment in individual offspring (including intensive parental care), and relatively long lifespans that characterize primates.

The distinctive set of characteristics shared by living primates reflects a suite of adaptations developed in their common ancestor. Taken in combination with various primitive features inferred for the ancestral condition, such as relatively small body size and nocturnal habits (Martin 1990), they yield a plausible reconstruction of the earliest primates. These were probably small-bodied, nocturnally active arboreal creatures that were particularly well adapted for exploitation of the fine branch niche, where they fed on a mixed diet of insects and fruit (the latter accounting for certain modifications of their molar teeth). Leaping and running in the fine terminal branches of trees and among lianas would account for their typical nail-bearing, grasping extremities, notably the prehensile foot, and for emphasis of the visual sense, with large, forward facing eyes and specialization of the brain for highly effective visual orientation. Development of prehensile extremities also involved a shift toward use of the hands rather than the snout in grasping food items, thus explaining shortening of the snout and the associated reduction in number of incisors. Adaptations for low reproductive turnover and high investment in individual offspring can be interpreted as responses to life under the relatively stable and predictable conditions of tropical forests combined with comparatively low predation levels among fine branches.

3. Phylogenetic Relationships among Living Primates

In their broad outlines, reconstructions of the phylogenetic tree of primates based on morphological evidence have been confirmed by analyses based on chromosomal or molecular data, such that a general consensus is now emerging (Martin 1990, Fleagle

1999). Although certain relationships in the tree remain controversial, notably in cases where very early divergences are involved, such confirmation derived from largely independent analyses of new data provides valuable support for earlier phylogenetic reconstructions based exclusively on morphological evidence.

The substantial body of evidence now available indicates that the five natural groups of living primates (lemurs; lorises and bushbabies; tarsiers; New World monkeys; Old World monkeys, apes, and humans) are, in fact, phylogenetically distinct subunits within the tree (Fig. 2). In other words, each of the five natural groups is monophyletic (derived from a specific common ancestor within the tree). Although certain cranial features led some authors to suggest that the mouse and dwarf lemurs (family Cheirogaleidae) are more closely related to lorises and bushbabies than to other lemurs, chromosomal and molecular evidence indicates overwhelmingly that the lemurs are monophyletic (Yoder 1997). Furthermore, it has consistently emerged that the Old World monkeys, and the apes and humans, respectively, belong to two separate monophyletic groups at a lower level. The overall pattern of relationships between the major groups of primates has also become relatively clear. On the one hand, it has emerged consistently that the Lemuriformes and the Lorisiformes are sister groups (that is, their individual common ancestors were derived from an earlier common ancestor). Together, the lemurs, lorises, and bushbabies constitute a larger-scale monophyletic group known as strepsirrhines, because of their common retention of a rhinarium (a naked, moist area of skin surrounding the nostrils in the primitive mammalian condition). On the other hand, it has emerged equally consistently that the simian primates (monkeys, apes, and humans) together constitute a second larger-scale monophyletic group. There is also a considerable body of evidence indicating that tarsiers and simians are sister groups, together constituting a high-level monophyletic group known as haplorhines, sharing complete suppression of the rhinarium (unique among mammals). Although some investigators have questioned an ancestral link between tarsiers and the simians, an overall review of evidence (Martin 1990) indicated that haplorhines do, indeed, constitute a monophyletic group (Fig. 2).

4. The Primate Fossil Record

The known record of reliably identified fossil primates dates back to the beginning of the Eocene epoch, about 55mya. An assemblage of earlier fossil forms mainly from the Palaeocene epoch (65–55mya), collectively labeled 'archaic primates' (Plesiadapiformes), has traditionally been allocated to the order Primates.

Figure 2

Outline phylogenetic tree of living nonhuman primates (excluding tree shrews) showing the likely pattern of relationships among the five monophyletic natural groups. Traditional classifications distinguish between the generally more primitive prosimians and the simians, which are characterized by a set of more advanced features

However, these early fossil forms (some of which survived into the Eocene) show few, if any, of the features in the definition given above and recent evidence indicates that their connection with primates is questionable. Even if Plesiadapiformes did have some early connection with primates, they surely diverged at such an early stage that they are of little relevance to the later adaptive radiation leading to modern primates and their direct fossil relatives ('primates of modern aspect').

The currently documented primate fossil record, excluding Plesiadapiformes, is divided fairly sharply into two segments separated by a gap of at least 6 million years in the middle of the Oligocene epoch (35–25mya). Approximately equal numbers of fossil primate species (about 225) are known from each half of the record. Initially, primates of the Eocene epoch (55–35mya) were documented only by early prosimians from Europe and North America. On both continents, they can be divided fairly clearly into two families, generally larger lemur-like Adapidae (e.g.,

Adapis in Europe, *Notharctus* in America), and generally smaller tarsier-like Omomyidae (e.g., *Necrolemur* in Europe, *Shoshonius* in America), and many authors have linked them to modern strepsirrhines and haplorrhines, respectively. Almost the entire skeleton is known for *Notharctus*; it is very lemur-like and certainly demonstrates that many defining features of modern primates were present at that stage.

This initial picture from America and Europe has been modified radically by subsequent fossil finds from North Africa, Asia and South east Asia. In North Africa, fossils from the latest Eocene and early Oligocene, notably from the Egyptian Fayum site, have documented the presence of a variety of early simians (e.g., *Aegyptopithecus* and *Apidium*) along with some potential relatives of modern strepsirrhines and tarsiers. More recently, Chinese middle Eocene fossil deposits have yielded evidence of early simians (*Eosimias*) and a putative direct ancestor of modern tarsiers (*Tarsius eoceanus*), along with adapids and omomyids. Furthermore, late Eocene sites in Myan-

Figure 3

Overall phylogenetic tree of primates (excluding tree shrews) showing the likely pattern of relationships among the five monophyletic natural groups of living primates. This tree also includes major groups of fossil representatives (excluding plesiadapiforms). Note that the initial date of divergence for 'primates of modern aspect' is set at about 80 mya. mar and Thailand have yielded several fossil simians (e.g., *Amphipithecus* and *Siamopithecus*). Thus, both prosimians and simians were present in the Eocene.

The situation is entirely different in the second half of the primate fossil record, extending from the late Oligocene to the present day. Direct fossil relatives of New World monkeys are known from South America, beginning in the latest Oligocene (*Branisella*) and extending into the Miocene (e.g., *Homunculus*). In the Old World (notably Africa), early Miocene deposits have yielded fossil relatives of bushbabies and lorises (e.g., *Progalago*), of tarsiers (albeit just one molar tooth from Thailand), and of monkeys and apes (e.g., *Victoriapithecus* and *Proconsul*). Thus, four of the five modern natural groups of primates can be traced back to about 25mya, and one (tarsiers) can be tentatively traced back to 40mya. Nevertheless, there are also notable gaps in the known fossil record. The most striking gap is in Madagascar, where no single fossil from the major radiation of lemurs is known prior to the recently extinct subfossils. Similarly, in the New World, no single fossil form can be linked reliably to the marmosets and tamarins, a substantial proportion of the modern species.

Gaps in the fossil record influence directly the inferred date for the origin of primates. The standard practice has been to assume that primates diverged during the Palaeocene epoch, perhaps 60–65mya, just a few million years prior to the first known fossil primates. However, direct inference from the known fossil record will lead to serious underestimation if there are substantial gaps in the fossil record, as is true of primates (Martin 1993). Several recent studies that calibrated molecular phylogenies for mammals using various dates for fossils of well documented groups outside the primates have all concluded that primates diverged from other mammals about 90mya. Given some allowance for the elapse of time between this initial divergence and initiation of the adaptive radiation leading to modern primates, their common ancestor can be dated at about 80mya (Fig. 3).

Primates, Social Behavior of

The distribution of individuals within a species is related to such factors as the distribution and abundance of resources, predation pressure, and genetically determined behavioral propensities. In some animal species, individuals spend most of their time alone, whereas in others most or all of their time is spent in groups. With one exception, all diurnal primates live in social groups. In many animal taxa temporary aggregations form under certain conditions (e.g., schools of fish, flocks of birds, herds of ungulates) but in most of these cases, aggregations are made up of different individuals each time the animals congregate. One of the most common features of primate groups is the relative constancy of group membership. There are many theories attempting to explain why diurnal primates live in groups and the reasons for different types of groups (see Janson 2000).

1. Definition of Terms

There is a great deal of debate concerning what factors may have led to group living among diurnal primates and the relationships that may exist between primate social structure and ecology. However, before discussing some of these issues, it is necessary to define some terms.

1.1 The Term 'Social Group'

If one searches the primate literature for a definition of the term 'social group,' it is quite difficult to find. It seems that primatologists know a social group when

they see one but are reluctant to define the term generally. In the literature, there are few attempts to formally define the primate 'social group' (e.g., Altmann 1962, Kummer 1967, Struhsaker 1969, Sussman 1999) and few critical evaluations of these definitions. Altmann (1962) defines a group as consisting of conspecific, intercommunicating individuals bounded by frontiers of far less frequent communication. Kummer (1967) considers that a group as a 'spatial aggregation of primates that travel and rest together and at the same time avoid the proximity of other such aggregations is, at closer inspection, also a functional and reproductive unit' (p. 359). These are both broad definitions that emphasize social proximity, social interaction, and synchrony of activity. However, all of these criteria are not equally useful in defining the social group.

Reproduction was once thought to be a major *raison d'être* of primate groups but a number of factors indicate that it is not a major common denominator of the primate group. For example, in many species breeding is seasonal but the group is stable throughout the year. In fact, in some species, behavior during the breeding season actually disrupts the social group. In the Madagascar sifaka, *Propithecus*, groups break up during the short mating season and reformulate after breeding takes place. Most species of primates have mechanisms that ensure continuous gene flow between groups. Groups exist within a breeding population (or deme) and genetic exchange is common between groups, at higher or lower frequencies, depending on the species.

Struhsaker (1969) offered a more detailed definition of the social group. He included in his definition the following factors: (a) membership in the same social network; (b) the majority (at least 80 percent) of nonaggressive social interactions take place within this social network; (c) membership is temporally stable; (d) group members occupy the same home range; (e) group members have distinct social roles; (f) progressions between members are synchronized; (g) group members exhibit different behavior toward nongroup conspecifics; and (h) social groups are relatively closed to new members.

Using some but not all of the above criteria, the following definition of a 'social group' in primates is proposed: a number of individuals who interact socially more frequently among themselves than with other individuals; group members exhibit different behavior towards nongroup members and occupy the same home range. Group membership is relatively stable over time and group members have distinct social roles but, although these two factors are characteristics of the group, the particulars of group stability and of social roles are extremely variable from species to species and are not necessary components of this definition.

It is also true that most social groups are relatively closed to new membership but this is also highly

variable and would be difficult to include in a general definition. In fact, the only social groups that were thought to be closed to new membership are monogamous pairs, and this does not appear to be as true as was previously believed (Fuentes 1998, Strier 2000); individual exchange between groups is a common occurrence in most diurnal primate species. Synchronized progressions, mentioned in the definitions of both Kummer and Struhsaker, are not common to all primate groups. A number of groups divide into subgroups for various periods of time and these subgroups do not necessarily synchronize movements or activity while separated. Because of the dynamics of individual social relationships, Dunbar (1988, p. 12) preferred to view primate groups or social systems in terms of their constituent relationships. 'Where the sets of relationships of several individuals coincide and are reciprocated, a formal group emerges as a stable cohesive unit. ... These clusterings are sufficiently distinctive in their cohesion in time and space that we can define them as levels of groupings.'

There are many different types of social group found among the diurnal primates. At a very general level these include: monogamous pairs (i.e., one adult male, one adult female, and their immature offspring); multimale groups (groups containing more than one adult male); one-male groups (groups containing only one adult male); and fission-fusion groups (groups that form dispersing and coalescing subgroups). Of course, each of these superficial categories does not include groups of identical social structure or social organization. For example, multimale groups of lemurs are quite different from those of baboons in structure, function, evolutionary history, and ecological advantage. This is even more obvious when we compare species with 'fission-fusion' group structures.

1.2 The Terms 'Social Structure' and 'Social Organization'

The terms social structure and social organization have now been introduced. These terms are often used interchangeably; however, it is useful to distinguish between them. Following definitions similar to those proposed by Rowell (1972), the social structure of a species can best be divided into two components: group structure and population structure. Group structure is the size and composition (as to age and sex) of a primate group. Population structure is the demographic character of the population, population density, and the density and dispersal of groups within the breeding population or deme. One measures social structure using censusing techniques. Social organization is the pattern of social interactions that occurs between individuals within and between groups: it is a description of social behavior.

Thus, social structure refers to the components of the social system, whereas social organization refers to

the patterns of interaction between the components. Both patas monkeys and Hamadryas baboons live in one-male groups that can have essentially similar age and sexual composition. However, in Hamadryas one-male groups, the male is the center of attention of the group and directs group travel. In the patas monkey, the male takes a peripheral position in the group and the females initiate and direct group travel. Thus the patas monkey and the Hamadryas baboon have groups with similar structure but the social organization of the two species is very different. Furthermore, differences in degrees of tolerance between adult males result in very different distribution patterns of one-male groups. Hamadryas one-male groups often sleep and move together, whereas patas males are intolerant of each other and one-male groups are usually widely dispersed. Although the group structure is similar, the structure of the populations of these two species is radically different.

1.3 Spacing Between and Within Groups

When dealing with animals living in groups, two levels of social spacing must be considered: between groups of the same species and between individuals living within the same group. Each species has developed complex communication patterns for both intergroup and intragroup spacing.

These patterns are part of the social organization of a species and they help to maintain the species-specific social structure. In group-living animals, such as diurnal primates, the terms home range, core area, area of exclusive use, and territory relate to intergroup spacing, whereas dominance hierarchies, roles, kinship lines, and peer groups are usually pertinent to spacing patterns within a group.

In the above definition of a 'social group,' group members were said to occupy the same home range. Home range can be defined as the area over which a group normally travels in pursuit of its routine activities. Other terms such as day range and monthly range are used to denote the area over which the group travels in a given time period. If a group uses a particular part of its home range more frequently, or with greater regularity, than other parts, this zone is referred to as a core area. The core area often contains many of the major resources of the group. In some species of primates, the boundaries of different groups overlap only slightly, whereas in others home ranges overlap a great deal and each group may have a very small area that is not shared by other conspecific groups (referred to as an area of exclusive use). In a number of primate species, home ranges of groups may overlap completely.

Mechanisms used for intergroup spacing also vary between species. In some species, spacing between groups involves the maintenance of exclusive use of a particular area, but in others it seems to involve the

maintenance of intragroup integrity and a patterned use, by two or more groups, of the same space. However, a unitary definition of territoriality and a simple dichotomy between territorial and nonterritorial species might do more to confuse the issue than to aid in an understanding of ecological parameters of spatial relationships between individuals and groups of conspecifics (see Sussman 1999). For example, active, ritualized, agonistic defense behaviors are used by many species of primates to maintain the integrity of home range boundaries or areas of exclusive use. However, in other species, spatial integrity is maintained between groups by exchange of vocalizations or with no apparent outward behavioral spacing mechanisms. In fact, very few species of primates could be considered territorial in the strict sense of the term.

A large number of species that do not maintain exclusive areas employ ritualized postures and gestures, and/or vocalizations, to maintain group integrity and to regulate spatial relationships within a shared home range. Some of these species were thought to be highly territorial until recent studies have shown this not to be the case. Thus, there appears to be two separate phenomena: (a) the behavioral mechanisms that control spacing and (b) the degree of isolation or overlap between groups. The use of the term territoriality often confounds these two factors and a more clear definition might be the active defense of individual or group home range boundaries by actual or ritualized agonistic encounters, thereby maintaining essentially exclusive use of the home range. This, then, describes a very specific set of behaviors that control spacing and a particular pattern of spacing. However, even using this strict definition may conceal important variation in conditions of spacing between two species labeled as territorial.

2. Natural Selection and Primate Behavior

An important question relating to group-living among diurnal primates is why, in fact, do they live in groups? What advantage does this habit confer on individuals? The theory of natural selection predicts that evolution will act to increase the frequency of traits that improve an individual's ability to survive and to reproduce more successfully than other members of its species. Traits that confer survival and reproductive advantages upon an individual are referred to as adaptations. There were, however, a number of characteristics that Darwin found difficult to explain when he developed the theory of natural selection. These included morphological and behavioral differences between the sexes that occur in many species, such as larger canines or body size, or greater aggressiveness in males than in females. In many cases it was not obvious how these secondary sexual characteristics gave any direct advantage to individuals in their attempt to obtain resources.

To explain these traits, Darwin formulated the theory of sexual selection. He proposed that many morphological and behavioral differences between the sexes evolved because they contributed directly to an individual's reproductive success, either by improving his or her competitive ability against members of the same sex, or by increasing attractiveness to the opposite sex. Some of the traits Darwin believed to be sexually selected were subsequently shown to proffer direct adaptive advantage to individuals. However, sexual selection is not an important mechanism in evolution.

A basic assumption of sexual selection theory is that there is a direct relationship between particular traits and genetics. If dominance in males is directly related to increased fitness, then males must be able to pass on this trait to their offspring. However, dominance is complex and involves a number of morphological and behavioral characteristics as well as a social and ecological context. This is true of many other traits proposed to be sexually selected. It is often extremely difficult, if not impossible, to explain the genetics of these complex traits.

Another phenomenon scientists found difficult to explain was cooperative behavior. Why would animals cooperate if this did not increase their evolutionary fitness? If an animal avoids being eaten by a predator by joining forces with others, cooperation easily fits within the rubric of individual selection. However, there are many cooperative behaviors, especially among group-living animals, that appear to be of no benefit or are even dangerous to the individual. To explain these behaviors, the concepts of kin selection and reciprocal altruism were formulated.

Darwin was unaware of Mendelian genetics and thus genetic inheritance did not figure in his explanation of natural selection. Hamilton (1964) examined the potential genetic consequences of cooperative behavior and developed the theory of kin selection to explain altruistic behavior between related individuals. An individual's traits, and the genes responsible for them, are more likely to be shared by close relatives than by unrelated individuals. Thus, by sacrificing oneself for a number of one's kin, an individual may be ensuring the survival of genetically inherited traits. Since more closely related individuals are more likely to share copies of the same genes, altruism is expected to be selectively directed toward kin, and more close kin will accrue more costly altruism (Silk 1987).

However, many altruistic acts are performed by unrelated individuals. Trivers (1971) formulated the theory of reciprocal altruism to explain cooperation and assistance in these cases. He believed that altruistic acts would only occur between unrelated individuals if they were likely to reciprocate in the future and had the opportunity to do so, if the benefits to the recipient were greater than the costs to the altruist, and if there was little chance of cheating. Thus, both parties improve their individual fitness in the long term. In

practice both types of altruistic interactions are often difficult to identify, and predictions derived from these theories are difficult to evaluate empirically (see Silk 1987 for an excellent review).

These concepts formed the basis of the subdiscipline of Sociobiology (Wilson 1975), which was developed to explain the influences of biology on social behavior. Sociobiology was very controversial when first formulated because of the questionable genetic nature of many of the behaviors it attempted to explain. Were behaviors such as aggressiveness or dominance inherited or the result of a complex interaction between genetics and environment? However, many of the theories currently in vogue in socioecology are also based on sexual selection, kin selection, and reciprocal altruism. These include theories attempting to interpret variation in social structure, social organization, and social behavior in group-living primates, and the relationships between ecology and social systems. For example, one of the major theories attempting to relate individual spacing to that of resource distribution is based on sexual selection. In most vertebrates, females must invest a great deal of time and energy in successfully reproducing offspring, whereas males invest a small amount. Because of this, the distribution of females in the environment is presumed to be more closely related to resources than is that of males. The distribution of males is related to the dynamics of male competition for females (Wrangham 1987). Thus, females compete for energy resources and males compete for females, and the social system of a primate species can be understood by studying these relationships. In fact, this theory was proposed when it was believed that, in most primates, females remained in the same home range throughout their lives and males dispersed. Now researchers have shown that, in the majority of primate taxa, either females or both sexes disperse (Strier 2000).

To date it still is not possible to relate patterns of resource distribution to patterns of social spacing among primates. Very little is known about the factors that underlie the enormous amount of variability in primate social systems. These theories so far have not led to a better understanding of the relationships that might exist between ecology and social structure.

3. Ecology and Social Behavior Among Primates

Many of the theories currently attempting to explain the relationship between ecology and social structure among primates are one-dimensional (e.g., distribution of resources, predation pressure, infanticide avoidance). However, there are probably a multitude of factors interacting to cause the great variety of social groups among these animals.

We would expect that there will be some relationship between the spacing of resources in the environment and the spacing of those individuals using the re-

sources. However, to explain the adaptive significance of specific differences between the types of social structure and organization found among primates, diachronic as well as synchronic factors must be considered.

A complete understanding of the relationship between ecology and social behavior among primates will most likely have to take into account at least the following factors: (a) the resources and periodicity of these resources within the total geographical range of the species, as well as those in any particular area; (b) the selectivity of the species—those resources chosen by the species vs. those available; (c) the evolutionary history of the species leading to its current phylogenetic (genetic) propensities (these should be related to the present and past geographic distribution of the species and the environments and resources which exist(ed) within these ranges); (d) the history of the particular population and group, since the conditions in a given area may select for population-specific or group-specific adaptations. This latter factor should take into account stochastic and demographic phenomena which can have a major influence on a population at any particular time (Altmann and Altmann 1979, Chan 1992, Rowell 1993).

R. W. Sussman

Priming, Cognitive Psychology of

Priming refers to the phenomenon whereby the identification of a word or an object can be enhanced either by the presentation of a related stimulus or by a prior processing episode involving that word or object. In the case of priming with a related stimulus, enhancement is assessed relative to identification performance following an unrelated stimulus or some neutral stimulus. Priming effects are used to support inferences about the time course of component processes that contribute to stimulus identification and about the structure of knowledge representation. Priming induced by an earlier processing episode involving the target is referred to as *repetition priming*. Enhancement due to repetition priming is assessed relative to performance on targets that were not included in any earlier processing episode. Repetition priming effects provide evidence regarding the influence of memory on skilled task performance.

1. Priming with Related Stimuli

The widespread use of related primes to examine word and object identification has its origins both in the classic era of verbal learning and in the more recent study of visual attention.

Experiments on verbal learning tasks such as memorizing word lists showed that prior learning of a target word's associate (e.g., *joy* is an associate of *happy*) improved subsequent learning of that target

(Cofer 1967). These early studies foreshadowed some of the well-established aspects of priming obtained in more recent research (e.g., priming dissipates rapidly over time).

In the visual attention domain, it has been proposed that presentation of a prime stimulus that is of the same type as the target could benefit the processing of the target through two mechanisms (Posner and Snyder 1975). First, the prime automatically can activate the pathway used in processing the target. Second, the observer can be induced consciously to attend to activation produced by the prime, creating an expectancy and amplifying the benefit of the prime but also creating a cost if the prime is unrelated to the target and the expectancy is not met.

1.1 Semantic Priming

Building on the seminal work of Meyer and Schvaneveldt (1971), who provided one of the first demonstrations that a pair of semantically related words (e.g., *nurse–doctor*) was identified faster than a pair of unrelated words, early investigations of semantic priming examined automatic and conscious contributions to priming. These studies were motivated in part by the idea that semantically related concepts could automatically activate one another (Collins and Loftus 1975). This automatic spreading activation was the hypothesized basis for the facilitative effect of presenting a prime prior to identifying a semantically related target word. Experiments demonstrating this effect typically employed a word identification task such as lexical decision, in which word and nonword targets are presented and the observer is required to classify each target as a word or nonword. Accuracy in this task is high, so the aspect of performance that is of greatest interest is the time taken to make a response. The benefit of a related prime is revealed by a shorter response latency relative to when a neutral prime such as *XXX* is used.

By varying the time interval between the onset of the prime stimulus and the subsequent onset of the target (stimulus onset asynchrony, or SOA) it was shown that automatic activation of a target word by a semantically related prime can occur within 250ms of the onset of the prime (Neely 1977). At an SOA of 400ms or more, however, not only was there a facilitative priming effect, there also was an interference effect, such that relative to the neutral prime condition, a longer response latency was found when an unrelated prime was used. This pattern of benefit and cost suggested that in the earliest stages of processing a prime word, semantic information related to that prime was automatically activated. Shortly thereafter, attention was directed to the activated information allowing the benefit of activation to be maintained but also leading to a cost if the target was unrelated to the expected domain of semantic knowledge.

1.2 Models of Semantic Priming

The idea that semantic priming may be amplified by conscious attention, perhaps owing to expectations about what related target word might follow a particular prime, is generally accepted. In contrast, however, the proposal that activation spreads automatically from the prime concept to semantically related concepts in semantic memory has been challenged. One type of alternative theory, compound-cue theory, proposes that rather than activation spreading from the prime, the prime stimulus combines with the target to form a compound cue that is matched with the contents of long-term memory (Ratcliff and McKoon 1988). Related prime–target pairs are likely to be represented in memory owing to a prior history of co-occurrence, so this compound cue has a high degree of familiarity and permits a relatively rapid lexical decision. Unrelated prime–target pairs have lower familiarity and more time is needed to make a lexical decision. This theory correctly predicts that presenting an unrelated stimulus between the prime and target eliminates the priming effect.

Whittlesea and Jacoby (1990) extended the compound-cue idea by proposing that processing a target can induce automatic retrieval of a related prime event, producing an integrated or compound prime–target cue. They demonstrated that forming a prime–target compound is situation dependent. When a target is degraded (e.g., by using alternating case: dOcToR), the prime is more likely to form a compound with the target because independent identification of the target is more difficult. The result is a larger priming effect with degraded targets.

A second alternative account of semantic priming derives from neural network models of word identification. In many of these models, knowledge about words is represented by a pattern of activation across a collection of processing units. It is the instantiation of this pattern in the network that supports a response to a word target on tasks such as lexical decision. Related words have similar patterns of activation. Presentation of a related prime moves the network into a pattern similar to that associated with the target, giving the network a head start at instantiating the target's pattern of activation, thereby creating a priming effect. As in the compound-cue theory, presenting an unrelated word between the prime and target is expected to reduce or eliminate the priming effect, although neural network theory attributes this reduction to disruption of the pattern of activation created by the prime (Masson 1995).

Although semantic priming can be disrupted by an intervening unrelated word, prime events appear to modify long-term memory in a manner that supports semantic priming even when a period of minutes intervenes between prime and target. The survival of semantic priming across such time intervals requires that the task performed on the target demand sub-

stantial semantic processing, such as deciding whether the target represents a living or a nonliving object (Becker et al. 1997). A neural network model developed by Becker et al. accounts for this effect by assuming that the prime event modifies connection weights in the network to favor related words, which is equivalent to modifying long-term memory.

Recent work on semantic priming, then, is largely consistent with the idea that short and long timescale priming effects arise from different mechanisms: transient patterns of activation or compound cueing of memory in the former case and incremental learning in the latter.

1.3 Phonological and Other Forms of Priming

The role of *phonological recoding* in the reading of words has been studied by presenting phonologically related primes with target words. Perfetti and Bell (1991) used nonword primes that were phonologically related to target words (*baik-bake*) and control primes that were graphemically but not phonologically related to the targets (*bawk-bake*). In this paradigm, the target word was presented briefly (about 15–30ms) and was *followed* by the prime, which served as a backward mask and was in view for a similarly brief time. Finally, a pattern mask consisting of a row of Xs was presented. Subjects were more accurate in their report of the target word when phonologically related primes were used, even though the primes were usually not consciously perceived. Phonological information derived from the prime can thus contribute to the process of identifying a target. Results such as this one, which have been replicated using Hebrew and Chinese materials, suggest that phonological recoding of words is the default processing mode in reading.

Other types of primes bearing various relations to target words, such as orthographic (*cord-card*) or morphological similarity (*swim-swam*), have also been used to determine whether these knowledge sources play a role in reading. Related primes of these types usually improve performance on target identification tasks relative to primes that bear no relation to the target, implicating these sources of knowledge in reading. In addition, priming paradigms have been used to study clinical populations in an effort to understand the knowledge retrieval processes associated with particular disorders. For example, semantic priming of alcohol-related words is enhanced among subjects who suffer from alcohol dependence. Medications have been shown to reduce this priming effect, suggesting that such interventions are capable of reducing the retrieval of alcohol-related memories.

2. Repetition Priming

Stimulus identification can be enhanced not only by priming with a related item but also by an earlier

presentation of the target itself. Repetition priming of words or objects has been demonstrated in experiments in which a preliminary presentation of an item is followed minutes, hours, or even days later by a repetition of that same item. Improved processing typically is evidenced either by a reduction in the time taken to identify the item or increased accuracy in its identification. In a particularly striking demonstration of this phenomenon, Kolers (1976) showed that even when over 1 year intervened between the first and second reading of text passages presented in inverted typography, subjects were able to read repeated passages faster than ones they had not read earlier. An important aspect of repetition priming that separates it from many other studies of memory is the fact that subjects are often unaware that their performance is being influenced by prior experience with the target stimulus (see *Implicit Memory, Cognitive Psychology of*).

2.1 Long-term Priming

The fact that repetition priming can persist over relatively long periods of time provides an important theoretical constraint. The proposal that repetition priming results from sustained activation of the mental representation of a target item has been criticized on the grounds that it would be implausible for activation to be sustained over long periods of time. Moreover, repetition priming effects involving novel stimuli such as nonwords and novel shapes indicate that activation of pre-existing mental representations is not a necessary condition for priming.

A more plausible account proposes that a representation of the first encounter with an item is encoded into long-term memory and is recruited, usually without conscious intention, when that item is repeated on a later occasion. To the extent that the processing operations performed on the item are similar on the two occasions, recruitment of memory for the original processing episode will benefit current task performance—a principle known as *transfer-appropriate processing*.

Because many of the tasks used to study repetition priming involve the identification of a stimulus, perceptual operations that support identification have been of particular interest in this work. Consistent with the transfer-appropriate processing principle, it has been shown that altering the perceptual characteristics of an item between its first and second presentations (e.g., spoken to printed presentation, or male to female voice) reduces or eliminates repetition priming.

The perceptual specificity of repetition priming has also been taken as support for the proposal that this form of priming is mediated by a neurologically distinct memory system that represents perceptual forms. This memory system is assumed to be in-

dependent of other memory systems, such as the one responsible for supporting conscious recollection of prior episodes. The independent system assumption receives support from the finding that amnesic subjects who are severely impaired on tasks requiring conscious recollection nevertheless show normal repetition priming on various tasks.

Although the processing and memory systems accounts of repetition priming constitute potentially opposing views of memory organization and function, these two approaches are seen by many researchers as complementary (Roediger 1990). In particular, consideration of the memory systems account has encouraged the integration of informative findings from cognitive neuroscience studies, particularly those involving cases of amnesia, into behavioral theories of priming.

2.2 Masked Priming

A second form of repetition priming appears to be short-lived. In *masked repetition priming*, a prime is presented briefly (e.g., 60 ms) and is both preceded and followed by a mask. The second mask is in fact the target item that the subject is required to identify. On repetition priming trials, the target is identical with the prime, except for a change in case (*house*–*HOUSE*), whereas on unrelated trials the prime is unrelated to the target. Presentation of a repetition prime enables subjects to identify the target item more quickly or accurately. This kind of repetition priming has been dissociated from long-term repetition priming in two ways. First, it appears to dissipate within less than 1 s if a delay is introduced between the prime and target. Second, masked repetition priming is equally strong for common, high-frequency words and for uncommon, low-frequency words, whereas in long-term priming low-frequency words show a larger priming effect than high-frequency words.

Dissociations between masked and long-term repetition priming have supported the view that whereas the latter type of priming may be due to a form of episodic memory, the former is due to temporary activation of lexical knowledge (Forster and Davis 1984). The apparent lack of masked priming for nonwords in the lexical decision task also is consistent with this proposal. More recent evidence, however, has challenged two of these dissociations. First, there are cases in which masked repetition priming is stronger for low-frequency words, just as in long-term priming. Second, masked repetition priming of nonwords can occur when the experimental design allows subjects to overcome the tendency to classify fluently processed repetition-primed nonwords as words.

Similarities between masked and long-term repetition priming encourage the view that both phenomena may reflect the operation of a form of episodic

memory. Presentation of a prime is assumed to create an episodic representation that can later be recruited as a resource to assist in the identification of that item on a subsequent presentation. This interpretation of repetition priming fits with the retrieval interpretation of semantic priming described above and promises to provide a fruitful framework for interpreting priming effects in general.

2.3 Negative Priming

There is an interesting circumstance under which repetition of an item can, paradoxically, interfere with task performance. *Negative priming* arises when a pair of items is presented on a *prime* trial, and another pair is presented on the subsequent, *probe* trial. On each trial, the subject is cued to respond to one member of the pair and to ignore the other (e.g., a drawing of a dog in red and a drawing of a violin in green; name the green item). If the ignored item on the prime trial then appears as the cued item on the probe trial, a longer response time is observed than when unrelated items appear on both trials (Tipper 1985). One interpretation of this result is that the act of ignoring an item on the prime trial inhibits the mental representation of that item, rendering it more difficult to identify it on the subsequent probe trial.

The inhibition interpretation of negative priming has prompted some researchers to apply the technique as a measure of inhibitory processing in studies of special populations such as older adults and clinical groups (e.g., individuals with obsessive-compulsive disorder). These applications appear to be premature, however, given recent evidence for an interpretation of negative priming that does not involve inhibition.

On this alternative view, negative priming does not result from selecting against an item on the prime trial. Rather, the appearance of the target on the probe trial automatically retrieves memory for its appearance on the prime trial as in semantic and repetition priming. Because the target must be selected over a distracter item, however, the subject must discriminate between the current perceptual representation of the target and the retrieved memory representation of the target's appearance on the prime trial, among other targets. It is this discrimination process that slows responding and produces negative priming (Milliken et al. 1998). Two important findings support this proposal. First, negative priming is found even when a single stimulus that requires no response is presented on the prime trial, eliminating the need for any inhibition of or selection against that stimulus. Second, when no selection is required on the probe trial, negative priming is not obtained. Thus, in keeping with the memory retrieval account, it is selection on the probe trial, not the prime trial, that induces negative priming.

3. Conclusion

Although the initial theoretical frameworks for understanding priming with related stimuli and repetition priming advocated the idea that priming reflects the relationship between stable mental structures such as a mental lexicon or semantic memory and the activation of those representations, an alternative class of theories is emerging in both domains. These alternative theories emphasize the role of specific episodes in modifying memory representations and in constructing resources that are recruited when a target event is to be identified. The emergence of this new class of theories holds significant promise for the development of a unified account of how memory and perception interact to enable skilled identification of words and objects.

Primitive Society

In popular usage, 'primitive society' distinguishes ourselves from other people who have made little progress towards what we understand as civilization. There are very few such people left today: they live in scattered communities in deserts or rainforests, and they interest us mainly because we think of them as the living relics of our own distant ancestors. The comparison is usually unflattering. Until the beginning of the nineteenth century 'primitive' simply meant 'first' or 'earliest,' but as the word was applied to the original inhabitants of territories colonized by European and American states, it acquired the connotations of inferior, backward, rude.

In the evolutionary social science which developed towards the end of the nineteenth century, 'primitive society' came to be regarded as the defining subject matter of the emerging discipline of anthropology. The new natural science of biology provided the basic inspiration, and physical anthropology remains one of the four subfields of the discipline. However, although physical (or 'biological') anthropologists are much concerned with comparisons among primates they no longer distinguish human bodies as more or less primitive. We vary from one population to another in average body size, skin color, hair type, etc., and people within each community (neighbors or family members, young and old) look unlike, but unless we wish to be regarded as 'racist' we studiously avoid implying that any of these differences connotes inferiority or even some sort of adaptive advantage. Physically we are neither less 'primitive' nor more 'modern' than our ancestors 50–100,000 years ago.

It is, therefore, somewhat ironic that Darwinian hypotheses of the 'ascent of man' by natural selection have provided such a tenacious metaphor for distinguishing among human societies and cultures. For most social scientists for most of the twentieth century, being 'primitive' was a relative judgment about how people think and behave, not about their genes, brains, or bodies. Nineteenth-century explanations of social evolution construed Western civilization not just as the most successful human adaptation, but also as an inevitable and morally necessary path of progress.

While metabolizing or copulating might have changed little over the millennia, there were certainly more and less civilized ways of dining or marrying. And it was significant that only civilized modern man had the capacity to understand and explain the difference.

The first generation of modern anthropologists sought a general, empirically valid definition of the 'primitive,' and used the word without inhibition. Tylor's article defining anthropology in the famous 11th edition of *Encyclopedia Britannica* (1911) may represent the apogee of the technical use of the term. Thereafter, 'primitive' continued to appear in the title of ethnographic monographs, more as a generic label for subject matter than as an analytical concept. By the middle of the twentieth century, even the label had gone out of favor in the social sciences. The dissolution of the European empires and the emergence of new, transnational political-economic interests brought a shift in intellectual attitudes. Ideas of 'underdevelopment' as a natural, primitive condition which would be relieved by technically-enhanced progress towards modernity, soon yielded to ideas of 'underdevelopment' as a political-economic predicament inflicted on citizens of the 'Third World' by the expansion of industrial capitalism from its metropolitan centers. Peoples in the new states who were once classified as 'primitive' were now identified as the least privileged members of a widely distributed 'Fourth World,' which included the impoverished citizens of 'developed' countries.

The only entry under 'primitive' in the 1968 counterpart of this *Encyclopedia* referred to naive styles in art. 'Primitive society' has resurfaced in the present work as a historical curiosity rather than as current terminology. The phrase says more about changing interests, attitudes, and theories in anthropology than about the peoples to whom it once referred. In trying to come to terms with their designated subjects during a century of radical social change, anthropologists have buried 'primitive' society in layers of definition. These include specification of a distinctive sort of social structure, mode of livelihood, spatial distribution, and mentality, all defined (tacitly or explicitly) by a contrast with, and presumed progress towards, civilization as we understand it. Very occasionally an anthropologist will resort to 'primitive' as a portmanteau term: Hallpike (1976) uses it 'simply as a convenient abbreviation for "non-literate, small-scale, face-to-face-societies with subsistence economies."' Although the pejorative implications are resisted sternly, there is still an evident need to refer contrastively to people who have not yet been absorbed within the ambit of 'literate, large-scale, impersonal societies with industrial economies.' Rejecting one word around which a discipline was constructed is not enough to dismiss the assumptions about evolutionary progress which linger on in our understanding of the differences between 'Us' and the sorts of people who are 'Our' anthropological subjects.

1. Livelihood

The simplest and least obviously offensive definition of the primitive has been the material circumstances of their lives. Anthropology as a discipline is still organized around a sequence of social types based on technical developments in the means of production. The prototypical human population of 'hunter-gatherers' lived in nature, taking what they needed day-by-day, whereas subsistence farmers were obliged to work on nature with tools and skills, taking possession of land and other resources, and thereby setting in motion the larger political and economic organization of the state. Technical complexity increased the division of labor, which produced societies in which larger numbers of people depended on more specialized functional relationships with each other. This was especially true of the second great technical revolution which began with the industrialization of cloth production in north-west Europe towards the end of the eighteenth century. With capitalism as its social vector, industrialism swept out to transform the world, creating among other things a new and palpable contrast between the modern and the primitive. It also produced the first generation of social scientists whose role in the ever-expanding division of labor was to explain what was going on.

2. Social Structure

In the pattern of evolutionary contrasts which emerged in the writing of Morgan, Tylor, Rivers, and the other early anthropologists, the social world of the primitive was the small, technically, and socially 'simple' community. In this evolutionary formulation, 'primitive society' was almost a contradiction in terms, "society" being seen as the multiplication of roles and relationships in expanding populations, with heterogeneous individuals bound by new forms of rational contract into complex entities like the modern nation state. The primitive, by contrast, was a 'society of clones' (Kuper 1988), held together 'mechanically' (Durkheim's term) by the relations of reproduction. Social anthropologists pieced together the logic of systems of descent and marriage which apparently gave these 'homogeneous' communities their cohesion. For example, the simple rule 'reckon that you are the child of your father rather than your mother' was enough to tease a whole population out into mutually-exclusive (patri-) lineages, conferring distinct political identities on people who might never actually meet each other. Debates raged about whether paternity or maternity was the more primitive mechanism of social solidarity. The 'elementary structures of kinship' (clans, demes, moieties, etc.) conferred statuses and roles by birth, but these 'ascribed' relationships were less useful as people were drawn into much larger fields of interaction in technically more advanced societies where

survival and progress depended on geographical movement and the exercise of choice and imagination.

Governed by the biologically-derived moral mechanisms of kinship, the primitive tribe could manage without officials and rulers. From an imperial perspective, these emerging definitions of the 'tribe,' boosted by romantic writings of the period, were both intellectually attractive and administratively useful. The tribe suggested a prototypical democracy, a predominantly male political structure, and a paradigm of nationalism—the great seductive and destructive passion of the twentieth century. After two world wars which revealed the barbarity of civilization and cast doubts on who was more primitive than whom, the natural logic of the 'tribe' (as expounded, e.g., by Evans-Pritchard for *The Nuer* (1940) of the southern Sudan) was appealing. In the 1968 *Encyclopedia*, 'Primitive society' was broken down into seven cross-references: Anthropology, Culture, Evolution, Hunting and Gathering, North American Indians, and—the principal entry—Tribal Society. However, the 'Tribal' label could not stick. The year 1968 also brought the revival of the intellectual left, and the association of 'tribalism' with the ideologies and practices of imperialism quickly made it taboo. Anthropologists were now being accused of complicity in the task not just of identifying but inventing the tribes which had been the units of European and North American colonial government.

At this time, the other substitution for 'primitive' was traditional, the preferred counterpart for modern in the evolutionary scheme. But very soon this too was found to be pejorative, mainly because the innumerable books juxtaposing the two words in their titles seemed to presume an ethnocentric convergence on a Euro-American paradigm of modernity. 'Traditional societies' were scattered and diverse, stuck in the inertia of custom until history drew them inexorably into the global monotype of 'modern society.' In the 1980s such teleologies of modernization were rejected by scholars who defined themselves philosophically as postmodern. They wrote critically of our historic and ideological self-centeredness and in praise of a diverse category of 'The Other', which stood mostly against the hegemony of (Western) scholarship itself. An emblematic study was Clastres's (1977) account of the Tupi-Guarani Indians of the Amazon, whose profoundly primitive social structure supposedly set up antibodies for the development of inequality, leadership, capitalism, the state, and the other vices of modern civilization. Such writing paved the way for a revival of sympathetic interest in the 'primitive.' Postmodern characterizations of 'Otherness' invoked a much older assumption about primitive society: its spatial isolation. Earlier anthropologists had pursued the prototypical primitive to the ends of the earth, especially Australia and Oceania, and ethnographic accounts of these tiny encapsulated communities in turn fleshed out the definition of 'primitive.' Post-

modern anthropologists pointed out that the (relatively) concerted forces of worldwide capitalism had tended to marginalize people physically remote from the metropolitan centers, making 'peripheralness' a common denominator of what had hitherto been called traditional, tribal, or primitive. The desire to see 'Others' entirely in their own terms as just 'different' not only meant abandoning pernicious comparisons with 'Us' but also the assumption that the 'Others' had anything specific in common among themselves—some generic sort of 'traditional' culture or 'primitive' social structure.

Most problematically, it was not even safe to assume that everyone had essentially the same sort of body, because biology or physiology themselves were only historically specific sets of ideas for coming to terms with the human condition. This deliberate affront to science has exacerbated a split in anthropology, set in motion by the invention of 'sociobiology' in the 1970s. With 'evolutionary psychology' as the link, a new genre of anthropology is pursuing genetically endowed physical mechanisms which shape culture, for example, through the processes of language acquisition or mate selection. From this point of view, 'primitive society' as represented by today's vanishing hunter populations are living testimony to the 'Environment of Evolutionary Adaptedness' in which modern man was physically constructed and mentally endowed. Virtual banking or an appreciation of Beethoven is fundamentally as 'primitive' as gnawing bones. These exciting speculations have captivated public attention, putting the denser, relativistic theories of idealist anthropologists at a disadvantage.

However, it is ironic that the radically Cartesian postmodern approaches to society have taken the psychic unity of human beings entirely for granted: it is not our minds which differ, but the way they are culturally made up. This returns us to some very old and persistent mental assumptions underlying the meaning of 'primitive' in its various transmutations.

3. *Mentality*

In drawing analytical metaphors from biology or botany the social sciences and humanities have not always kept pace with theoretical advances in the natural sciences themselves. The nineteenth century evolutionist idea of recapitulation was absorbed by the emerging social sciences, and lingers as a latent assumption about human behavior in forms which biological scientists would now barely recognize. The original formula, as specified by Ernst von Haeckel, was that the life history of the individual organism repeats, from the embryo onwards, the stages of its species evolution ('ontogeny recapitulates phylogeny'). Transposed to the social domain, this fostered

the notion that children are primitive—and, by a facile converse, that primitives are children. Thus, Lubbock (1875) was fascinated by ‘The similarity of savages and children,’ and struggled to prove that the childish trait of phonetic reduplication (words like *bonbon*) was an infantile characteristic of primitive languages, absent from civilized English, French, German, and Greek. For social philosophers like Henry Sumner Maine, primitive society was ‘the infancy of man,’ and as late as 1953 Robert Redfield commended the human race for its tendency ‘to grow up.’

The metaphoric transfer of this early biological concept to society and culture continues to create much confusion. Although it is implausible that a modern child could be reliving the traumatic experiences of ancestral adults, the idea that children relive primitive urges remains at the heart of Freudian psychology. Indeed, in his study of *Totem and Taboo* Freud (1938 [1919]) pursued the argument to ‘resemblances between the psychic lives of savages and neurotics.’ The logic of recapitulation leads inexorably to the conclusion that the metamentality of ‘culture’ is, for primitive people, childish and crazy, and that their world is a kindergarten which can only benefit from some civilized parenting—a good excuse for colonization and imperialism. This elaborate equation of the mad, the childish, and the primitive is extraordinarily tenacious, despite many attempts to sort out the confusion. Margaret Mead, for example, sought to demonstrate that primitive Melanesian children were actually ‘more rational’ than their ‘animistic’ parents. This subverts Enlightenment assumptions that rationality increases as a function of both of individual and species development. But for such a devout idealist and anti-evolutionist as Mead, it also raises disturbing question about how children everywhere come ready-equipped with this sort of scientific rationality, and think straight until ‘enculturation’ fills their primitive minds with superstitious rubbish.

Anthropologists have always traded on public fascination with the magic and superstition we associate with primitive (and childish) thought. Given its persistence in modern society, religion itself has not been an acceptable marker of the primitive. The discriminating variable here is, once again, scale: the universalistic ‘World Religions’ (Christianity, Judaism, Islam) deal with the mass of individual souls, while the narrow-minded particularistic religions of primitive society connect people spiritually to community and locality (‘animism’, ‘fetishism’) often through the biosocial idiom of descent (‘ancestor worship,’ ‘totemism’). These peculiarities of primitive thought have interested French anthropologists particularly, immersed as they are in the idealist tradition. Inspired by Franz Boas, Kroeber, Mead, Benedict and other American anthropologists tried very explicitly to reject the evolutionary premises, and pursued a relativistic interpretation of culture (rather than ‘society’) which

sought to avoid the prejudices of a superior western civilization. However, the central conundrum of relativism seems inescapable: how can we distinguish one culture from another if we have no agreed definition (some sort of ‘metaculture’) of what culture is in the first place? Simply to insist that all human beings have the mental capacity to ‘do’ culture evades the issue of how that capacity is physically embodied, how it constrains behavior, and (the evolutionary question) how and why we need it.

The most fundamental belief, which very few modern anthropologists would dare challenge, is of psychic unity, a conception of the human mind as inhabiting a standard brain which may determine how but not what we think. In the idealist tradition, what we think is determined outside of ourselves in an integral, self-reproducing system of ideas—culture, with a ‘mind’ of its own. The trouble is how to reconcile the enormous differences in culture with the primitive sameness of our minds. A symptom of lingering evolutionism has been the association of this primitive mentality with a closeness to nature.

This is captured in the old term *savage*, a synonym for primitive which appeared in anthropological titles well into the twentieth century, though increasingly in ironic quotation marks (Lévi-Strauss (1966) *The Savage Mind*; Goody (1971) *The Domestication of the Savage Mind*; LaFontaine (1981) *The Domestication of the Savage Male*, etc.). Although in French ‘sauvage’ still has a more benign, Rousseauian ring, the English connotations of fierceness and intemperateness latterly made it at least as stigmatic as ‘primitive.’

Seeking a general and objective axis of intellectual difference, many anthropologists have settled on literacy as a key technical distinction between primitive and modern mentality. Thus, in the early 1930s, Margaret Mead uses the word ‘primitive’ to refer to those peoples who are completely without the benefits of written tradition, and in 1953 Robert Redfield declared ‘I shall use “primitive” and “preliterate” interchangeably’ (he also used a range of cognate terms including ‘folk’ and ‘precivilized’). By the 1970s pre- or nonliterate had become the favored term for the societies traditionally discussed by anthropologists, and it remains a key universal classification for those working in the idealist tradition.

4. Nostalgia

A final reason for the persistence of notions of the primitive within and beyond anthropology is plain old-fashioned nostalgia—the old image of the noble savage as a counterpoint to the vices of civilization. Anthropologists are notorious for their populist commitment to the people among whom they have their main (usually first) ethnographic experience. Indeed, it has often been said that anthropologists are people

seeking a special sort of redemption in the notion that the moral virtue lacking in so-called civilized society may be rediscovered among simple people who are more in tune with nature. Defense of primitive peoples, usually in conjunction with the protection of their forest or desert environments, has become a respectable political commitment for many anthropologists. Despite Marx's rage against populist utopianism, his own material laws of history imagined a return to the perfect altruism of primitive society. This image of our natural selves before we were corrupted by the rise of capitalism was inspired by the ethnographic vision of 'Ancient Society' in North America constructed in the mid-nineteenth century by one of the founding fathers of anthropology, Lewis Henry Morgan. Marxists have been rebuked for urging the violent recovery of this old society without offering any plausible account of its structure. That it should somehow combine the benefits of the scale, technical expertise, occupational specialization and intellectual achievements of modern industrial society directly contradicts most of what has been learned about primitive society.

Today, the idea of the primitive lives on in a schizophrenia of admiration and disgust. On the one hand, popular writers like Robert Kaplan have promised the return of the modern world to barbarism, while anthropologists like Paul Richards explain that what appears as primitive lapses in Sierra Leone or Cambodia is a wholly modern circumstance—the global failures of industrial capitalism. In whatever guise, the concept of the primitive seems irrepressible in our imagination of ourselves, lurking in the shadows as we struggle to detach our vile, ancient bodies from the dream of a transcendent modern mind.

Printing as a Medium

Printing is a technique for producing all kinds of paper-based records (books, periodicals, musical scores, ephemera, etc.) by means of ink, a press, and reusable characters. It permits the mechanical production of many identical copies, thereby eliminating the corruption inevitable in hand-copying. Printing has had profound consequences in all spheres of social life. In particular, it has often been ascribed a major role in the transition to modernity that took place in the Western world after the Renaissance.

1. The History and Impact of Printing

1.1 The Invention of Printing

Techniques for the mechanical reproduction of texts are not a uniquely Western invention. Such techniques existed in Korea and China hundreds of years before they did in the West. Yet it is in the West that the press had its greatest impact. It is customary to divide the history of printing there into two periods: the hand-press era, lasting from the mid-fifteenth century to the early nineteenth; and the industrial era, beginning shortly after 1800 with the invention of the steam press and lasting into the present. Social scientists' arguments about the effects of printing as a medium tend to

concentrate on the former, in an effort to help explain modernization in terms of a putative 'printing revolution.' But, as will be suggested below, they would often be more aptly applied to the latter.

There is no plausible route by which Asian technologies may have influenced Johann Gutenberg (c. 1398–1468), a goldsmith from the Rhineland town of Mainz who built the first European press, so he may legitimately be called its inventor. At first, his intent was anything but revolutionary. When he constructed his first press, Gutenberg did so as a calculated intervention in the world of commercial manuscript production that already existed. His earliest printed books were designed to resemble manuscripts, and he intended to sell them as such. He also swore his workmen to confidentiality about his new technique, apparently, in the manner of apprentices in any late-medieval craft. But the strategy did not last. In 1462 Mainz was besieged and sacked, and Gutenberg's printing house broke up. His workers went to other towns and set up their own operations. Before long, printers had appeared in a score of German, Dutch, Italian, and French cities, often fostering legends that printing had been invented locally. Venice, Avignon, Strasbourg, and Haarlem created the most plausible of such histories, as a result of which determining the true origins of the press remained a notoriously intractable problem well into the nineteenth century. William Caxton set up his printing house in London at the end of this first wave of expansion. By that time, in 1480 or so, a new European craft was firmly established.

1.2 The Practice of Early Printing

That craft centered on the *press*—a simple, largely wooden machine, capable of being made by semi-skilled workmen and, if small enough, amenable to concealment and transport from place to place. This press would normally be operated in a place called a printing house. Here, a compositor would set type into a frame called a *form*, which would then be placed in the press itself, which two pressmen would operate to make up to 1,000 impressions per day. The resulting sheets would then be dried, and collated to make books. It sounds, and in essence it was, a simple process. But in practice it was hard to sustain. Most printing houses were severely under-capitalized, and depended for their day-to-day survival not on the printing of books, but on that of ephemera and pamphlets—anything, in fact, that furnished regular and frequent influxes of cash. Almost all of these products were destroyed soon after manufacture. The population of books that has lasted to the present day to fill our great research libraries therefore represents an extreme distortion of the reality of early modern print culture.

This being so, printing raised an immediate question: whether culture could be allowed to be defined by

commercial necessity. Early modern Europe attempted to answer that question by constraining printing on three social levels: the household, the craft, and the polity (where the polity might be a religious one, such as the Catholic church).

In the first place, a printing house, like most places of work in early modern Europe, was normally supposed to be a residence as well. The master printer generally lived in the same building—as, quite frequently, did his journeymen and apprentices. There was a reason why this was held to matter. It was conventional to believe that the moral structure of the patriarchal household largely guaranteed the legitimacy of practices pursued within that household, and printing was to be subjected to the same moral oversight.

In the second place, printing was also organized into guilds, one of which existed in every major city. To be a master printer was to be a respected member of such a group. Each maintained its own conventions, expected to be honored by all members of the book trade. Violations were identified and remedied by book-traders themselves, generally behind closed doors, so that for outsiders the image of an intrinsically harmonious order of print was sustained. Again, there was nothing strange about this; it was how all early modern crafts operated.

And in the third place, such guilds operated in fragile harmony with regulations imposed by church and state. Chief among these were 'privileges' (patents) and licenses. Privileges were grants of literary property, to use an anachronistic phrase, given out by the monarch or equivalent authority. They conflicted in principle with titles allocated by the guilds internally, which was one reason why they were eventually replaced by copyright conventions. A license, on the other hand, was a permission to print (in Latin, *imprimatur*, 'it may be printed'), granted by an authorized individual to the printer or bookseller. In principle, all works had to be vetted by such an official before publication, but in practice this was rather less severe than the censorship sometimes portrayed by modern historians. Most books were never licensed, and only a tiny minority were pursued for lack of an *imprimatur*. The Counter-Reformation Catholic Church extended this principle of licensing into a systematic *Index of Prohibited Books*, which listed titles the ecclesiastical licensors had decreed too unsound for general readers. Again, while this undoubtedly affected the availability of certain books and authors (Machiavelli and Copernicus, for example) in Catholic lands, protestant publishers quickly realized that appearing on the *Index* virtually guaranteed best-seller status in their own countries, and they rushed to print large impressions.

In these ways, then, the social order of early modern Europe sought to accommodate the potentially revolutionary new craft. It was never an entirely stable arrangement, and by the late seventeenth century it

was breaking down. In England, first, licensing lapsed in 1695. With it went much of the authority of the local guild, called the Stationers' Company. Nobody wanted outright deregulation, however, and the major result was a hard-won new compromise between state, authorial, and trade interests. It was articulated in the so-called 'Copyright Act' (1710—the term copyright never actually appears in it). This Act became the basis for the entire subsequent history of copyright and intellectual property law. By the late eighteenth century, agitation for reform of printing and literary property on similar lines had occurred across Europe, and in the years around 1800 broadly similar copyright provisions were established in all major Western states; they extended beyond Europe and the colonies in the nineteenth century. The modern conventions of printed authorship thus owe their origin to the existence and instability of early modern attempts to define and regulate printing: to licensing, patents, and the craft practices of printers themselves (Chartier 1992).

1.3 Industrial Printing

The technology of printing remained virtually unchanged from soon after Gutenberg's invention until around 1800. At that time, however, change came rapidly. Not only did the legal and conventional practices governing the industry alter once and for all; so did the technology of printing itself. First came Stanhope's metal press. This was soon followed by the steam press, which at a stroke increased production rates by an order of magnitude. Stereotyping finally made the dream of truly identical copies a reality. And at the same time, the technology of papermaking changed dramatically with the success of Henry and Sealy Fourdrinier's machines in Hertfordshire. Although it never had the iconic status of the steam press, the papermaking machine had as great a role in the changes of this period, and Brunel himself hailed it as 'one of the most splendid inventions of our age.' With the advent of all these new devices occurring within a generation, between 1800 and 1840 printing underwent its own industrial revolution.

The first commercial steam printing was done at the office of *The Times* in London. It vastly increased the print run of the newspaper, quite literally overnight (the management had the machines installed in secrecy to prevent unrest among the soon-to-be-redundant workers, and unveiled them only when they produced their first day's issue). Nor did the improvements cease there: by 1827 *The Times* had new presses that were producing 5,000 copies an hour. Steam printing was understandably slower to take hold in smaller publishing markets, since it required a large capital outlay—Cambridge University Press, for example, was unusually avant-garde among specialist houses in adopting the technology, yet still did not do so for more than a

generation. And in general the book publishing business was less immediately affected by industrialization than the newspaper and periodical press. But the advent of industrial technology nonetheless changed printing forever, and vastly increased its social impact.

In fact, many of the attributes that historians and social scientists attribute to the hand press may more properly be assigned to the steam press, in conjunction with mechanical papermaking and stereotyping. Typographical fixity in particular was never as clear a component of hand printing as we tend, anachronistically, to assume—in an edition of perhaps 300–1,000 copies, any number of variations would occur across different copies, as correction would be done on the fly. This kind of variability now ceased. Print runs 10 or 100 times as great as had previously been viable also represented a quantitative leap as great as that associated with Gutenberg. They made possible, indeed in economic terms virtually necessitated, the first national daily press. The development of mass literacy, too, was really much more a phenomenon of the nineteenth and especially twentieth centuries than of the sixteenth and seventeenth; mass education of the kind parodied by Dickens in *Hard Times* relied on steam printing. At the same time, since industrial printing required a great deal more concentration of capital than had hand printing, it encouraged agglomeration and uniformity within the publishing industry itself. The press barons of the twentieth century, with their incalculable influence on social and political life, owed their baronies to the printing techniques introduced in the nineteenth century. In effect, printing had become a branch of factory culture.

2. A Printing Revolution?

Gutenberg's invention had profound social and cultural consequences, and modern historians and social scientists have tried hard to discover what they were. First and foremost, the press produced texts in unprecedented quantities. Lucien Febvre and Henri-Jean Martin (1958), in the first modern work to focus on the history and impact of printing, calculated that the number of printed books soon exceeded the number ever produced in manuscript up to that time. Sheer quantity of this order had its own consequences. Books were suddenly available in unprecedented numbers, in more places, and at lower costs. As they spread through social ranks, people—especially town-dwellers—made these new objects their own. Literacy increased markedly, and that alone constitutes one of the major turning-points in the development of modern social order. But mere numbers cannot explain the more specific cultural consequences of the press. Major *qualitative* changes were also brought about by print. These have been described most exhaustively by Elizabeth Eisenstein (1979). They were of two major

kinds: transformations in the making and appearance of the page, and innovations in the uses of books by writers and readers.

After Gutenberg's brief experiment with imitation, the printed page soon began to look very different from its manuscript predecessor. Typefaces and layouts became standardized. Cross-referencing, indexes, errata, and notes came into use, according to conventions that themselves grew more uniform. Woodcuts and engravings allowed the use of repeatable images, permitting diagrams, charts, and scientific illustrations to be communicated with a security never before possible (Ivins 1953, McKenzie 1986). Hitherto, it had been very difficult to express sophisticated claims in pictorial form, so rapidly did images degrade in the hands of copyists. The simple ability to juxtapose and compare reliable representations of competing claims revolutionized the possibilities for learned work.

This textual 'fixity,' as Eisenstein calls it, affected a number of cultural realms, among which religion and science may be singled out. It is not a coincidence that Luther's reformation lasted, while previous attempts at reform (such as those of Hus, or the Lollards) had withered or been wiped out. The permanence and cornucopic plenty of print made Luther's program impossible to suppress. Indeed, it is in the furor over Lutheranism that some of the most characteristic forms of mass communication were invented, such as the pamphlet and the polemical cartoon (Scribner 1981). And, most fundamentally, only such a machine could truly hope to permit a 'priesthood of all believers' by making the Bible available as an object to innumerable readers.

In the sciences too the advent of print permitted great upheavals. The contemplative natural philosophy of the schoolmen gave way before a newly active interrogation of natural processes, modeled, allegedly, on the practices of craftsmen. Print not only circulated this new natural knowledge but also helped to create it, since printers' homes became 'polyglot households' where scientists of all nationalities could meet and correspond. Print thus helped forge the norm of open communication that is so central to science. And men like Henry Oldenburg secured the status of the new science in novel forms of printed communication. Oldenburg's *Philosophical Transactions*, launched in 1665, survived to rank today as the oldest of all scientific journals.

But printed texts alone did not change the world; printed texts plus new ways of using them did. Not least, the sheer mass of printed matter required new classification techniques—in effect, a science of bibliography—to master a worldwide 'library without walls.' But more profound was the change in reading practices that print facilitated. From its early days, the *Philosophical Transactions* was the central plank of a new, transnational readership of naturalists, gentlemen, mathematicians, and scholars—the ancestor of

today's scientific community. The common readership of such periodicals was rapidly recognized as uniting a novel kind of collective, called the *republic of letters* or, rather later, the *public sphere*. This 'public' was defined by its engagement with print. And with Baconian ambition, it took all knowledge to be its province (Habermas 1962). It marked a decisive break from traditional and absolutist societies. In Habermas' very influential account, it therefore laid the foundations for true socio-political transformation, most notably in the form of the French revolution. In that sense, the 'printing revolution' ushered in by Gutenberg warranted its name.

3. Theories about Print

It was in the context of the Jacobins that printing was first recognized as an explicitly revolutionary force. True, Francis Bacon's salute to the press (along with gunpowder and the mariner's compass) was much cited; yet it was little more than an aphorism. The first fully articulated and contextual interpretation of printing's impact was that of the Marquis de Condorcet (1795), who was seeking to explain the overthrow of the French monarchy. Condorcet sketched out a history of 'the human spirit' in a series of stages, with the invention of the press constituting a major turning-point and effectively making the deposition of the Bourbons into 'the revolution that the discovery of printing must bring about.' In composing this sequence, he became the first writer to chart a trajectory of print-based modernization that saw its effects manifested first in the sciences, and only later in general social life. That trajectory has retained its persuasive power in modern times, but its meaning has been construed in very different ways.

Heirs to Condorcet, modern historians, and social scientists have continued to concentrate their interpretative efforts on the typographical *ancien régime* that came to an end with the dual inventions of copyright and the steam press. Compared with this, the period of industrial printing has received comparatively slight attention. There have been many empirical histories of printing, publishing, and reading in the nineteenth and twentieth centuries, but nothing as influential in social-scientific terms as Habermas or Eisenstein. Indicative is the reception of Habermas's work on the public sphere: most Anglophone readers neglect its second half, which tells a depressing story of the replacement of Enlightenment public culture with industrial mass culture. His story is far more elegiac than celebratory, but one would not realize this to read most of the Anglo-American commentators on *The Structural Transformation of the Public Sphere* (1962).

Where they do not ignore the later history of printing, most scholars simply conflate it with the earlier history, and speak of 'print' as though it were a

single, uniform entity. Probably the most famous and notorious of construals along these lines has been that of Marshall McLuhan (1911–1980), the Canadian literary critic and scholar. McLuhan's *The Gutenberg Galaxy* (1962) and *Understanding Media* (1964) set the pattern for a series of works published in the 1960s that made extravagant claims for the cultural and even psychological impact of print. His works used what he called 'probes'—unsystematic, radical aphorisms delivered scattergun fashion to jolt readers out of the formulaic thinking that, he believed, typography inevitably instilled. The probes worked, in at least one sense. McLuhan himself became a cult figure: Tom Wolfe remarked that he sounded like 'the most important thinker since Newton, Darwin, Freud, Einstein, and Pavlov.'

What McLuhan achieved was to make 'media' the subject of analysis in their own right. He argued that these media, of which print was the archetype, brought the world together, dissolving boundaries. The most important of these boundaries were socio-psychic in character. Indeed, McLuhan's very definition of a medium was that it acted as an 'extension of man,' transcending the material constitution of the human frame. In effect, he believed that the state of media determined not only how humans lived, but what humans were. This he presented as a matter of evolution. In particular, McLuhan portrayed what he called 'typographic man,' namely the kind of being who lived according to the cultural logic of print. Typographic man thought in terms of linear logic and objectivity, because his reference points were fixed texts, in what later became the Eisensteinian sense of fixity. Typographic man was both individualist (he could be sure who he was) and nationalist (he could see the bounds of his community, and tell the difference consistently between it and others). There had been no such being before about 1450. At that point, typographic man had begun to displace 'tribal man,' who had been restricted to local contacts and communication by hand. And in his turn typographic man was now becoming extinct, to be replaced by something else that McLuhan himself left nameless, but who could easily be called 'electronic man.'

McLuhan remarked that it was in the nature of electronic media to integrate with the nervous system itself, establishing humans as nodes on a worldwide network. In effect, the skin itself would dissolve as a social constraint, as neurology became inseparable from sociology. Written in the early 1960s, before the first computer network, it is easy to see why McLuhan has recently been rediscovered by the digerati and labeled a 'prophet of the Web.'

Yet McLuhan's arguments were ultimately too faddish in their tone, and too determinist in their content, to remain convincing beyond their bare outlines. Criticisms soon started to mount up (an influential example is Jonathan Miller's short 1971 introduction, which leaves little doubt where its author

stands). There are few social scientists or historians today who would openly acknowledge McLuhan as a leading influence on their representations of print and its consequences. But that influence is nonetheless real. For the most part, it is refracted through the historical analysis of Eisenstein. Eisenstein's careful arguments about the impact of the hand press gave empirical weight to McLuhan's aphorisms. Through her, his proposals have gained academic respectability. An example is Benedict Anderson's widely-praised account of nationalism (1983), which rests on an explicitly Eisensteinian argument linking print to time reckoning, and thence to consciousness of national identity. Similarly once-removed arguments of this kind can be found in many of the analyses of 'print culture' to have appeared in the 1980s and 1990s.

Yet there is one important respect in which current trends in sociological and historical research are starting to depart consciously from this approach. This is the move towards an empirical history of the practice of reading. The immediate origins of this trend lie in France, where the postwar enterprise of the history of the book was born. The spur came from the responses of both history and sociology to the dominant *Annales* school. In both fields, a realization took hold in the later 1970s that quantitative social-scientific accounting failed to capture something fundamental about the cultural impact of print. At the same time, Pierre Bourdieu (1979) was emphasizing the importance of active cultural appropriation by readers of the press rather than passive cultural reception by those readers (Hoggart (1957) had earlier made similar arguments for an English readership). By the early 1980s it looked as though attention to the varied ways of using books, building on Bourdieu's approach, might stand a chance of seeing what the quantitative *Annalistes* were clearly missing. Since then the history of reading has become a burgeoning field in its own right.

The leading proponents of the history of reading have been cultural historians like Roger Chartier in France and Robert Darnton in the USA, who have pioneered the reinterpretation of the French Revolution in these terms. Chartier in particular objects to the determinism about print that is implicit in the work of Habermas, and would direct attention more to changes in reading practice in the eighteenth century (Chartier 1990). In particular, he argues that it is hard to understand how the scatological and pornographic literature that admittedly flooded eighteenth-century France was intrinsically more devastating to the priesthood, say, than the rich seam of libels that appeared in Luther's day. Instead, Chartier would point to a newly skeptical and extensive practice of reading that was devoted to these materials, making them far more damaging in use. This practice contributed substantially to the desacralization of kingship. It hence made regicide possible, and with it the origins of modernity. In this light, the printing revolution

needs to be redefined as part of a broader reading revolution (Cavallo and Chartier 1999).

As a result, research into printing as a medium is today leaving behind quasi-determinist accounts of print exerting some kind of cultural 'logic' on societies, and towards empirical and historical research into the different ways in which societies have made use of the technology and its products. Important examples include the national histories of the book now being published in Britain, the USA, and other countries (Chartier and Martin 1982–1986; Amory and Hall 1999; Hellinga and Trapp 1999). D F McKenzie's 1984 study of a decisive cultural encounter mediated by print in his native New Zealand shows how this modern approach can influence anthropological understandings as well as historical. In McKenzie's terms, excessively schematic talk of 'print logic' is being replaced by a properly contextual 'sociology of texts' (McKenzie 1986). It is interesting to speculate whether, with print logic thus banished, the use of 'print culture' as a catch-all explanatory device may eventually fall into abeyance too. And that may happen, not coincidentally, just as the advent of electronic media signals the end of half a millennium in which print was the predominant communicative medium.

A. Johns

Prison Life, Sociology of

The sociology of prison life concentrates on thick descriptions of the actions and accounting practices that make up the distinctive social organization of a prison. Chief amongst its preoccupations have been how administrators and staff strive to maintain an authority which can never be wholly legitimate in the eyes of their captives; how, in turn, those captives contend individually and collectively with conditions of deprivation and adversity, including the adversities inflicted by their fellow inmates (Morris and Morris 1966, pp. 168–9); how a negotiated social order can emerge out of the exchanges between the two; and how, as a result, prisons manage to persist at all.

The proper study of prison had to await the emergence of universities and other institutions that could sustain social research, deploy some form of fieldwork as part of its methodology, and appreciate

that the prison is a strange institution which 'challenges the anthropological imagination' (Sparks et al. 1996, p. 33). It was not until the 1940s and beyond that those three strands converged in what are commonly held to be the first significant pieces of writing about the sociology of prison life, Clemmer's (1940) *The Prison Community* and, perhaps more important, Sykes's (1958) *The Society of Captives* and Goffman's (1961) *Asylums*. Because they set a pattern and foil for much of what was to come, it is useful to recite their principal arguments.

The Prison Community reported research conducted in the 1930s in a penitentiary for adult felons by a sociologist attached to the mental health staff. Clemmer used the methods of anthropology to study what he called the 'facts of social life,' the groupings, patterns of leadership, controls, leisure pursuits, sex, and work of prison, and to illustrate the complex relations, and the informal relations in particular, of a predatory, suspicious and atomized world of inmates banded publicly against authority but privately riddled by informers and mistrust.

The Society of Captives depicted inmates suffering 'the pains of imprisonment' and striving for the goals of better food, more rewarding work, fuller information, access to sex and pornography, security, status, and autonomy, formally denied them by an administration that purported to treat all prisoners more or less alike and certainly completely distinct from staff. It was in this sense that prison was held to engender anomic pressures that led, in their turn, to the production of illegitimate stratagems, informal social structures and a code of conduct that could satisfy a number of the inmates' aspirations. Inmates were enjoined not to interfere in one another's business, not to 'lose their head,' not to exploit one another, not to weaken, and not to trust the guards. Like many another code, it was largely exhortatory, a form of 'figurative action' rather than a reliable predictor of behavior and its accompanying social relations generated neither 'a perfect solidarity ... [nor] a warring aggregate' (Sykes 1958, p. 83). In practice, some prisoners were forced or encouraged to service the sexual demands of others; some asserted their social standing by violence, defiance or conspicuous example; some supported illegal markets in the provision of goods; and overlapping hierarchies emerged.

The ensuing social order was ostensibly clandestine and based on a rejection of the rejecters, and the staff were supposed to suppress it, but the staff confronted their own difficulties. They themselves wielded great power in principle but little in effect, they were constrained by rules and the practical exigencies and limits of control, they were outnumbered, troubled by the precariousness of their authority, and discouraged from drawing their weapons lest they be disarmed by inmates. Their reply was to replace a formal equality of treatment by a *de facto* recognition and rewarding

of the stronger inmates and inmate groupings, and they did so in exchange for a devolved social order in which inmates effectively regulated one another. The consequence was what Sykes called 'functional corruption,' but it could as readily be seen in functionalist language as a drift towards system integration, equilibrium, or homeostasis, an exemplification of the doctrine that the latent functions of action can work in seemingly paradoxical fashion to promote stability in social systems.

Goffman (1961) worked as a participant-observer in a mental hospital in Washington, DC, to construct a model of asylums, prisons, and like organizations as 'people-processing' 'total institutions' that were substantially cut off from the larger world by symbolic and physical boundaries; a continuous round of activity lived publicly within the walls; a relative lack of internal differentiation of space, role, and temporal schedule; an unbridgeable divide between staff and inmates; and, through what he called a 'mortification of the self,' the discarding of old identities and the assumption of new, degraded, and formally homogeneous identities peculiar only to the institution.

Five main processes have shaped the character and development of much of the work that followed. First has been the adoption of a somewhat critical stance. It was unavoidable that criminologists, penologists, and sociologists came motivated to the study of prison life, sometimes wishing to reform prisons, sometimes to abolish them, and sometimes—more rarely—to analyze them with the dispassion that they might extend to any other social institution. But it has been a strong distaste for prisons that has colored much of what they have written, and a number have been avowedly partisan and, indeed, polemical in their work. That stance has, in its turn, led to methodological difficulties in winning access to, and trust from, a number of key groups in prison, and prison officers especially.

Work has, second, selectively incorporated interpretations of transformations occurring in the political, administrative, and demographic conditions of penal institutions. In the United States, for instance, the sociology of prison life was born in descriptions of autocratic, *laissez-faire* regimes and the resistance that was waged by conservative inmates who feared they might lose power in the face of administrative reform. It moved on through a rehabilitation of American penology's flirtation with rehabilitation in the early 1960s and the dilemmas that arose when the particularistic ethos of treatment confronted the universalism of disciplinary control. It looked at the radical politicization of prisoners, and particularly of black prisoners, in the late 1960s and early 1970s. It analyzed the efforts at legalistic reform, the organizational instabilities, fragmentation of inmate communities, and new waves of riots of the 1970s and early 1980s. And it has culminated most recently in an analysis of the new, racialized politics of mass incarceration and incapacitation that, in Simon's phrase,

is the consequence of 'governing through crime' (Simon 1993).

Internally, American prisons were to become 'Balkanized' into antagonistic racial camps based in some measure on a prior membership of street gangs. Externally, Simon has claimed, the logic of the penal system was to be extended out from the prisons through parole, policing, and probation to subject large blocks of the population, and particularly the young, black male population of the cities of the United States, to a tight control based on actuarial and risk-driven calculations of propensities to offend. Prison life has, in effect, spread beyond the walls of the American penitentiary to the ghetto.

Third, like the sociology of almost any other substantive area, the study of prison life has tended to edit and import some of the more general and evolving theoretical preoccupations of sociology at large as they have appeared to illuminate, and be illuminated by, those structural changes. It has already been observed, for instance, that work was launched inside a context set by the structural-functionalism and anomie theory of the 1940s and 1950s, a context suited to the study of willful, autocratic repression. Current work focuses on issues of resistance and authority, gender and power, 'governmentality' and 'structuration,' and other matters now engaging a number of the wings of sociology.

Fourth, like any other method, and aided by those transformations, interpretations and theoretical pre-occupations, its focus has advanced restlessly from one phenomenon to another, continually introducing new 'facts' with which to re-interpret prison life. Above all, it has produced what is in effect a running series of footnotes or qualifications to the foundational models of the 1950s and 1960s.

It was easy enough at the beginning to overlook some of the finer and more nuanced details of structure. The social anthropologist in the American penologist would have been fascinated by the inmate community's vividly phrased argot and roles. What was less often reported—because it was less obtrusive and less interesting at first sight—was the presence of those who were relatively disengaged and played no part in the clandestine life of the prison, the 'retreatists' and others: who tried to serve their time uneventfully and discreetly and who eventually became interesting precisely because of their earlier neglect. What was also partially obscured at first was the lives of those apart from the inmate. Sociologists moved away from the inmate and towards chaplains, medical officers, and others: for example, the male prison officer beset by problems of violence, and the female prison officer and her gendering of control.

Studies report not only the features that were neglected in the earliest work, but also new features that have emerged since that work was done, but much remains unexplored, for instance, the structural repercussions of the social class of prisoners, aging and the

age composition of prison populations, the world of prison administration, and such groupings as gay prisoners and the prison untouchables (the 'nonces' or nonsenses of English prison argot) imprisoned for sexual and violent offences against children or the elderly.

Most important, the political control of discreditable information and the absence of a sense of anthropological curiosity and of a robust ethnographic tradition in much of the world have ensured that there have been almost no studies of prison life outside Britain, North America and a few small pockets of northern Europe. Sociologists began to emphasize how the early models had tended to extrapolate from one form of time-bound regime alone, the American, authoritarian, maximum security prison for men. It is a model that works well enough where power is arbitrary and formally unchecked, controllers are outnumbered and resistance is fragmented, and it applies broadly to German concentration camps and Soviet labor camps as well as to some of the prisons of the United States. But doubts have been raised about how far or strictly it should otherwise be generalized. It is clearly a limited model. Take Ketchum (1965), who described how in Ruhleben, an internment prison camp established in Berlin for the citizens of countries hostile to Germany in the First World War, there could be seen almost none of the informal responses to incarceration listed by Clemmer, Goffman or Sykes. To the contrary: the inmate population behaved cooperatively, peacefully, and without mutual exploitation, and its conduct invites questions about the impact of class, shame, and pre-existing patterns of organization on the social construction of prison life.

Again, take research on a number of therapeutic or rehabilitative regimes outside the United States. Sparks (1994) studied Barlinnie, a small unit for long-term prisoners in a Scottish prison, and Genders and Player (1995) examined Grendon Underwood, an English therapeutic prison to which serving prisoners in other establishments could elect to go. The three authors declared that neither Barlinnie nor Grendon was critically troubled by the legitimization crises or conflicts of other prisons, but both institutions did benefit from being regimes within regimes—inmates could always be transferred back to the larger and more coercive system from which they had come—and it would be wrong to assume that therapy alone is a proof against disorder or confrontation. So it was that Mathieson's (1965) *Defences of the Weak* described a medium-secure Norwegian prison, organized on therapeutic lines, whose disunited and cynical inmates challenged those who guarded them in a language of 'ensoriousness' that turned therapeutic ideology into a medium of criticism, defense, and attack. Theirs was a response very dissimilar to that of other models.

A second, allied form of qualification to the foundational model attacked the proposition that prisons are

total institutions which sever biographies and create new men and women within an indigenous culture (Sparks et al. 1996, p. 44). Instead of the fractured identities described by Goffman, study after study has revealed that inmates actually bring with them beliefs, associations, and styles of behavior from the outer world.

The importation into prison of social forms from the street gangs and antagonistic racial politics of America has already been noted, and there are other borrowings that have presumably been colored by local and national traits in the world outside the walls. Thus, Irwin and Cressey (1962) talked in America of *thieves* who carried a wider criminal culture into prisons, treating imprisonment as a career contingency; *convicts* whose behavior was a localized adaptation to the special travails of prison life; and *square Johns* who had an allegiance to neither convict nor thief but to a show of obedience to authority. Also, Cohen and Taylor (1972) talked about the affinities between the manner in which long-term inmates in Durham Prison in England managed problems of serving time and the offenses for which they had been convicted, armed robbers worrying about physical deterioration and concentrating on body-building exercises, and fraudsters engaging in copious attempts at litigation.

The discovery of the gendered character of imprisonment is as revealing. The very first studies dwelt on institutions for men. Whilst it was recognized from the outset that male inmates confronted largely male problems stemming from a loss of liberty, status, and heterosexual contact, gender itself was not treated as especially problematic or interesting. It was only when ideas about sexual identity were applied in explanations of the behavior of women inmates in the 1960s, women who were said to form themselves into pseudo-families in response to a loss of emotional sustenance, that the influence of gender itself became notable. Other sociologists have subsequently extended and modified that early work, but the thesis that women combine together differently remains. Later, ideas about masculinity were themselves turned back on the social organization of men's prisons to translate them into places ordered by a 'hegemonic masculinity.' Male prisons, it was argued, must be understood as institutions that are dominated by a very masculine exercise of violence, reliance on hierarchy, ritualized combativeness, and the suppression of displays of emotion and vulnerability.

Last, it must be stressed how closely, although never absolutely, the study of prison life has been bound up with the use of ethnographic methods (Terence and Pauline Morris said of their base in Pentonville Prison, London, that it was 'like the anthropologist's hut on the village street' (Morris and Morris 1966, p. 8)). Its history has, by extension, roughly paralleled the rise and fall of sociological ethnography itself. It was probably at its most vigorous between the 1950s and

early 1970s, when, according to Janowitz, it 'contain[ed] some of the most outstanding research monographs in sociology' (Foreword to Jacobs 1977, p. ix). Its decline may be linked in part to the seemingly inevitable half-life enjoyed by any body of theory and research, and to problems of access and publication that began to surface in the 1970s when prisons were turbulent and their managers became politically defensive and defeatist. But it may also be attributed to the ascent to influence of Michel Foucault (1979), whose political economy of discipline prompted scholars to turn *en bloc* to reflections about what they called 'penality' in a markedly more abstract and empirically disengaged manner.

Foucault took Bentham's plans for a concentric, panopticon prison to be an especially telling representation of the new technologies of control that were emerging in society at large. Prisoners in the brightly lit rim could never know whether they were being observed by guards in the shadowy inspection tower at the center, and the result was supposed to be that they would discipline themselves, colluding in their own subordination in a decentralized, self-sustaining, economical and dispersed system of power. The panopticon was never finally constructed in England, and Foucault's history was flawed, but so seductive and wide-reaching was his metaphor that it became an archetype for a large new family of ideas, and sociologists came to adopt Foucault rather than Clemmer, Sykes or Goffman as their mentor. Jonathan Simon (1999, p. 4) observed that, 'the great tradition of studies of prison social organization that begins with Clemmer and Sykes ... has largely ceased in the last twenty years ... Much of the research now is conducted from afar [and] ... the new distance introduces important interpretive problems ...'

Prisoners' Dilemma, One-shot and Iterated

The Prisoners' Dilemma is the formal structure of a common sort of collective action problems. It is also a vivid scenario embodying that structure. It offers a useful framework for the analysis of interaction where there are certain conflicts of interests.

1. Two Agents, One Meeting

Adam and Eve have been arrested. The District Attorney (DA) now tells them this. They can either talk or keep silent. If they both talk, they will each get a 10-year sentence. If one of them talks (confessing for both) and the other does not, the one who talked will go free; the other will get a 20-year sentence. If they both keep silent, each will get a one-year sentence on some trumped-up charge. The DA lets them discuss it. Then he puts them in separate cells and goes to take their pleas.

Say that neither Adam nor Eve cares about how the other makes out or thinks he will meet the other again. Each considers only the length of his or her own sentence. For each, that person's talking (*D*) dominates that person's being silent (*C*); that is, whatever Eve will do, Adam prefers the outcome of his talking to that of his *not* talking, and correspondingly for Eve. So if both Adam and Eve are rational, both of them will talk. But since each prefers the outcome of *C, C* (both of them silent) to that of *D, D*, both will be sorry for it.

This is the familiar prisoners' scenario, first presented by Albert Tucker in 1950. The story speaks of two people as agents, but the structure of the in-

teraction allows the agents to be teams or nations—some of the earliest applications were to the Cold War race (on these matters, see Poundstone 1992). The arms story is meant to demonstrate that, in certain conflicts of interests where there is some agreement too, rational agents won't cooperate though it would be better for each if they both did than if they did not.

2. Two Agents, Many Meetings

Where the agents are rational and they think they won't meet again, there is no way out for them. Neither party will cooperate (*C*). Both will defect (*D*), and both will be sorry. But say that they think they *will* meet again, that their present interaction is only the first of many just like it. (In place of the possible jail-sentences, let the payoffs be sums of money reflecting the same ranking of the outcomes.) Here it may seem that the prospect each faces of having to live with the other's resentment ought to deter defection. Still, it often is argued that, where the number of rounds is finite and known to both of the agents, if they both are rational (and think each other to be rational ...), both will defect from the start to the finish.

The argument first appeared in Luce and Raiffa (1957). Suppose that the number of rounds is known by both Adam and Eve to be *n*, and that they both are rational. At the *n*th round, each will know that there will be no further meetings, no need to guard against penalties, so they both will defect. Let Adam think that Eve is rational—let him think this throughout. He will then think in the (*n*–1)st round that Eve will defect in the *n*th round whatever *he* does in the (*n*–1)st, that his cooperating in the (*n*–1)st, wouldn't be rewarded by Eve in the *n*th. He will therefore defect in the (*n*–1)st round, and Eve, thinking likewise about Adam, will too. The same in round *n*–2: each expecting the other to defect in the round that follows, each will here defect, though we must now also assume that Adam thinks that Eve thinks *him* rational—let him think this too throughout—and that Eve thinks he thinks *her* rational. So we move stepwise back to round 1 (both agents defecting all the way), though with a heavier load of assumptions at each preceding stage.

This backward induction rests on assumptions about these people's beliefs about each other. It calls for supposing that, from the start to the finish, Adam believes Eve to be rational, believes she believes *him* to be rational, believes she believes he believes *her* to be rational, etc., and so too with the names transposed—call this Iterated Mutual Belief, or IMB. Some writers have noted that IMB isn't credible (Basu 1977, Bicchieri 1989, Pettit and Sugden 1989). Where in fact it fails, rational people might cooperate in at least some of the rounds; they need *not* defect throughout. Both parties may thus want it to fail, and one or the other may act in some way he thinks would get it to fail.

What sort of action would do that? If either cooperated in any round, the other would have to make sense of that, and this alone would suffice. Let Adam cooperate at $n-1$. Then Eve will either think (a) that Adam isn't rational (that he thinks this best for him however Eve responds to it) or (b) that he thinks *she* isn't rational (that he expects her to respond by cooperating at n). If he cooperates at $n-2$, she will think (a) or (b) or (c), that he thinks *she* thinks *he* isn't rational (that he expects her to respond by cooperating at $n-1$ in the hope of getting *him* to cooperate at n), etc. Whether Eve thinks (a), (b), or (c) (or the next-level d at $n-3$), IMB will have failed.

But would it ever be rational for Adam or Eve to cooperate? More generally, how should two rational people act in a sequence of Prisoners' Dilemmas (the number of rounds being known)? The answer depends on what each thinks the other party would do. Let B be the strategy of starting with C and then tit-for-tatting, doing in every subsequent round what the other did just before. Also let B_x be starting with C , then tit-for-tatting in all but the last x rounds, and then defecting in those. It would be rational for Adam to adopt B_x if he thought Eve will defect in round 1 but would then adopt B_{x-1} , and *that* would be rational for Eve if she took Adam's cooperating in round 1 to mean that he was pursuing B_{x-2} . There may be many such pairs of courses. In each, both Adam and Eve cooperate in some (or many or almost all) of the rounds, and what they are doing is rational. For each person's course is the best response to what that person thinks is the other's. But they still will defect in some (perhaps in many) rounds.

3. Two Agents, Equilibria

Facing a sequence of interactions, people seldom know how many there will be. So let us turn to cases in which their number is unknown to the agents. Here the backward-induction argument cannot get a foothold. We cannot begin with the round both parties know will be the last—none is here known to be last. But neither can we argue for the possibility of cooperation as we just did, for that too assumed that the agents reason backwards from some known final round. In game-theoretic terms, a Prisoners' Dilemma is a *game*. Where two people consider what strategy of action they should follow in some sequence of such games, they are facing what is called a Prisoners' Dilemma *supergame*. We are here speaking of *open-ended* supergames of this sort.

The fullest treatment is Taylor's (1987). Let each agent have a number of open-ended strategy options. If he is rational, he will choose among them in light of how he ranks the outcomes of their different pairings with the other agent's options, every such outcome being the sequence of the results of each agent's acting in each round as his strategy requires. Write each

outcome of, say, C, C as $[C, C]$. The outcome of Adam's taking B where Eve does too (of both starting with C and then tit-for-tatting) is thus $[C, C], [C, C], [C, C] \dots$. This is also the outcome of their both cooperating every time—of their both taking C^∞ . Let B' be starting with D and then tit-for-tatting; where Adam takes B and Eve takes B' , the outcome is $[C, D], [D, C], [C, D] \dots$. Where Adam takes D^∞ (defecting each time) and Eve takes B , the outcome is $[D, C], [D, D], [D, D] \dots$.

How Adam ranks these outcomes depends on how he values future benefits and costs. The more the future now matters to him—the smaller his *discount rate*—the more will it figure in his rankings. (If $1-d$ is Adam's discount rate, $0 \leq d \leq 1$, he values some benefit r rounds in the future at d^r times its worth to him now.) Where the future matters enough, he will prefer $[C, C], [C, C], [C, C] \dots$ to $[D, C], [D, D], [D, D] \dots$, the prospect of the long run of $[D, D]$'s offsetting the appeal of the initial $[D, C]$. Thus if the future matters enough, he will prefer his taking B where Eve does too to his taking D^∞ where Eve is taking B .

If he is rational, what strategy will he follow? A supergame is a game, and the central concept of game theory is that of (Nash) equilibria. An equilibrium in a two-person game is a pair of options, each a best response to the other. The idea is that, if Adam knows the situation (including the operative discount rates), he will choose a strategy in an equilibrium pair. What if there are several equilibria? Call an equilibrium *admissible* if the outcome of no other equilibrium is either preferred to it by both agents or preferred by one of them while the other is indifferent. Taylor suggests that a rational person will choose an option in an admissible equilibrium pair.

He notes that several equilibria are possible in a supergame of the Prisoners' Dilemma: D^∞, D^∞ is always an equilibrium, and some other pairings of strategies are equilibria where the agents' discount rates meet certain conditions. His basic conclusion is that where the discount rates of both agents are sufficiently small, B, B and D^∞, D^∞ are equilibria and all other strategy pairs he thinks would be considered are not. Since only B, B is admissible (both agents prefer its outcome to that of D^∞, D^∞), each of the agents will choose B . It follows that, where their discount rates are sufficiently small, both agents will cooperate in every round.

This last may overstate the case. Whether it is rational to cooperate in every round depends not only on the discount rates but also on the strategies considered. Where only $B, B', C^\infty, D^\infty$, and certain others are in view, Taylor's conclusion holds. But still others might come up. Let the agents consider E^m (being an *exploiter*): taking B only after defecting m times while the other cooperated. Let them also consider P^m (being *patient*): cooperating m times and then taking B . The E^m, P^m pair is an admissible equilibrium (where the future matters enough to the

patient)—if Adam followed E^m and Eve followed P^m , they would both be rational. But Adam would be exploiting Eve in each of the first m rounds.

4. Many-person Interactions

Say that there are many people each of whom must either cooperate (pay their dues, pull their weight, etc.) or defect (*not* pay, *not* pull). Each would be better off defecting, whatever the others did. But if all defected, or more than a certain number, all would be worse off than they would be if they all had cooperated. Here we have a *many-person Prisoners' Dilemma*.

A frequently cited scenario is Hardin's (1968) commons story. Each farmer in the village sends his cows to graze on the just barely adequate commons. Each knows that his sending out a new cow would degrade that commons. Since each knows too that his share of the cost would be less than the benefit to him of having an extra cow, each will send out another cow and the commons will collapse. This is the logic of the underprotection (and underprovision) of *public goods*, of the *free rider* problem, the commons (the oceans, the forests, clean air) being the public good, the overgrazing (overfishing, polluting) being free riding.

Refinements are possible here. In a many-person Prisoners' Dilemma, each agent would be better off defecting than cooperating, whatever the others did. Each would also be better off if all cooperated than if all defected. But say that there is some lone defector who exploits all the others. Where these others remain better off than they would be if all defected, the defector is a mere nuisance—he is a free rider proper. Where he leaves some others worse off than they would be if all defected, the defector is injurious—he is a *foul dealer*. (For this distinction, see Pettit 1986.)

Let all the parties expect to be facing the same sort of cases many times over and let each consider what to do in the whole sequence of them. They are then facing a many-person Prisoners' Dilemma supergame. Much has been written about this (see Taylor 1987 for references). It appears that here, as above, cooperating in each round may be rational. This too is argued by Taylor, who shows that everyone's cooperating in round 1 and then also in all the rest if each of the others cooperated just before is an admissible equilibrium if each agent's discount rate is sufficiently small. But so is a lone defector's taking E^m (moving to B only after defecting m times while all the others cooperated) and the others taking P^m —the conditional cooperation after round m being dependent on everyone's cooperating in the round just before. So here too rationality allows for extensive exploitation.

The question of the rationality of cooperation in such many-person contexts has some resonance in political theory. The claim that it *isn't* rational (and so can't be expected) provides the principal backing for the idea that people need a strong governing state. Hobbes and Hume based their case for authority, for a

Sovereign on this, and Hardin argues for strict enforcement of access rights to commons (for limiting procreation and entry into wealthy countries). Taylor uses his proof to the contrary to argue for the viability of voluntarism and for communal rule. So some large issues are involved.

5. Evolution and Stability

The above has been about questions of the rationality of various strategies. There is also a second sort of question. How well in the long run would various strategies fare in different contexts of others? Which (if any) would gain more adherents—which would *evolve*? And which (if any), if pursued by all, would resist invasion by others—which would then be *stable*? Much of the recent discussion derives from Axelrod (1984), a study relating Prisoners' Dilemma to current work in evolutionary biology.

Axelrod ran computer simulations of two round-robin tournaments of two-agent supergames, each supergame pairing a strategy with either itself or some other in the pool. Strategy B won both tournaments, and Axelrod notes that it would have won too in many other contexts (other strategy pools). Suppose that a tournament were repeated many times, the agents in each a new *generation*. Letting the change in the numbers of those pursuing the different strategies in each generation be in proportion to the relative fitness (the yield divided by the average yield) of those who pursued them in the one just before, Axelrod also ran a simulation of a many-fold repetition of tournaments. He found that B was the strategy pursued most often in the end. Conditional cooperation can thus *evolve*.

Would any strategy, if pursued by all, resist an invasion by others? Would any strategy be *stable*? Axelrod held that B would be stable (if the future mattered enough). This has been challenged by Boyd and Lorberbaum (1987), who hold that no strategy is ever stable. Which of these claims is correct?

Resistance to invasion might be *weak*, the invaders being kept from multiplying. Or it might be *strong*, their being pushed to extinction. Biologists speak only of *monotone* dynamics, in which greater fitness implies faster increase in numbers. Under such a dynamic, no strategy is *strongly* stable: none can strongly resist invasion. Say that the natives now pursue B . Let $B2$ be tit-for-two-tats, that is, starting with C and then cooperating unless the other defected in the preceding two rounds. $B2$ is a *neutral mutant* of B : it yields exactly what B yields in all interactions with either B or $B2$. Since B can't gain on $B2$, can't *strongly* resist an invasion by it, it isn't strongly stable. And neither is any other strategy, for every strategy has neutral mutants.

What about weak stability? Let us allow for *heterogeneous* invasions, not all the invaders pursuing the same strategy, and let us allow for (monotone) dynamics other than that of proportional fitness. Say

that *B* is the native strategy, that some of the invaders follow *B2* and the rest *B'*, and that the dynamic is that of imitating the preceding tournament's winner. *B* and *B2* do well against themselves and against each other, *B2* doing slightly worse against *B'*, against which *B* does badly. *B'* does badly against *B*, very badly against itself, and slightly better than *B* against *B2*. *B2* will win the first tournament, and having won, will be imitated and become the only strategy followed. (It in turn will be vulnerable to the alternation of cooperation and defection!) So *B* isn't weakly stable under the imitation dynamic, and neither is any other strategy, for there always is some other, inept (like *B'*) against itself, against which certain neutral-mutant invaders do better than the natives.

No strategy is strongly stable under any monotone dynamic, and (allowing for heterogeneous invasions) none is weakly stable under every such dynamic. Thus Boyd and Lorberbaum are partly right. Still, it can be shown that *B* is weakly stable under the proportional-fitness dynamic: it is (weakly) stable in that special context. So Axelrod is partly right too. (These results are in Bendor and Swistak 1998.)

The basic thesis here is that greater fitness implies faster increase in numbers. This is true of the genes that render their carriers fitter to reproduce. But are we here speaking of genes? Are there genes (or alleles) for *B'*ing and for *B2'*ing and the like? If not, the thesis must refer to the numbers of people *X'*ing or to the numbers of replicas of the *X'*ing-meme (for memes, see Dawkins 1976 and Dennett 1995). Increases in these are independent of reproductive fitness. They depend on imitation (by progeny or by others), and people's reproductive fitness needn't increase the number of their imitators.

What sort of fitness promotes imitation? There may be no single answer, for sets of memes co-adapt to their situations. 'Natural selection among genes chooses those that prosper in the presence of certain other genes ... [and] gene pools come to consist of genes that do well in each others' company ...' (Dawkins 1980, p. 354). The same holds for selection among memes. So the prospects of *X'*ing may hinge on the support of co-adapting memes, among them the agents' ideologies, their concepts of morality. In the context of some common ideologies of behavior toward others, *B'*ing may be imitated. In the context of more patient ideologies, *B2'*ing or *B3'*ing or *P^m'*ing may be imitated. Where it goes along with an *exploiter* ideology, even *E^m'*ing may be imitated. What fits a strategy for imitation depends (at least partly) on the co-evolving ideology. Whether or not this is good news depends on the ideology.

Prisons and Imprisonment

Imprisonment is the principal form of punishment in most countries for people convicted of serious crimes. People charged with crimes are often held in pretrial confinement until the charges are resolved. The institutions in which convicted offenders and pretrial detainees are held are usually called prisons. In the United States, however, the word 'prisons' refers only to state and federal institutions for offenders sentenced to terms of a year or more. Pretrial detainees and offenders sentenced to shorter terms are held in 'jails' operated by local governments. This article examines the history of prisons, historical and comparative patterns of imprisonment, and the collateral and direct effects of imprisonment on prisoners, their families, and their communities, and on crime rates and patterns.

1. Origins

The modern prison dates from the period 1780–1840, though recognizable precursors existed. Imprisonment as punishment for convicted criminals dates from classical times, but such incarceration occurred only

intermittently and on a small scale. By the sixteenth and seventeenth centuries, many Western countries had created debtors' prisons and houses of correction for paupers, and gaols for holding people pending trial.

Development of the Penitentiary is usually attributed to American Quakers. Penitentiaries were to be places of solitude and introspection where, guided by religious instruction, convicted offenders would repent, realize their errors, and prepare for law-abiding futures. The earliest such regime was established in 1790 in the Walnut Street Jail in Philadelphia. The first purpose-built American penitentiaries were in New York, and in Pennsylvania (see *Punishment: Social and Legal Aspects*).

In its extreme form, the Quaker regime, known as the 'silent system' and associated with Pennsylvania prisons, required prisoners to live in solitary confinement with only limited contacts with staff and clergy. Later, work was permitted in the one-person cells. Because the silent system led to the mental breakdown of many prisoners, it was soon abandoned for the 'congregate system' associated with New York prisons, in which inmates lived alone but worked together in enforced silence.

Europeans including Charles Dickens and Alexis de Tocqueville visited America to examine the penitentiaries and to consider their feasibility. Millbank, the first national penitentiary in England, was built in 1816, although the first on the American model, Pentonville, was not built until 1842. The first French penitentiary, La Petite Rocquette, opened in 1836. Penitentiaries soon existed in every European country.

A second wave of innovation occurred in the late nineteenth century, exemplified by the 1877 opening of New York's Elmira Reformatory. This prison, for male offenders up to the age of 30, was premised on rehabilitative ideas. It strove to reform offenders by providing a wide range of educational and vocational programs together with discipline and religious instruction. These rehabilitative ideas led to the first parole release systems, since there was no point in holding prisoners after they had been reformed. They also precipitated creation of indeterminate sentencing systems in which judges, prison managers, and parole boards exercised broad, standardless discretion over the lives of offenders.

Historians point out that the bursts of enthusiasm were short, that even in their own eras the innovative institutions were atypical, and that most prisons at most times have been brutal, inhumane places. Marxist accounts tied the development of the prison to the emergence of the industrial economy and portrayed the prison as a mechanism for labor discipline (see *Marxism and Law*). Michel Foucault in *Discipline and Punish* (1978) argued that the prison, like public education and the army, was a reaction to the breakdown of the *ancien régime* and served as a

socializing institution, producing disciplined individuals suited to bureaucratic and conformist roles provided by the modern state. David Rothman, in *The Discovery of the Asylum* (1971), described prison developments in Jacksonian America as an attempt by philanthropic reformers to respond to social dislocation and rapid change by trying to reform the by-products of a disordered society: the deviant, disorderly, and deranged. In *Conscience and Convenience* (1980), Rothman considered why new Progressive Era institutions were created and why they endured. 'Conscience,' an idealistic wish to improve the lives of troubled people, explains their creation, and 'convenience,' the autonomy and flexibility given managers by indeterminate sentencing, explains their durability. Michael Ignatieff, in *A Just Measure of Pain* (1978), emphasized the humanitarian intentions of prison reformers but, like Foucault, saw the penitentiary as a product of a series of nineteenth-century social crises and the emergence of the modern state.

During most of the twentieth century, researchers, the media, and the public knew little of life inside prisons. The laws, traditions, and rehabilitative rationale of indeterminate sentencing gave prison and parole officials broad authority over the day-to-day lives of prisoners. In the United States, a 'hands-off doctrine' led courts to refuse even to consider prisoners' complaints, reasoning that prisoners were 'slaves of the state' and that courts should defer to the professional expertise of prison administrators.

Developments in the 1960s and 1970s undermined indeterminate sentencing and transformed American prisons. The prison's rehabilitative rationale lost credibility. Reviews of rehabilitative programs concluded that there was little credible evidence that correctional treatment programs reduced recidivism. The civil rights movement and social ferment of the 1960s led prisoners, especially minority prisoners, to become more assertive. This resulted in high-visibility prison riots, most famously in New York's Attica Prison in 1971, and led to abandonment of the hands-off doctrine. Conditions in many American prisons were then racist, squalid, and brutal. By the late 1970s, federal courts declared conditions in many jails and prisons to be unconstitutional. Prisons in more than 40 states came under federal court control in the 1980s.

Beginning in the 1960s, crime and punishment became central political issues in the United States. Many politicians ran for office on 'law and order' platforms, and supported harsher policies. Fifteen states abolished parole release. Many states enacted laws to make conditions in prisons less comfortable, including reducing or eliminating access to televisions and recreational facilities; others eliminated recreational and treatment programs. In the 1990s, nearly 30 states enacted 'three-strikes-and-you're-out' laws requiring mandatory life sentences for people convicted of a third serious crime. Most prosecutors requested

harsher penalties, most judges imposed them, and most parole boards released fewer prisoners.

Other changes affected prisons. By the late 1990s, private corporations operated hundreds of institutions and provided comprehensive services, such as medical care, to others. Efforts to build new facilities before 1980 were often stymied by not-in-my-backyard movements; communities thereafter competed for new prisons as local economic development initiatives. In the 1960s, there were no labor unions for prison guards; in California in the 1990s, the guards' union was a major campaign contributor and an active lobbying group.

Most developments affecting American prisons also occurred elsewhere. Compared to the USA, prison-guard unions developed earlier and were stronger in Australia, England, and France. Prison privatization occurred extensively in Australia, New Zealand, and England, though nowhere else in Europe. Riots precipitated by prisoners' complaints occurred in many countries. In England and in some Australian states, conservative legislators in the 1990s enacted harsher laws and mandated more Spartan prison conditions, but nowhere as harshly as in the United States. Prisoners' rights movements arose in many countries but, because US constitutional traditions give more legal protections to citizens than are recognized in most countries, no other courts intervened extensively in prisons. The exception is in Europe, where prisoner grievances can be redressed under the European Convention on Human Rights, and where the European Convention Against Torture and Inhuman Treatment influences improvements in prison conditions (see *Torture: Legal Perspectives*).

In 2000, prisons outside the Western countries were typically inhumane, unhygienic, overcrowded, and understaffed, with notable exceptions in a few Asian countries, especially Japan. The United Nations Declaration on Human Rights pertains to prisons, but no international body has authority to enforce such provisions. As a result, reform pressures must come from local groups, with occasional support from human rights groups such as Amnesty International and Human Rights Watch.

2. Imprisonment Patterns

Countries vary widely in how they use imprisonment. In the United States, from 1925 to 1972 the incarceration rate fluctuated between 90 and 130 per 100,000 residents (state and federal prisons only), leading some scholars to argue that self-balancing processes maintained relative stability over time in the incarceration rate. However, since 1972, American incarceration rates have increased every year, quintupling by the century's end. Trends in other countries vary widely, though generally the 1990s were a period of rising incarceration rates. In Holland, the incar-

ceration rate increased continually after 1976, although the 1998 rate was still only 80 per 100,000. In Finland, however, the incarceration rate dropped continually after 1975 and in 1998 was around 60 per 100,000, only 40 percent of the rate in the mid-1960s. In Japan, the incarceration rate fell rapidly in the 1950s and then fluctuated around 35 per 100,000. In Southern European countries, including France, Italy, and Spain, incarceration rates varied erratically with sharp rises and declines.

National incarceration rates vary greatly. The United States' rate in 1998, 680 per 100,000 (prison and jail inmates combined), was among the highest in the world. Only Russia had a comparable rate (685 per 100,000 in 1998). As a region, Eastern Europe had the world's highest rates in the late 1990s, typically varying between 200 and 500 prisoners per 100,000. England, Ireland, Australia, Canada, and New Zealand had rates of 100–130 per 100,000. Most Western and Southern European countries had rates between 50 and 100 per 100,000, and most Scandinavian countries incarcerated approximately 60 people per 100,000. With the notable exception of Singapore (465 per 100,000 in 1997), most Asian countries had incarceration rates of 20–50 per 100,000.

Very different penal strategies can lie behind incarceration rates. Some Scandinavian countries, notably Sweden and Finland, have low absolute rates (55–60 per 100,000 in the 1990s), but large percentages of convicted offenders receive short-term prison sentences. In Germany, a much smaller percentage of offenders are sentenced to prison, and sentences shorter than six months are disapproved. In most European and English-speaking countries, only 1 to 3 percent of prison sentences are for 2 years or longer. In the United States in 1991, 56 percent of state prisoners were serving sentences of 10 years or longer. In part, these differences result from different penal ideologies. Many American policy makers believe crimes are primarily the product of wrongful moral choices of criminals, that punishment policies can affect crime rates, and that prison sentences should be harsh to provide deterrent disincentives, or lengthy to incapacitate incorrigible offenders. Many European policy makers believe that decisions to commit crimes are powerfully influenced by social conditions and inadequate socialization, and that punishment policies are unlikely to influence crime rates.

Imprisonment is used in most countries primarily as a punishment for violent crimes, serious property crimes, and drug trafficking, and seldom for white collar, regulatory, or environmental crimes. In many countries, prison sentences for violent and drug offenders are getting longer, and populations of drug offenders are increasing. Most prisoners in every country are young, male, unmarried, and economically and socially disadvantaged, and have extensive criminal records. Large percentages are drug dependent and committed their crimes under the influence of

alcohol or other drugs. Women constitute only 3 to 8 percent of prisoners in most countries but their numbers and percentages are increasing faster than men's (see *Crime and Gender*). Disadvantaged minority groups are disproportionately present in most prison systems, though the identity of the minority groups varies widely. Relative to population, blacks in the USA and Afro-Caribbeans in England are eight times more likely than whites to be in prison. In Australia and Canada, the aboriginal/nonaboriginal differences are as high as 15 and 20 to 1. Similar disproportions affect North Africans in Belgium, Holland, France, and Italy, Turks and Eastern Europeans in Germany and Scandinavia, and Koreans in Japan (see *Race and the Law*).

3. Collateral Effects of Imprisonment

At least five kinds of collateral effects can be identified. First, what are the effects on prisoners' later lives? Economic and ethnographic literature in the United States and Europe show that imprisonment reduces ex-offenders' subsequent incomes and employment. In the United States, state and federal laws deny ex-offenders the right to vote or to hold office, the opportunity to engage in certain occupations, and the right to receive various public benefits and services.

Second, what are the effects on offenders' spouses or partners, and their children? The relevant literature is thin and fragmented, and the most pressing task is to pull together existing knowledge in order to formulate plausible, testable hypotheses. Hypotheses would address the effects of imprisonment on the financial and social stability of prisoners' families while they are in prison and afterwards, on the maintenance of prisoners' relationships with families, and on the short- and long-term well-being and social functioning of prisoners' children. Sometimes families and partners benefit from the removal of abusive, disordered, or dysfunctional parents and spouses. However, given the strong negative effects on children's well-being of being raised in disadvantaged, single-parent households, the major effects of imprisonment on spouses and children are often likely to be negative.

Third, what are the effects on prisoners' later physical and mental health? Controlling for age, sex, and social variables, suicide rates are higher in prison than elsewhere. Psychological literature on coping and adaptation concludes that even long-term imprisonment has few lasting mental health effects, although some researchers doubt this. It would be surprising if established adverse effects on income, employment, and family functioning were unrelated to former prisoners' mental and physical health. However, a long-term, multiple-measure, longitudinal study is needed to answer such questions, and none has ever been done.

Fourth, what are the effects on prisoners' later crime involvement? The negative effects on ex-prisoners' incomes, employment prospects, and family involvement are predictive of increased offending probabilities. At least since the time of John Howard, the eighteenth-century prison reformer, the proposition has been put forward that prisons are 'schools for crime,' that inexperienced prisoners are socialized into antisocial and oppositional attitudes and leave prison more likely to commit crimes than when they entered. Sociologists refer to this as 'prisonization.' No informed person doubts that this process sometimes happens, and at least partly offsets any crime-reductive effects of imprisonment achieved through deterrence, incapacitation, and rehabilitation. Many European scholars accept as proven that prison is criminogenic. They contend that for crime-prevention reasons, prison terms should be avoided whenever possible. Such arguments explain why German and Austrian policies impose prison terms only for serious crimes and discourage imposition of short sentences (under six months).

Fifth, what are the effects on the larger community? Plausible hypotheses can be offered about effects of American prison expansion on the diversion of public resources (from higher education particularly, and from other public services, to prisons), on economic development (from inner cities where most offenders and victims live, to rural communities where prisons are built), and on community cohesion (in disadvantaged minority communities, large fractions of the young men are or have been in prison and are thereby disabled from working, parenting, marrying, or otherwise contributing to the community). In some disadvantaged communities, imprisonment is so common that it may no longer carry meaningful stigma, and it may have lost whatever deterrent effects it once had.

4. Crime-control Effects of Imprisonment

The literature on crime control effects is inconclusive, small, and for the most part old. First, has increased imprisonment reduced crime rates? Most people probably assume that a quarter-century's quintupling of the American prison and jail population has reduced crime rates. There has, however, been relatively little research in recent years on deterrence and incapacitation effects (see *Deterrence: Legal Perspectives*). Most authoritative reviews of the subject, including the famous 1978 report of the National Academy of Sciences Panel on Research on Deterrent and Incapacitative Effects, conclude that such effects exist, but are modest (Blumstein et al. 1978). Similar conclusions were reached after an exhaustive survey of deterrence research carried out in 1998 by Andrew von Hirsch et al. for the English Home Office.

Second, can prison treatment programs reduce recidivism rates? The pessimism associated with the 'nothing works' findings of the 1970s and 1980s has passed, and there are grounds for cautious optimism about the positive effects, under some conditions, of some cognitive-skills, drug-treatment, vocational training, educational, and other programs in adult prisons. The conditions, however, are stringent: program eligibility must be carefully matched to prisoners' needs and risks, programs must be well implemented and adequately funded, and compatible aftercare programs in the community must sustain treatment.

Third, without distinguishing among deterrent, incapacitative, and rehabilitative effects, does increased imprisonment reduce crime rates in general, and have the increases of recent years done so? The prevalent answer appears to be yes, but the literature, much of it by economists, is technical and inaccessible to nonspecialists. Moreover, research mostly dates from the 1970s and suggests that effects are more modest than is widely understood.

Fourth, in cost-benefit terms is increased imprisonment worth it? This is the smallest and most primitive of the prison effect literatures, and provides few policy-relevant findings. The work to date is useful mostly for methodological reasons, by showing how not to pursue such inquiries. For example, the most widely publicized recent work greatly exaggerates the costs of crime by means of inflated imputed costs of victim 'pain and suffering,' and takes no account of suffering by offenders or pains of imprisonment borne by their partners, children, or communities. It may be, as Franklin Zimring and Gordon Hawkins (1991) suggested, that cost-benefit assessments of the effects of imprisonment require weighing of inherently incommensurable values and have reached a dead end.

5. Prisoners and Prison Staff

In 1970, a sociological literature on prison and prisoner subcultures was the best known body of prison scholarship. Since then, prisons have changed a great deal, as have inmate and staff subcultures and interactions between them, and the learning of earlier times may no longer be valid. American prisons are much larger, inmate populations and staffs are more disproportionately black and Hispanic, more line and management staff are women, gangs are larger and their influence more pervasive, more prison staff are unionized, a large and growing fraction of prisons is under private management, and judicial oversight and intrusion are greater. Because larger fractions of prisoners are serving very long sentences, we have witnessed increased need for medical care and geriatric services.

Behavioral, cultural, and social changes in the larger society impinge on life inside prisons. AIDS and HIV, for example, are more prevalent inside prisons than outside. The proportions of mentally ill and mentally defective prisoners increased as a result of the 1960s and 1970s movement to deinstitutionalize the mentally ill. The civil rights and women's movement have affected prisons, as has the political conservatism of recent years. Programs premised on restorative justice ideas are beginning to appear inside prison walls.

Studies of women prisoners and life inside women's prisons are conspicuously underdeveloped. There is a small quality literature, but a paucity of research on life inside prisons since 1975 has had an especially impoverishing effect on traditionally under-studied subjects.

Privacy: Legal Aspects

Serious social and legal concern with privacy is a relatively modern matter, though themes of privacy and its importance form part of all known human civilizations.

1. *The Meaning of Privacy*

The definition of privacy is a matter of some controversy. Its characterizations move from the all-encompassing 'right to be left alone,' covering a general interest in not being interfered with in any way that violates human dignity, advocated by Edward Bloustein (1964), to the more limited interest in control over personal information and accessibility, argued for by Westin Allen (1967) and Parent (1983). Somewhere in the middle we find characterizations of privacy as only those aspects of liberty that relate to intimate and highly personal aspects of one's life (e.g., Rubenfield 1989), such as those involved in sexual preferences and decisions about whether and when to procreate. The uses of 'privacy' in everyday language and in various legal systems are broad enough to cover all of these approaches, so the analysis of ordinary language cannot, by itself, decide the issue. The controversy is found in philosophical analyses of privacy as well as in the contexts of its legal protection. It has led some scholars to argue that the term be abolished in order to promote clarity of thought and analysis (Prosser 1960, Thomson 1975).

Conflating privacy with all claims for noninterference, or with the value of an 'inviolable personality,' is indeed much too broad, and threatens the distinctiveness and the practical utility of privacy. All concede that there are ways to violate dignity (e.g., subjecting one to torture) and to interfere with one's important liberties (e.g., freedom of speech or freedom of religion) without raising concerns of privacy. It is also possible to violate privacy (by watching or by eavesdropping) without limiting the person's liberty. The need to stress this distinction between privacy and liberty is one of the main reasons for defining privacy in terms of control over information, or, in the somewhat broader analysis suggested by Gavison (1980), of accessibility. According to this approach, the hard core of concerns and interests covered by the label 'privacy' is related to the interest of individuals in limiting access to themselves. Privacy can be lost through the invasion of a person's physical space by either presence, wiretapping, or clandestine super-

vision; the acquisition and dissemination of information about a person; or the 'lifting' of a person's anonymity, which in turn may encourage loss of privacy in either of these other ways. Privacy in this sense is thus distinct from liberty, but it is connected to liberty and to dignity in a variety of ways. These connections to liberty and to 'inviolable personality,' to be discussed below, are in part responsible for the importance of privacy as a central value in modern life.

The need to distinguish privacy from a general interest in liberty is challenged by those who identify issues such as abortion, contraception, and choice of sexual expression as matters of privacy. While scholars like Rubenfield (1989) and DeCew (1997) concede that these claims concern liberty, they argue that the special strength of these claims derives from the highly personal and intimate nature of these decisions, and that these features of the decisions are what makes them matters of privacy. This argument, which is supported by our linguistic and moral intuitions, is based on an important ambiguity in the term 'privacy' and the related distinction between 'private' and 'public.' There is a sense in which the 'private' is that which is intimate and personal. But 'private' is also that which is held, or used, or owned, or financed by individuals (as compared to that which is held, used, or financed by the public or at least by some group). In addition, 'private' also means that which one is entitled to keep secret or inaccessible, but also that which the individual is entitled to claim as belonging to her own realm of autonomous decision-making. Abortions and sexual practices are both matters of great intimacy and personal import and matters that most people desire to keep unknown and unpublicized. In addition, the principle of offense suggests that we may prohibit the public performance of activities that are fully legitimate when conducted 'in private' (e.g., sexual intercourse).

Against this background, any attempt to provide one definition of privacy and to reject others must be arbitrary to some extent. Those who use the term in descriptive or normative statements should be aware of these ambiguities and clarify the sense(s) in which they use the terms. In the remainder of this essay, only concerns of privacy in terms of accessibility and information will be discussed. Issues of personal autonomy, important as they are, are better discussed under different headings. The importance of stressing the distinctive definition of privacy has grown as modern technology has created a variety of new challenges to privacy. Modes of surveillance, eavesdropping, photographing, and processing of such information, as well as the development of computerized data banks with huge abilities of storage, retrieval, and processing and linking of information, and the growing possibilities of quick dissemination of such information, both verbal and pictorial, have made the threats of loss of privacy more serious and

acute. It is thus important to connect these urgent practical concerns with the reasons for privacy's importance.

2. The Importance of Privacy

While most individuals seek privacy, at least some of the time and for some purposes, it is not clear whether this wish for privacy should always be protected or granted. Some scholars point out that privacy, at least in the sense of keeping personal information unknown, is simply the scoundrel's best friend (notably, Posner 1978). While these scholars may concede the coherence of the concept of privacy, they argue that privacy is in fact undesirable, encouraging tendencies to individualism and downplaying the importance of community and accountability. Some feminist writers argue that treating privacy as an ideal is just a way to perpetuate the exclusion of women from public life, and to facilitate their continued exploitation and vulnerability within the realm of the private (notably MacKinnon 1989 but see also Gavison 1993).

Proponents of privacy (see, e.g., Bloustein 1964, Westin 1967, Gavison 1980, Fried 1968, Benn 1971) do not argue that all wishes to limit access to information about one or of one's realm should be respected. They may well concede that total privacy is both impossible and highly undesired and undesirable. They do insist, however, that interests in privacy are important, and that privacy is related, and contributes, to other important values such as freedom, autonomy, and intimacy. These values are an integral part of our ideals of personhood and society, and our normative landscape will be impoverished if we do not recognize both the uniqueness and the importance of privacy claims.

It is easier to see the many ways privacy functions in our lives if we try to imagine a world in which we have lost all the privacy we enjoy at present. Imagine the loss in terms of intimacy, friendship, trust, and love that we would have suffered if we could not choose in whom to confide, and with whom to share personal information about ourselves. Or if we had known that whatever we said to any individual would immediately be broadcast on the Internet. Imagine the loss in learning and acquisition of skills we would have suffered if all our drafts and early attempts at mastering a skill had been made public, open to the judgment and ridicule of all. Imagine the loss in terms of self-respect and autonomy that would ensue from a life in which we would not have the benefit of experimenting and trying things alone, or in a protected and supportive environment, which could teach us and give us the courage to face audiences less supportive. Imagine democracy without a secret ballot and the freedom to develop ideas and associations without constant police surveillance, or rehabilitation without the ability to start afresh. It is no accident that

people have sought privacy from the inception of human society, and that extensive loss of privacy (of the kind that is suffered in total institutions like prisons or mental hospitals) is regarded by many as degrading and humiliating.

Even if this argument is conceded, and people accept that some claims to privacy should be morally protected, this does not say that claims to privacy or limitation of accessibility are absolute. Like all other claims, they must be balanced against other important interests and rights. The importance of privacy means only that we should be aware that the costs we pay in terms of privacy are important, and that we should try, as far as possible, to decrease them. While total loss of privacy is dangerous and bad, some claims of privacy are merely self-serving and instrumental. Naturally, a candidate for a job does not want her prospective employer to know her weaknesses. A con-man does not want his victims to know of his past record. In all these cases we may well prefer the interest in knowledge and thus refuse to defend the claim of secrecy or privacy. As a matter of fact, in many situations of conflict, privacy gives way to other claims. Some scholars, have concluded from this fact that it is therefore misleading to talk about a 'right to privacy' in morality or in law (Prosser 1960, Thomson 1975, Davis 1959). They argue that privacy claims can never trump other claims on their own. The cases in which we feel that claims of privacy have the upper hand are ones in which there is another interest involved, such as the interest in reputation, or in physical seclusion, or in property. It is the presence of these other interests, they argue, not the claim of privacy, that explains (and justifies) the fact that we find the privacy argument persuasive.

A closer analysis of cases of conflict, in both mortality and law, does not support this generalization. Norms defending the rights of prominent gay people not to be 'outed,' and laws prohibiting the publication of rape victims' names, are two examples in which claims of privacy are seen as morally justifying, on their own, the limitation of the freedom of others to disseminate information. Moreover, even if it is the case that in many situations privacy claims win only when they are reinforced by other interests, this does not mean that the costs in terms of privacy are not important. It may mean only that claims of privacy, on their own, cannot defeat some conflicting claims. It is misleading to conclude that the costs in terms of privacy are nonexistent.

3. Legal Protection of Privacy and its Limits

Part of the debate around the concept of privacy and the justification for granting a right to privacy was triggered by claims for legal protection against various sorts of losses of privacy. One of the consequences of the conceptual ambiguity mentioned above is that the

extension of the term 'privacy' may be different in different legal systems. Thus, the initial decisions concerning the use of contraceptives and abortion in the US were made in terms of privacy (Griswold 1965 and Roe 1973). While the US Supreme Court has moved to discuss abortion as an issue of liberty rather than one of privacy (Planned Parenthood 1992), there are still scholars seeking to justify dealing with issues, such as the liberty to behave in certain intimate matters, in terms of privacy (Rubinfeld 1989, DeCew 1997, Allen 1988). Other scholars see these decisions as based on conceptual and normative confusion between issues of liberty and issues of privacy (Gross 1971, Henkin 1974, Gavison 1980).

Legal systems vary a great deal in their positive protection of privacy. Most Western countries now try to regulate computerized data banks in some ways. The legal frameworks seek to make sure that data is accurate, that individuals know what information about them is held in such data banks, and that acquisition and dissemination of information are controlled. The first two issues, while of extreme practical importance, are not—strictly speaking—privacy concerns. My privacy is not enhanced by the fact that I know what information about me is available to others. In fact, such knowledge may threaten my sense of privacy, because it may reveal to me that I am in fact more exposed than I had thought. Most legal systems include in their protection of property rights the liberty and the power to exclude others from entrance. Most legal systems now contain regulation of practices such as wiretapping and electronic eavesdropping. While the details of legal regulation differ, all systems seek to reduce abuses resulting from the existence of extensive data banks. The law has been slow to respond to the implication of technological innovations in the realm of dissemination of information. Cable TV and satellite technologies, as well as the Internet, create fascinating and difficult problems for imposing legal liability for the dissemination of information, including privacy-violating publications.

Legal systems differ also in the extent to which they are willing to grant legal protection to individuals' concerns that true information about them not be published against their will. In the European continent, legal systems protect this interest through a 'right to personality.' England still has no recognition of a general right to privacy, and no legal liability for such publication, while in the US a right to privacy is recognized, but it usually gives way to the paramount interest in free speech. Finally, the question of the extent to which public figures are entitled to the protection of their privacy remains controversial, with different answers given by different legal systems and cultures. The US seems to take the lead in denying its public figures their right to privacy, and in a willingness not to stop short of explicit and detailed public discussion of their most intimate affairs. However, this

area of privacy claims illustrates that, very frequently, social realities are not dictated only by the law. The actual privacy enjoyed by public figures in Western countries depends on cultural and journalistic norms much more than on the legal arrangements existing in them.

Violations of privacy, especially in the field of dissemination and publication of personal information, also illustrate the limits of law in effective protection of values. Once the information is published, or the embarrassing picture aired, there is nothing that can delete it from memory or consciousness. Money awards cannot undo the harm, and the publicity of the trial just adds to the magnitude of the original injury. We encounter here a paradox of law in some areas: Laws may, to some extent, serve as the basis of injunctions, or they may deter people from violations. If they fail in doing that, they are unlikely to be invoked to impose subsequent liability.

Privacy of Individuals in Social Research: Confidentiality

1. Definitions

The word privacy here refers to the state of the individual, including individuals' right to control information about them at times. Confidentiality refers to the state of information, that is, information in an individual's record may not be disclosed without the individual's consent except under certain conditions. Security here refers to the state of physical or electronic records, especially protection against unauthorized access to the record.

2. An Ethical and Legal Context

People may provide information in social surveys, randomized field trials, and in other studies. Their doing so may be voluntary. Or it may be mandatory, that is, required by law.

Generally, the researcher is under an explicit ethical obligation to assure the privacy of the individual, the confidentiality of information generated on the individual, and the security of the record. These obligations may be reflected in professional codes of ethics. The obligations may be verified through government regulations and review processes that foster assurance of privacy, such as Institutional Review Boards in the United States. Or, the obligation may be verified in law. Statutes that govern the activity of census bureau interviewers and statisticians in countries, such as Sweden, the United States, Canada, and elsewhere, are plain on this account and include penalties for failure to meet the obligation.

3. Assessing Privacy in Surveys and Randomized Field Trials

The social scientist's statutes must be met in a variety of ways at each stage in the process of a study. At the study's design stage, for instance, one minimizes the information that is asked of a respondent and minimizes the intrusiveness of questions, that is, one restricts questions so as to meet the study's object. One

also minimizes the number of people who are engaged in a study. This is determined partly by technical concerns such as the level of statistical precision or statistical power that is needed.

Under many codes of ethics and certain broad legal regulations, individuals to whom questions are put must be told whether their participation in the research is voluntary. People usually must be told the purpose of the research, and the disposition and functions of the data that they provide. Usually, they are assured that the information they provide will remain confidential, that is, the assurance is that information will be used only for research purposes and that the information they provide will not be disclosed with their identity attached to anyone else.

Under certain circumstances, the information provided by individuals can be assured of confidentiality even in the face of government or private threat. In the United States, for example, researchers who are involved in studies on alcohol and substance abuse, and criminological research can receive a certificate of confidentiality. The rules are such that researchers are prohibited under penalty of law from disclosing identifiable microrecords, and are legally immune from any obligation to provide microrecords to law enforcement agencies.

More generally, statutes that govern statistical agencies in the United States and other countries require that the agencies refrain from disclosing records on individuals to other people, that is, the statutes say that records on identifiable individuals cannot be appropriated legally by anyone else, including the courts, legislatures, and law enforcement agencies.

The researcher is under an ordinary obligation to cooperate with courts and other government agencies in providing information. This obligation becomes problematic if the researcher made promises of confidentiality and then, when confronted with a government demand, discovers that the promise has no legal standing. Keeping track of such episodes and their frequency is important. Shield laws that assure that the social scientist cannot be compelled to disclose information about identifiable individuals who have agreed to participate in the research are then important.

4. Privacy and Researchers' Use of Statistical Data Bases

Producing high quality data in social research can be costly irrespective of the benefits of the information. To the extent that the same data set can be put to work frequently to benefit the public, the cost/effectiveness ratio decreases.

For instance, good scholars undertook multiple reanalysis of data from the statewide class size randomized trial in Tennessee. These analyses informed

policy debates about reducing the size of classrooms in 20 states of the United States.

Making local, regional, or national data available to statisticians, however, may put one ethical standard against another: public interest in the results of statistical analysis versus the possibility that records will be used for nonresearch purposes.

Learning how to make individual records available for statistical analysis in ways that do not compromise the privacy of the individuals who are the source of the record information is not easy. Since the 1970s, serious research on this topic has been done by federal statistical agencies in many different countries. Virtually all such agencies concern themselves with surveys rather than active randomized trials on the effects of social programs. Nonetheless, the lessons from the survey research community are applicable to people who attempt to mount evaluations of program effects, such as randomized field trials.

The approaches that have been developed to assure researchers' access to existing data sets without compromising privacy concerns can be classified into two categories. The first involves simple procedures that focus on assuring that records cannot be used for learning about an individual. The second involves legal arrangements, including statutes, regulations, and contractual agreements.

Consider, first, the approaches to making data available and protecting individual privacy. Typically, the data custodian who releases a file for the public's use deletes the direct and clear identifiers from data files, that is, the addresses and other unique information about individuals are deleted. Further, because individual records are often detailed and external collateral information is available, sophisticated statistical approaches may be used to eliminate the possibility of deductive disclosure. Such approaches include deletion of certain variables from the file, eliminating certain microrecords that allow disclosure on small samples of particular individuals, reducing the precision of entry by making the reporting categories crude, introducing controlled random perturbation, controlled random swapping, and other techniques. These technical approaches fall under the rubric of statistical disclosure limitation technology. Advances in this technology by statisticians in the Netherlands, the United Kingdom, the United States, Israel, and Luxemburg are given in Fienberg and Willenborg (1998).

Data enclaves are organizations created to (a) permit intensive sophisticated analyses by people other than the original data custodian, and (b) protect the confidentiality of microrecords with the same rules that govern the original custodian. At the University of California at Los Angeles and at Berkeley, for instance, enclaves have been established that permit university-based researchers to analyze data that would be accessible ordinarily only to federal civil servants. The rules that govern the data's use, in-

cluding security procedures and the threat of criminal and civil sanctions, apply to the enclave's researcher as it does to civil servants.

A variant on the enclave idea involves licensing agreements. A specific example of this arrangement, developed by the National Center for Education Statistics, is a license granted to particular individuals to analyze specific data sets that would not otherwise be accessible on privacy grounds. The justifications for such privilege must be made. The licensing agreement includes requirements for security of the microrecords, sanctions and rules of disclosure, and so on.

5. Privacy and the Use of State Data Bases

In the United States, each state of the 50 states has laws governing third party access to certain administrative record systems and administrative data bases. The state laws differ appreciably in their provisions for permitting a researcher (and certain others) to access individually identifiable microrecords. The administrative records that are laws and regulations also differ across systems within schools, hospitals, child welfare and adult welfare agencies, crime and justice agencies, runaway shelters, and others.

There exists no national compendium for identifying which administrative record systems are legally open to legitimate researchers and which systems are closed to them. A compendium for each country and for each political jurisdiction and agency within each country is important as a way of understanding how privacy of individuals and confidentiality of microrecords can be assured in a research context.

Despite the absence of a national, regional, and local compendium, there exist useful compendiums that have been constructed for special purposes. They identify the State and its laws on particular record systems and summarize access rules for certain individuals including perhaps researchers (see, for instance, the Office of Juvenile Justice and Delinquency Research 1995 on missing children and the relevant databases and the National Criminal Justice Information and Statistics Service (1978, 1988, 1992) on criminal history information. Among federal agencies in the United States, the Bureau of Justice Statistics (BJS) has been consistent in preparing and updating related information. It has produced eight reports since 1972; more recent reports supplant earlier ones. They all focus on state laws regarding criminal history record information.

In the BJS (1992) compendium, each state's laws are cited, the full text of laws being given in a national repository that is itself accessible to researchers. The compendium outlines information about each state law on 28 dimensions. One such dimension is whether the particular law contains 'provision for and regulation of' access to criminal justice information by outside researchers (BJS 1992, p. 12).

The compendium identifies 29 states that have laws or regulations that permit research access and the relevant statute or regulation. No analysis is provided. But researchers can obtain full text documents for the statutes and regulations from the criminal justice clearinghouse.

6. Privacy and Record Linkage

Linking records from different databases in the interest of research presents privacy problems. The rules governing one data custodian, such as a census bureau, may differ from the rules of another statistical agency such as an education statistics or a labor statistics bureau. Such rules differ across agencies for a less centralized government such as the United States. They may not differ across agencies for a more centralized government such as Canada, Sweden, or Japan. The matter is very complex and generalizations are hard to make.

Certainly, the case for linkage has to be made. Identifying the discernable benefits to society of a linkage and the absence of discernable costs to individual privacy is important. This can be done through example and systematic study. An early example of an effort to discover the benefits and costs of linkage for administrative purposes, not research purposes, is given in USGAO (1986a, 1986b). The bottom line was that certain administrative linkages are not worth the effort. Recent examples, more to the point for social scientists, are given in the work of the National Research Council (1999).

Privatization of the Economy

State ownership has characterized most market and, *a fortiori*, planning economies in the twentieth century, the United States being the most notable, albeit partial, exception. To an extent that has somewhat varied across countries and decades, financial, strategic, political, and technological reasons have been advanced to justify either the nationalization of existing private-sector firms or the *ex novo* creation of state-owned enterprises (SOEs). State ownership of utilities has been justified on the ground of technological conditions leading to natural monopolies, external economies, and diverging social and private discount rates. Moreover, many governments argued that only the state could overcome critical ‘bottle-necks’ in terms of physical, financial, and human capital investments required by industrialization. A further motive has been the desire to keep domestic control on monopoly rents produced exploiting non-renewable natural resources. On weaker economic grounds, SOEs have been established to build a coalition in support of new regimes, to assure national independence in strategic industries, or to avoid that unpopular minorities could eventually control the economy. SOEs were used for different distributional

aims—to make available essential goods and services, to create new jobs, to reduce geographical concentration of economic power—but they were also crucial elements for playing patronage politics through jobs and the servicing of constituencies. A further explanation for the diffusion of state ownership in semiperipheral countries, especially in Latin America, was advanced by the dependency literature. While accepting the primacy of private ownership, ‘bureaucratic-authoritarian regimes’ considered that the role of the state had to go beyond that of a subsidiary character to that of supplying the complementary inputs to the process of private capital accumulation (Evans 1978).

Since the rise of oil prices in the 1970s, the whole postwar model of economic development has been heavily criticized, and SOEs have not been exempted from this swing in the ideological pendulum from the structuralist to the neo-liberal end. The appropriateness of public management of productive units was put in doubt, and SOEs were found to have negative income distribution effects, to worsen budget and trade balances, and to divert resources from much more needed social goals, such as education and health expenditures. The efficiency of SOEs was found to be lower *ceteris paribus* than in the private sector. Inefficient SOEs do not face the risk of bankruptcy, and the market for corporate control, because of the state’s tight grip through majority stakes, cannot act as an adequate device for disciplining managers. In theory, this concentration of ownership in the hands of a single majority investor could have served to circumvent the collective action problem that impedes small, dispersed shareholders in listed companies to wield efficient monitoring on corporate managers. This relative advantage of public ownership, however, has often been offset by agency problems stemming from the multiplicity of ties linking the government, ministries with specific competencies, Parliament, political parties, and the management of SOEs, all with different goals, possibly at cross-purpose. Moreover, SOEs’ managers are often appointed for political reasons, rather than for their management skills. As regards the utilities more specifically, fast technological advances have substantially weakened the argument that public ownership of integrated monopolies is necessary to assure investment growth, service quality, and price declines in real terms.

Over the last two decades, the initially timid progress recorded in some pioneering countries (United Kingdom, Chile, New Zealand) were matched and sometimes even surpassed by new countries joining the privatization bandwagon, first in the developing world (Argentina, Mexico, Malaysia), then in Europe (France, Italy), and finally in transition economies. (Possibly the first large-scale sale of a public enterprise was the Volkswagen issue in the early 1960s. Nonetheless, the dramatic fall of the share price after markets

were hit by the Cuban missile crisis had a lasting negative impact on equity ownership culture in Germany.) Yet, while a central issue in the debate for almost two decades, privatization has been a rather restricted phenomenon from a quantitative point of view (Shirley 1998). Selling SOEs is part of the political game: it requires the creation of supportive coalitions and it impacts on the distribution of power resources. Strong vested interests, such as organized labor, the military, parts of the urban bourgeoisie, and most economic groups, mount in defense of nationalization. Moreover, privatization is a typical example of a collective action situation: actors more likely to gain from it are widely dispersed, and it is thus simpler for beneficiaries of the status quo to organize an opposition than it is for future beneficiaries to create a support group. Finally, in developing countries where capital markets are thin and scarcely organized, and where it is thus difficult to realize popular capitalism through public placing of SOEs, the potentialities of privatization in terms of coalition building are rather remote.

In practice, the intrinsic allure of free-market economics has proven less important a factor for the success of privatizations than more conjunctural conditions (Armijo 1998). The nature and the seriousness of crisis deeply influence both the perceived need of radical changes and the central themes of the political debate. The tighter the fiscal constraint, and the greater the contribution of SOEs to the deficit, the quicker the recourse to divestiture to solve problems. An important issue is therefore the choice of firms to be sold and the method of sale. Understanding the economic goals to be met through divestiture, in particular the choice between an immediate reduction of macroeconomic imbalances and the medium-term achievement of efficiency improvements by liberalization and more effective regulation, is crucial. The least productive enterprises are harder to dispose of, which might make it necessary to concede easy terms well beyond a low price, when not liquidating them altogether. At the same time, countries in dire economic straits need quick ‘leading cases’ to build their reputation *vis-à-vis* foreign investors. The choice has thus often been to start from the best managed and more profitable SOEs, such as telecommunications, at the risk of making learning mistakes in those very cases where state assets should be more coveted by international investors. Moreover, such industries present technological and tariff complexities, requiring sophisticated tools for asset valuation and regulation that developing countries seldom possess.

Timing and organizational structure also matter. New political incumbents have higher chances of implementing reforms, thanks not only to the ‘post-election honeymoon,’ but also because, according to the electoral cycle theory, there are less incentives to put off adopting risky and painful actions. Likewise, although the relationship between regimes and econ-

omic policies is indeterminate, being able to use emergency powers opens smoother roads on the reforms' path. 'Insulated change teams' or 'technopols' are important, especially where governments came to power with the backing of the lower class and need to prove themselves credible in the face of international investors' fears. However, not all technopols are alike, and the priority they assign to privatization (and the resources they demand politicians to earmark for this as opposed to other structural measures) also depends on their ideological values and on their appraisal of their country's riddle.

Third, given the short-term adjustment costs of economic reforms, it is necessary to introduce compensatory mechanisms. While scholarly attention has been focused on specific, targeted measures to face the reduction of fiscal subsidies to the poor, large business groups that dominate the industrial sector in most developing countries are hit by falling trade barriers, positive real interest rates, and more careful awarding of public credit. In order to win their support, some countervailing measures may be needed, such as cheap (relative to book value) sales of SOEs (Schamis 1998).

Studies of privatization in industrial countries have reported very positive results in firms' performance (e.g., Meggison and Netter 1999). As for developing economies, there are significant increases in profitability, operating efficiency, capital spending, output, and employment, which are usually greater in countries with higher per capita income (Boubakri and Cosset 1998). (In the case of transition economies, empirical tests of the relationship between enterprise performance and ownership generally refute the hypothesis that privatization *per se* is associated with improved performance (e.g., Estrin and Rosevear 1999). The belief that mass privatization, by providing powerful incentives for efficient restructuring, would release entrepreneurial endeavors has also proved naïf (e.g., Spicer et al. 1999).) The substitution of private to public ownership, however, has been accompanied by the emergence of new regulatory challenges for policy-makers. First, in the hitherto natural monopolies that constituted the core of public enterprises (telecoms, energy, water, transport), how to prevent the new private owners from simply pocketing monopoly rents. Especially in the electricity industry, weaknesses in the regulatory framework have sometimes reduced the benefits of privatization and deregulation (Nicoletti 2000). Public authorities must devise sectoral policies that introduce and maintain competition; establish and maintain a sound regulatory framework for the remaining monopolies, public and private; keep transparency in transactions and convince investors that their investments are secure; negotiate, monitor, and enforce contracts with private suppliers of management and financing; ensure that resources from privatization sales are put to productive uses; and manage the inevitable political and social tensions that arise as enterprise reforms are

implemented, especially the critical issues of foreign ownership and labor layoffs. There is, however, much less agreement on how to approach the next set of challenges (second-generation issues) for countries facing the consolidation of initial reforms. In general, these issues are related to postprivatization disputes and renegotiations between governments and the private sector and to the mechanisms necessary to promote competition in the reformed industries.

Second, in view of the goal of creating a people's capitalism, how to provide appropriate mechanisms of corporate governance that protect small shareholders, while also allowing management the required flexibility to pursue long-term corporate goals. Advances in the theory of corporate finance and industrial organization, as well as the ongoing debate over the 'best' capitalist model, have made the analysis of corporate governance—the mechanisms whereby economic systems (in their broadest possible sense) cope with the information and incentive problems inherent in financing investments and facilitate the intertemporal transfer of income claims—a burgeoning theme in comparative institutional economics. Key elements of this literature are the sources of financial resources for corporations, the concentration of ownership, the relevance of listing, the role and composition of boards of directors, the rules governing the market for corporate control and the obstacles that they may pose to corporate control activity, and the relative importance of the voice and exit mechanisms (boardroom pressures and takeovers, or internal and external control, respectively) in disciplining managers.

Links between privatization and corporate governance are of two main kinds: selling SOEs exposes them to the takeover and bankruptcy threats, thereby easing the corporate governance problems proper of public ownership, and it provides an opportunity to modify the distribution of ownership rights among different classes of investors by extending public listing among large firms, increasing the number of small shareholders, and reducing ownership concentration. But while creating 'people's capitalism' has always ranked high among governments' goals, tackling the issues that remain after ownership is transferred from public to private hands and when no (absolute) majority shareowner emerges has seldom been an overriding concern. Potential improvements in technical efficiency following control transfer may be jeopardized if corporate control is not contestable: in this case, and especially if conduct regulation proves insufficient to open up protected markets, managers can exploit rents accruing from market position without having to worry about the threat of takeovers. Privatization policies should take such elements into account, making it imperative to introduce reforms and redress perceived inefficiencies. Governments have great discretion in pricing the SOEs they sell, especially those being sold via public share offering, and they use

this discretion to pursue political and economic ends. Most experiences, however, suggest the limited power of privatization in changing the modes of governance which are prevalent in each country's large private companies. Further, those countries which have chosen the mass (voucher) privatization route have done so largely out of necessity and face ongoing efficiency problems as a result. In the UK, a country whose privatization policies are often referred to as a benchmark, 'control [of privatized companies] is not exerted in the forms of threats of take-over or bankruptcy; nor has it for the most part come from direct investor intervention' (Bishop et al. 1994, p. 11). After the steep rise experienced in the immediate aftermath of privatizations, the slow but constant decline in the number of small shareholders highlights the difficulties in sustaining people's capitalism in the longer run. In Italy, for example, privatization was accompanied by a legislative effort aimed at providing noncontrolling shareholders (i.e. both individual and collective investors) with more adequate safeguards and at introducing the necessary conditions to allow them to monitor managers. But successive governments were unsuccessful in broadening the number of large private business groups, whereas enhancing the mobility of control to investors outside the traditional core of Italy's capitalism was explicitly included among the authorities' strategic goals. On the other hand, experiences such as those of the UK and Chile underscore that mass sell-offs require the development of new institutional investors such as pension funds that may later play an active role in corporate governance. (In Chile, for example, the takeover of the country's dominant electricity utility, Enersis, one of the largest in emerging markets, was stalled for some months in 1998 as pension funds' questioned lucrative additional terms that the management had negotiated for themselves based on important agreements concerning the future strategic direction of Enersis that they had never told other shareholders about.)

To conclude, although privatization's promise has been frequently oversold, not least by international organizations, its ills have also been greatly exaggerated. When ownership transfer has been accompanied by market liberalization and proper implementation, in OECD and non-OECD countries alike, consumers and end-users have benefited in terms of choice, quality, and prices. If public opinion and policy-makers wish so, much remains to be sold and the future challenges for the regulatory state remain substantial to ensure maximization of welfare benefits.

A. E. Goldstein

Probabilistic Grammars and their Applications

1. Introduction

Natural language processing is the use of computers for processing natural language text or speech. Machine translation (the automatic translation of text or speech from one language to another) began with the very earliest computers (Kay et al. 1994). Natural language interfaces permit computers to interact with humans using natural language, for example, to query databases. Coupled with speech recognition and speech synthesis, these capabilities will become more important with the growing popularity of portable computers that lack keyboards and large display

screens. Other applications include spell and grammar checking and document summarization. Applications outside of natural language include compilers, which translate source code into lower-level machine code, and computer vision (Fu 1974, 1982).

Most natural language processing systems are based on formal grammars. The development and study of formal grammars is known as computational linguistics. A *grammar* is a description of a language; usually it identifies the sentences of the language and provides descriptions of them, for example, by defining the phrases of a sentence, their interrelationships, and perhaps also aspects of their meanings. *Parsing* is the process of recovering a sentence's description from its words, while *generation* is the process of translating a meaning or some other part of a sentence's description into a grammatical or well-formed sentence. Parsing and generation are major research topics in their own right. Evidently, human use of language involves some kind of parsing and generation process, as do many natural language processing applications. For example, a machine translation program may parse an input language sentence into a (partial) representation of its meaning, and then generate an output language sentence from that representation.

Modern computational linguistics began with Chomsky (1957), and was initially dominated by the study of his 'transformational' grammars. These grammars involved two levels of analyses, a 'deep structure' meant to capture more-or-less simply the meaning of a sentence, and a 'surface structure' which reflects the actual way in which the sentence was constructed. The deep structure might be a clause in the active voice, 'Sandy saw Sam,' whereas the surface structure might involve the more complex passive voice, 'Sam was seen by Sandy.'

Transformational grammars are computationally complex, and in the 1980s several linguists came to the conclusion that much simpler kinds of grammars could describe most syntactic phenomena, developing Generalized Phrase-Structure Grammars (Gazdar et al. 1985) and Unification-based Grammars (Kaplan and Bresnan 1982, Pollard and Sag 1987, Shieber 1986). These grammars generate surface structures directly; there is no separate deep structure and therefore no transformations. These kinds of grammars can provide very detailed syntactic and semantic analyses of sentences, but even today there are no comprehensive grammars of this kind that fully accommodate English or any other natural language.

Natural language processing using handcrafted grammars suffers from two major drawbacks. First, the syntactic coverage offered by any available grammar is incomplete, reflecting both our lack of understanding of even relatively frequently occurring syntactic constructions and the organizational difficulty of manually constructing any artifact as complex as a grammar of a natural language. Second, such grammars almost always permit a large number of

spurious ambiguities, that is, parses which are permitted by the rules of syntax but have unusual or unlikely semantic interpretations. For example, in the sentence 'I saw the boat with the telescope,' the prepositional phrase 'with the telescope' is most easily interpreted as the instrument used in seeing, while in 'I saw the policeman with the rifle,' the prepositional phrase usually receives a different interpretation in which the policeman has the rifle. Note that the corresponding alternative interpretation is marginally accessible for each of these sentences: in the first sentence one can imagine that the telescope is on the boat, and in the second, that the rifle (say, with a viewing scope) was used to view the policeman.

In effect, there is a dilemma of coverage. A grammar rich enough to accommodate natural language, including rare and sometimes even 'ungrammatical' constructions, fails to distinguish natural from unnatural interpretations. But a grammar sufficiently restricted so as to exclude what is unnatural fails to accommodate the scope of real language. These observations led, in the 1980s, to a growing interest in stochastic approaches to natural language, particularly to speech. Stochastic grammars became the basis of speech recognition systems by outperforming the best of the systems based on deterministic handcrafted grammars. Largely inspired by these successes, computational linguists began applying stochastic approaches to other natural language processing applications. Usually, the architecture of such a stochastic model is specified manually, while the model's parameters are estimated from a *training corpus*, that is, a large representative sample of sentences.

As explained in the body of this article, stochastic approaches replace the binary distinctions (grammatical vs. ungrammatical) of nonstochastic approaches with probability distributions. This provides a way of dealing with the two drawbacks of nonstochastic approaches. Ill-formed alternatives can be characterized as extremely low probability rather than ruled out as impossible, so even ungrammatical strings can be provided with an interpretation. Similarly, a stochastic model of possible interpretations of a sentence provides a method for distinguishing more plausible interpretations from less plausible ones.

The introduction sets out formally various classes of grammars and languages. Probabilistic grammars are introduced in Sect. 2, along with the basic issues of parametric representation, inference, and computation.

2. Grammars and Languages

The formal framework, whether used in a transformational grammar, a generalized phrase-structure grammar, or a more traditionally styled context-free grammar, is due to Chomsky (1957) and his co-

workers. This section presents a brief introduction to this framework. But for a thorough (and very readable) presentation we highly recommend the book by Hopcroft and Ullman (1979).

The concept and notation of a formal grammar is perhaps best introduced by an example:

Example 1: Define a grammar, G_1 , by $G_1 = (T_1, N_1, S, R_1)$, where $T_1 = \{\text{grows, rice, wheat}\}$ is a set of words (a 'lexicon'), $N_1 = \{S, \text{NP}, \text{VP}\}$ is a set of symbols representing grammatically meaningful strings of words, such as clauses or parts of speech (e.g., S for 'Sentence,' NP for 'Noun Phrase,' VP for 'Verb Phrase'), and $R_1 = \{S \rightarrow \text{NP VP}, \text{NP} \rightarrow \text{rice}, \text{NP} \rightarrow \text{wheat}, \text{VP} \rightarrow \text{grows}\}$ is a collection of rules for rewriting, or instantiating, the symbols in N_1 . Informally, the nonterminal S rewrites to sentences or clauses, NP rewrites to noun phrases and VP rewrites to verb phrases. The language, L_{G_1} , generated by G_1 is the set of strings of words that are reachable from S through the rewrite rules in R_1 . In this example, $L_{G_1} = \{\text{rice grows, wheat grows}\}$, derived by $S \Rightarrow \text{NP VP} \Rightarrow \text{rice VP} \Rightarrow \text{rice grows}$, and $S \Rightarrow \text{NP VP} \Rightarrow \text{wheat VP} \Rightarrow \text{wheat grows}$.

More generally, if T is a finite set of symbols, let T^* be the set of all strings (i.e., finite sequences) of symbols of T , including the empty string, and let T^+ be the set of all nonempty strings of symbols of T . A language is a subset of T^* . A *rewrite grammar* G is a quadruple $G = (T, N, S, R)$, where T and N are disjoint finite sets of symbols (called the *terminal* and *nonterminal* symbols respectively), $S \in N$ is a distinguished nonterminal called the *start* or *sentence symbol*, and R is a finite set of productions. A *production* is a pair (α, β) where $\alpha \in N^+$ and $\beta \in (N \cup T)^*$; productions are usually written $\alpha \rightarrow \beta$. Productions of the form $\alpha \rightarrow \varepsilon$, where ε is the empty string, are called *epsilon productions*. This entry restricts attention to grammars without epsilon productions, that is, $\beta \in (N \cup T)^+$, as this simplifies the mathematics considerably.

A rewrite grammar G defines a *rewriting relation* $\Rightarrow_G \subseteq (N \cup T)^* \times (N \cup T)^*$ over pairs of strings consisting of terminals and nonterminals as follows: $\beta A \gamma \Rightarrow \beta \alpha \gamma$ iff $A \rightarrow \alpha \in R$ and $\beta, \gamma \in (N \cup T)^*$ (the subscript G is dropped when clear from the context). The reflexive, transitive closure of $\Rightarrow$ is denoted $\Rightarrow^*$. Thus $\Rightarrow^*$ is the rewriting relation using arbitrary finite sequences of productions. (It is called 'reflexive' because the identity rewrite, $\alpha \Rightarrow \alpha$, is included.) The language generated by G , denoted L_G , is the set of all strings $w \in T^+$ such that $S \Rightarrow^* w$.

Rewrite grammars are traditionally classified by the shapes of their productions. $G = (T, N, S, R)$ is a *context-sensitive* grammar if for all productions $\alpha \rightarrow \beta \in R$, $|\alpha| \leq |\beta|$, that is, the right-hand side of each production is not shorter than its left-hand side. G is a *context-free* grammar if $|\alpha| = 1$, that is, the left-hand side of each production consists of a single nonterminal. G is a *left-linear* grammar if G is context-free

and β (the right-hand side of the production) is either of the form Aw or of the form w where $A \in N$ and $w \in T^*$; in a *right-linear* grammar β always is of the form wA or w . A right or left-linear grammar is called a *regular* grammar. G_1 , in Example 1, is context sensitive and context free.

It is straightforward to show that the classes of languages generated by these classes of grammars stand in strict equality or subset relationships. Specifically, the class of languages generated by right-linear grammars is the same as the class generated by left-linear grammars; this class is called the *regular* languages, and is a strict subset of the class of languages generated by context-free grammars, which is a strict subset of the class of languages generated by context-sensitive grammars, which in turn is a strict subset of the class of languages generated by rewrite grammars.

It turns out that context-sensitive grammars (where a production rewrites more than one nonterminal) have not had many applications in natural language processing, so from here on we will concentrate on context-free grammars, where all productions take the form $A \rightarrow \beta$, where $A \in N$ and $\beta \in (N \cup T)^+$.

An appealing property of grammars with productions in this form is that they induce tree structures on the strings that they generate. And, as Sect. 3 shows, this is the basis for bringing in probability distributions and the theory of inference. We say that the context-free grammar $G = (T, N, S, R)$ generates the labeled, ordered tree ψ , iff the root node of ψ is labeled S , and for each node n in ψ , either n has no children and its label is a member of T (i.e., it is labelled with a terminal) or else there is a production $A \rightarrow \beta \in R$ where the label of n is A and the left-to-right sequence of labels of n 's immediate children is β . It is straightforward to show that w is in L_G if G generates a tree ψ whose *yield* (i.e., the left-to-right sequence of terminal symbols labeling ψ 's leaf nodes) is w ; ψ is called a *parse tree* of w (with respect to G). In what follows, we define Ψ_G to be the set of parse trees generated by G , and $\mathcal{Y}(\cdot)$ to be the function that maps trees to their yields.

Example 1 (continued): The grammar G_1 defined above generates the following two trees, ψ_1 and ψ_2 .
